Department of Energy
Washington, DC 20585

Dear Reader:

Enclosed is the U.S. Department of Energy's (DOE's) Final *Environmental Impact Statement for the Plains & Eastern Clean Line Transmission Project* (DOE/EIS-0486; Final EIS). Included with the Final EIS is a Reference CD, which includes key Project-specific documents. The Final EIS also is available on the DOE National Environmental Policy Act (NEPA) website at http://nepa.energy.gov/nepa and on the Plains & Eastern EIS website at http://www.plainsandeasterneis.com/. DOE has prepared this Final EIS in consultation with the following cooperating agencies: the Bureau of Indian Affairs, Natural Resources Conservation Service, Tennessee Valley Authority, U.S. Army Corps of Engineers, U.S. Environmental Protection Agency, and the U.S. Fish and Wildlife Service.

In 2010, DOE, acting through the Southwestern Power Administration (Southwestern) and the Western Area Power Administration, both power marketing administrations within DOE, issued *Request for Proposals for New or Upgraded Transmission Line Projects Under Section 1222 of the Energy Policy Act of 2005* (75 *Federal Register* 32940; June 10, 2010). In response to the Request for Proposals, Clean Line Energy Partners LLC of Houston, Texas, the parent company of Plains and Eastern Clean Line LLC and Plains and Eastern Clean Line Oklahoma LLC (collectively referred to as Clean Line or the Applicant in the EIS) submitted a proposal to DOE for the Plains & Eastern Clean Line Project (Applicant Proposed Project).

The Applicant Proposed Project would include an overhead ± 600-kilovolt (kV) high voltage direct current (HVDC) electric transmission system and associated facilities with the capacity to deliver approximately 3,500 megawatts primarily from renewable energy generation facilities in the Oklahoma and Texas Panhandle regions to the Mid-South and Southeast United States via an interconnection with the Tennessee Valley Authority in Tennessee. Major facilities associated with the Applicant Proposed Project consist of converter stations in Oklahoma and Tennessee; an approximately 720-mile HVDC transmission line; an alternating current collection system; and access roads. The Final EIS also analyzes potential environmental impacts of a No Action Alternative and a range of reasonable alternatives to the Applicant Proposed Project, including alternative routes for the HVDC transmission line and adding a converter station in Arkansas (to deliver power to the Arkansas electrical grid). The potential environmental impacts resulting from connected actions (wind energy generation and currently identified substation and transmission upgrades related to the Project) are also analyzed.

The Final EIS considers comments submitted on the Draft EIS, including those submitted during the public comment period that began on December 19, 2014, and ended on April 20, 2015, after an extension to the original 90-day comment period. During the comment period, DOE held 15 public hearings in Oklahoma, Texas, Arkansas, and Tennessee. Approximately 950 comment documents (including several email and letter campaigns) were received during the public comment period. Late comments have been considered to the extent practicable. The primary topics raised include, concern about electric and magnetic fields from the transmission line; concern about reductions in property value; concern about impacts to agricultural resources such as crop production, irrigation, and aerial spraying; concern about the use of eminent domain; and concern about visual impacts from the transmission line and requests to bury the electric transmission line underground. Appendix Q of this EIS contains the comments received on the Draft EIS and DOE's responses to these comments.

This Final EIS was revised to incorporate new information gathered since the issuance of the Draft EIS, including updated resource-specific analytical data as well as information received from commenters on the Draft EIS. Vertical bars in the margins of the pages of the Final EIS indicate where revisions, including deletions, were made. Appendices M–Q are entirely new parts of this EIS; therefore, they do not contain bars indicating changes from the Draft EIS.

DOE's purpose and need for agency action is to implement Section 1222 of the Energy Policy Act of 2005. To that end, this Final EIS will assist DOE as it decides whether and under what conditions it would participate in the Applicant Proposed Project. DOE has considered the range of reasonable alternatives, the comparison of potential impacts for each resource area, and the input received on the Draft EIS. Based on the information presented in the Final EIS, DOE has identified participation in the Project as its preferred alternative in the Final EIS. The Project would include the Oklahoma converter station and AC interconnection, the AC collection system, the Applicant Proposed Route for the majority of the HVDC transmission line (with the exception of route variation Region 4, APR Link 3, Variation 2), and the Arkansas converter station and AC interconnection.

DOE has continued consultation pursuant to Section 106 of the National Historic Preservation Act (NHPA), which considers the potential effects of the Project on historic properties. The Final EIS includes a draft Programmatic Agreement in Appendix P developed pursuant to 36 CFR 800.14(b) to address obligations under NHPA Section 106, including government-to-government consultation with Indian Tribes and Nations that may attach religious and cultural significance to historic properties that may be affected by the undertaking, and consultation with the Arkansas, Oklahoma, Tennessee, and Texas State Historic Preservation Officers. DOE intends to execute the PA prior to issuance of the ROD or otherwise comply with procedures set forth in 36 CFR Part 800.

DOE and the Applicant have prepared a Biological Assessment of potential impacts on special status species protected under the Endangered Species Act (ESA) as part of the Section 7 consultation between DOE and the U.S. Fish and Wildlife Service. The Section 7 consultation review is a parallel, but separate, process to the NEPA process, conducted pursuant to the requirements of ESA and the applicable implementing regulations. The Biological Assessment and associated addendum are included as Appendix O to the Final EIS. The Biological Opinion, to be issued by the U.S. Fish and Wildlife Service prior to the issuance of the Record of Decision, may identify additional protective measures may be identified and adopted to avoid or minimize impacts to special status species.

For additional information, contact me at Jane.Summerson01@nnsa.doe.gov or visit the EIS website at: http://www.plainsandeasterneis.com.

Thank you for your interest and participation in the NEPA process.

Sincerely,

Jane Summerson, Ph.D.
NEPA Document Manager
on behalf of DOE’s Office of Electricity Delivery and Energy Reliability

Units of Measure

Common units of measure and conversion factors used in this report include:

Linear Measure

1 inch = 2.54 centimeters

1 foot = 0.3048 meter

1 yard = 0.9144 meter

1 mile = 1.6 kilometers

Area Measure

1 acre = 0.4047 hectare

1 square mile = 640 acres = 259 hectares

Capacity Measure (Liquid)

1 US gallon = 4 quarts = 3.785 liter

1 cubic meter per hour = 4.403 U.S. gallons per minute

From Socioeconomics

Jobs are full-time equivalents (FTEs) for a period of one year (1 FTE = 2,080 hours)

*Other EIS figures presented in Appendix A.

This page intentionally left blank.

1. Introduction

In June 2010, the U.S. Department of Energy (DOE), acting through the Southwestern Power Administration (Southwestern) and the Western Area Power Administration (Western), both power marketing administrations within DOE, issued *Request for Proposals for New or Upgraded Transmission Line Projects Under Section 1222 of the Energy Policy Act of 2005* (EPAct; 75 *Federal Register* [FR] 32940; June 10, 2010). In response to the DOE request for proposals (RFP), Clean Line Energy Partners LLC of Houston, Texas, the parent company of Plains and Eastern Clean Line LLC and Plains and Eastern Clean Line Oklahoma LLC (collectively referred to as Clean Line or the Applicant in this Environmental Impact Statement [EIS]) prepared a proposal (submitted in July 2010, updated in August 2011, and supplemented in January 2015) to develop new transmission facilities to be located in Oklahoma, Arkansas, Tennessee, and possibly Texas. Figures 1.0-1 and 1.0-2 (located in Appendix A) show topographic and aerial imagery of the Project.

Prior to making a decision as to whether and under what conditions to participate in Clean Line's proposed Plains & Eastern Project (the Applicant Proposed Project), DOE must fully evaluate the Project. This EIS will inform DOE's decision by analyzing the potential environmental impacts of the Project[1]. This chapter provides an overview of DOE's purpose and need for agency action, a description of requirements under Section 1222 of the EPAct, and Clean Line's goals and objectives as they relate to the Project. This chapter also includes a description of cooperating agencies and their roles, applicable federal agency regulations, and the environmental review process including a description of the National Environmental Policy Act (NEPA) process and stakeholder and agency involvement.

Commonly Used Terms

Throughout the Plains & Eastern EIS, the following terms are used to describe different elements of the proposal being evaluated.

Applicant Proposed Project—Based on Clean Line's modified proposal to DOE,[2] the basic elements include converter stations in Oklahoma and Tennessee, alternating current (AC) interconnections at each converter station, an AC collection system, and a high-voltage direct current (HVDC) transmission line from the Oklahoma Panhandle to western Tennessee. The Applicant Proposed Project is described in detail in Sections 2.1.2 through 2.1.7.

Proposed Action—For DOE to participate, acting through the Administrator of Southwestern, in the Applicant Proposed Project in one or more of the following ways: designing, developing, constructing, operating, maintaining, or owning a new electric power transmission facility and related facilities located within certain states in which Southwestern operates, namely Oklahoma, Arkansas, and possibly Texas,[3] but not Tennessee.

Applicant Proposed Route—The single 1,000-foot-wide route alternative defined by Clean Line to connect the converter station in the Oklahoma Panhandle to the converter station in western Tennessee. The analyses of impacts are typically based on a representative 200-foot-wide right-of-way (ROW) within the 1,000-foot-wide corridor. The Applicant Proposed Route is described in detail in Section 2.4.2.

DOE Alternatives—Pursuant to NEPA, DOE has identified and analyzed potential environmental impacts for the range of reasonable alternatives in addition to the Applicant Proposed Project. These alternatives include an Arkansas converter station and alternative routes for the HVDC transmission line. In each instance, these alternatives have been discussed and evaluated with Clean Line for feasibility. The DOE Alternatives are described in detail in Section 2.4.3.

---

1 This Final EIS was revised to incorporate new information gathered since the issuance of the Draft EIS, including updated resource-specific analytical data as well as information received from commenters on the Draft EIS. Vertical bars in the margins of the pages of the Final EIS indicate where revisions, including deletions, were made.

2 In response to DOE's *Request for Proposals for New or Upgraded Transmission Line Projects under Section 1222 of the Energy Policy Act of 2005.*

3 Depending on AC collection system routes implemented (some of which are in Texas).

The Project—A broad term that generically refers to elements of the Applicant Proposed Project and/or DOE Alternatives when differentiation between the two is not necessary. The term also refers to whatever combination of project elements would be built if a decision is made by DOE to participate with Clean Line.

1.1 Department of Energy Purpose and Need

DOE is the lead federal agency for the preparation of the Plains & Eastern EIS. DOE has prepared this EIS pursuant to NEPA (42 United States Code [USC] § 4321; NEPA), the Council on Environmental Quality (CEQ) NEPA regulations (40 Code of Federal Regulations [CFR] Parts 1500 through 1508), and the DOE NEPA implementing regulations (10 CFR Part 1021). DOE's purpose and need for agency action is to implement Section 1222 of the EPAct. To that end, DOE needs to decide whether and under what conditions it would participate in the Applicant Proposed Project.

1.1.1 Section 1222 of the EPAct

Section 1222 of the EPAct, in relevant part, authorizes the Secretary of Energy, acting through and in consultation with the Administrator of Southwestern (provided the Secretary determines that certain statutory requirements have been met), to participate with other entities in designing, developing, constructing, operating, maintaining, or owning new electric power transmission facilities and related facilities located within any state in which Southwestern operates. Southwestern is one of four power marketing administrations that operate within DOE. Southwestern is authorized to market and deliver power to customers in the southwestern United States, including Arkansas, Oklahoma, and Texas, with a preference to public bodies and cooperatives.

As mentioned above, Clean Line submitted a proposal and supporting information in response to DOE's RFP on July 6, 2010. Clean Line's original proposal included two high-voltage direct current (HVDC) lines, each rated at 3,500 megawatts (MW), and which together would have had the capacity to deliver 7,000MW. Subsequently in August 2011, Clean Line modified its proposal to a single HVDC line with the capacity to deliver 3,500MW (Clean Line 2011). DOE concluded that Clean Line's modified proposal was responsive to the RFP (DOE 2012). Clean Line subsequently submitted a Part 2 Application in January 2015 (Clean Line 2015). This Part 2 Application provides additional details and information regarding the Project as requested by DOE. The statutory criteria from Section 1222 (42 USC 16421) include:

1. The proposed project
    a. is located in an area designated under section 216(a) of the Federal Power Act (16 USC §824p(a)) and will reduce congestion of electric transmission in interstate commerce, or
    b. is necessary to accommodate an actual or projected increase in demand for electric transmission capacity
2. is consistent with
    a. transmission needs identified, in a transmission expansion plan or otherwise, by the appropriate Transmission Organization (as defined in the Federal Power Act [16 USC 791a et seq.]), if any, or approved regional reliability organization, and
    b. efficient and reliable operation of the transmission grid
3. will be operated in conformance with prudent utility practice
4. will be operated by, or in conformance with the rules of, the appropriate Transmission Organization, if any, or if such an organization does not exist, regional reliability organization; and

5. will not duplicate the functions of existing transmission facilities or proposed facilities which are the subject of ongoing or approved siting and related permitting proceedings.

The decision whether to participate in a project is discretionary. In the June 2010 RFP, DOE explained that, in evaluating whether to participate in projects that have met the statutory eligibility criteria, DOE would also consider the following evaluation criteria that are not explicitly set forth in the statute:

1. Whether the project would be in the public interest
2. Whether the project would facilitate the reliable delivery of power generated by renewable resources
3. The benefits and impacts of the project in each state it traverses, including economic and environmental factors
4. The technical viability of the project, considering engineering, electrical, and geographic factors, and
5. The financial viability of the project

The purpose of the Plains & Eastern EIS is to evaluate the potential environmental impacts from the Applicant Proposed Project and the range of reasonable alternatives that also meet the purpose and need to implement Section 1222 of the EPAct and a "No Action" alternative. Potential environmental impacts are one of several factors that DOE will consider when deciding whether to participate in the Applicant Proposed Project.

The Plains & Eastern EIS analyzes the potential environmental impacts of the entire Project. This ensures that any decision by DOE or another agency is fully informed. DOE may decide to participate in any or all of the states in which Southwestern operates, namely Oklahoma, Arkansas, and Texas. However, DOE would not participate in the Project in Tennessee because that state is outside Southwestern's operational area. Other agencies, federal or state, may have jurisdiction over parts of the Project that are located in Tennessee. Some of these agencies could include, but not be limited to, Tennessee Valley Authority (TVA), U.S. Army Corps of Engineers (USACE), and Tennessee state agencies.

In addition to the NEPA process, on April 28, 2015, DOE published a notice in the *Federal Register* (80 FR 23520) requesting public comment on Clean Line's complete Section 1222 application. The initial public comment period was set to expire on June 12, 2015. In response to public and Congressional requests, DOE extended the public comment period through July 13, 2015. The notice stated, "Prior to making a determination whether or not to participate in the proposed Project, DOE, in consultation with Southwestern, must evaluate the proposed Project for compliance with section 1222 of EPAct, the criteria in the 2010 RFP, and NEPA." In addition to this public review, DOE is conducting due diligence on other factors related to the statutory criteria identified in Section 1222. DOE's review will include making all required statutory findings and will consider all criteria listed in Section 1222 of EPAct as well as all factors included in DOE's 2010 RFP. In the *Federal Register* notice dated April 28, 2015, DOE requested comments on whether the proposed Project meets the statutory criteria and the factors identified within the 2010 RFP.

1.2 Cooperating Agencies

DOE is the lead agency for the preparation of the Plains & Eastern EIS. As lead agency, DOE retains overall responsibility for the NEPA process, including the Draft and Final EIS and DOE's Record of Decision (ROD), if any. DOE's responsibilities include determining the purpose and need for DOE's agency action, identifying for analysis the range of reasonable alternatives to its Proposed Action, identifying potential environmental impacts of the Proposed

Action and reasonable alternatives, identifying its preferred alternative, and determining appropriate mitigation measures.

DOE is also the lead agency for consultation required under Section 106 of the National Historic Preservation Act (NHPA), 54 USC § 306108. DOE is using the NEPA process and documentation required for the Plains & Eastern EIS to comply with Section 106 of the NHPA in lieu of the procedures set forth in Sections 800.3 through 800.6 of the NHPA. This approach is consistent with the recommendations set forth in the NHPA implementing regulations that Section 106 compliance should be coordinated with actions taken to meet NEPA requirements (36 CFR 800.8(a)(1)). Additional information regarding compliance with Section 106 of the NHPA is provided in Section 3.9.

In addition to DOE acting as the lead agency for the Plains & Eastern EIS, several other agencies are participating as cooperating agencies as described in 40 CFR 1501.6. These cooperating agencies have also participated, along with other federal and state agencies, in routing and siting activities related to their jurisdiction, authority, or expertise (Section 1.6). Appendix B contains copies of primary correspondence between DOE and these agencies.

The cooperating agencies for the Plains & Eastern EIS are identified in Table 1.2-1.

Table 1.2-1:
Plains & Eastern EIS Cooperating Agencies

Cooperating Agencies
Bureau of Indian Affairs (BIA)
Natural Resources Conservation Service (NRCS)
Tennessee Valley Authority (TVA)
U.S. Army Corps of Engineers (USACE)
U.S. Environmental Protection Agency (EPA) Regions 4 and 6
U.S. Fish and Wildlife Service (USFWS)

Also, DOE has invited certain federal, state, Indian Tribes or Nations, and local agencies to consult under Section 106 of the NHPA in accordance with 36 CFR 800.2(c).

The following sections provide information regarding each cooperating agency. The sections include a description of the agency and its responsibilities, the basis for participation as a cooperating agency, and the extent to which the agency will rely on the Plains & Eastern EIS to fulfill its obligations under NEPA or related laws.

1.2.1 Bureau of Indian Affairs

The BIA is a bureau within the Department of the Interior responsible for the administration and management of land held in trust for American Indians and federally recognized Tribes. The BIA is recognized to have jurisdiction by law over Rights-of-Way over Indian Lands (25 CFR Part 169).

The BIA will, to the extent permitted by law, rely on the environmental analyses and Section 106 consultation developed through this NEPA process and resulting Plains & Eastern EIS to fulfill its obligations under NEPA and Section 106 of the NHPA for any action, permit, or approval by the BIA for the Project.

1.2.2 Natural Resources Conservation Service

NRCS is a federal agency within the Department of Agriculture whose mission is to provide national leadership in the conservation of soil, water, and related natural resources. The NRCS provides balanced technical assistance and cooperative conservation programs to landowners and land managers throughout the United States. NRCS is recognized to have jurisdiction by law and/or has special expertise in the following areas:

- Farmland Protection Policy Act (7 USC § 4201 et seq.; 7 CFR Part 658)
- Watershed Protection and Flood Prevention Act (16 USC §§ 1001–1009; Public Law 83–566)
- Agricultural Conservation Easement Program (Subtitle D of the Agricultural Act of 2014; 128 Stat. 649, Public Law 113-79)
- Healthy Forests Restoration Act of 2003 (16 USC § 6501 et seq., Public Law 108–148)
- Federal Agriculture Improvement and Reform Act of 1996 (110 Stat. 888–1197, Public Law 104–127)

The NRCS will, to the extent permitted by law, rely on the environmental analyses developed through this NEPA process and resulting Plains & Eastern EIS to fulfill its obligations under NEPA for any action, permit or approval by the NRCS for the Project.

1.2.3 Tennessee Valley Authority

TVA is a federally owned corporation that provides electricity to about 9 million people in parts of seven southeastern states. TVA is a cooperating agency in the preparation of the Plains & Eastern EIS and is recognized to have jurisdiction by law by virtue of the approvals that would need to be obtained from TVA before interconnecting the Project to the transmission system TVA operates in the Tennessee Valley region. TVA has extensive experience in the planning, construction, and operation of electrical transmission lines and substations. As a federal agency, TVA is also recognized as having special expertise in assessing, under NEPA, the potential environmental impacts of federal projects undertaken in the Tennessee Valley region, including electricity transmission systems and related facilities.

TVA will, to the extent permitted by law, rely on the environmental analyses and Section 106 consultation developed through this NEPA process and resulting Plains & Eastern EIS to fulfill its obligations under NEPA and Section 106 of the NHPA for any action, permit, or approval by TVA for the Project.

TVA's purpose and need for agency action is to respond to Clean Line's request to interconnect the Project to the TVA transmission system. In response to the interconnection request, TVA conducted studies that indicate certain upgrades are needed to the TVA transmission system to maintain system reliability while transmitting the power injected by the Project. TVA anticipates tiering from this EIS in completing its NEPA review to assess the potential environmental impacts of these upgrades.

1.2.4 U.S. Army Corps of Engineers

The USACE is a federal agency within the Department of Defense. The USACE is a cooperating agency in the preparation of the Plains & Eastern EIS and is recognized to have jurisdiction by law and/or has special expertise in the following areas:

- Section 404 of the Clean Water Act (33 USC § 1344)

- Section 10 of the Rivers and Harbors Appropriation Act of 1899 (33 USC § 403)
- Modification to existing USACE projects (33 USC § 408)

Authorization from the USACE is required for features of the Project that cross over, through, or under navigable waters as defined under Section 10 of the Rivers and Harbors Appropriation Act of 1899. Authorization from the USACE is also required for any activity that would result in discharges of dredged or fill material into waters of the United States as defined in Section 404 of the Clean Water Act. If granted, the USACE authorization would be issued in the form of a permit verification.

In addition to responsibilities identified above, 33 USC § 408 provides the authority to USACE to evaluate and approve proposed modifications and activities on and near existing federally constructed projects, which includes levees, navigation channels, flood channels, and harbors. Additionally, work performed within 1,500 feet of Mississippi River levees has the potential to adversely affect the ability of the levees to perform as intended. Any excavation or subgrade construction within 1,500 feet of a levee would require coordination with the USACE to ensure no negative impact to the level of flood risk reduction provided by the levee occurred.

Permits and permit verifications would be necessary from the USACE for portions of the Project (including areas within the state of Tennessee). As a cooperating agency, the USACE will review the route alternatives contained in the Plains & Eastern EIS. The USACE may consider the routing alternatives in Tennessee as presented in this EIS when making its permit decisions and will use the analysis contained in this EIS to inform all of its permit decisions for the Project. The USACE could, to the extent permitted by law, rely on the environmental analyses developed through this NEPA process and resulting EIS to fulfill its obligations under NEPA for any action, permit, or approval by the USACE for the Project.

1.2.5 U.S. Environmental Protection Agency

EPA is a federal agency that was created in 1970 for the purpose of protecting human health and the environment. EPA has ten regional offices, each of which is responsible for execution of their program. Region 4 (Southeast) includes the state of Tennessee. Region 6 (South-Central) includes the other states potentially involved in the Project (Arkansas, Oklahoma, and Texas). The EPA (Regions 4 and 6) is a cooperating agency in the preparation of the Plains & Eastern EIS and is recognized to have jurisdiction by law and/or has special expertise in the following areas:

- Environmental laws
- Executive Orders dealing with environmental review of actions
- NEPA assessment and procedures

In addition, under Section 309 of the Clean Air Act, the EPA is required to review and publicly comment on the environmental effects of major federal actions, including actions that are the subject of EIS documents. If the EPA determines that the action is environmentally unsatisfactory (per the Section 309 criteria), it is required by Section 309 to refer the matter to the CEQ.

1.2.6 U.S. Fish and Wildlife Service

USFWS is a bureau within the Department of the Interior whose mission is to conserve, protect, and enhance fish, wildlife, and plants and their natural habitats for the continuing benefit of the American people. USFWS is a cooperating agency in the preparation of the Plains & Eastern EIS and is recognized to have jurisdiction by law and/or has special expertise in the following areas:

- Endangered Species Act (16 USC § 1531 et seq.)
- Migratory Bird Treaty Act (16 USC § 703 et seq.)
- Bald and Golden Eagle Protection Act (16 USC § 668 et seq.)
- The National Wildlife Refuge System Administration Act (16 USC § 668dd–68ee)
- Executive Order 13186 and DOE and USFWS Memorandum of Understanding (DOE and USFWS 2013)

The USFWS will, to the extent permitted by law, rely on the environmental analyses developed through this NEPA process and resulting Plains & Eastern EIS to fulfill its obligations under NEPA for any action, permit, or approval by the USFWS for the Project.

In March 2015, DOE, Southwestern, and TVA requested the initiation of formal consultation and conference with the USFWS under Section 7(a)(2) of the Endangered Species Act (DOE 2015) and submitted a Biological Assessment regarding the Project and its potential effects on listed species and designated critical habitat. The Biological Assessment and addendum have been included as Appendix O of this EIS. The Biological Opinion, to be issued by the USFWS prior to the issuance of the ROD, may identify additional protective measures to avoid or minimize impacts to special status species.

1.3 Other Federal Agency Involvement

This section describes the potential roles and responsibilities of additional federal agencies other than those identified above as cooperating agencies. Additionally, Appendix C presents an overview of potential federal and state permits and consultation that could be required for construction of the Project.

1.3.1 Advisory Council on Historic Preservation

The Advisory Council on Historic Preservation (ACHP), in accordance with 36 CFR 800.2(b), issues regulations to implement Section 106 of the NHPA, and provides guidance, advises, and generally oversees operation of the Section 106 process. Section 106 of the NHPA requires federal agencies to consider effects of federal undertakings on historic properties. Historic properties include those on the National Register of Historic Places (NRHP) or that meet the criteria for the National Register (ACHP 2013). DOE informed the ACHP and the State Historic Preservation Officers (SHPOs) of Oklahoma, Texas, Arkansas, and Tennessee by letter of DOE's intent to use the NEPA process and documentation required for the Plains & Eastern EIS to comply with Section 106 of NHPA in lieu of the procedures set forth in Sections 800.3 through 800.6 of the NHPA. The ACHP has been consulting with DOE on various topics, including the potential programmatic agreement as part of the Section 106 consultation.

1.3.2 National Park Service

The National Park Service (NPS) is a bureau of the Department of the Interior and would be responsible for issuing ROW permits if the Project crosses land managed by the NPS per 16 USC § 79. Portions of the congressionally designated Trail of Tears National Historic Trail are under the managing jurisdiction of the NPS. The Project route alternatives would cross segments of the Trail; however, neither the Applicant Proposed Route nor the DOE alternative routes cross any portions managed by the NPS. DOE has provided the NPS with the location data for each of the route alternatives. The NPS is also participating as a consulting party under Section 106.

The NPS has administrative responsibilities for the Trail of Tears National Historic Trail under the Secretary of the Interior, pursuant to the National Trails System Act of 1968, as amended. Further, the NPS has responsibilities for the Route 66 Preservation Program under Public Law 106–45, enacted in 1999.

1.3.3 U.S. Department of Transportation, Federal Highway Administration

The Federal Highway Administration (FHWA) is an agency within the U.S. Department of Transportation (DOT) that would be responsible for issuing encroachment permits if the Project crosses federally funded highways.

1.3.4 U.S. Forest Service

The U.S. Forest Service (USFS) is a federal agency within the Department of Agriculture that manages Ozark-St. Francis National Forests (Forests). A Revised Land and Resources Management Plan (RLRMP) for the Forests was developed in 2005 with public input that provides direction for its management (USFS 2005). An HVDC alternative route (HVDC Alternative Route 4-B), a portion of which would cross the Ozark National Forest, was proposed as a result of public scoping comments and analyzed in the Plains & Eastern EIS. DOE has consulted with the USFS regarding this alternative route.

1.4 Clean Line's Goals and Objectives

According to Clean Line's proposal prepared in response to the DOE *Request for Proposals for New or Upgraded Transmission Line Projects under Section 1222 of the Energy Policy Act of 2005* (submitted in July 2010, modified in August 2011, and supplemented in January 2015), Clean Line proposes to develop new transmission facilities to be located in Oklahoma, Arkansas, Tennessee, and possibly Texas. According to Clean Line's proposal, "The Plains and Eastern Clean Line is necessary to accommodate the actual and projected increase in demand for additional electric transmission capacity to deliver renewable energy from western SPP to load centers in the southeastern United States." Further, Clean Line's stated objectives for development of the Applicant Proposed Project include:

- Improving public access to renewable energy at a competitive cost by facilitating the transfer of available wind energy in the Oklahoma and Texas Panhandle regions to areas with increasing demands
- Providing an efficient and reliable interconnection between the Southwest Power Pool (SPP) and TVA that facilitates the delivery of 3,500MW of wind generated electricity and is consistent with applicable transmission system plans
- Assisting in satisfying the growing customer demand for renewable energy
- Providing safe, efficient and reliable transmission infrastructure consistent with prudent utility practice

1.5 National Environmental Policy Act

Major federal actions that may significantly affect the quality of the human environment require preparation of an EIS to comply with NEPA. NEPA requires that all federal agencies consider the potential environmental impacts of their proposed actions. Under NEPA, the term environment encompasses both the physical environment (e.g., air, water, geography, geology) and the human environment (e.g., health and safety, jobs, housing, schools, transportation, cultural resources).

1.5.1 NEPA Process

The CEQ established NEPA regulations for all federal agencies, including procedures for preparing EIS documents (40 CFR Parts 1500 through 1508). Individual agencies, including DOE, have established their own implementing procedures to supplement and use in conjunction with these requirements (DOE's implementing regulations are found at 10 CFR Part 1021). The major steps in the NEPA process for preparing an EIS are issuing a Notice of Intent (NOI) to prepare an EIS; gathering input on the scope of the EIS from federal, state, and local agencies, Tribal governments, the public, and other stakeholders; preparing the Draft EIS; receiving public comments on the Draft EIS; preparing a Final EIS, including responses to comments received on the Draft EIS; and issuing a ROD. Each of these steps is discussed below and Figure 1.5-1 illustrates the process.

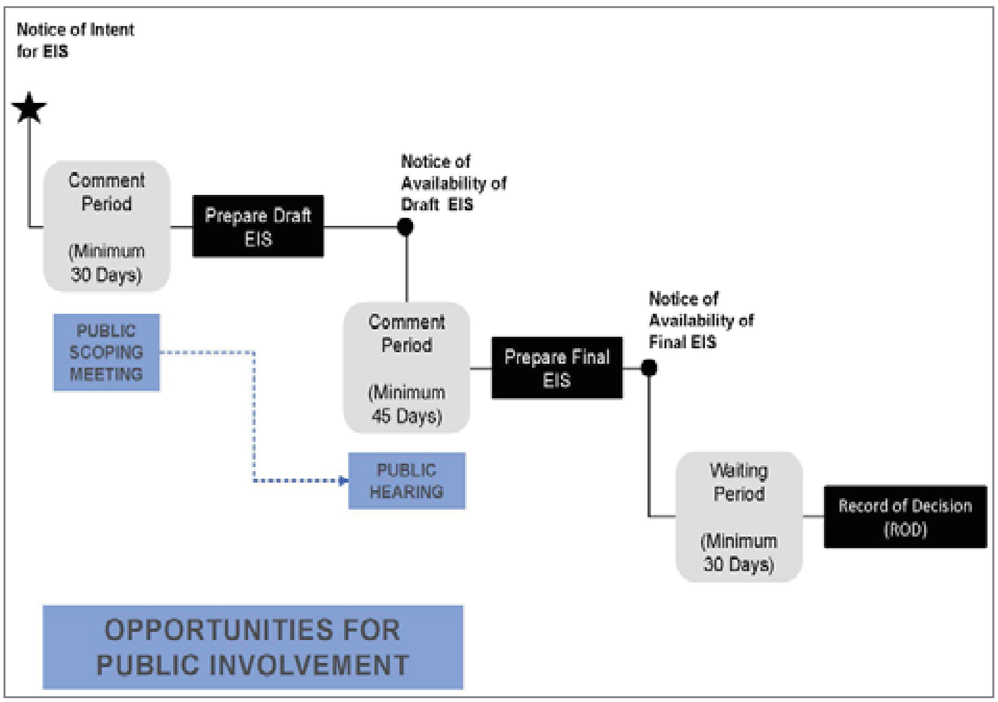

Figure 1.5-1: The EIS Process

1.5.2 Public Scoping

The public scoping period for the Project began with DOE's publication of the NOI on December 21, 2012. The NOI is included in Appendix D. The public scoping period continued for ninety days through March 21, 2013. DOE held thirteen public scoping meetings in communities along the proposed and alternative routes and five interagency meetings during the scoping period. The purpose of scoping was for DOE to request and receive comments on the scope of the EIS and alternatives from the public, agencies, tribes, and other interested parties. At the public and agency scoping meetings, DOE presented large-scale maps (42 inches by 60 inches) of the potential project area to gather input on the potential transmission line routing. These maps are shown in Appendix E of the DOE Alternatives Development Report (DOE 2013). (The DOE Alternatives Development Report is discussed in more detail in Section

2.3 of the Plains & Eastern EIS.) The Native American Tribes and federal, state, and local agencies contacted during public scoping are addressed in Section 1.6.

DOE received 664 scoping comment documents; many of which included multiple scoping comments. DOE reviewed all scoping comments and prepared a Scoping Summary Report (Appendix E). Comments pertaining to potential Project locations were categorized and compiled by location in a spreadsheet shown in Appendix F of the DOE Alternatives Development Report (DOE 2013). Issues that were identified during scoping are categorized by environmental resource area and presented in Table 1.5-1.

Table 1.5-1:
Issues Identified through Scoping

Resource or Issue Area and Issues to be Analyzed	Location in EIS
Accidents, Intentional Destructive Acts, and Hazards (including air space)	
Analyze impacts of aircraft operating in the area of the transmission lines, specifically associated with aerial application of pesticides and fertilizers (Segment L-3, Jackson and Poinsett counties, Arkansas).[1]	Sections 3.8 and 3.16
Avoid locating the line in areas near personal airstrips and small airports.	Sections 3.8 and 3.16
Consider impacts of tornadoes, fire, earthquake, snow, and ice storms. Discuss the liability and responsibility to maintain the line and ROW in the event of an accident caused by such events.	Section 3.8
Agriculture	
Analyze effects of Project on agricultural operations, water management systems (e.g., surface water reservoirs, underground oil and gas pipelines, and tail-water recovery systems), irrigation and/or drainage systems (specifically the use of two center pivot irrigation systems), removal/damage of acreage, seeding, impacts on planting and harvesting, crop production, and aerial applications of fertilizer, insecticide, and herbicide.	Section 3.2
Analyze potential impacts of Project on precision-graded rice and farm fields (Regions 5, 6, and 7).[1]	Section 3.2
Describe and consider impacts to rice production and indirect impacts on migrating waterfowl that rely on rice producing lands for feeding and winter habitat.	Sections 3.2 and 3.20
Analyze how loss of land may reduce area for grazing and hay production.	Section 3.2
Air Quality and Climate Change	
Analyze the impacts on air quality and climate change once the Project is completed. Compare and contrast these impacts with the impacts of various other resources (renewable and non-renewable) that could be used to produce and transmit power.	Section 3.3
Consider impacts on climate change associated with destruction of trees.	Section 3.3
Alternatives—General	
Opposition to the Project being built across areas/states that will receive no benefit from it, specifically Arkansas and Oklahoma; Project should be built in the areas that will receive the electricity needed/produced.	Section 2.4
Update and revise location of gas pipelines and electric transmission lines, including new Oklahoma Gas & Electric (OG&E) transmission lines.	Figures 1.0-1 and 1.0-2 in Appendix A
Identify locations of oil/gas wells within proximity to route corridors.	Section 3.6, Figure 3.6-6 (located in Appendix A)
Route along field/property lines and avoid bisecting properties and fields.	Section 2.3 and Appendix G
Identify additional/missing homes on maps showing the network of potential routes.	Figures 1.0-1 and 1.0-2 in Appendix A
Identify location of springs used to water livestock and farms.	Figures 1.0-1 and 1.0-2 in Appendix A
Follow ROWs (highways, interstates, other lines/oil and gas pipelines/utilities).	Appendix G
Bury the proposed transmission line.	Section 2.4

Table 1.5-1:
Issues Identified through Scoping

Resource or Issue Area and Issues to be Analyzed	Location in EIS
Consider other alternatives such as hydroelectric (dam), nuclear, solar, or Atlantic seaboard-based wind farms.	Section 2.4
Avoid populated areas.	Appendix G
Avoid routes that cross cemeteries.	Appendix G
Place line on government/public lands.	Appendix G
Avoid National Audubon Society Important Bird Areas.	Section 3.20
Avoid conservation areas on public and private lands.	Appendix G
Avoid public lands.	Appendix G
Commenters requested implementation timeline, Gantt charts detailing resources and critical path, and information about phone lines in Pope County, Arkansas.	Appendix F (Section 3.2 and Appendix C)
Commenters requested information about cost of project and the cost to federal government.	Section 3.13
Commenters requested information about use of solar panels with HVDC for better efficiency and production of electricity.	Section 2.4
Connected Actions	
Analyze impacts of wind farms that will be constructed in conjunction with the Project.	Section 2.5, Chapters 3 and 4
Address responsibility for removal of turbines and towers in the event the Project is terminated at some point in the future.	Chapter 3
Cultural, Historic, and Archaeological Resources	
Analyze impacts to cultural, historical, and archaeological resources, including Native American relics and artifacts (Segments K and L), burial sites; family cemeteries (Segment C and M-5); historic sites, including Butterfield Trail Stage Route, the Trail of Tears, and area battlefields, and routes connecting to those sites (Segment G); Sheridan's Roost; Sequoyah Home Museum and other Cherokee heritage sites; and other cultural activities and sites along the proposed route.[1]	Section 3.9
Consider impacts on cultural values of landowners and residents of remote areas, including the impact on future generations who may wish to reside on or farm their families' ancestral properties.	Section 3.9
Analyze impacts to "Centennial" farms and trees in Oklahoma.	Section 3.9
Cumulative Impacts	
Analyze cumulative impacts of wind farms associated with the Project.	Chapter 4
Discuss impacts of potential future projects that may be located near the Project.	Chapter 4
Analyze cumulative impacts on agriculture, wildlife, aesthetic and scenic values, and the economy and the culture of areas that would be impacted by the Project.	Chapter 4
Address cumulative impacts of past, current, or future, local, state, and/or federal projects.	Chapter 4
Address impacts of the construction of Interstate 69 in and around Munford, Tennessee (Segment M-4).[1]	Chapter 4
Electric and Magnetic Fields	
Analyze health impacts of high-voltage transmission lines to humans, livestock, and plants.	Section 3.4
Address impacts of electric and magnetic fields (EMF) on Global Positioning System (GPS), cell phones, medical devices, television, and internet.	Section 3.4
Discuss potential for stray voltage and how structures are grounded.	Section 3.4
Environmental Justice	
Consider environmental justice implications in the use of private land for private gain, specifically percentage of landowners that rely on income from the land that could be devalued by construction of the transmission line.	Sections 3.5 and 3.13
Geology and Soils (including minerals)	
Analyze impacts of construction equipment and installation of towers and power lines on erosion, scouring, silting, (Segment G).[1]	Section 3.6

Table 1.5-1:
Issues Identified through Scoping

Resource or Issue Area and Issues to be Analyzed	Location in EIS
Address erosion control activities on the ROW, specifically in hilly areas where removal of trees will cause impacts on Federal Scenic Waterways.	Section 3.6
Analyze impacts of Project to rice production/irrigated agriculture, specifically clay hardpan. Consider that soil structure is crucial to these activities and damage to hardpan will cause loss of topsoil and loss of productivity.	Section 3.2
Consider features such as rough terrain, buffalo wallows, fault lines (Mulberry Fault), and steep-sided hills.	Section 3.6
Human Health and Safety	
Analyze impacts of high-voltage transmission lines on health of humans, especially the young and elderly, as well as livestock (Segments C, F-8, G-3, K, L, and M-4).[1]	Section 3.4
Discuss health impacts of high-voltage transmission lines on GPS, pacemakers, farm equipment, defibrillators, neurostimulators, and medical equipment.	Section 3.4
Analyze potential for the Project to cause faulty GPS signals that may cause GPS-guided aircraft and or farm equipment to collide with structures and wires erected.	Section 3.4
Address health impacts of the Project resulting from grass/wild fires, structures or towers that fail, and electrocution due to downed lines.	Section 3.4
Analyze impacts on water quality of a drinking water supply (Segment G-3, under the EPA and Arkansas Department of Health's Source Water Protection Program).[1]	Section 3.15
Land Acquisition and Land Rights	
Describe the potential use of eminent domain or other land easements to obtain private property.	Section 2.1.3
Discuss how ROW access may invite trespassing on private property.	Appendix F (EPM GE-8)
Describe how construction and maintenance debris will be removed from private property.	Appendix F (Section 3.2.8)
Analyze how the Project may negatively impact the ability for small oil/gas producers to lease property for oil and natural gas exploration and production.	Section 3.6
Discuss whether access to lands would also provide access to mineral rights below the surface for fracking.	Sections 2.6 through 2.11
Evaluate utilizing existing levee system, easements, or ROWs.	Section 2.3
Land Use	
Discuss impacts on future oil and gas drilling activities	Section 3.6
Discuss the restrictions the Project will place on future land use (public and private) and cultivation/development.	Section 3.10
Discuss possibility that Project may impair or delay conservation efforts and agreements, impacts to status of federally designated areas, including Blueway (water trail), scenic byway, and wildlife refuge designations.	Sections 3.12 and 3.15
Mitigation	
Consider mitigation needs in areas where wetland mitigation banks do not exist.	Section 3.19
Address use of best management practices (BMPs[2]) for construction to mitigate impacts to wildlife habitat, including sensitive species and species of concern.	Sections 3.14 and 3.20
Discuss plans to prevent soil erosion during and after construction, including responsibility for long-term effects of erosion, sediment in streams, and duration of responsibility.	Section 3.6
NEPA Process	
The NEPA process should be held in abeyance until there is a full and fair hearing on the merits of Clean Line's application [under Section 1222].	Section 1.1
Individuals received notification of scoping meetings with too short notice or after meetings in their area had been held.	Appendix E
Requests for extension of scoping period.	Appendix E
Continue the level of public involvement during public hearings on Draft EIS. Commenter suggested that Clean Line has been very open with level of information and interaction with public.	Appendix E

Table 1.5-1:
Issues Identified through Scoping

Resource or Issue Area and Issues to be Analyzed	Location in EIS
Commenters expressed dissatisfaction with lack of communication about the Project and the quality of the maps at the scoping meetings and on the EIS website.	Appendix E
Address concerns that Northern route (Segment M-4) was announced during scoping period.[1]	Appendix E
Comments should have been recorded during scoping meetings.	Appendix E
Petitions	
A petition was submitted by residents of Cedarville, Arkansas, and Crawford County, Arkansas, who are against the power transmission line coming through the county (Segment G). Four hundred eleven people signed the petition. Specific comments were identified in the petition and were included in the summaries for the following topics discussed above: route-specific alternatives, socioeconomic, agriculture, and cultural, historical, and archaeological resources.[1]	Appendix E
Purpose and Need	
The federal government should not be involved in the Project, because the Project would benefit a private corporation.	Chapter 1
Recreation	
Analyze impacts on recreational uses including fishing, hunting, hiking, camping, canoeing (Lake Poinsett; Poinsett County, Arkansas; Segment K-1 Jackson County, Arkansas).[1]	Section 3.12
Consider impacts on recreational areas, including national and state parks and forests.	Section 3.12
Consider disturbance of recreational activities such as hang-gliding or riding all-terrain vehicles on private lands.	Section 3.12
Avoid crossings of resources that are Scenic Byways, Extraordinary Resource Waters, or National Blueways, in areas that may have recreational importance. [A National Blueway designation includes the entire river from its “headwaters to mouth” as well as the river’s watershed (American Rivers 2014).]	Section 3.12
Address use of easement areas for recreational activities such as hiking and camping.	Section 3.12
Socioeconomic Resources	
Evaluate and quantify expected impacts on property and land values along the route.	Section 3.13
Address compensation of land owners along the proposed ROW.	Section 3.13
Describe the economic benefits of the Project to the residents and state of Arkansas.	Section 3.13
Analyze the direct and indirect economic impacts of the proposed route, including to industries such as agriculture, tourism, rice farmers, duck hunting operations (Segments L, L-2, and L-4), and timber farmers.[1]	Section 3.13
Analyze impacts of short and long-term employment associated with the Project.	Section 3.13
Discuss the impacts of the Project on plans for future development and mineral exploration opportunities.	Section 3.13
Discuss how much the Project will cost the state of Tennessee.	Section 3.13
Discuss the impacts of the Project on smaller communities within the Project area that may not be able to absorb the influx of population.	Section 3.13
Traffic and Noise	
Analyze noise emitted by power lines.	Sections 3.4 and 3.11
Consider impacts of noise caused by ROW crews, including the possibility for extended work hours.	Section 3.11
Consider impacts of increased traffic from construction and maintenance, including increase in dangerous conditions and damage to roads.	Sections 3.11 and 3.16
Address road improvements that will be made before, and after, construction of the Project (Segment H; Woodward, Oklahoma).[1]	Section 3.16, Chapter 4
Vegetation	
Identify and address use of BMPs[2] to minimize disturbance to natural resources, including ground cover, hay production, pecan groves, and sensitive plants along the entire route.	Sections 3.2, 3.10, and 3.17

Table 1.5-1:
Issues Identified through Scoping

Resource or Issue Area and Issues to be Analyzed	Location in EIS
Address potential impacts that removal of vegetation would have on impaired water bodies, specifically related to filtering of pollutants.	Sections 3.15 and 3.17
Describe impacts of Project on significant grassland habitat in central Oklahoma (Segment F-8).[1]	Section 3.17
Discuss how vegetation will be managed along the ROW, specifically the use of chemicals and ability of landowners to manage vegetation as they desire (i.e., without the use of herbicides and defoliants).	Sections 3.8 and 3.17
Visual and Aesthetic	
Quantify and evaluate the visual impacts of the Project, including on scenic vistas.	Section 3.18
Describe the impacts to property owners' views that may be impacted by the proposed route.	Section 3.18
Avoid crossings/routes in Arkansas in areas that negatively impact scenic sections of Extraordinary Resource Waters; high quality fisheries; Arkansas Water trails; Arkansas Heritage Trails; and National Blueways; and National Scenic Byways.	Section 3.18
Analyze how the visual impacts of the Project may have negative effects on tourism and recreational activities.	Section 3.18
Discuss design aspects of the Project, including tower structures and distance between towers.	Section 3.18
Discuss impacts created by light pollution.	Section 3.18
Waste Management	
No scoping comments were received in this category.	
Water Resources	
Analyze impacts to water resources including water quality, pollutant sources, load allocations associated with drinking water standards, drinking water sources, wells, springs, wetlands, alluvial aquifers, rivers, streams, creeks, and lakes.	Section 3.15
Discuss impacts to floodplains.	Section 3.19
Discuss impacts to several sensitive, designated, and navigable resources being crossed or in the vicinity of the Project (Segments J, L-4, L-5, and M-5).[1]	Sections 3.15 and 3.19
Discuss impacts to aquifers, specifically in Jackson and Poinsett counties where alluvial aquifer begins at 15 feet below the surface.	Section 3.15
Discuss mitigation measures to protect underground water and water wells.	Section 3.15
Wildlife (including fish and critical habitat)	
Discuss potential for the Project to cause fragmentation of wildlife habitat, including to significant grassland habitat in central Oklahoma.	Sections 3.14 and 3.20
Address the impact to threatened and endangered species, and their habitat, found along the proposed routes, including mitigation and plans to avoid sensitive species.	Section 3.14
Analyze impacts of the Project on migratory bird habitat and flyways (including Mississippi Flyway).	Sections 3.14 and 3.20
Discuss impacts of Project on migrating birds.	Sections 3.14 and 3.20
Proposed routes should avoid lands recognized by the National Audubon Society as Important Bird Areas.	Section 3.20
The route that includes Cedarville, Arkansas, will impact the Ozark Mountains habitat currently protected by a partnership with the U.S. Geological Survey and the Arkansas Natural Heritage Commission.	Sections 1.5 and 2.5
Discuss impacts to old growth forests and the American burying beetle (Segment J).[1]	Sections 3.4 and 4.3
Describe potential impacts to the Cache River National Wildlife Refuge.	Sections 3.10, 3.12, 3.18, 3.20
Discuss impacts to the lesser prairie-chicken.	Sections 3.14 and 4.3

1 Segment identifications are based on the segment letters and numbers for the network of potential routes provided during public scoping (See Appendix E of the Alternatives Development Report (DOE 2013) for more information).

2 Best management practices (BMPs), as used in this table, is a general term used in scoping comments and does not reflect the same meaning as used in the balance of the Final EIS.

Several comments received during the scoping period identified the lack of benefits from the Applicant Proposed Project to residents in Arkansas (e.g., ability to accept increased amounts of renewable energy, tax revenues from property and ad valorum taxes associated with new facilities, and increased number of jobs). As a result of these scoping comments, DOE requested that Clean Line evaluate the feasibility of an alternative that would add a converter station in Arkansas in order to facilitate the delivery of up to 500MW of electricity to the state. The DOE Alternatives evaluated in the Plains & Eastern EIS include a converter station alternative in Arkansas. The details of this converter station alternative are presented in Chapter 2 (Sections 2.1.2.1 and 2.4.3.1).

The development of route alternatives considered the numerous scoping comments on the topic of transmission line routing. The details of the route selection process are provided in Sections 2.3 and 2.4 of the Plains & Eastern EIS and in the DOE Alternatives Development Report (DOE 2013).

1.5.3 Draft Environmental Impact Statement

The Draft EIS analyzed and compared the potential environmental impacts of the Applicant Proposed Project, the range of reasonable alternatives, and the "No Action" alternative. DOE considered all scoping comments received as well as information collected during consultations with state and federal agencies and Tribal governments in the preparation of the Draft EIS. The Draft EIS provided information on the methodologies and assumptions used for the analyses and identified environmental protection measures (EPMs) and BMPs that could prevent or minimize the potential environmental impacts of the Project. CEQ NEPA regulations require that a Draft EIS identify the agency's preferred alternative or alternatives, if one or more exists (see Section 2.14).

EPA published a Notice of Availability in the *Federal Register* (79 FR 78088) announcing the comment period for the Draft EIS. DOE published a separate Notice of Availability for the Draft EIS in the *Federal Register* (79 FR 75132), which included the locations, dates, and times of the public hearings regarding the Draft EIS and identified the methods for submitting comments during the 90-day public comment period. This information was also posted on the Project's EIS website (http://www.plainsandeasterneis.com).

The 90-day public comment period for the Draft EIS began on December 19, 2014, and was scheduled to end on March 19, 2015 (79 FR 78079). On February 12, 2015, DOE announced in the *Federal Register* that it was extending the comment period until April 20, 2015 (80 FR 7850). DOE considered comments submitted after the close of the comment period to the extent practicable.

During the comment period, DOE held 15 public hearings in the following locations: Woodward, Oklahoma; Guymon, Oklahoma; Beaver, Oklahoma; Perryton, Texas; Muskogee, Oklahoma; Cushing, Oklahoma; Stillwater, Oklahoma; Enid, Oklahoma; Newport, Arkansas; Searcy, Arkansas; Marked Tree, Arkansas; Millington, Tennessee; Russellville, Arkansas; Fort Smith, Arkansas; and Morrilton, Arkansas. There were 1,400 people signed in at the 15 meetings for an average sign-in attendance of 93 individuals. Attendance at the meetings ranged from 34 to 273 individuals who signed the registration sheet. Approximately 270 commenters spoke at the 15 public hearings.

Approximately 950 comment documents were received from individuals, interested groups, Tribal governments, and federal, state, and local agencies during the public comment period on the Draft EIS. This total includes a single copy of documents that were received as part of 50 e-mail and letter campaigns (i.e., identical letters signed and submitted by more than one commenter). The total number of campaign documents was approximately 1,700 emails or letters. The comment documents consisted of emails or electronic submittals, hand-ins at the public hearings, campaigns or petitions, comments received through the U.S. mail, and hearing transcripts. The comments contained within these comment documents have been addressed in the Comment Response Document (Appendix Q). Late comments have been considered to the extent practicable. The primary topics raised include, but are not limited to: easement acquisition and property rights, routing issues, and potential health effects associated with electromagnetic fields.

1.5.4 Final Environmental Impact Statement

DOE has prepared this Final EIS, which addresses public comments received on the Draft EIS and includes new information not available at the time of the Draft EIS (e.g., Biological Assessment and draft Programmatic Agreement developed by certain tribes, SHPOs, DOE, and ACHP to address potential adverse effects to historic properties under Section 106 of the NHPA). The environmental analyses have been updated or revised to address the public comments and the introduction of the route variations of the Applicant Proposed Route (see Section 2.4.2). The Final EIS identifies DOE's preferred alternative in Section 2.14. EPA will publish a Notice of Availability of the Final EIS in the *Federal Register*.

1.5.5 Record of Decision

The ROD is the formal agency decision document for the EIS process. DOE's ROD would announce and explain DOE's decision pursuant to Section 1222 of the EPAct of 2005 on whether and under what conditions to participate in the Project and describe any conditions, such as mitigation commitments, that would need to be met. DOE may issue a ROD no sooner than 30 days after EPA's Notice of Availability of the Final EIS is published in the *Federal Register*. The identification of a preferred alternative in an EIS (Section 2.14) does not guarantee that such an alternative will be the alternative selected in DOE's ROD. Rather, identification of the preferred alternative serves to notify the public which alternative DOE currently favors.

1.6 Consultation and Coordination with Federal, State, and Local Governments and Indian Tribes

In addition to the cooperating agencies identified in Section 1.2, DOE contacted Native American Tribes and Nations and federal, state, and local agencies during the DOE EIS scoping process and, in some instances, during the development of the EIS. The agencies and Tribes and Nations that DOE contacted during EIS scoping are listed in Tables 1.6-1 and 1.6-2, respectively, in alphabetical order.

Table 1.6-1:
Agencies Contacted during Scoping

Agency	Agency
Advisory Council on Historic Preservation	Oklahoma Office of the Secretary of Energy
Arkansas Department of Environmental Quality	Oklahoma Tourism and Recreation Department
Arkansas Farm Service Agency	Oklahoma Turnpike Authority
Arkansas Game and Fish Commission	Oklahoma Water Resources Board
Arkansas Governor Beebe's Chief of Staff	St. Francis Levee District, Arkansas
Arkansas Highway and Transportation Department	Tennessee Department of Environment and Conservation
Arkansas Historic Preservation Program	Tennessee Department of Environment and Conservation, Division of Water Resources
Arkansas Natural Heritage Commission	Tennessee Department of Environment and Conservation, Natural Areas Program

Table 1.6-1:
Agencies Contacted during Scoping

Agency	Agency
Arkansas Parks and Tourism	Tennessee Department of Environment and Conservation, Natural Heritage Inventory Program
Arkansas Riverbed Authority	Tennessee Department of Transportation
Bureau of Indian Affairs (Cherokee Nation, Eastern Oklahoma Region, Horton Agency, Pawnee Nation, Southern Plains Region)	Tennessee Historical Commission
Farm Service Agency (Arkansas, Oklahoma, Tennessee)	Tennessee Office of the Governor
Federal Highway Administration (Arkansas, Oklahoma, Tennessee)	Tennessee Valley Authority
Natural Resources Conservation Service (Arkansas, Oklahoma, Tennessee; Eastern Programs Division, Washington, DC)	Tennessee Wildlife Resources Agency
Oklahoma Biological Survey	U.S. Army Corps of Engineers (Little Rock, Memphis, and Tulsa Districts; U.S. Army Corps of Engineers Regulatory Office-Oklahoma)
Oklahoma Conservation Commission	U.S. Coast Guard Tennessee
Oklahoma Department of Agriculture, Food, and Forestry	U.S. Department of Agriculture
Oklahoma Department of Environmental Quality	U.S. Environmental Protection Agency (Regions 4 and 6)
Oklahoma Department of Transportation (Ada and Oklahoma City, Oklahoma)	U.S. Fish and Wildlife Service (Ecological Services Offices in Arkansas, Oklahoma, Tennessee); Central Arkansas National Wildlife Refuge
Oklahoma Department of Wildlife Conservation	Vance Air Force Base Oklahoma
Oklahoma Historical Society State Historic Preservation Office	

Table 1.6-2:
Tribes Contacted during Scoping

Tribe	Tribe
Absentee-Shawnee Tribe of Indians of Oklahoma	Kiowa Indian Tribe of Oklahoma
Alabama Quassarte Tribal Town	Modoc Tribe of Oklahoma
Apache Tribe of Oklahoma	Quapaw Tribe of Oklahoma
Caddo Nation of Oklahoma	Sac & Fox Nation, Oklahoma
Cherokee Nation	Santee Sioux Nation, Nebraska
Cherokee Nation (Real Estate Service)	Seneca-Cayuga Nation
Choctaw Nation of Oklahoma	Cheyenne and Arapaho Tribes
Comanche Nation, Oklahoma	The Muscogee (Creek) Nation—Eastern Oklahoma Region
Delaware Nation, Oklahoma	The Osage Nation
Delaware Tribe of Indians	Thlopthlocco Tribal Town
Eastern Band of Cherokee Indians	Tonkawa Tribe of Indians of Oklahoma
Iowa Tribe of Oklahoma	United Keetoowah Band of Cherokee Indians in Oklahoma
Kaw Nation, Oklahoma	Wichita and Affiliated Tribes, Oklahoma
Kialegee Tribal Town	

As part of these communications, DOE invited the federal and state agencies and Tribes that may attach religious and cultural significance to historic properties that may be affected by the Project to participate, as related to their authority or expertise, in the routing process for the HVDC transmission. DOE sent maps and information regarding potential routes to agencies and these Tribes for review and input during the development of the routing alternatives. Details of each agency and Tribal involvement in the routing process are included in the Alternatives Development Report (DOE 2013).

Indian Tribes and Nations that have agreed to be consulting parties in the Section 106 process are the Absentee-Shawnee Tribe of Indians of Oklahoma, the Cherokee Nation, the Chickasaw Nation, the Choctaw Nation of Oklahoma, the Iowa Tribe of Oklahoma, the Muscogee (Creek) Nation, the Osage Nation, the Quapaw Tribe of Oklahoma, the Sac and Fox Nation, the Thlopthlocco Tribal Town, the United Keetoowah Band of Cherokee Indians in Oklahoma, and the Wichita and Affiliated Tribes (Appendix P). DOE intends to execute the PA prior to issuance of the ROD or otherwise comply with procedures set forth in 36 CFR Part 800.

1.7 Organization of the Final EIS

This EIS examines the potential environmental impacts of the Applicant Proposed Project, the DOE Action Alternatives, and a No Action Alternative, and as explained in Section 3.1, addresses 19 environmental resources.

The EIS is organized into eight chapters with supporting appendices. Chapter 1 describes DOE's purpose and need for agency action, cooperating agency and federal government involvement, Clean Line's objectives, NEPA requirements, and consultation efforts with federal, state, and local governments and Tribes. Chapter 2 includes a description of the Project, alternatives considered, and potential connected actions, and provides a summary of the potential environmental impacts by resource area. Chapter 3 describes the affected environment and potential environmental impacts of the Project. Chapter 4 describes the potential cumulative impacts of the Project. Chapter 5 provides the list of preparers of the EIS. Chapter 6 provides the references used in the preparation of the EIS. Chapter 7 contains a glossary of terms, and Chapter 8 contains an index. Supporting information to the EIS is provided in 17 appendices as listed in Table 1.7-1. The appendices in the Draft EIS were labeled sequentially in the order in which they were cited in the document. These labels have not been changed for the Final EIS, even though new appendices have been added (Appendices M–Q).

Appendix Q	Comment Response Document

1 ROI (Region of Influence): To examine the potential impacts of the Project components, the EIS examines the area potentially affected by the Applicant Proposed Project and the DOE Alternatives. The EIS defines the area potentially affected by the Project as the ROI. A description of the ROI is provided in Section 3.1. The ROI may be expanded or modified on a resource specific basis where appropriate as described in each resource section.

2. Project Description and Alternatives

2.1 Project Overview

The Applicant Proposed Project would include an overhead ±600 kilovolt (kV) HVDC electric transmission system and associated facilities with the capacity to deliver approximately 3,500MW primarily from renewable energy generation facilities in the Oklahoma and Texas Panhandle regions to load-serving entities in the Mid-South and Southeast United States via an interconnection with TVA in Tennessee. One of the DOE Alternatives (as described in Section 2.4.3) would increase the capacity of the proposed transmission system and facilities by 500MW (to 4,000MW) to facilitate delivery of electricity to the grid in Arkansas. A description of the Applicant Proposed Project's major facilities and improvements is included in Section 2.1.2. Further details and information for each of the Applicant Proposed Project's major facilities, construction procedures, and environmental protection measures (EPMs) are included in Appendix F.

Commonly Used Terms

Throughout the Plains & Eastern EIS, the following terms are used to describe different elements of the proposal being evaluated.

Applicant Proposed Project—Based on Clean Line's modified proposal to DOE,[1] the basic elements include converter stations in Oklahoma and Tennessee, AC interconnections at each converter station, an AC collection system, and an HVDC transmission line from the Oklahoma Panhandle to western Tennessee. The Applicant Proposed Project is described in detail in Sections 2.1.2 through 2.1.7.

Proposed Action—For DOE to participate, acting through the Administrator of Southwestern, in the Applicant Proposed Project in one or more of the following ways: designing, developing, constructing, operating, maintaining, or owning a new electric power transmission facility and related facilities located within certain states in which Southwestern operates, namely Oklahoma, Arkansas, and possibly Texas,[2] but not Tennessee.

Applicant Proposed Route—The single 1,000-foot-wide route alternative defined by Clean Line to connect the converter station in the Oklahoma Panhandle to the converter station in western Tennessee. The analyses of impacts are typically based on a representative 200-foot-wide right-of-way (ROW) within the 1,000-foot-wide corridor. The Applicant Proposed Route is defined in detail in Section 2.4.2.

DOE Alternatives—Pursuant to NEPA, DOE has identified and analyzed potential environmental impacts for the range of reasonable alternatives in addition to the Applicant Proposed Project. These alternatives include an Arkansas converter station and alternative routes for the HVDC transmission line. In each instance, these alternatives have been discussed and evaluated with Clean Line for feasibility. The DOE Alternatives are described in detail in Section 2.4.3.

The Project—A broad term that generically refers to elements of the Applicant Proposed Project and/or DOE Alternatives when differentiation between the two is not necessary. The term also refers to whatever combination of project elements would be built if a decision is made by DOE to participate with Clean Line.

2.1.1 DOE Proposed Action

DOE's Proposed Action is to participate, acting through the Administrator of Southwestern, in the Applicant Proposed Project in one or more of the following ways: designing, developing, constructing, operating, maintaining, or owning a

1 In response to DOE's *Request for Proposals for New or Upgraded Transmission Line Projects under Section 1222 of the Energy Policy Act of 2005.*

2 Depending on AC collection system routes implemented (some of which are in Texas).

new electric power transmission facility and related facilities located within certain states in which Southwestern operates, namely Oklahoma, Arkansas, and possibly Texas.

2.1.2 Applicant Proposed Project Description

The Applicant Proposed Project would include an overhead ±600kV HVDC electric transmission system and associated facilities with the capacity to deliver approximately 3,500MW primarily from renewable energy generation facilities in the Oklahoma and Texas Panhandle regions to load-serving entities in the Mid-South and Southeast United States via an interconnection with TVA in Tennessee.

Major facilities associated with the Applicant Proposed Project consist of converter stations in Oklahoma and Tennessee, an approximate 720-mile, ±600kV HVDC transmission line, an AC collection system, and access roads. The following sections summarize the Applicant Proposed Project's major facilities and improvements.

2.1.2.1 Converter Stations and Other Terminal Facilities

The Applicant Proposed Project includes two AC/ DC converter stations, one at each end of the transmission line. The Applicant proposes to locate a converter station in Texas County, Oklahoma, and a converter station in Shelby County, Tennessee. At each converter station, an AC interconnection to the existing grid would be required. These interconnections would include:

- One double-circuit 345kV AC transmission line connecting to the future Xcel Energy/Southwestern Public Service Co. Optima Substation in Oklahoma
- 500kV AC ties connecting to the TVA Shelby Substation in Tennessee

An additional converter station and associated interconnection facilities in Arkansas are also being evaluated as part of the DOE Alternatives. Information on this alternative is provided in Section 2.4.3.

2.1.2.1.1 Elements Common to the Converter Stations

Some elements are common to all of the converter stations, regardless of location. These elements are described in this section. Elements that are unique to a specific converter station are discussed in Sections 2.1.2.1.2 and 2.1.2.1.3. A converter station would be similar to a typical AC substation, but with additional equipment to convert between AC and DC. Ancillary facilities such as communications equipment and cooling equipment would be required at each converter station. Each converter station would include:

- DC switchyard
- DC smoothing reactors
- DC filters
- Valve hall(s) (which contain the power electronics for converting AC to DC and vice versa)
- Ancillary building(s) (containing control and protection equipment, cooling, etc.)
- AC switchyard
- AC filter banks
- AC circuit breakers and disconnect switches
- Transformers

A typical converter station may require 45 to 60 acres. The AC switchyard would occupy the largest area of the electrical facility within the converter station footprint. There could be up to two buildings (valve halls) to house the power electronic equipment used in AC/DC conversion, each approximately 275 feet long by 80 feet wide. Valve halls protect the converter equipment from ambient conditions and impede the audible noise generated by the equipment. The valve halls could be 60 to 85 feet tall. Additionally, smaller buildings would house the control room, control and protection equipment, auxiliaries, and cooling equipment. Other electrical equipment may be required within the AC portion of the switchyard. Transformers would be located adjacent to the valve hall(s) and surrounded on two sides with concrete fire walls. In addition to preventing a fire in one transformer from spreading to adjacent ones, the walls would also impede audible noise generated by the transformers. The Applicant would utilize a 10- to 20-acre laydown area during construction and post construction as parking and for locating warehousing facilities within the fenced converter station if needed. Figure 2.1-1 (located in Appendix A) shows a typical converter station layout. Tables 2.1-1 and 2.1-2 provide the typical facility dimensions and anticipated land requirements for converter stations during construction and operations and maintenance.

Figure 2.1-2 (located in Appendix A) depicts the potential siting areas under consideration for the converter stations and interconnection facilities for the Project. Figures 2.1-3 and 2.1-4 (located in Appendix A) depict the converter station siting area locations in Oklahoma and Tennessee, respectively.

Typical structures for AC Interconnection include lattice structures and tubular pole structures and their respective dimensions are summarized in Tables 2.1-1 and 2.1-2. The typical pole structures for AC interconnection are depicted on Figures 2.1-5 through 2.1-10 (located in Appendix A).

2.1.2.1.2 Oklahoma Converter Station and Associated Facilities

In addition to the common features described in Section 2.1.2.1.1, the Oklahoma Converter Station would also include the features/facilities as described below. Table 2.1-1 summarizes the facilities, dimensions, and land requirements for the Oklahoma converter station.

The western terminus of the Project would interconnect to the existing transmission system operated by the Southwest Power Pool (SPP) in Texas County, Oklahoma. To facilitate this interconnection, Xcel Energy/Southwestern Public Service Company would construct a new 345kV substation called Optima. A double-circuit 345kV transmission line up to 3 miles in length would be needed to interconnect the proposed converter station with the Optima Substation. The Applicant would use lattice and/or tubular pole structures to support the transmission line.

The double circuit 345kV AC line would consist of an arrangement of three electrical phases per circuit. Each phase would have a two-conductor bundle (two subconductors) in a vertical configuration with approximately 18 to 24 inches of separation between the subconductors. Each conductor would be an approximate 1- to 1.5-inch-diameter aluminum conductor with a steel reinforced core, or a very similar configuration. The exact height of each structure and required vertical clearances would be governed by topography and safety requirements. The Applicant would design minimum conductor height above the terrain, assuming no clearance buffers, per Rule 232D of the 2012 edition of the National Electrical Safety Code (NESC), which requires 25 feet of clearance above general areas and areas with vehicular traffic (for a 345kV AC line). The NESC provides for minimum distances between the conductors and the ground, crossing points of other lines, the transmission support structure, and other conductors on the same structure. The NESC also provides minimum working clearances for personnel during energized operations and maintenance activities (IEEE 2011).

Table 2.1-1:
Oklahoma Converter Station and Associated Facilities Dimensions and Land Requirements

Facility	Construction Dimensions[1]	Operation Dimensions[1]
Converter Station	45 to 60 acres of land would be required for the station, plus an additional 5 to 10 acres for construction.	45 to 60 acres of land would be required for the station; approximately 45 acres would be fenced.
Converter Station Access Roads	All weather access roads 20 feet wide x less than 1 mile long would be required. Construction of the access roads may disturb an area up to 35 feet wide.	20-foot-wide paved roadways.
ROW	One 345kV ROW; 150–200 feet wide x 3 miles long.	One 345kV ROW: 150–200 feet wide x 3 miles long.
345kV—Lattice Structures	Structure assembly area: 150 feet wide (ROW width) x 150 feet long (within ROW) 5 to 7 structures per mile. 3 miles x 6 structures per mile = 18 structures for 345kV AC.	Structural footprint 28 feet x 28 feet (typical for lattice structures) 75 to 180 feet tall; 5 to 7 structures per mile.
345kV—Tubular Pole Structures	Structure assembly area 150 feet wide (ROW width) x 150 feet long (within ROW); 5 to 7 structures per mile.	Structural footprint 7 feet x 7 feet (typical for tubular pole structures) 75 to 180 feet tall; 5 to 7 structures per mile.
AC Interconnection Point	Inside the Xcel Energy/Southwestern Public Service Co., substation that is planned to be built in the future (identified by transmission planning studies as Optima).	Inside the Xcel Energy/Southwestern Public Service Co. substation that is planned to be built in the future (identified by transmission planning studies as Optima).

1 Final design and/or dimensions may differ from typical dimensions expressed here.

2.1.2.1.3 Tennessee Converter Station and Associated Facilities

In addition to the common features described in Section 2.1.2.1.1, the Tennessee converter station would also include the following features/facilities. Table 2.1-2 summarizes the facilities, dimensions, and land requirements for the Tennessee converter station. Based on preliminary designs and studies, this converter station would have a nominal capacity of 3,500MW.

The proposed eastern converter station would interconnect to the existing transmission system operated by TVA at the existing TVA 500kV Shelby Substation, located in Shelby County, Tennessee. Based on TVA's final Interconnection System Impact Study (SIS), TVA would need to make substation and transmission upgrades to accommodate interconnection of the Project to the transmission system in Tennessee. The substation upgrades (also referred to as direct assignment facilities) include additional bays, breakers, switches, line relays, and interchange meters, which would be installed within the Shelby Substation. Network upgrades to the TVA transmission system are described in more detail in Section 2.5.2 and are addressed as connected actions in this EIS.

The 500kV AC ties connecting the Tennessee converter station to the existing Shelby Substation would consist of an arrangement of three electrical phases each with a three-conductor bundle (i.e., three subconductors). Final configuration and design of these interconnection facilities is ongoing as part of the TVA facilities study. Because the Tennessee Converter Station Siting Area would be located adjacent to the existing Shelby Substation (Figure 2.1-4), the 500kV AC ties are expected to be contained entirely within the converter station footprint and the Shelby Substation footprint.

Table 2.1-2:
Tennessee Converter Station and Associated Facilities Dimensions and Land Requirements

Facility	Construction Dimensions[1]	Operation Dimensions[1]
Converter Station	45 to 60 acres of land would be required, plus an additional 5 to 10 acres for construction.	45 to 60 acres of land would be required for the station; approximately 45 acres would be fenced.
Converter Station Access Roads	All weather access roads 20 feet wide x less than 1 mile long would be required. Construction of the access roads may disturb an area up to 35 feet wide.	20-foot-wide paved roadways.
AC Interconnection Point	Inside the existing Shelby Substation	Inside the existing Shelby Substation

1 Final design and/or dimensions may differ from the typical dimensions expressed here.

2.1.2.2 HVDC Transmission Line

The Applicant Proposed Project would transmit energy from the Oklahoma converter station to the Tennessee converter station via an approximate 720 mile ±600kV HVDC overhead electric transmission line. HVDC transmission technology includes the ability for bi-directional power flow, or the flow of power in either direction through the converters. Under normal operating conditions for the Project, power would flow from the wind farms (directly connected to the Oklahoma converter station via the AC collection system) in an eastward direction with power injection in Arkansas (under a DOE alternative) and Tennessee. Because of its unique characteristics as a direct current interconnection, system operators in each of the three states could utilize the Project to help stabilize the regional electric grids by changing the direction of power flow within seconds if necessary. In these rare conditions, power could be injected from the Project to the western SPP in Oklahoma. The power for injection into the Oklahoma grid could come from either of two sources: (1) power generated from the wind farms connected through the AC collection system, or (2) power from the Arkansas or Tennessee electrical grids temporarily flowing westward into Oklahoma.

As part of its Applicant Proposed Project, Clean Line proposed one route for the HVDC transmission line. As required by NEPA, DOE has identified and analyzed other reasonable alternative routes. To simplify and organize the analysis of impacts from the HVDC transmission line, DOE has divided the 720-mile-long transmission line into seven sequential regions, numbered Region 1 to Region 7, and describes impacts from the Applicant Proposed Project by region. All HVDC alternatives, including the Applicant Proposed Route, considered for development and analyzed as part of this EIS are described in Section 2.4 and in the Alternatives Development Report (DOE 2013). As a result of public comments on the Draft EIS, DOE and Clean Line have developed 23 route variations for the Applicant Proposed Route. In all but one instance, Clean Line concluded that the route variations were technically feasible and expressed support for DOE's adoption of these route variations to replace the Applicant Proposed Route that was evaluated in the Draft EIS. DOE has evaluated these route variations both individually and collectively and has concluded that they do not constitute substantial changes in the Proposed Action or significant new circumstances or information relevant to environmental concerns. These route variations are described by region in Sections 2.4.2.1 through 2.4.2.7.

The Applicant would complete final design for the HVDC transmission line after a final route has been identified and subsequent detailed engineering studies and ROW acquisition activities have been completed. The final design and location of the transmission line would be consistent with the project description and analysis contained in this Final EIS. If future deviations from the 1,000-foot-wide corridor analyzed in this Final EIS become necessary, DOE would evaluate those deviations in accordance with DOE's NEPA implementing regulations at 10 CFR 1021.314 to determine whether additional environmental analysis is required.

The regions potentially affected by the HVDC Applicant Proposed Route (and the counties included in each region) are listed in Table 2.1-3. Figures 2.1-17a though 2.1-17f in Appendix A present an illustration of the Project (Applicant Proposed Route and DOE alternative routes). HVDC transmission facilities, which are described in detail in Appendix F, include:

- ROW easements for the transmission line, with a typical width of approximately 150 to 200 feet
- Tubular and lattice steel structures used to support the transmission line
- Electrical conductor (transmission line) and metallic return
- Communications/control and protection facilities (optical ground wire [OPGW], static wire, and fiber optic regeneration sites)

Table 2.1-3:
Counties Potentially Affected by the Applicant Proposed Route

Feature	Length (Miles)	State	Counties
Region 1 (Oklahoma Panhandle)	115.9	Oklahoma	Texas, Beaver, Harper, and Woodward
Region 2 (Oklahoma Central Great Plains)	106.3	Oklahoma	Woodward, Major, and Garfield
Region 3 (Oklahoma Cross Timbers)	162.6	Oklahoma	Garfield, Kingfisher, Logan, Payne, Lincoln, Creek, Okmulgee, and Muskogee
Region 4 (Arkansas River Valley)	126.4	Oklahoma and Arkansas	Muskogee and Sequoyah counties, Oklahoma, and Crawford, Franklin, Johnson, and Pope counties, Arkansas
Region 5 (Central Arkansas)	113.8	Arkansas	Pope, Conway, Van Buren, Cleburne, White, and Jackson
Region 6 (Cache River, Crowley's Ridge Area, and St. Francis Channel)	55.1	Arkansas	Jackson, Cross, and Poinsett
Region 7 (Arkansas Mississippi River Delta and Tennessee)	42.8	Arkansas and Tennessee	Poinsett and Mississippi counties, Arkansas, and Tipton and Shelby counties, Tennessee
Total Length of the Applicant Proposed Route	722.9		

1 These lengths reflect the route variations to the Applicant Proposed Route.

2.1.2.2.1 Right-of-Way

Construction and operations of the HVDC transmission line would require ROW easements, which would typically be 150 to 200 feet wide. The analyses of impacts in Chapter 3 are based on a representative 200-foot-wide ROW within a 1,000-foot-wide corridor. The final transmission line ROW could be located anywhere within the 1,000-foot-widecorridor identified in this Final EIS. The final location would be determined following the completion of the NEPA process, engineering design, and ROW acquisition activities. Determination of this final location is referred to as micrositing. The easement acquisition process is described in Section 2.1.3. Figure 2.1-18 (located in Appendix A) depicts the ROW requirements for the HVDC transmission line.

The width of easements is related to the required clearance distances for the conductors, which are dictated by the NESC. They are directly related to the structure height, span length, and terrain. The width of an easement would be wider than typical where tall structures, longer spans, or terrain demands greater horizontal clearance to maintain safe clearances. To date, the Applicant has identified two locations where the easement would be significantly wider than the typical 150 to 200 feet. These include the Arkansas River and the Mississippi River crossings, where the easement could be as wide as 200 to 550 feet. Preliminary engineering indicates that the easement widths in these two locations are likely to be near the middle of this range.

Section 2.1.3 provides information relating to the acquisition of ROW easements and Section 2.1.5.1 describes restrictions on other uses within the ROW during operations and maintenance.

2.1.2.2.2 Structures

The structures used to support the HVDC transmission line would be constructed using a mix of either tubular (monopole) or lattice steel and would typically range in height from 120 to 200 feet. Preliminary engineering indicates that most structures would be less than 160 feet when lattice structures are used and would tend to be less than 140 feet when monopole structures are used. Structure heights, span lengths, and vertical clearance would be determined in accordance with the NESC, the Applicant's design criteria, terrain and land use, and applicable standards and laws. The Applicant may use taller structures in circumstances where additional clearances and/or longer spans are required. The dimensions and land requirements of typical lattice and monopole structures are summarized in Table 2.1-4 and depicted in Figures 2.1-19 through 2.1-21 (located in Appendix A). In addition to typical structures, there would be limited use of lattice crossing structures (presently planned for the crossing of the Mississippi River and the Arkansas River). These crossing structures would be constructed of lattice steel and could approach 350 feet in height at the Mississippi River crossing and 200 to 250 feet in height at the Arkansas River crossing (up to 200 feet on the western bank and up to 250 feet on the eastern bank) in order to maintain necessary clearance over the navigable channels. There could also be limited use of guyed structures, either tubular or lattice steel.

Table 2.1-4:
HVDC Transmission Line Facility Dimensions and Land Requirements

Facility	Construction Dimensions[1]	Operation Dimensions[1]
ROW	200 feet wide x approximately 720 miles long.	200 feet wide x approximately 720 miles long.
Lattice Structures	Structure assembly area 200 feet wide (ROW width) x 200 feet long (within ROW), 4 to 6 areas per mile (one for each structure).	Structural footprint 28 feet x 28 feet (typical); 120 to 200 feet tall, 4 to 6 structures per mile.
Monopole Structures	Structure assembly area 200 feet wide (ROW width) x 200 feet long (within ROW), 5 to 7 areas per mile (one for each structure).	Structural footprint 7 feet x 7 feet (typical); 120 to 160 feet tall, 5 to 7 structures per mile.
Guyed Structures	Structure assembly area 200 feet wide x 300 feet long with the ROW as necessary in limited situations.	Structural footprint 7 feet x 7 feet typical (does not include guy wire[s]), 120 to 200 feet tall, as necessary in limited situations.
Lattice Crossing Structures	Structure assembly area 200 to 550 feet wide x 300 feet long as necessary in limited situations (e.g., Mississippi River and Arkansas River crossings), assumed within the 1,000-foot-wide corridor.	Structural footprint 64 feet x 64 feet (350-foot-tall version) 200 to 350 feet tall as necessary in limited situations.
Fiber Optic Regeneration Sites	100 feet wide x 100 feet long with one site every 180 to 200 miles (720 miles/1 site every 180 miles = approximately 4 sites), typically outside the ROW (but within 500 feet) and within the 1,000-foot-wide corridor.	100 feet wide x 100 feet long, 75 feet wide x 75-foot-long fenced area, control building 12 x 32 feet and 9 feet tall and within the fenced area, permanent access road to the fenced area, power supply to control building, backup power generator and fuel supply.

1 Final design and/or dimensions may differ from typical dimensions expressed here.

The span length for a transmission line is measured along the centerline between structures. For perspective, a structure spacing of six structures per mile would result in an average span length of 880 feet. At the Arkansas River, preliminary engineering indicates that the span length would be approximately 2,000 feet. At the Mississippi River, preliminary engineering indicates that the span length would be approximately 3,300 feet. These preliminary estimates are subject to change based on final engineering and site conditions (e.g., soil, structural, or geotechnical constraints).

The Applicant would select structure types at locations along the Project ROW based on these and other factors: land use, engineering efficiency, and existing facilities. Generally, the Applicant expects to use lattice structures for longer spans in open and wooded terrain and tubular (monopole) steel structures for spans that are shorter in length. The Applicant anticipates using guyed structures only in open grass or shrub terrain.

The Applicant would use either galvanized or weathering steel structures. Pier foundations, screw piles, caissons, concrete footings, guying, or other appropriate foundations would support the structures based on engineering considerations, cost, and land use. Structures could be directly embedded if loading and soil conditions at a specific site allow for direct burial. The structure footprint would vary by structure type as provided in Table 2.1-4.

The Applicant would complete final design for the HVDC transmission line after a final route has been chosen and subsequent detailed engineering studies and ROW acquisition activities have been completed. The final design and location of the transmission line would be consistent with the project description and analysis contained in this Final EIS. If future deviations from the 1,000-foot-wide corridor analyzed in this Final EIS become necessary, DOE would evaluate those deviations in accordance with DOE's NEPA implementing regulations at 10 CFR 1021.314 to determine whether additional environmental analysis is required. Drawings of the guyed structures are included as Figures 2.1-22 through 2.1-24 (located in Appendix A). A lattice crossing structure is shown in Figure 2.1-25 (located in Appendix A).

Further information and details regarding the HVDC transmission line including conductor types, metallic return, optical ground wire, static wire, communication facilities, and fiber optic regeneration sites are included in Appendix F.

2.1.2.3 AC Collection System

In addition to the HVDC transmission line, the Applicant Proposed Project would also include construction and operations and maintenance of AC collection system transmission lines to collect energy from generation resources in the Oklahoma and Texas Panhandle regions. The collection system would consist of four to six AC transmission lines up to 345kV from the Oklahoma converter station to points in the Oklahoma and Texas Panhandle regions to facilitate efficient interconnection of wind energy generation. Components of the AC collection system include:

- ROW easements for the transmission line, with a typical width of 150 to 200 feet
- Tubular or lattice steel structures used to support the transmission line
- Electrical conductor
- Communications/control and protection facilities (optical ground wire (OPGW), static wire, and fiber optic regeneration sites)

The Applicant expects that the points of interconnection from generation facilities would be located in the Oklahoma Panhandle and the Texas Panhandle, within approximately 40 miles of the Oklahoma converter station. The Applicant based the 40-mile radius on preliminary studies of engineering constraints and wind resource data, industry knowledge, and economic feasibility. Wind energy generation facilities (wind farms) would connect to the AC collection system by way of a number of possible configurations. These configurations could range in size from a direct tap, a bus ring, or even a small substation (about 2 to 5 acres in size) with transformer and switching equipment. The type and size of these AC connections is unknown at this time; the final design of these facilities would depend on a number of factors including their location, the number of connections, and the nameplate capacity and voltage of generation facilities.

Figures 2.1-17a and 2.1-26 (in Appendix A) depict the siting area for the AC collection system in the Oklahoma and Texas Panhandle regions. This EIS refers to possible locations of the AC collector lines as the AC collection system routes. These routes do not represent alternatives for DOE selection. Rather, future development of AC transmission lines within these possible routes would be driven by the locations of wind farms that may be constructed in the future to connect to the Project. Of the 13 possible routes identified, the Applicant anticipates that only 4 to 6 of these routes would be developed (Clean Line 2014b). The counties crossed by the AC collection system routes are provided in Table 2.1-5. Table 2.1-6 provides the typical facility dimensions and land requirements for construction and operations and maintenance of the AC collection facilities.

Table 2.1-5:
Counties Potentially Crossed by the AC Collection System Routes

Route	Length (Miles)	State	Counties
E-1	29.0	Oklahoma	Texas and Beaver
E-2	40.0	Oklahoma	Texas and Beaver
E-3	40.1	Oklahoma	Texas and Beaver
NE-1	29.9	Oklahoma	Texas
NE-2	26.2	Oklahoma	Texas
NW-1	51.9	Oklahoma	Texas and Cimarron
NW-2	56.0	Oklahoma	Texas and Cimarron
SE-1	40.2	Oklahoma	Texas
		Texas	Hansford and Ochiltree
SE-2	13.3	Oklahoma	Texas
		Texas	Hansford
SE-3	49.0	Oklahoma	Texas and Beaver
		Texas	Ochiltree
SW-1	13.3	Oklahoma	Texas
		Texas	Hansford
SW-2	37.0	Oklahoma	Texas
		Texas	Hansford and Sherman
W-1	20.8	Oklahoma	Texas

Table 2.1-6:
AC Collection System Facility Dimensions and Land Requirements

Facility	Construction Dimensions[1, 2]	Operation Dimensions[1, 2]
ROW	Four to six 345kV ROWs each: 150–200 feet wide x extending to the points of interconnection within approximately 40 miles of the converter station, (assumes 300 miles of 345kV for the AC collection system on the western end of the Project).	Four to six 345kV ROWs each: 150–200 feet wide x extending up to 40 miles from the converter station
345kV—Lattice Structures	Structure assembly area 150 feet wide (ROW width) x 150 feet long (within ROW), 5 to 7 structures per mile.	Structural footprint 28 feet x 28 feet (typical for lattice structures) 75 to 180 feet tall, 5 to 7 structures per mile.
345kV—Tubular Pole Structures	Structure assembly area 150 feet wide (ROW width) x 150 feet long (within ROW), 5 to 7 structures per mile, (300 x 6 structures per mile = 1,800 total structures for 345kV AC, it is assumed that half [900] would be monopole).	Structural footprint 7 feet x 7 feet (typical for tubular pole structures), 75 to 180 feet tall, 5 to 7 structures per mile.
345kV H-Frame Structures	Structure assembly area 150 feet wide (ROW width) x 150 feet long (within ROW), 5 to 7 structures per mile.	Structural footprint two poles spaced 25 feet apart each with a 7 feet x 7 feet footprint (typical for H-frame structures) 75 to 180 feet tall, 5 to 7 structures per mile.
Fiber Optic Regeneration Site	100 feet wide x 100 feet long (outside the ROW), approximately 6 sites required, outside the ROW and near the ROW (within 750 feet) but not necessarily abutting the ROW.	100 feet wide x 100 feet wide, 75 feet wide x 75-foot-long fenced area, control building 12 x 32 feet and 9 feet tall, within the fenced area, permanent access road to the fenced area, power supply to control building, backup power generator and fuel supply

1 Final design and/or dimensions may differ from typical dimensions expressed here.
2 The AC collection system transmission lines may not consist of a straight line from the converter station to the wind farms and therefore could be longer than 40 miles.

2.1.2.3.1 Right-of-Way

ROW easements for the AC transmission lines, with a typical width of approximately 150 to 200 feet, would be required. The final AC collection line ROWs could be located anywhere within the 2-mile-wide corridors identified in this Final EIS. The final location would be determined following the completion of the NEPA process, engineering design, and ROW acquisition activities. The ROW requirements for the AC transmission line are depicted on Figure 2.1-27 (located in Appendix A). Restrictions on other uses within the ROW during operations and maintenance are described in Section 2.1.5.1. Section 2.1.3 provides information relating to the acquisition of ROW easements.

2.1.2.3.2 Structures

The structures used to support the AC transmission lines would be constructed of either tubular (monopole) or lattice steel and would generally range in height from 75 to 180 feet. The Applicant would determine structure heights, span lengths, and vertical clearance in accordance with the NESC, the Applicant's design criteria, terrain and land use, and all applicable standards and laws. The Applicant may use taller structures in circumstances where additional clearances and/or longer spans are required based on engineering review.

The Applicant would construct the structures of either galvanized or weathering steel. Pier foundations, screw piles, caissons, concrete footings, guying, or other appropriate foundations would support the structures based on engineering considerations, cost, and land use. Structures could be directly embedded if loadings and soil conditions at a specific site allow for direct burial. The structural footprint would vary by structure type as described in Table 2.1-6 and depicted in Figures 2.1-5 through 2.1-10 (located in Appendix A).

Further information and details regarding the analytical assumptions for the AC collection system including conductor types, metallic return, optical ground wire, static wire, communication facilities, and fiber optic regeneration sites are included in Appendix F.

2.1.2.4 Access Roads

Access roads would be necessary for the Project during both construction and operation. The Applicant intends to maximize the use of existing public and private roads to the extent practicable, improve existing private roads where they are insufficient, and build new roads where existing roads are not available. During construction, use of existing and new roads would be required to access transmission ROWs, structure locations, fiber optic regeneration sites, and temporary construction areas during construction. During operations and maintenance, roads would be used for access to transmission ROWs (for vegetation management and movement of maintenance equipment), structure locations, and fiber optic regeneration sites. The Applicant does not anticipate the need for a new permanent access road along the entire length of transmission line ROWs and would locate access roads between structures in active agricultural areas along fence lines or field lines where practicable to minimize impacts. The Applicant has no plans for improvements to public roads (e.g., highways, state roads, or county roads). The Applicant plans to repair existing private roads before and after construction. Paving of roads would be limited to approach aprons at intersections with existing paved roads and all-weather access roads to converter stations, unless otherwise required by jurisdictional authorities.

Site conditions, engineering design, construction requirements, EPMs, and relevant permits would govern the specific locations of proposed new access roads. The Applicant's road construction standards would comply with the applicable jurisdictions' requirements.

The road types, definitions and the typical access road dimensions during construction and operations and maintenance are included in Table 2.1-7. Typical access roads are depicted on Figure 2.1-28 (located in Appendix A).

As described in Section 2.4 of Appendix F, the Applicant estimated access road miles for the HVDC transmission line (Table 2.1-8) based on preliminary engineering and access planning conducted in 2014. Preliminary engineering and access planning was conducted using assumed structure parameters from preliminary design, assumed span lengths, assumed conductor parameters from preliminary design, LiDAR (light detecting and ranging) data and aerial imagery from the Applicant Proposed Route. Estimated access road miles for the AC collection system and AC interconnection transmission lines (Table 2.1-9) were not based on preliminary engineering nor access planning, but are extrapolations based on quantities of line-miles. The details of this extrapolation are described in Appendix F. The estimated length (by road type within each region) for access roads associated with HVDC lines (which includes those associated with the fiber optic regeneration sites) is provided in Table 2.1-8. The estimated length for access roads associated with AC transmission lines (which includes those associated with the fiber optic regeneration sites) is provided by road type within each state in Table 2.1-9. The Applicant would use existing public roads during construction and operations and maintenance of the Project to the extent practicable, and has no plans for improvements to public roads.

Table 2.1-7:
Access Roads Dimensions and Land Requirements

Road Type	Definition	Construction Dimensions[1]	Operation Dimensions[1]
Existing Roads			
Existing Roads with No Improvements or Repairs (Public or Private Roads)	Existing roads with no improvements or repairs include public roads maintained by local or state jurisdictions. Private roads that can support construction traffic with no improvements or repairs are also included in this category.	Existing roads that require no improvements or repairs would support construction of the Project as is. No road construction or ground disturbance expected.	Existing roads with no improvements or repairs are suitable for operations as is.
Existing Roads that May Need Repairs (Private Roads)	Existing roads that may need repairs include most dirt and unimproved two-track roads on private land (not publically maintained roads), which are generally in a condition that supports construction traffic with repairs in some spots. No improvements to public roads are planned for construction. Examples of repairs would include grading to remove potholes or surface ruts over short distances. In many cases, grading would include reshaping the surface to promote drainage from the travel surface. In some cases, it may be necessary to replenish and re-grade gravel-surfacing material.	Typically, 14-foot-wide travel surface at straight sections and 16 to 20 feet wide at corners. Construction disturbance would typically include a total corridor up to 35 feet wide for these roads in limited areas where repairs are needed. It is assumed that the new disturbance width would be reduced by the width of the existing road (e.g., 35-foot-wide construction corridor – 16-foot-wide existing road = 19-foot-wide new disturbance). In areas with steep side slopes (greater than 15%), the construction disturbance corridor may be up to 50 feet wide.	Repairs to existing roads will be left in place to facilitate access during Project operations and maintenance.
Existing Roads that Need Improvements (Private Roads)	Existing roads that need improvements include private roads along which modifications to alignment, structural improvements, or drainage improvements would be required before they could be used for construction and/or operations and maintenance of the Project. These roads could not support construction traffic without significant upgrades. Examples include private roads that traverse numerous drainages, exhibit severe rutting, or have sharp switchbacks. Structural improvements typically involve excavation and replacement of unstable roadbed with structural embankment fill over geotextile and gravel surfacing.	Typically, 14-foot-wide travel surface at straight sections and 16 to 20 feet wide at corners. Construction disturbance would typically include a total corridor up to 35 feet wide for these roads. It is assumed that the new disturbance width would be reduced by the width of the existing road (e.g., 35-foot-wide construction corridor – 16-foot-wide existing road = 19-foot-wide new disturbance). In areas with steep side slopes (greater than 15%), the construction disturbance corridor may be up to 50 feet wide.	Improvements to existing roads will be left in place to facilitate access during Project operations and maintenance.

Table 2.1-7:
Access Roads Dimensions and Land Requirements

Road Type	Definition	Construction Dimensions[1]	Operation Dimensions[1]
New Roads			
New Overland Travel Roads (no improvements needed) (Private Roads)	Overland-travel roads include routes that are created by direct vehicle travel over low-growth vegetation and do not require clearing or grading. Existing low-growth vegetation would be maintained where practicable. These roads require no preparation prior to use by vehicles and equipment.	Typically, 14-foot-wide travel surface at straight sections and 16 to 20 feet wide at corners. There would be no clearing or grading for these roads. Construction traffic would occur over an area 14–20 feet wide.	The Applicant estimates that 75% of construction roads would be re-used for operations and maintenance access. The remaining 25% would be abandoned and terrain would be restored to the extent practicable.
New Overland Travel Roads with Clearing (Private Roads)	New overland travel roads with clearing include overland travel routes that require clearing and minor grading using heavy machinery to remove larger vegetation or other obstructions in some locations to ensure safe vehicle operation and access.	Typically, 14-foot-wide travel surface at straight sections and 16 to 20 feet wide at corners. Construction disturbance would typically include a total corridor up to 35 feet wide for these roads. In areas with steep side slopes (greater than 15%), the construction disturbance corridor may be up to 50 feet wide.	The Applicant estimates that 90% of construction roads would be re-used for operations and maintenance access. The remaining 10% would be abandoned and terrain would be restored to the extent practicable.
New Bladed Roads (Private Roads)	New bladed roads may be constructed to access structure locations or temporary work areas in steep or uneven terrain. Bladed roads are generally used on side slopes greater than 8% and are shaped to provide drainage. New bladed roads are typically un-surfaced unless required by the applicable jurisdiction, where soil and moisture conditions contribute to surface erosion or rutting.	Construction disturbance for these roads would typically be 35 feet wide (for 90% of the new bladed roads used for the Project). In areas with steep side slopes (greater than 15%), construction disturbance may be up to 50 feet wide. (It is assumed that less than 10% of new bladed roads for the Project would be up to 50 feet wide.)	The Applicant estimates that 90% of construction roads would be re-used for operations and maintenance access. The remaining 10% would be abandoned and terrain would be restored to the extent practicable.
New Temporary Matted or Aggregate Roads (Private Roads)	New matted or aggregate roads are temporary driving surfaces used to access structures or temporary work areas in soft, wet conditions. These would include a timber or composite temporary mat or aggregate underlain by geotextile fabric.	Construction disturbance would typically include a total corridor up to 35 feet wide for these roads.	No roads of this type would be retained for operations and maintenance access.

1 Final design and/or dimensions may differ from typical dimensions expressed here.

Table 2.1-8:
Estimated Access Road Miles by Road Type for HVDC Transmission Lines (by region)

Road Type	1	2	3	4	5	6	7	Totals
Existing Roads that May Need Repairs (miles)	80.5	21.5	42.9	58.3	46.3	32.7	19.4	301.7
Existing Roads that Need Improvements (miles)	2.3	4.5	21.9	20.9	23.6	37.6	14.7	125.6
New Overland Travel Roads (miles)	26.4	44.2	49.4	37.7	1.5	0.3	2.3	161.9
New Overland Travel Roads with Clearing (miles)	20.6	24.3	40.2	19.6	27.6	0.5	3.9	136.9
New Bladed Roads (miles)	3.5	14.9	33.9	41.7	58.6	11.9	4.6	169.1
New Temporary Matted or Aggregate Roads	0	0	0	0	0	21.5	14.1	35.7
Totals (miles)	133.4	109.5	188.4	178.2	157.6	104.6	59.1	930.8
Total Disturbance (acres)	190.7	291.5	500.6	420.6	445.0	240.8	140.6	2,229.8
Road Miles In ROW (percentage)	62	87	71	59	63	51	58	83
Road Miles Outside ROW (percentage)	38	13	29	41	37	49	42	17
Inside ROW (acres)	115.6	267.0	407.6	319.5	366.7	176.7	100.0	1,753.1
Outside ROW (acres)	75.1	24.4	93.0	101.0	78.3	64.2	40.6	476.8

Table 2.1-9:
Estimated Access Road Miles by Road Type for AC Transmission Lines (by state)

Road Type[1]	OK/TX[2]	AR	TN	Totals
Existing Roads that Need Improvements (miles)	4	1	0	5
Existing Roads that May Need Repairs (miles)	145	2	0	147
New Overland Travel Roads (miles)	48	0	0	48
New Overland Travel Roads with Clearing (miles)	38	1	0	39
New Bladed Roads (miles)	7	4	1	12
New Temporary Matted or Aggregate Roads	0	1	0	1
Totals (miles)	243	9	1	253
Total Disturbance (acres)	639.3	28.9	4.4	672.6
Road Miles In ROW (percentage)	85	78	85	
Road Miles Outside ROW (percentage)	15	22	15	
Inside ROW (acres)	543.4	22.6	3.8	
Outside ROW (acres)	95.9	6.4	0.7	

1 AC transmission lines include those proposed for AC interconnection at the converter stations and those proposed for the AC collection system.
2 The column for access road miles represents both Oklahoma and Texas and is not further segregated since the locations of the actual AC transmission lines for the AC collector system are not yet known and would be determined based on the locations of future wind farms.

2.1.3 Easements and Property Rights

Prior to construction, the Applicant or DOE, if it elects to participate in the Project, would acquire property interests from owners of land along the path of the Project. These interests could take the form of a temporary easement to allow for access roads and storage yards that will be needed during construction. They could also take the form of longer term easements or fee estates (i.e., full ownership), for siting transmission line structures, converter stations, and other facilities. The acquisition of these property interests would not in themselves result in any environmental impacts. Any potential environmental impacts to these property interests would be associated with the land use and activities that would occur within the ROW, which are evaluated in this EIS.

Any property interests in land needed for the Project would be acquired through a negotiated sale or eminent domain proceedings, where the land owners would be compensated for their property interests. According to the Applicant's expressed intent, the first step would be for the Applicant to offer compensation to landowners in exchange for easements or other property interests needed for the Project. If the Applicant is unable to acquire the necessary property interests from a landowner through a negotiated agreement, DOE may choose to acquire those property interests through a negotiated agreement for compensation. Where a negotiated agreement is not possible, DOE, acting through Southwestern, may in appropriate circumstances exercise the federal government's eminent domain authority to acquire the interests. Consistent with the Constitution of the United States and other applicable law, the landowner would be paid just compensation for the real estate interest. Real estate acquisition by federal entities, such as DOE, is governed by the Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970 (Public Law 91-646) (42 USC 4601 et seq.). DOE must also comply with 49 CFR Part 24, Subpart B, "Real Property Acquisition," the government-wide regulation that implements Public Law 91-646.

2.1.4 Proposed Project Construction

This section provides an overview for typical construction activities associated with different elements of the Project. A detailed description of construction of the converter stations, HVDC and AC transmission lines, AC collection system, and access roads is provided in Appendix F. Appendix F also provides estimates of the construction workforce, crew types (based on construction activities), crew numbers, average daily production rates per crew, construction equipment, local traffic from construction, and local vs. non-local workers.

The Applicant would implement the EPMs listed in Appendix F to avoid or minimize potential impacts from construction of the Project. Construction activities described in Appendix F would incorporate and be subject to the EPMs as well as measures/requirements imposed as part of federal or state permits and authorizations. The implementation and monitoring of these EPMs are discussed in Section 3.1 of the Plains & Eastern EIS.

The construction of a typical converter station would include:

- Land surveying and staking
- Pre-construction surveys for biological and cultural resources
- Clearing and grubbing, grading, and construction of all-weather access roads
- Fencing
- Compaction and foundation installation
- Installation of underground electrical raceways and grounds
- Steel-structure erection and area lighting
- Installation of insulators, bus bar, and high-voltage equipment
- Installation of control and protection equipment
- Placement of final crushed-rock surface
- Installation of security systems, including cameras
- Testing and electrical energization

The construction of a typical converter station would begin with survey work, geotechnical sample drillings, and soil resistivity measurements. The site-development work would include grubbing and reshaping the general grade to form a relatively flat working surface. This effort also would include the construction of all-weather access roads. The Applicant would erect a chain-link fence (8 to 10 feet tall) around the perimeter of the station to prevent unauthorized personnel from accessing the construction and staging areas. The perimeter fence would be a permanent safety feature to prevent the public from accessing the station. The Applicant would compact the excavated and fill areas to the required densities to allow structural foundation installations. Following the foundation installation, underground electrical raceways and copper ground-grid installation would take place, followed by steel-structure erection and area lighting. The steel-structure erection would overlap the installation of the insulators and bus bar as well as the installation of the various high voltage apparatus (typical of an electrical substation). The installation of the high voltage transformers would require special high-capacity cranes and crews (as recommended by the manufacturer) to be mobilized for the unloading, setting-into-place, and final assembly of the transformers. Construction of a single converter station is estimated to take 32 months. The construction personnel peak is estimated to be 242 workers, and the average over the construction duration is estimated to be 138 workers.

Construction activities for the HVDC and AC transmission lines would typically include the following activities:

- Preparation of multi-use construction yards
- Pre-construction surveys for biological and cultural resources
- Preparation of the ROW
- Clearing and grading
- Foundation excavation and installation
- Structure assembly and erection
- Conductor stringing
- Grounding
- Cleanup and site restoration

Figure 2.1-29 located in Appendix A illustrates these activities and the typical transmission construction sequence.

The duration of construction is expected to be approximately 36 to 42 months for the entire Project, including the time from initiation of clearing and grading through cleanup and restoration. The actual construction duration would depend on a number of factors such as weather and availability of labor. The Applicant would most likely divide the construction of the HVDC transmission line into several segments with multiple contractors working concurrently on different portions of the route to accomplish the Project's construction schedule and to maintain effective management of construction activities and allocation of resources. For the purposes of estimating resource needs for construction, the Applicant has assumed that the HVDC transmission line would be divided into five construction segments of approximately 140 miles in length. The Applicant would construct the four to six AC collection lines that would range in length from 13 to 56 miles, depending on the routes required (based on the location of future wind farms) (see Table 2.1-5). The construction crews would complete each of the individual activities required for construction along each segment in assembly line fashion (see Figure 2.1-29 in Appendix A and Appendix F). Construction may be active on any or all segments at any given time and activities may occur in parallel with other segments or staggered.

The Applicant expects that the duration of construction for either a single HVDC segment or the complete AC collection system would be approximately 24 months from mobilization of equipment to site restoration. The construction personnel peak for the AC collection system would be approximately 428 workers, and the average over the construction duration of the AC collection system would be approximately 305 workers. The construction personnel peak in any HVDC segment would be approximately 290 workers and the average over the construction duration of one HVDC segment would be 207 workers. The peak would occur when the structure setting operations begin, while several other operations are occurring at the same time. The size, number, and average daily production of each crew type are included in Appendix F, along with an estimate of construction workforce over time. The Applicant would stage construction on each segment of the HVDC transmission line and the AC collection system from multi-use construction yards located at regular intervals (approximately every 25 miles) along the route.

Project-wide, the workforce would reach a peak of approximately 2,431 workers. The average workforce across the Applicant Proposed Project would be approximately 1,260 people during an assumed 36-month construction duration.

2.1.4.1 Temporary Construction Areas

Temporary construction areas would be required to support construction. Temporary multi-use construction yards and fly yards (landing areas for helicopters used during construction) would be used for staging construction personnel and equipment, and for storage of materials to support construction activities. Tensioning or pulling sites and wire-splicing sites (described in more detail below) would also be staged at 2- to 3-mile intervals along the Project ROW. Typically (with the exception of tensioning or pulling sites addressed below), temporary construction areas would be outside the ROW. These areas would be sited at regular intervals and at convenient distances (described below) from the facilities being constructed for the Project.

2.1.4.1.1 Tensioning or Pulling Sites

Tensioning or pulling sites are temporary construction areas located adjacent to certain structures. These sites contain the stringing equipment required to pull conductor through a series of structures or tension conductor that has already been pulled such that the required conductor sag between structures is achieved. Because the stringing equipment needs to be located a sufficient distance away from structures during pulling or tensioning, these sites can extend up to 650 feet from the base of a structure. Tensioning or pulling sites would typically be approximately 2 to 3 miles apart to accommodate the maximum distance of a single conductor pull. Land requirements for typical tensioning or pulling sites (listed in Appendix F) would be either entirely within the ROW or partially outside the ROW, depending on the structure’s turning angle and type (e.g., mid-span or deadend). Where the transmission line turns, the tensioning or pulling sites may extend outside the ROW to maintain a straight line with the ground wire and conductor being pulled as shown in Figure 2.1-30 (located in Appendix A). Based on the Applicant’s preliminary engineering, approximately 755 pulling or tensioning sites would be required for the HVDC transmission line. Approximately 230 acres outside the ROW would be required for these tensioning or pulling sites. Approximately 200 pulling or tensioning sites would be required for the AC collection system. Approximately 64 acres outside the ROW would be required for these AC collection system tensioning or pulling sites.

2.1.4.1.2 Multi-use Construction Yards

Multi-use construction yards would be used primarily for staging of construction personnel and equipment and for material storage to support construction activities (Figure 2.1-31 in Appendix A). The Applicant would locate multi-use construction yards outside the ROW and typically at intervals of approximately 25 miles. Additionally, they would be located within approximately 10 miles of the ROW or Project facility. Typical multi-use construction yards would be approximately 25 acres in size, fenced, and access-controlled.

The Applicant may arrange individual multi-use construction yards differently, but typical sites would include areas designated for a field office, crew parking, sanitation, waste management, fueling, equipment wash, material storage, equipment storage, and fly yard. The Applicant would base fuel trucks, maintenance trucks, and construction crews in multi-use construction yards. The Applicant would store any fuel, lubricants, antifreeze, detergents, paints, solvents, and/or other chemicals used during construction at the multi-use construction yards consistent with standard practices and relevant permits.

To the extent practicable, the Applicant has committed to employ site-selection criteria to determine preferred locations for the multi-use construction yards; exceptions are noted below. The site-selection criteria for both temporary multi-use construction yards and fly yards include:

- The Applicant would prefer site multi-use construction yards on previously disturbed, privately owned parcels (e.g., vacant industrial yards, commercial lots) or on other such suitable parcels.
- Sites would be located in a manner to minimize conflict with nearby and adjacent land uses.
- Sites would have good access to public roads.
- Sites would be relatively flat.
- Sites would be selected for their relative ease of restoration.

Portable concrete batch plants would be located within multi-use construction yards where needed. Concrete would be required for construction of foundations for transmission structures, foundations for transformers and electrical equipment at converter stations, and foundations at fiber optic regeneration sites. Concrete would be delivered to structure sites and ancillary facilities in concrete trucks with a capacity of up to 10 cubic yards. The Applicant would obtain concrete from commercial ready-mix concrete producers to the extent practicable. In locations where haul times exceed 45 minutes (a haul distance of approximately 25 to 30 miles), concrete would be dispensed from portable concrete batch plants located within a multi-use construction yard. Based on preliminary review of commercial ready-mix plants in proximity to the Project, the Applicant may require up to four temporary batch plants for the HVDC transmission line and two for the AC collection system (where the haul distance may exceed 25 to 30 miles).

2.1.4.1.3 Fly Yards

The Applicant would use helicopters for conductor stringing operations and/or for transport and erection of structure sections during construction. The Applicant would locate helicopter landing areas (fly yards) at approximately 5-mile intervals along the ROW. Approximately 20 percent of fly yards would be collocated within multi-use construction yards. All other fly yards would be located near the ROW. Typical fly yards would be approximately 5 acres or less in size.

The Applicant may arrange individual fly yards differently, but typical sites would include areas designated for helicopter landing, crew parking, sanitation, waste management, refueling, and temporary material staging. Fly yards would be operated and maintained consistent with standard practices and relevant permits. To the extent practicable, the Applicant would employ the same site selection criteria for fly yards as provided in Section 2.1.4.1.2 for multi-use construction yards.

2.1.4.1.4 Wire Splicing Sites

Typically, wire-splicing sites would be located within the ROW. Conductors and shield wires (wires) are strung into their supporting structures over a length of two reels. The wire from the two reels would be mechanically joined at the wire ends with a temporary steel wire-gripping sleeve (stringing sock) which would pass through the stringing blocks. After the wire is strung and secured, the stringing sock would be replaced with a compression splice connector. The splice connector installation would occur at the wire splicing site. Typical wire splicing sites include a wire splicing truck and a line truck to facilitate installation.

2.1.4.1.5 Fiber Optic Cable Regeneration Sites

As a data signal passes through fiber optic cable, it degrades with distance. This data signal must be regenerated or amplified every 180 to 200 miles at fiber optic regeneration sites. The facilities and land requirements for a regeneration site are shown in Figure 2.1-32 (located in Appendix A). Fiber optic cable would be buried using the two basic methods of direct burial installation: trenching and plowing. Trenching involves digging a trench, placing the cable in the trench, and backfilling with native soils. Trenches are often dug with backhoes using narrow buckets (18 inches wide or less) to a depth of approximately 42 inches and are visually inspected for rocks or debris that could potentially damage the cable. In some instances, conduit is laid in the trench and the cable pulled through the conduit. Plowing involves a cable-laying plow designed to simultaneously excavate a ditch and lay the cable. Native soil would be used to backfill the trench.

2.1.5 Operations and Maintenance

All transmission lines would be inspected regularly or as necessary using fixed-wing aircraft, helicopters, ground vehicles, all-terrain vehicles, and/or personnel on foot. The frequency of inspections and maintenance would be meet or exceed standards, such as those specified by the NESC and North American Electric Reliability Corporation (NERC). Applicable federal, state, and local permits would be obtained prior to conducting maintenance. Maintenance activities for facilities would be similar to activities during construction but generally smaller in scale and more localized.

The ROW would be maintained during operations and maintenance in accordance with a Project-specific Transmission Vegetation Management Plan that would be developed by the Applicant, consistent with rules developed by NERC. A wire zone (Figures 2.1-18 and 2.1-27 located in Appendix A) typically consists of low-growing grasses, legumes, herbs, crops, ferns, and shrubs where the conductor is 50 feet or less from the ground to prevent accidental grounding contact with conductors. A border zone (i.e., to the edge of the ROW) is managed to consist of tall shrubs or short trees (up to 25 feet in height at maturity), grasses, and other low-growing vegetation. In most areas, accepted standard utility practices consistent with the Transmission Vegetation Management Plan, such as tree-trimming, tree removal, and/or brush removal, would be utilized to maintain vegetation within the ROW. In addition, vegetation clearing practices may vary based on dominant plant communities.

The Applicant expects that operations and maintenance of the Project would require 72 to 87 full-time workers. This would include up to 15 workers at each of the converter stations and 42 workers in Oklahoma and Arkansas for the HVDC transmission line.

2.1.5.1 Permitted Uses within the Right-of-Way

Land uses compatible with reliability and safety requirements for HVDC and AC facilities would be permitted in and adjacent to the ROW. Existing land uses such as agriculture and grazing, vehicle and pedestrian access, recreation uses, and pre-existing compatible land uses are generally permitted. Incompatible land uses within the ROW include construction and maintenance of inhabited dwellings and any use requiring changes in surface elevation that affect electrical clearances of existing or planned facilities.

Good utility practice, NERC rules, and the planned design, maintenance, and operations of the line were used to develop height restrictions of activities within the ROW that would maintain the minimum clearance requirements as determined from the NESC. Once a route has been established, the Applicant would review the route for non-standard activities that may require adjustments to minimum clearances.

Limitations on land uses would be described in the easement agreements; these limitations could be modified in the easement based on site-specific conditions and/or coordination with landowners. For example, limitations on uses within the ROW could include the following:

- A prohibition on placing a building or structure within the ROW
- Restrictions on timber or the height of orchard trees within the ROW
- Restrictions on grading and land re-contouring within the ROW that would change the ground surface elevation within the ROW such that required electrical clearances are no longer maintained
- Restrictions and/or required coordination for the construction of future facilities such as fences and/or irrigation lines within the ROW
- Restrictions on access for safety considerations where maintenance activities are being performed

Restrictions on land use within the ROW would be determined based on site-specific conditions and/or in coordination with landowners. These are not blanket limitations or restrictions that would apply to every parcel associated with the Project. For example, the Applicant recognizes that agricultural areas are graded, contoured, and ditched as part of routine agricultural practices. These types of routine practices are compatible with the reliability of the HVDC and AC facilities and would not be restricted. Similarly, the Applicant has no intent to displace or prohibit livestock grazing in pastures overlapped by the ROW during construction, operations or maintenance, unless otherwise desired by the landowner. The Applicant anticipates that livestock would continue grazing during the construction and operations and maintenance phases of the Project.

To illustrate the typical activities, restrictions, and temporal nature of construction, the Applicant has developed the *Example of Typical Construction Activities on Agricultural Property* (included in Appendix F), which describes a typical construction sequence that could occur on a single parcel.

Construction EPMs (further described in Section 2.1.7) would be implemented and carried forward into the operations and maintenance phase. For example, the Applicant would work with landowners to develop compensation for lost crop value caused by operations and maintenance activities. To avoid the potential of operations and maintenance activities resulting in loss of or injuries to livestock, the Applicant would continue to coordinate with landowners regarding access controls (e.g., cattle guards, fences, gates).

2.1.5.2 Safety and Reliability

Safety and reliability of the transmission system are primary concerns. The Project would be designed to meet or exceed applicable criteria and requirements outlined by organizations such as the Federal Energy Regulatory Commission (FERC), NERC, NESC, SPP, TVA, the American Society of Civil Engineers, and other applicable federal, state, or local requirements. Safety measures would meet or exceed applicable occupational safety and health standards. The transmission line would be protected with circuit interruption equipment (circuit breakers, disconnects, etc.). If the conductor were to fail, power would be automatically removed from the line. Lightning protection would be provided by overhead ground wires. Electrical equipment and fencing at the converter stations and substations would be grounded. Vegetation management would occur to minimize potential hazards; trees would be trimmed or removed to prevent accidental grounding contact.

As is done with typical transmission line operations, the Applicant would turn over functional control of the Project to a Regional Transmission Organization (RTO)/Independent System Operation (ISO) or an RTO-like entity. For the Project, this could include SPP, TVA, or a third party. Functional control of a facility means that the RTO ensures the Applicant's tariff is administered transparently. In addition, a NERC compliance program would be established and maintained either by the Applicant or by a third party to which the compliance requirements are delegated. Coordination agreements—also known as seams agreements—would be negotiated and executed with all interconnection parties. Balancing area functions would be performed by the Applicant or a third party acting as the Transmission Operator on behalf of the Applicant.

2.1.6 Decommissioning

Decommissioning could occur at the end of the useful life and if the facilities were no longer required. However, a transmission system lifetime can exceed 80 years with proper maintenance. At the end of the service life of the Project, assuming that the facilities were not upgraded or otherwise kept in service, conductors, insulators, and structures could be dismantled and removed. The converter stations and regeneration stations, if not needed for other existing transmission line projects, could also be dismantled and removed. The station structures would be disassembled and either used at another station or sold for scrap. Access roads that have a sole purpose of providing maintenance crews access to the transmission lines could be decommissioned following removal of the structures and lines, or could be decommissioned with the lines in service if determined to no longer be necessary. The Applicant would consult with landowners to assess whether access roads may be serving a purpose for landowners, at which point in time, the Applicant may elect to leave the access roads in place. A Decommissioning Plan would be developed prior to decommissioning and would follow applicable governing requirements at that time.

2.1.7 Environmental Protection Measures

For the purpose of all analyses for the EIS, it is assumed that the Applicant would conduct each phase of the Project in compliance with applicable federal, state and local laws, regulations and permits related to construction, operations and maintenance and decommissioning of the Project. Appendix C presents an overview of potential federal and state permits and consultation that could be required for construction of the Project. Local permits and approvals could also be required for the Project.

The Applicant has developed general and resource-specific EPMs to avoid or minimize effects to environmental resources during construction, operations and maintenance, and/or decommissioning of the Project. The Applicant would identify certain areas as "environmentally sensitive" and implement relevant EPMs to avoid and/or minimize adverse effects on these identified areas to the extent practicable. Environmentally sensitive areas may include wetlands, certain water bodies, cultural resources, and wildlife habitat. The general EPMs (General Measures GE-1 through GE-31) are designed to minimize environmental impacts across multiple resources. Other General Measures EPMs address avian mortality, vegetation management, herbicide use, transportation, road maintenance, hazardous materials, and other topics of concern. The resource-specific EPMs include measures to protect land use; soils and agriculture; fish, vegetation, and wildlife; and waters, wetlands, and floodplains. The complete list of EPMs is presented in Appendix F. The EPMs would be made binding through the ROD and terms of Participation Agreements between DOE and the Applicant. The EPMs would be implemented through a combination of environmental-related plans; compliance with federal, state, and local environmental regulations; and permitting requirements. The specific environmental-related plans that the Applicant has identified and described in Appendix F include:

- Transportation and Traffic Management Plan
- Blasting Plan
- Restoration Plan
- Spill Prevention, Control and Countermeasures Plan
- Stormwater Pollution Prevention Plan
- Transmission Vegetation Management Plan
- Avian Protection Plan
- Construction Security Plan
- Cultural Resources Management Planning Documents including Historic Properties Treatment Plan and Unanticipated Discoveries Plan

2.2 Transmission System Planning Processes

2.2.1 System Planning, Interconnections and Reliability

This section explains the processes applicable to the Applicant’s requests for interconnections to the existing electrical grid, including the study and assessment of the upgrades and improvements needed for such interconnections. The details of the interconnections are provided in Sections 2.1.2.1.2, 2.1.2.1.3, and 2.4.3.1 for Oklahoma, Tennessee, and Arkansas, respectively. These interconnections are an integral part of the Project. The details of any required upgrades to the transmission systems in these states are provided in Section 2.5.2. These upgrades are being evaluated as connected actions. The Applicant’s execution of interconnection agreements (which establish the basic terms and conditions of the interconnection but neither commit Clean Line to build the project nor to identify a specific route) with the two regional transmission organizations and TVA would neither have adverse environmental impacts nor limit the choice of reasonable alternatives.

2.2.1.1 Oklahoma/SPS/SPP Interconnection

Clean Line requested a Point of Interconnection in Oklahoma at the 345kV Hitchland Substation. This substation is owned by Southwestern Public Service (SPS), a subsidiary of Xcel Energy and member of the SPP RTO. This interconnection would be necessary to enable the AC to DC conversion process within the Oklahoma converter station. The interconnection between the proposed Oklahoma converter station and the SPS system would be controlled to a nominal value of zero megawatts.

For Clean Line to interconnect to the SPS system, a series of studies must be performed to review the potential interconnection and identify any upgrades to existing facilities or additions of new facilities to allow a reliable interconnection. SPS has completed a facilities study of the requested interconnection to the SPS 345kV system. Based on the SPS analysis, a new substation would be necessary to accommodate the interconnection due to space constraints at the existing Hitchland 345kV substation. To alleviate these space constraints, SPS has proposed a new substation nearby, tentatively named “Optima.” The interconnection of the Oklahoma converter station to the new substation would be facilitated by a new, approximately 3-mile-long double-circuit 345 kV transmission line. Clean Line’s selected HVDC vendor will incorporate the facilities study results into its study work on the final converter station design. This final study work will identify specific technology solutions such as reactive power requirements and filter design that would be included in the final converter station design. In the future, Clean Line anticipates that it would enter into an interconnection agreement with SPS and SPP for the Project.

For the purpose of ensuring integration of the Project into the SPP transmission planning process, and to ensure that the interconnection of the Project would not affect the security or reliability of the SPP system, Clean Line contracted Siemens PTI to conduct steady-state and dynamic power system studies to comply with SPP planning requirements under SPP Criteria 3.5. Clean Line and Siemens PTI presented the results of these studies to the SPP Transmission Working Group and SPP staff for review. Excel Engineering, an external consultant hired by SPP, reviewed the results and confirmed that Siemens PTI’s studies were complete and correct. In November 2012, the SPP Transmission Working Group found that Clean Line’s reliability study was “consistent with SPP planning processes and as having met [the Project’s] coordinated planning requirements under SPP Criteria.” The SPP Transmission Working Group indicated that Clean Line may need to update the study after selection of a vendor for the Project. These updates would ensure that the final design of the HVDC converter station complies with criteria set forth in the final interconnection agreement.

2.2.1.2 Arkansas/Entergy/MISO Interconnection

In response to comments received during the public scoping process, an intermediate converter station in Arkansas is being considered as a DOE Alternative (see Section 2.4.3.1). An AC interconnection would be required to deliver power from the intermediate converter station to the existing transmission system owned by Entergy Arkansas, a subsidiary of Entergy Corporation. Entergy Arkansas is part of the Mid-Continent Independent System Operator (MISO) system. Clean Line submitted the interconnection request to MISO in November 2013. Under MISO rules, interconnection requests involve three parties: the system operator (MISO), the transmission owner (Entergy Arkansas), and the interconnecting customer (Clean Line).

Clean Line began the interconnection process in Arkansas by requesting interconnection service from Entergy Arkansas for up to 500MW along the existing Arkansas Nuclear One-Pleasant Hill 500kV transmission line. Clean Line identified and proposed an AC interconnection consisting of a new 500kV transmission line connecting the proposed intermediate converter station to a new substation along the Arkansas Nuclear One-Pleasant Hill 500kV transmission line. Clean Line selected the Arkansas Nuclear One-Pleasant Hill 500kV Point of Interconnection to accommodate a 500MW injection. MISO performed a feasibility study of the request and delivered results to Clean Line in February 2014. The purpose of this feasibility study was to identify the cost to Clean Line to enter into the Definitive Planning Phase, which consists of several steps that include a system impact study and an interconnection facilities study. These studies would begin to identify the upgrades required to MISO’s system, if any, and the next steps for Clean Line to proceed with the Project.

In April 2015, MISO began the Definitive Planning Phase. The interconnection SIS and facilities study are anticipated to take six months in total to complete. Following completion of the Definitive Planning Phase process, Clean Line would enter into an interconnection agreement with Entergy Arkansas and MISO.

2.2.1.3 Tennessee Valley Authority Interconnection Process

Clean Line requested interconnection service in Tennessee at the TVA Shelby 500kV substation for interconnection of up to 3,500MW of power. To place this level of power injection in perspective, it is slightly higher than the generating capacity of TVA's three-unit Browns Ferry Nuclear Plant, and is described by Clean Line as capable of supplying electricity for over a million homes. Clean Line originally requested interconnection in late 2009, at which time TVA performed feasibility studies on the following three potential options: 500kV Shelby Substation, a combination of the TVA Cordova 500kV and Weakley 500kV substations, and a new substation that would have connected the Shelby–Lagoon Creek and Cordova–Haywood 500kV transmission lines. Based on studies of these options, Clean Line pursued interconnection at the Shelby Substation.

The final interconnection SIS, completed in March 2014, identified direct assignment facilities and network upgrades associated with the Project. Direct assignment facilities included additional bays, breakers, switches, line relays, and interchange meters to be installed within the Shelby Substation before interconnecting the Project. Direct assignment facilities are required to be constructed and in operations to facilitate the physical interconnection of the Project and are therefore analyzed as part of the Project. The ROI (defined in Section 3.1.1) for direct assignment facilities would occur within the Shelby Substation.

Network upgrade projects are those that TVA identified that would allow injection of up to 3,500MW to the TVA transmission system. Per TVA, some network upgrades may be constructed after initial energization of the interconnection. The interconnection SIS identified scenarios that would be resolved by 30 network upgrades, including upratings, reconductoring, and terminal upgrades on 27 existing 161kV system elements and 3 existing 500kV system elements. The interconnection SIS also identified certain reliability scenarios that would be resolved by a new 500kV transmission line and associated substation upgrades. Following good utility practice, in accordance with a final interconnection agreement, and depending on the results of a facilities study, Clean Line may be asked to operate the Project in a way that restricts its full delivery capacity under some limited scenarios until completion of certain network upgrade projects. It should be noted that the ROI for the direct assignment facilities would occur within the Tennessee Converter Station Siting Area. The ROI for the network upgrades, and in particular TVA's future 500kV transmission line, cannot be fully determined at this time. Additional details regarding these system upgrades are presented in Section 2.5.2.

The next step in the interconnection process is the performance of a facilities study in which TVA will determine the detailed designs, costs, and projected schedules for the identified direct assignment facilities and network upgrade projects. The facilities study, which is currently underway, will include a transient stability analysis, which could identify additional network upgrades. TVA anticipates the facilities study work will be complete in 2016. Following completion of the facilities study, Clean Line would negotiate an interconnection agreement with TVA.

In addition, given the regional connection of the Shelby Substation to nearby transmission systems operated by other parties, TVA identified the need for two Affected System Impact Studies (ASIS) to evaluate any impacts from the injection of up to 3,500MW into the electric grid. Memphis Light, Gas and Water completed the first ASIS, which showed the need for two wavetraps (terminal equipment) at an existing 161kV substation. MISO conducted the second ASIS, showing no need for modifications to its system to accommodate the Project's TVA interconnection.

Prior to providing service as a wholesale interstate electric transmission utility in the state of Tennessee, Clean Line must obtain a certificate of public convenience and necessity (CCN) from the Tennessee Regulatory Authority (TRA) for the Project (Tennessee Code Annotated 65-4-201 and 208). Clean Line submitted an application for the CCN in April 2014 (Clean Line 2014a). To obtain the CCN, Clean Line must show that it has the managerial, technical, and financial ability to operate as a utility within the state of Tennessee, and Clean Line must also show that granting a CCN for the construction of the portion of the Project in Tennessee would serve the public interest. In January 2015, the TRA granted without restriction Clean Line's Petition for a CCN to construct and operate electric transmission facilities in the state of Tennessee (TRA 2015).

2.3 Route and Alternative Development

This section briefly describes the process used to identify the proposed locations for each of the Applicant Proposed Project components and alternative routes for the HVDC transmission line. DOE independently reviewed and verified the Applicant-supplied information (per 40 CFR 1506.5[a]).

2.3.1 HVDC Route Development

Clean Line employed a multi-disciplinary team of professionals (referred to as the Clean Line Routing Team) to undertake the route identification process for the HVDC transmission line. Clean Line used a multi-stage approach to develop guidelines and criteria and to apply these guidelines and criteria to identify corridors and refine them. At each stage, Clean Line incorporated public stakeholder input on the development of criteria and the identification of corridors and routes. The Clean Line Routing Team began by identifying potential interconnection locations at the western and eastern endpoints of the Project (DOE 2013). Using these endpoints, the Clean Line Routing Team conducted a route development process that used progressively more detailed and restrictive siting criteria. Through this process, Clean Line identified the proposed converter station siting areas, the Applicant Proposed Route, and route alternatives for the HVDC transmission line.

The Clean Line Routing Team considered and utilized guidelines and criteria consistent with transmission line siting principles used by federal entities such as the Rural Utilities Service, Western, and Bonneville Power Administration. These principles included identification of opportunity areas (e.g., existing linear corridors, areas of land consistent with or compatible with linear utilities, etc.) and sensitive resources that limited or conflicted with transmission line development (e.g., residences, schools, USFWS-designated critical habitat under the Endangered Species Act, etc.).

The Clean Line Routing Team applied general and technical guidelines intended to avoid conflicts with existing resources, developed areas, and existing incompatible infrastructure; maximize opportunities for paralleling existing compatible infrastructure; and consider land use and other factors. Clean Line's siting criteria focused on avoiding environmentally sensitive areas irrespective of underlying land ownership. Clean Line's technical guidelines included considerations related to design and engineering of the transmission line. Details regarding the route development process described in the DOE Alternatives Development Report (DOE 2013) are provided in Appendix G of this EIS.

During the public comment process on the Draft EIS, DOE received numerous comments requesting or recommending re-routing of the Applicant Proposed Route for a variety of reasons. DOE did not receive specific route variation requests for any of the HVDC alternative routes. The process used to develop the route variations is described in Appendix M. DOE and Clean Line have developed 23 route variations for the Applicant Proposed Route. These route variations are described in detail in Sections 2.4.2.1 through 2.4.2.7. The potential environmental impacts of these route variations are addressed for each resource area in Chapter 3. These route variations have been included on the maps depicting the HVDC transmission line routes (Figures 2.1-17a through 2.1-17f in Appendix A).

2.3.2 Converter Station Siting

The following section discusses the process that the Clean Line Routing Team used to identify each of the converter station siting areas in the Applicant Proposed Project. An additional converter station in Arkansas also is being evaluated as part of the DOE Alternatives. Information on this alternative is provided in Section 2.4.3.

2.3.2.1 Oklahoma Converter Station

The Clean Line Routing Team identified a western endpoint in Oklahoma based on its evaluation of wind resources, the existing high-voltage transmission system, land use, and environmental sensitivities. Clean Line began the identification process for the western converter station by studying a broad region of northwestern Oklahoma. Clean Line narrowed the study area by considering criteria such as wind resources, available AC transmission interconnection, regional land use compatibility, and environmental sensitivities. Clean Line identified the proposed western converter station siting area based on three primary factors: (1) proximity to a large area of concentrated high capacity factor wind resources; (2) proximity to a point on the existing or planned AC transmission system that would support the interconnection; and (3) proximity to large areas of land uses compatible with wind farm development and which are known to be relatively low in environmental sensitivities. Clean Line concluded that the Oklahoma Converter Station Siting Area best met these criteria.

2.3.2.2 Tennessee Converter Station

The Clean Line Routing Team identified an eastern endpoint in Tennessee based on its evaluation of existing transmission facilities capable of reliable interconnection and delivery of up to 3,500MW of energy to points in Tennessee and elsewhere in the Mid-South and Southeast, the level of potential upgrades required to accommodate the Project, historical transmission congestion, market access, land use, and environmental considerations. Clean Line began the identification process for the eastern converter station by studying a broad geographic region from central Arkansas to western Tennessee. Clean Line concluded that the Tennessee Converter Station Siting Area best met their site selection criteria.

2.4 Alternatives

In the Plains & Eastern EIS, DOE analyzes the potential environmental impacts of the Proposed Action, the range of reasonable alternatives, and a No Action Alternative. In addition, DOE describes below other alternatives to the Proposed Action identified during the EIS scoping process that DOE considered but eliminated from detailed analysis.

This EIS analyzes the potential environmental impacts of the entire Project. This ensures that any decision by DOE or another agency is fully informed. DOE may decide to participate in any or all of the states in which Southwestern operates, namely Oklahoma, Arkansas, and Texas. However, DOE would not participate in the Project in Tennessee because that state is outside Southwestern’s operational area. Other agencies, federal or state, may have jurisdiction over parts of the Project that are located in Tennessee. Some of these agencies could include, but not be limited to, TVA, USACE, and Tennessee state agencies.

2.4.1 No Action Alternative

This Plains & Eastern EIS analyzes a No Action Alternative, under which DOE would not participate with the Applicant in the Applicant Proposed Project or DOE Alternatives. Under the No Action Alternative, DOE assumes for analytical purposes that the Project would not proceed and none of the potential environmental effects associated with the Project would occur.

2.4.2 Applicant Proposed Route

As identified in Section 2.1.2.2, the Applicant has proposed a specific route for the HVDC transmission line from the Oklahoma Panhandle Region to interconnect with TVA's electrical system in western Tennessee. For purposes of analysis, the Applicant Proposed Route is described below in terms of seven regions, which were based on geographic similarities and common node points along the route (where the Applicant Proposed Route and HVDC alternative routes converge). Within each region, the Applicant Proposed Route is divided into links. These links represent sections of the Applicant Proposed Route between points where alternative routes intersect with it. The alternative routes (described in Section 2.4.3.2) diverge from the Applicant Proposed Route and provide an alternative to the corresponding links of the Applicant Proposed Route. The links are labeled on the figures of the Applicant Proposed Route (Figures 2.1-17a through 2.1-17f located in Appendix A).

In some regions the Applicant Proposed Route is outside the 1-mile-wide route corridors presented at the public scoping meetings (referred to as the Network of Potential Routes). Areas where this occurs are described below for each region. Details regarding the route development process are described in the DOE Alternatives Development Report (DOE 2013) and are summarized in Appendix G of this EIS.

As identified in Section 2.3.1, DOE and Clean Line have developed several route variations to the Draft EIS Applicant Proposed Route to respond to comments on the Draft EIS. In all but one instance, DOE adopted these route variations, and the route variations are now part of the Applicant Proposed Route (they replace the Applicant Proposed Route that was evaluated in the Draft EIS). In one instance (Region 4, Applicant Proposed Route Link 3, Variation 2), DOE retained the original Applicant Proposed Route, and analyzed the variation as an alternative route in that area (see Section 2.4.2.4).

2.4.2.1 Region 1 (Oklahoma Panhandle)

Region 1 includes primarily grassland/herbaceous land cover. Region 1 begins at the converter station site in Texas County, Oklahoma, and continues east through Texas, Beaver, Harper, and Woodward counties in Oklahoma approximately 116 miles to the area north of Woodward, Oklahoma. The Applicant Proposed Route in Region 1 would parallel the existing Xcel/OG&E Woodward-to-Hitchland 345kV transmission line for the majority of its length. The Region 1 Applicant Proposed Route is shown on Figure 2.1-17a (located in Appendix A).

The AC collection system is located within Region 1 and within a 40-mile radius centered on the Oklahoma Converter Station Siting Area. To facilitate efficient interconnection of wind generation, it is expected that four to six AC collection transmission lines of up to 345kV from the Oklahoma converter station to points in the Oklahoma and Texas Panhandle regions would be constructed. The Clean Line Routing Team developed thirteen 2-mile-wide AC collection system route corridors between the Oklahoma Converter Station Siting Area and wind development zones. DOE, however, will not be making decisions on the locations on these transmission lines; their location will be driven by future wind development. The AC collection system routes analyzed as part of the Applicant Proposed Project are as follows:

- E-1 parallels section lines, a natural gas transmission pipeline, and the Guymon to Beaver 115-kV electrical transmission line for the majority of its length.
- E-2 parallels the Applicant Proposed Route (HVDC) and the OG&E/Xcel Energy Hitchland to Woodward 345kV transmission line for the majority of its length.
- E-3 parallels section lines, roads, and a natural gas transmission pipeline to the extent practicable.
- SE-1 parallels the Applicant Proposed Route (HVDC), the OG&E/Xcel Energy Hitchland to Woodward 345kV transmission line, section lines and county roads to the extent practicable.
- SE-2 parallels the Finney to Hitchland 345kV electrical transmission line and the Texas County to Spearman 115kV electrical transmission line to the extent practicable.
- SE-3 parallels the Applicant Proposed Route (HVDC), the OG&E/Xcel Energy Hitchland to Woodward 345kV transmission line, section lines and county roads to the extent practicable.
- SW-1 parallels the Finney to Hitchland 345kV electrical transmission line, the Hitchland to Porter 345kV electrical transmission line to the extent practicable.
- SW-2 parallels section lines, the Texas County to Moore County 115kV electrical transmission line for the majority of its length.
- W-1 parallels sections lines and county roads to the extent practicable.
- NW-1 parallels section lines, the Texas County to Moore County 115kV electrical transmission line, county roads, and U.S. Highway 412 to the extent practicable.
- NW-2 parallels sections lines and county roads to the extent practicable.
- NE-1 parallels county roads and section lines to the extent practicable.
- NE-2 parallels section lines, the Finney to Hitchland 345kV electrical transmission line, county roads, and Oklahoma State Route 94 to the extent practicable.

The AC collection system route corridors are shown on Figures 2.1-17a and 2.1-26 (located in Appendix A).

No route variations are analyzed for the Applicant Proposed Route in Region 1.

2.4.2.2 Region 2 (Oklahoma Central Great Plains)

Region 2 includes primarily grassland/herbaceous and cultivated crop land covers. Region 2 begins north of Woodward, Oklahoma, and continues southeast through Woodward, Major, and Garfield counties in Oklahoma, for approximately 106 miles to end approximately 16 miles southeast of Enid, Oklahoma. Attributes of the Applicant Proposed Route in Region 2 include:

- The Applicant Proposed Route parallels Western Farmers Electric Cooperative’s existing 115kV transmission line, U.S. Route 60, section lines and parcel boundaries, and county roads to the extent practicable.
- A portion of the Applicant Proposed Route is outside the 1-mile-wide area of Link D-2 of the Network of Potential Routes presented at the public scoping meetings. The Clean Line Routing Team sited the Applicant Proposed Route outside the Network of Potential Routes in this area to avoid several center-pivot irrigation systems that were identified during scoping.

The Region 2 Applicant Proposed Route and route variations are shown on Figure 2.1-17b in Appendix A.

Two route variations are analyzed that replace previous links of the Applicant Proposed Route in Region 2. The details of these variations are presented in Appendix M, which includes a detailed map of the variations and the corresponding link of the original Applicant Proposed Route that they would replace:

- Link 1, Variation 1. The location is in Woodward County, approximately 6 miles east of Woodward, Oklahoma. Clean Line developed the variation in response to public comments by the affected landowner. The variation would shift the Applicant Proposed Route to the northeast by about 2,500 feet and would transfer potential impacts from cultivated land to existing pasture land. The variation is about 0.07 mile (370 feet) longer than, and would replace approximately 2.3 miles of, the original Applicant Proposed Route.
- Link 2, Variation 2. The location is in Major County, starting approximately 3.5 miles south of Fairview, Oklahoma. Clean Line developed the variation in response to comments from several landowners to avoid impacts to agricultural operations and increase the distance from several homes. The variation would shift the Applicant Proposed Route south by about 1,100 feet near the quarter-section line that parallels many of their parcels. The variation is about 0.02 mile (100 feet) longer than, and would replace approximately 9.7 miles of, the original Applicant Proposed Route.

2.4.2.3 Region 3 (Oklahoma Cross Timbers)

Region 3 includes primarily grassland/herbaceous, deciduous forest, and pasture/hay land covers. Region 3 begins southeast of Enid, Oklahoma, and continues southeast through Garfield, Kingfisher, Logan, Payne, Lincoln, Creek, Okmulgee, and Muskogee counties in Oklahoma for approximately 162 miles and ends north of Webbers Falls, Oklahoma, at the Arkansas River. The eastern portion of Region 3 from Stillwater to the region’s terminal point on the eastern end has more residential development than the other portions of Region 3. Attributes of the Applicant Proposed Route in Region 3 include:

- The Applicant Proposed Route parallels OG&E’s Cottonwood Creek-to-Enid 138kV transmission line, section lines, county roads, parcel boundaries, gas pipeline, the KAMO Electric Cooperative, Inc. Stillwater-to-Ramsey 115kV transmission line, KAMO Electric Cooperative, Inc. Stillwater-to-Cushing 69kV transmission line, OG&E’s Muskogee to Pittsburgh 345kV transmission line, Public Service Company (PSCo)-OK’s Bristow to Silver City 161kV transmission line, and OG&E’s Cushing to Bristow 138kV transmission line, and the OG&E’s Beggs-to-Pecan Creek 138kV transmission line for the majority of its length.
- Portions of the Applicant Proposed Route are outside the 1-mile-wide area of Link F-7 of the Network of Potential Routes presented at the public scoping meetings. The Clean Line Routing Team sited the Applicant Proposed Route outside the Network of Potential Routes in response to scoping comments that identified additional residential areas and residences.

The Region 3 Applicant Proposed Route and route variations are shown on Figure2.1-17c in Appendix A.

Five route variations are analyzed that replace previous links of the Applicant Proposed Route in Region 3. The details of these variations are presented in Appendix M, which includes a detailed map of the variations and the corresponding link of the original Applicant Proposed Route that they would replace:

- Link 1, Variation 2. The location is in Payne County, starting approximately 7 miles east of Mulhall, Oklahoma, and about 10 miles southwest of Stillwater. Clean Line developed the variation in response to comments from several landowners to avoid impacts to no-till cropland and to shift the Applicant Proposed Route to cross pastureland. The variation would shift the route north by about 2,400 feet to parallel the half-section line. The variation is about 0.41 mile longer than, and would replace approximately 3.3 miles of, the original Applicant Proposed Route.
- Links 1 and 2, Variation 1. The location is in Payne County, approximately 5 miles south of Stillwater, Oklahoma. Clean Line developed the variation in response to comments from several landowners to avoid recently built homes and two new residential subdivisions. The route variation would generally be about 1,900 feet south of the original Applicant Proposed Route to avoid these homes. The variation is about 0.02 mile (160 feet) longer than, and would replace approximately 2.8 miles of, the original Applicant Proposed Route.
- Link 4, Variation 1. The location is in Lincoln County, approximately 3 miles south-southwest of Cushing, Oklahoma. Clean Line developed the variation in response to comments concerning an operating quarry. The route variation would avoid the quarry to the west. The variation is about 0.08 mile (420 feet) longer than, and would replace approximately 0.92 mile of, the original Applicant Proposed Route.
- Link 4, Variation 2. The location is in Creek County, approximately 6 miles north-northwest of Bristow, Oklahoma. Clean Line developed the variation in response to comments concerning a new house under construction within the ROW. The route variation would avoid the home. The variation is about 0.05 mile (260 feet) longer than, and would replace approximately 1.23 miles of, the original Applicant Proposed Route.
- Link 5, Variation 2. The location is in Muskogee County, approximately 6 miles southwest of Muskogee, Oklahoma. Clean Line developed the variation in response to comments concerning an existing house that was not identified in the initial routing process. The route variation would avoid the home. The variation is about 0.08 mile (420 feet) shorter than, and would replace approximately 2.5 miles of, the original Applicant Proposed Route.

2.4.2.4 Region 4 (Arkansas River Valley)

Region 4 includes primarily pasture/hay and deciduous forest land covers. Region 4 begins north of Webbers Falls in Muskogee County, in Oklahoma and continues east though Muskogee and Sequoyah counties in Oklahoma and Crawford, Franklin, Johnson, and Pope counties in Arkansas for approximately 127 miles and ends north of Russellville, Arkansas. Attributes of the Applicant Proposed Route in Region 4 include:

- The Applicant Proposed Route parallels several existing transmission lines across the Arkansas River. The Applicant Proposed Route continues into Arkansas parallel to OG&E's Muskogee-to-Fort Smith 345kV transmission, Southwestern's Gore-to-Alma 161kV transmission line, Interstate-40, Southwestern's Alma-to-Dardanelle 161kV transmission line, county roads, and parcel lines to the extent practicable.
- The Applicant Proposed Route includes the Lee Creek Variation, which refers to a route variation near the Oklahoma-Arkansas state line. It was developed by Clean Line prior to evaluation in the Draft EIS to address concerns expressed regarding avoidance of a buffer zone around the Lee Creek Reservoir. It begins in Sequoyah County, Oklahoma, at a point approximately 1.9 miles west of the state line, where it proceeds east-northeast for approximately 2 miles, then east-southeast, ending in Crawford County, Arkansas, approximately 1.5 miles east of the state line, where it rejoins the Applicant Proposed Route.
- Portions of the Applicant Proposed Route are outside the 1-mile-wide area of Links H-I and H-5 of the Network of Potential Routes presented at the public scoping meetings. The Applicant Proposed Route was sited outside

the Network of Potential Routes in this area to avoid residences and agricultural structures identified in comments submitted to DOE during scoping.

The Region 4 Applicant Proposed Route and route variations are shown on Figure 2.1-17d in Appendix A.

Six route variations are analyzed in Region 4. The details of these variations are presented in Appendix M, which includes a detailed map of the variations and the corresponding link of the original Applicant Proposed Route that they are associated with. DOE has not adopted Link 3, Variation 2, to replace the corresponding link of the original Applicant Proposed Route, but has analyzed this variation as an alternative route in that area. The other variations would replace the corresponding link of the original Applicant Proposed Route.

- Link 3, Variation 1. The location is in Sequoyah County, approximately 3.5 miles northeast of Sallisaw, Oklahoma. Clean Line developed the variation in response to a landowner comment regarding impacts to their home. The variation would shift the Applicant Proposed Route north to parallel the property line, avoid the home, and avoid a newly identified cemetery. The variation is essentially the same length as, and would replace, the original Applicant Proposed Route.
- Link 3, Variation 2. The location is in Sequoyah County, starting approximately 1 mile northeast of Vian, Oklahoma, and ending approximately 3.3 miles northwest of Sallisaw. The variation was proposed in response to landowner comments regarding potential impacts to their commercial operations, ranching, Deer Management Assistance Program area, airstrips, and residence. The variation would shift the route north approximately 0.8 to 1.4 miles. The variation is essentially the same length as the corresponding link of the Applicant Proposed Route. This route variation differs from others that have been presented in the Final EIS in that it does not replace the Applicant Proposed Route; the variation referred to as Applicant Proposed Route Link 3, Variation 2, is being considered as a variation (potential alternative) to the Applicant Proposed Route (similarly to the Lee Creek Variation, it is also in Region 4, Link 3).
- Link 3, Variation 3. The location is in Crawford County, Arkansas, approximately 6 miles northwest of Van Buren, Arkansas, near the eastern end of the Lee Creek Variation. Clean Line developed the variation in response to landowner comments that provided confirmed information about a January 2015 discovery of federally protected (endangered) Ozark big-eared bats in two winter cave hibernacula near the Lee Creek Reservoir within the ROI for the Applicant Proposed Route. The variation would shift the Applicant Proposed Route north by approximately 0.75 mile and would resolve engineering constraints associated with complex terrain and proximity to recreational trails, Teardrop Falls, and locations of existing residences as well as reduce the amount of forested land and Ozark big-eared bat occurrence area crossed. The variation is about 0.25 mile (1,320 feet) shorter than, and would replace approximately 3.5 miles of, the original Applicant Proposed Route.
- Link 6, Variation 1. The location is in Crawford County and approximately 3 miles north of Van Buren, Arkansas. Clean Line developed the variation in response to landowner comments regarding a new home planned for construction as well as two newly constructed homes located directly adjacent to the Applicant Proposed Route. The variation would shift the Applicant Proposed Route to the south approximately 500 feet, parallel parcel boundaries, and avoid the proposed site for this home and increase the distance from the two newly constructed homes in the area. The variation is about 0.03 mile (160 feet) longer than, and would replace approximately 1.05 miles of, the original Applicant Proposed Route.
- Link 6, Variation 2. The location is in Crawford County and approximately 4 miles east of Alma, Arkansas, and 3.5 miles west of Mulberry, Arkansas. Clean Line developed the variation in response to landowner comments that the Applicant Proposed Route would cross the northwestern corner of a parcel subject to a NRCS Wetlands

Reserve Program (WRP) easement. The variation would shift the Applicant Proposed Route to the northwest approximately 500 feet to avoid crossing the parcel subject to the WRP easement. The variation is about 0.03 mile (160 feet) longer than, and would replace approximately 2.43 miles of, the original Applicant Proposed Route.

- Link 6, Variation 3. The location is in Crawford County and approximately 3 miles north of Van Buren, Arkansas, immediately east of Applicant Proposed Route Link 6, Variation 1. Clean Line developed the variation in response to landowner comments expressing concern about the proximity of the Applicant Proposed Route to a residence and complex terrain. The variation would adjust the route by about 500 feet from the original Applicant Proposed Route to avoid residences and the difficult terrain. The variation is about 0.1 mile (530 feet) shorter than, and would replace approximately 1.9 miles of, the original Applicant Proposed Route.
- Link 9, Variation 1. The location is in Pope County and approximately 8 miles east of Hagarville, Arkansas, where two bridges on Arkansas Highway 164 span Big Piney Creek. Clean Line developed the variation in response to landowner comments expressing concern about the proximity of the Applicant Proposed Route to a residence, a campground, and complex terrain. The variation would shift the Applicant Proposed Route from the western side to the eastern side of the existing Southwestern transmission line. This variation would avoid the home identified by the landowner, move the line away from the campground, and eliminate potential engineering challenges associated with both Arkansas Highway 164 bridges. The variation would maintain a parallel alignment to the existing SWPA transmission line. The variation is the same length as and would replace approximately 3.12 miles of, the original Applicant Proposed Route.

2.4.2.5 Region 5 (Central Arkansas)

Region 5 includes primarily pasture/hay, deciduous forest, and evergreen forest land covers. Region 5 begins north of Russellville, in Pope County, Arkansas, and continues east for 113 miles through Pope, Conway, Van Buren, Faulkner, Cleburne, White, and Jackson counties in Arkansas, and ends southwest of Newport, Arkansas. The Applicant Proposed Route in Region 5 parallels parcel boundaries and section lines, Entergy Arkansas Inc.'s Independence-to-Genpower Keo 500kV transmission line, the Cleburne County 69kV transmission line, and a natural gas transmission pipeline to the extent practicable.

The Region 5 Applicant Proposed Route and route variations are shown on Figure 2.1-17e in Appendix A.

Five route variations are analyzed that replace previous links of the Applicant Proposed Route in Region 5. The details of these variations are presented in Appendix M, which includes a detailed map of the variations and the corresponding link of the original Applicant Proposed Route that they would replace:

- Link 1, Variation 2. The location is in Pope County and approximately 3 miles north of Dover, Arkansas. Clean Line developed the variation in response to landowner comments expressing concern about the proximity of the Applicant Proposed Route to a previously undetected residence. The variation would shift the Applicant Proposed Route to the south by about 1,800 feet to avoid the previously undetected residence and other residences. The variation is about 0.14 mile (740 feet) longer than, and would replace approximately 2.01 miles of, the original Applicant Proposed Route.
- Link 2, Variation 2. The location is in Pope County and approximately 2 miles east of Caglesville, Arkansas. Clean Line developed the variation in response to landowner comments expressing concern about the impact of the Applicant Proposed Route on their timber production. The variation would shift the Applicant Proposed Route to the west by between 0.7 mile and 1 mile (3,700–5,280 feet) feet to follow property lines. The variation is about

0.21 mile (1,100 feet) longer than, and would replace approximately 2.51 miles of, the original Applicant Proposed Route.

- Links 2 and 3, Variation 1. The location is in Pope County and approximately 1.5 miles southeast of Applicant Proposed Route Link 2, Variation 2 (as described above). Clean Line developed the variation as a result of a previously undetected residence in the representative ROW and in response to landowner comments. The variation would shift the Applicant Proposed Route to the west and south by less than 1,000 feet to avoid the residence and to reduce the number of affected landowners. The variation is about 0.11 mile (580 feet) longer than, and would replace approximately 2 miles of, the original Applicant Proposed Route.
- Links 3 and 4, Variation 2. The location is in Van Buren County and approximately 2.4 miles east of Damascus, Arkansas. Clean Line developed the variation in response to landowner comments about an existing homestead structure and the identification of conservation easements, which are part of streambank mitigation site along Cadron Creek. The variation would shift the Applicant Proposed Route north by about 0.25 mile (1,320 feet) to avoid the homestead site and to minimize impacts to streambank resources protected by existing conservation easements. The variation is about 0.06 mile (320 feet) shorter than, and would replace approximately 4.28 miles of, the original Applicant Proposed Route.
- Link 7, Variation 1. The location is in White County and approximately 8.4 miles northeast of Letona, Arkansas. Clean Line developed the variation in response to landowner comments concerning a previously undetected house near the Applicant Proposed Route. The route variation would avoid the home. The variation is about 0.2 mile (1,060 feet) longer than, and would replace approximately 1.27 miles of, the original Applicant Proposed Route.

2.4.2.6 Region 6 (Cache River, Crowley's Ridge Area, and St. Francis Channel)

With the exception of the Crowley's Ridge area, Region 6 primarily includes cultivated crop land covers. Region 6 begins southwest of Newport in Jackson County, Arkansas, and continues northeast through Jackson, Cross, and Poinsett counties in Arkansas, for approximately 55 miles and ends south of Marked Tree, Arkansas. Crowley's Ridge consists mostly of hardwood forest. Attributes of the Applicant Proposed Route in Region 6 include:

- The Applicant Proposed Route parallels the Entergy Arkansas Inc.'s Fisher-to-Cherry Valley 161kV transmission line, the St. Francis Levee, parcel boundaries, and county roads to the extent practicable.
- Portions of the Applicant Proposed Route in Region 6 are outside the 1-mile-wide area of Links L-3, L-4, and L-5 of the Network of Potential Routes presented at the public scoping meetings for the EIS. These deviations outside the Network of Potential Routes resulted from aligning the Applicant Proposed Route to follow an existing electrical transmission line into Cross County, Arkansas, to follow the Spoil Bank Central Canal within the St Francis Oak Donnick Floodway, and to avoid private airfields and aerial applicator operations in Poinsett County, Arkansas.

The Region 6 Applicant Proposed Route and a route variation are shown on Figure 2.1-17f in Appendix A.

- Link 2, Variation 1, is presented in detail in Appendix M. The location is in Jackson County and approximately 8 miles southeast of Newport, Arkansas. Clean Line developed the variation in response to tenant farmer comments concerning potential interference with agricultural operations. The route variation would minimize these potential impacts. The variation is about 0.61 mile (3,220 feet) longer than, and would replace approximately 2 miles of, the original Applicant Proposed Route.

2.4.2.7 Region 7 (Arkansas Mississippi River Delta and Tennessee)

Region 7 includes primarily cultivated crop land covers. Region 7 begins south of Marked Tree, in Poinsett County, Arkansas, and continues east and southeast through Poinsett and Mississippi counties in Arkansas, across the Mississippi River and into Tipton and Shelby counties in Tennessee, for approximately 43 miles, ending near the Tipton-Shelby county line south of Tipton, Tennessee. Attributes of the Applicant Proposed Route in Region 7 include:

- The Applicant Proposed Route parallels Entergy Arkansas Inc.'s Marked Tree to Marion 161kV electrical transmission line, county roads, section lines, and parcel boundaries to the extent practicable.
- Portions of the Applicant Proposed Route are outside the 1-mile-wide area of Links M-2 and M-5 of the Network of Potential Routes presented at the public scoping meetings for the EIS. In Link M-2, the Clean Line Routing Team identified a route that more closely follows Entergy Arkansas Inc.'s Marked Tree-to-Marion 161kV electric transmission line. In Link M-5, the Clean Line Routing Team identified a route that more closely followed field lines and parcel boundaries and that avoided residential areas identified during aerial reconnaissance.

The Region 7 Applicant Proposed Route and route variations are shown on Figure 2.1-17f in Appendix A.

Three route variations are analyzed that replace previous links of the Applicant Proposed Route in Region 7. The details of these variations are presented in Appendix M, which includes a detailed map of the variations and the corresponding link of the original Applicant Proposed Route that they would replace:

- Link 1, Variation 1. The location is in Mississippi County and approximately 1.8 miles west of Frenchman's Bayou, Arkansas. Clean Line developed the variation in response to comments concerning potential interference with agricultural operations. The route variation would minimize these potential impacts by following property boundaries. The variation is about 0.23 mile (1,200 feet) longer than, and would replace approximately 0.69 mile of, the original Applicant Proposed Route.
- Link 1, Variation 2. The location is in Mississippi and Tipton counties and approximately 4.2 miles southeast of Joiner, Arkansas. Clean Line developed the variation in response to landowner comments concerning potential interference with agricultural operations. The route variation would minimize these potential impacts. The variation is about 0.37 mile (1,950 feet) shorter than, and would replace approximately 4.38 miles of, the original Applicant Proposed Route.
- Link 5, Variation 1. The location is in Shelby and Tipton counties, Tennessee, and approximately 0.2 mile west of the Tennessee Converter Station Siting Area. Clean Line developed the variation in response to landowner feedback and based on new information, including the location of a proposed home site and planned residential area that was not identified during route development. The variation would avoid the proposed home site and addresses landowner concerns about the planned residential area. The variation is about 0.03 mile (160 feet) longer than, and would replace approximately 1.23 miles of, the representative ROW of the original Applicant Proposed Route. This variation does not result in a change of the Applicant Proposed Route 1,000-foot-wide corridor analyzed in the Draft EIS. This was identified as a variation so that DOE's analyses of the representative ROW would be consistent with Clean Line's application for a CCN with the Tennessee Regulatory Authority. The

CCN application includes the same ROW as depicted on these maps with no change to the Applicant Proposed Route 1,000-foot-wide corridor.

2.4.3 DOE Alternatives

The DOE Alternatives evaluated in this EIS include an intermediate AC/DC converter station in Arkansas and HVDC alternative routes in each region. The regions potentially affected by the alternatives (and the counties within each region) are provided in Table 2.4-1 and are shown in Figures 2.1-17a through 2.1-17f (located in Appendix A). The Arkansas Converter Station Alternative is discussed in Section 2.4.3.1. The HVDC alternative routes are described in Section 2.4.3.2. As identified previously in Section 2.4.2, the Applicant Proposed Route is divided into links, within each region. These links represent sections of the Applicant Proposed Route between points where alternative routes intersect with it. The alternative routes diverge from the Applicant Proposed Route and provide an alternative to the corresponding links of the Applicant Proposed Route. Table 2.4-1 includes information about the links of the Applicant Proposed Route to illustrate their relationship to the alternative routes.

Table 2.4-1:
Counties Potentially Affected by DOE Alternatives

Feature	Length (Miles)	State	Counties
Converter Station			
Arkansas Converter Station Alternative	N/A	Arkansas	Pope
Arkansas AC Interconnection	6.0	Arkansas	Pope
HVDC Alternative Routes			
Region 1 (Oklahoma Panhandle)			
Link 1 of the Applicant Proposed Route (no corresponding Alternative Route)	1.91	Oklahoma	Texas
Alternative Route 1-A	123.3	Oklahoma	Texas, Beaver, Harper, and Woodward
Corresponding Links (2, 3, 4, 5) of the Applicant Proposed Route	114.0	Oklahoma	Texas, Beaver, Harper, and Woodward
Alternative Route 1-B	52.1	Oklahoma	Texas and Beaver
Corresponding Links (2, 3) of the Applicant Proposed Route	54.0	Oklahoma	Texas and Beaver
Alternative Route 1-C	52.2	Oklahoma	Texas and Beaver
Corresponding Links (2, 3) of the Applicant Proposed Route	54.0	Oklahoma	Texas and Beaver
Alternative Route 1-D	33.6	Oklahoma	Beaver and Harper
Corresponding Links (3, 4) of the Applicant Proposed Route	33.7	Oklahoma	Beaver and Harper
Region 2 (Oklahoma Central Great Plains)			
Link 1 of the Applicant Proposed Route (no corresponding Alternative Route)	20.32	Oklahoma	Woodward
Alternative Route 2-A	57.3	Oklahoma	Woodward and Major
Corresponding Link (2) of the Applicant Proposed Route	54.5	Oklahoma	Woodward and Major
Alternative Route 2-B	29.9	Oklahoma	Major and Garfield
Corresponding Link (3) of the Applicant Proposed Route	31.3	Oklahoma	Major and Garfield
Region 3 (Oklahoma Cross Timbers)			
Alternative Route 3-A	37.7	Oklahoma	Garfield, Logan, and Payne
Corresponding Link (1) of the Applicant Proposed Route	40.1	Oklahoma	Garfield, Kingfisher, Logan, and Payne
Alternative Route 3-B	47.9	Oklahoma	Garfield, Logan, and Payne

Table 2.4-1:
Counties Potentially Affected by DOE Alternatives

Feature	Length (Miles)	State	Counties
Corresponding Links (1, 2, 3) of the Applicant Proposed Route	50.1	Oklahoma	Garfield, Kingfisher, Logan, and Payne
Alternative Route 3-C	121.9	Oklahoma	Payne, Lincoln, Creek, Okmulgee, and Muskogee
Corresponding Links (3, 4, 5, 6) of the Applicant Proposed Route	118.7	Oklahoma	Payne, Lincoln, Creek, Okmulgee, and Muskogee
Alternative Route 3-D	39.4	Oklahoma	Muskogee
Corresponding Links (5, 6) of the Applicant Proposed Route	35.2	Oklahoma	Muskogee
Alternative Route 3-E	8.5	Oklahoma	Muskogee
Corresponding Link (6) of the Applicant Proposed Route	7.8	Oklahoma	Muskogee
Region 4 (Arkansas River Valley)			
Link 1 of the Applicant Proposed Route (no corresponding Alternative Route)	8.31	Oklahoma	Muskogee
Alternative Route 4-A	58.6	Oklahoma and Arkansas	Sequoyah County, Oklahoma, and Crawford and Franklin counties, Arkansas
Corresponding Links (3, 4, 5, 6) of the Applicant Proposed Route	60.6	Oklahoma and Arkansas	Sequoyah County, Oklahoma, and Crawford and Franklin counties, Arkansas
Alternative Route 4-B	78.9	Oklahoma and Arkansas	Sequoyah County, Oklahoma, and Crawford and Franklin counties, Arkansas
Corresponding Links (2, 3, 4, 5, 6, 7, 8) of the Applicant Proposed Route	80.0	Oklahoma and Arkansas	Sequoyah County, Oklahoma, and Crawford and Franklin counties, Arkansas
Alternative Route 4-C	3.4	Arkansas	Crawford

Corresponding Links (4, 5) of the Applicant Proposed Route	6.6	Tennessee	Tipton and Shelby

2.4.3.1 Arkansas Converter Station

During the scoping period, DOE received comments from stakeholders in Arkansas who were concerned that the state would endure impacts from the Project without receiving any of the benefits (e.g., ability to accept increased amounts of renewable energy, tax revenues from property and ad valorum taxes associated with new facilities, and increased number of jobs). Based on these comments, DOE requested that Clean Line evaluate the feasibility of an alternative that would add a converter station in Arkansas. The Arkansas converter station would be an intermediate converter station; it would not replace the Oklahoma or Tennessee converter stations. Based on Clean Line's feasibility evaluation and ongoing considerations since issuance of the Draft EIS, an Arkansas converter station could be sited in Pope County, Arkansas. This alternative converter station would be similar to the Oklahoma and Tennessee converter stations, except that it would likely require a smaller land area, encompassing approximately 20 to 35 acres, and contain a smaller valve hall (approximately 175 feet long by 75 feet wide). The facility dimensions and land requirements are summarized in Table 2.4-2. Based on preliminary design and studies, it would be capable of interconnecting 500MW. With the implementation of this alternative, the delivery capability of the Project would be increased to 4,000MW.

Figure 2.1-17e (located in Appendix A) depicts the Arkansas converter station siting area.

The AC interconnection for the Arkansas converter station would include an approximate 5-mile 500kV AC transmission line (the interconnection requirements are discussed in Section 2.2.1) to an interconnection point along the existing Arkansas Nuclear One-Pleasant Hill 500kV AC transmission line by way of a direct tap or small switchyard. An additional 5 acres would be required during construction of the converter station and 500kV AC interconnection for materials staging and equipment storage. The interconnection would also include a new substation at the point where the 500kV AC interconnection line taps the existing Arkansas Nuclear One-Pleasant Hill 500kV line. The footprint of this substation is estimated to be between 25 and 35 acres, with an additional 5 acres for temporary materials staging and equipment storage. The design and layout of the interconnection facilities are dependent on the results of ongoing interconnection and engineering studies (see Section 2.2.1). Tensioning or pulling sites, wire-splicing sites, and multi-use construction yards would all occur within the AC interconnection siting area.

The 500kV AC interconnection line would consist of an arrangement of three electrical phases each with a three-conductor bundle (i.e., three subconductors) in a triangle configuration about 18 to 24 inches on each side. Each conductor would be an approximate 1- to 2-inch-diameter aluminum conductor with a steel reinforced core, or a very similar configuration. The Applicant would design minimum conductor height above the terrain, assuming no clearance buffers, per Rule 232D of the NESC, Edition 2012, requiring 29 feet of clearance for general areas and areas with vehicular traffic (for a 500kV AC line).

Table 2.4-2:
Arkansas Converter Station Alternative and Associated Facilities Dimensions and Land Requirements

Facility	Construction Dimensions[1]	Operation Dimensions[1]
Arkansas Converter Station Alternative-Pope County, Arkansas	20 to 35 acres of land would be required, plus an additional 5 to 10 acres for construction.	20 to 35 acres of land would be required for the station; approximately 20 acres would be fenced.
Arkansas Converter Station Access Road	All weather access roads 20 feet wide by less than 1 mile long would be required. Construction of the access roads may disturb an area up to 35 feet wide.	20-foot-wide paved roadways.
ROW	One 500kV ROW 150–200 feet wide x 5 miles long.	One 500kV ROW 150–200 feet wide x approximately 5 miles long.
500kV—Lattice Structures	Structure assembly area, 150 feet wide (ROW width) x 150 feet long (within ROW), 5 to 7 structures per mile.	Structural footprint 28 feet x 28 feet (typical for lattice structures) 75 to 180 feet tall, 5 to 7 structures per mile.
500kV—Tubular Pole Structures	Structure assembly area, 150 feet wide (ROW width) x 150 feet long (within ROW), 5 to 7 structures per mile.	Structural footprint 7 feet x 7 feet (typical for tubular pole structures), 75 to 180 feet tall, 5 to 7 structures per mile.
AC Interconnection Point	500kV AC: a 25- to 35-acre site where the alternative AC transmission line would interconnect with an existing 500kV transmission line. An additional 5 acres would be required during construction.	The 25- to 35-acre site would be fenced. Permanent access road to the fenced area. Power supply to fenced area.

1 Final design and/or dimensions may differ from typical dimensions expressed here.

2.4.3.2 HVDC Alternative Routes

DOE developed alternative routes as described in Section 2.3.1. These alternatives were discussed and evaluated with Clean Line for feasibility. Eventual selection of a route alignment for the HVDC transmission line could either follow the Applicant Proposed Route for the entire length or could bypass specific links of the Applicant Proposed Route by selecting specific alternative routes.

As discussed in Section 2.4.2.1 through 2.4.2.7, DOE and Clean Line developed 23 route variations to respond to public comments on the Applicant Proposed Route. These route variations caused shifts in the Applicant Proposed Route. There were four instances where the change in the Applicant Proposed Route caused a discontinuity with the linkage between the Applicant Proposed Route and the HVDC alternative routes. As a result of the route variations, DOE and Clean Line developed "route adjustments" to reestablish the continuity between the Applicant Proposed Route and the HVDC alternative routes. DOE has adopted these route adjustments into the applicable HVDC alternative routes. These occur in Regions 3, 5, and 6 and are discussed further below.

Descriptions of ROW easements, structure types, and access for the HVDC alternative routes would be the same as described in Sections 2.1.2.2.1, 2.1.2.2.2, and 2.1.2.4. Construction practices for the HVDC alternative routes or Arkansas converter station alternative would be the same as described in Section 2.1.4. Impacts of these alternatives could nonetheless vary due to differences in affected environment and the scale of the alternatives compared to the Applicant Proposed Project. The impacts that are relevant and material to the comparison of alternatives to the Applicant Proposed Project are described in Chapter 3 and summarized in Section 2.6.

2.4.3.2.1 Region 1 (Oklahoma Panhandle)

DOE and Clean Line identified four HVDC alternative routes for Region 1. The Region 1 HVDC alternative routes are shown on Figure 2.1-17a in Appendix A:

- 1-A parallels county roads and section lines for the majority of its length and parallels existing transmission lines for some short distances.
- 1-B parallels section lines for the majority of its length.
- 1-C is made up of portions of HVDC Alternative Routes 1-A and 1-B.
- 1-D follows sections lines for the majority of its length.

2.4.3.2.2 Region 2 (Oklahoma Central Great Plains)

DOE and Clean Line identified two HVDC alternative routes for Region 2. The Region 2 HVDC alternative routes are shown on Figure 2.1-17b in Appendix A:

- 2-A parallels OG&E's Woodward-to-Cleo's Corner 345kV electrical transmission line and the Cimarron River floodplain for the majority of its length.
- 2-B parallels section lines and parcel boundaries and OG&E's Cottonwood Creek-to-Enid 138kV transmission line for the majority of its length.

A portion of Proposed Alternative Route 2-B is outside the 1-mile-wide area of Link D-1 of the Network of Potential Routes presented at the public scoping meetings. HVDC Alternative Route 2-B is outside the Network of Potential

Routes in this area to avoid a private airstrip identified through review of Federal Aviation Administration (FAA) data and aerial imagery.

Additionally, there is only one route option in the western portion of Region 2 because the city of Woodward, the city of Moreland, Boiling Springs State Park, potentially high value lesser prairie-chicken habitat and rough terrain limit the potential opportunities for other route alternatives.

2.4.3.2.3 Region 3 (Oklahoma Cross Timbers)

DOE and Clean Line identified five HVDC alternative routes for Region 3. The Region 3 HVDC alternative routes are shown on Figure 2.1-17c in Appendix A:

- 3-A parallels county roads and parcel boundaries to the extent practicable.
- 3-B parallels parcel boundaries, section lines, and the KAMO Electric Cooperative, Inc. Stillwater-to-Cushing 69kV transmission line to the extent practicable.
- 3-C parallels OG&E's Cushing-to-Bristow 138kV transmission line, roads, section lines and property boundaries to the extent practicable.
- 3-D begins northwest of Boynton and joins HVDC Alternative Route 3-C approximately 1 mile to the southeast.
- 3-E begins north of Warner, Oklahoma.

Portions of HVDC Alternative Routes 3-C and 3-D are outside the 1-mile-wide area of Link F-8 of the Network of Potential Routes presented at the public scoping meetings. HVDC Alternative Routes 3-C and 3-D are sited outside the Network of Potential Routes in response to comments by the Oklahoma Department of Wildlife Conservation (ODWC) regarding the presence of federal grassland conservation easements and potential high-value greater prairie-chicken habitat.

Applicant Proposed Route Links 1 and 2, Variation 1, shifted the Applicant Proposed Route south in the same area that HVDC Alternative Route 3-A would have joined the Applicant Proposed Route. As a result, Clean Line developed a route adjustment that brings HVDC Alternative Route 3-A due south to connect with the modified Applicant Proposed Route. The route adjustment would shorten the length of HVDC Alternative Route 3-A by 0.16 miles (850 feet). The adjustment is illustrated on Figure 2.1-17c in Appendix A.

2.4.3.2.4 Region 4 (Arkansas River Valley)

DOE and Clean Line identified five HVDC alternative routes for Region 4. The Region 4 HVDC alternative routes are shown on Figure 2.1-17d in Appendix A:

- 4-A parallels parcel boundaries and the Nicut-to-Brushy Switching Station 69kV transmission line in Crawford County, Arkansas, to the extent practicable.
- 4-B is located partially within the Ozark National Forest in Crawford County, Arkansas.
- 4-C is a short route that parallels parcel lines to the extent practicable in the Van Buren, Arkansas area.
- 4-D is an alternative in the areas of Cedarville, Van Buren, and Mulberry, Arkansas.
- 4-E parallels parcel boundaries and the Dardanelle-to-Ozark 161kV transmission line to the extent practicable.

Portions of HVDC Alternative Route 4-A are outside the 1-mile-wide area of Links G-2 and G-5 of the Network of Potential Routes presented at the public scoping meetings to avoid residences and a municipality (Cedarville, Arkansas).

Portions of HVDC Alternative Route 4-B are outside the 1-mile-wide area of Links G-2 and G-6 of the Network of Potential Routes presented at the public scoping meetings. Alternative Route 4-B was sited outside the Network of Potential Routes in this area to avoid residences and a municipality (Cedarville, Arkansas) and to respond to comments received during scoping that requested an alternative route through the Ozark National Forest. As presented in Section 2.14, DOE has identified HVDC Alternative Route 4-B as a non-preferred alternative.

Portions of HVDC Alternative Route 4-C are outside the 1-mile-wide area of Link G-4 of the Network of Potential Routes presented at the public scoping meetings for the EIS. Alternative Route 4-C was sited outside the Network of Potential Routes in response to comments received by DOE during the EIS scoping period regarding the residential area north of Van Buren.

Portions of HVDC Alternative Route 4-D are outside the 1-mile-wide area of Link G-5 of the Network of Potential Routes presented at the public scoping meetings for the EIS to avoid residences. These residences were identified in comments submitted to DOE during the EIS scoping period and through comments received by Clean Line during Clean Line's stakeholder meetings.

2.4.3.2.5 Region 5 (Central Arkansas)

DOE and Clean Line identified six HVDC alternative routes for Region 5. The Region 5 HVDC alternative routes are shown on Figure 2.1-17e in Appendix A:

- 5-A is a short alternative that provides a route north of Dover, Arkansas.
- 5-B parallels an existing natural gas transmission pipeline, electrical transmission lines, parcel boundaries, and the Entergy Arkansas, Inc.'s Independence-to-Genpower Keo 500kV transmission line to the extent practicable.
- 5-C is a short alternative that provides a route northeast of Letona, Arkansas.
- 5-D parallels the Entergy Arkansas, Inc.'s Independence-to-Genpower Keo 500kV transmission line, parcel boundaries, and natural gas transmission pipelines to the extent practicable.
- 5-E parallels existing transmission lines to the extent practicable through Faulkner County, Arkansas.
- 5-F provides an alternative to the south of Letona, Arkansas.

Applicant Proposed Route Links 2 and 3, Variation 1, shifted the Applicant Proposed Route southwest in the same area that HVDC Alternative Route 5-B would have joined the Applicant Proposed Route. As a result, DOE and Clean Line developed a route adjustment that brings the northwestern end of HVDC Alternative Route 5-B south and west to connect with the Applicant Proposed Route variation. The route adjustment would shorten the length of HVDC Alternative Route 5-B by 0.12 mile (630 feet). The route adjustment is illustrated on Figure 2.1-17e in Appendix A.

Applicant Proposed Links 3 and 4, Variation 2, shifted the Applicant Proposed Route north in the same area that HVDC Alternative Route 5-E would have joined the Applicant Proposed Route. As a result, DOE and Clean Line developed a route adjustment that brings the northwestern node of Alternative Route 5-E east to connect with the Applicant Proposed Route variation. There would be no effect on the length of HVDC Alternative Route 5-E from the route adjustment. The adjustment is illustrated on Figure 2.1-17e in Appendix A.

2.4.3.2.6 Region 6 (Cache River, Crowley's Ridge Area, and St. Francis Channel)

DOE and Clean Line identified four HVDC alternative routes for Region 6. The Region 6 HVDC alternative routes are shown on Figure 2.1-17f in Appendix A:

- 6-A parallels parcel boundaries and roads to the extent practicable to provide a southern alternative river crossing location for the Cache River.
- 6-B parallels parcel boundaries, State Route 14, and existing transmission lines to provide a northern alternative river crossing location for the Cache River.
- 6-C parallels parcel boundaries and local roads to the extent practicable to provide alternative crossing of Crowley's Ridge and the St. Francis-Oak Donnick Floodway.
- 6-D is a short alternative that parallels a levee to the extent practicable to provide an alternative crossing location for the St. Francis-Oak Donnick Floodway.

Portions of HVDC Alternative Route 6-A are outside the 1-mile-wide area of Link L-4 of the Network of Potential Routes presented at the public scoping meetings. HVDC Alternative Route 6-A was sited outside the Network of Potential Routes in this area to follow parcel lines and traverse less forested wetlands.

Portions of HVDC Alternative Route 6-B are outside the 1-mile-wide area of Links L-2 and L-3 of the Network of Potential Routes presented at the public scoping meetings. HVDC Alternative Route 6-B was sited outside the Network of Potential Routes in this area to follow an existing electrical transmission line south of Amagon, Arkansas, and to avoid private airfields, aerial spraying, and agricultural operations in Poinsett County.

Applicant Proposed Route Link 2, Variation 1, changed the Applicant Proposed Route from an angled, northeast run to a northerly run with two 90-degree turns in the same area that HVDC Alternative Route 6-A would have joined the Applicant Proposed Route. As a result, DOE and Clean Line developed a route adjustment that brings the western node of HVDC Alternative Route 6-A east to connect with the Applicant Proposed Route variation. The route adjustment would shorten the length of Alternative Route 6-A by 0.62 mile (3,270 feet). The adjustment is illustrated on Figure 2.1-17f in Appendix A.

2.4.3.2.7 Region 7 (Arkansas Mississippi River Delta and Tennessee)

The Project includes elements (transmission line routes and facilities and the converter station and interconnections) in Tennessee. The EIS includes an impacts and alternatives analysis of all Project components; including those located in Tennessee. As explained in Section 1.1.1, DOE's participation in the Project would be limited to states in which Southwestern operates; namely Oklahoma, Arkansas, and possibly Texas, but not Tennessee.

DOE and Clean Line identified four HVDC alternative routes for Region 7. The Region 7 HVDC alternative routes are shown on Figure 2.1-17f in Appendix A:

- 7-A parallels existing canals, county roads, section lines, parcel boundaries, and field lines to the extent practicable to provide an alternative Mississippi River crossing location to the north. 7-A also parallels TVA's Shelby-to-Sans Souci 500kV transmission line.
- 7-B parallels property lines and local roads to provide an alternative in Tipton County, Tennessee.

- 7-C parallels local roads and TVA's Covington-to-Northeast Gate 161kV transmission line and provides a southern route into the converter station.
- 7-D parallels TVA's Shelby-to-Sans Souci 500kV electrical transmission line and provides a northern route into the converter station.

Portions of HVDC Alternative Route 7-A are outside the 1-mile-wide area of Link M-1 of the Network of Potential Routes presented at the public scoping meetings. HVDC Alternative Route 7-A was sited outside the Network of Potential Routes in this area to avoid a center pivot irrigation system and a perpendicular crossing of an airfield.

Portions of HVDC Alternative Route 7-B are outside the 1-mile-wide area of Link M-5 of the Network of Potential Routes presented at public scoping meetings. This alternative was sited outside the Network of Potential Routes in this area in response to scoping comments that requested the analysis of routes that were south of Millington, Tennessee.

Portions of HVDC Alternative Route 7-C are outside the 1-mile-wide area of Link M-5 of the Network of Potential Routes presented at the public scoping meetings. This alternative was sited outside the Network of Potential Routes in this area in response to comments that requested the analysis of routes south of the Millington Regional Airport that also would avoid Munford, Tipton, and Atoka.

HVDC Alternative HVDC Route 7-D is outside the Network of Potential Routes presented at public scoping meetings. This alternative was sited outside the Network of Potential Routes in this area in response to comments expressing concerns about the existing and planned airspace north of the Millington Regional Airport; this alternative is a greater distance from the airport than the Applicant Proposed Route and follows the TVA Shelby-to-Sans Souci 500kV existing transmission line for portions of its length.

2.4.4 Alternatives Considered but Eliminated from Detailed Analysis

DOE considered several additional potential alternatives, in part based on public scoping comments, but eliminated them from detailed analysis as discussed below.

2.4.4.1 Alternative Transmission Line Routes

During the iterative planning and siting process for the transmission line, a number of route alternatives were proposed and studied. These alternatives were evaluated for their feasibility and ultimately eliminated from further study and consideration based on route-specific factors and public scoping comments. Route alternatives that were studied and eliminated and the rationales for their elimination are discussed in the DOE Alternatives Development Report (DOE 2013). Excerpts from the DOE Alternatives Development Report (including the main body of the report and select appendices; including the Tier IV Routing Study) are provided in Appendix G of this EIS.

Additional route alternatives (with varying degrees of detail) were provided as public comments on the Draft EIS. DOE applied routing criteria in evaluating each request and recommendation for a route variation, including technical feasibility, potential impacts, and location relative to the 1,000-foot-wide corridor and representative ROW analyzed in the Draft EIS. After completing these evaluations, DOE chose to carry forward 23 of the recommended changes to the Applicant Proposed Route in the Final EIS. In one case, DOE chose to carry forward both the route variation and the original corresponding segment of the Applicant Proposed Route for analysis in the Final EIS. DOE dismissed other recommendations because they were not feasible, would result in potentially more adverse effects, or any overall reduction in potential environmental impacts was negligible. For example, DOE dismissed two route variations proposed in public comments from further consideration for Region 5, Link 9 because both variations would be closer to residences than the original Applicant Proposed Route. One of the route variations would be located in more areas of potential occurrence of the Indiana bat than the original Applicant Proposed Route. The other route variation would have potential greater impacts to wetlands compared with the original Applicant Proposed Route. The rationale for dismissal of individual routing requests is documented in Appendix Q.

2.4.4.2 Underground HVDC Transmission Line

During public scoping and in comments received on the Draft EIS, some commenters suggested that the HVDC transmission line be installed underground for either the entire length or for discrete segments to minimize visual impacts associated with construction and operations and maintenance. Based on the analysis below, DOE concluded that undergrounding the Project (all or portions thereof) is not a reasonable alternative and has eliminated it from further analysis.

HVDC technology and the voltage of 600kV were identified for the Project to meet the objective of delivering 3,500–4,000MW of renewable energy at a competitive cost and meet the objectives and criteria of Section 1222 of the EPAct. To date, underground electric transmission cable technology is not commercially available at the very high voltage and capacity levels (i.e., ±600kV and 3,500MW to 4,000MW) planned for the Project. HVDC transmission at ±600kV exhibits electrical characteristics that minimize electrical losses over long distances. If the line voltage for the Project were reduced, the Project would not deliver the planned capacity in Tennessee. The highest rated proposed cable system in the world at ±600kV is the Western Link Project in the United Kingdom, with a capacity of 2,200MW, and a distance of about 260 miles (418km). This submarine project is under construction and, at present, is expected to be in operation in 2016. The Western Link Project represents the limits of the application of current, commercially available cable technology to an undergrounding option.

Comments received on the Draft EIS mentioned the following projects:

- Murray Link Project in Australia—Capacity of 220MW at ±150kV, length: 112 miles (ABB 2015b)
- Champlain Hudson Power Express Project at the U.S.–Canadian border—Capacity of 1,000MW at ±300–320kV, length: 364 miles (DOE 2014a)
- Northeast Energy Link (proposed) in Maine and Massachusetts—Capacity of 1,100MW at ±320kV, length: 230 miles (Northeast Energy Link 2015)
- ABB HVDC underground cables—ABB reports the voltage limit is up to ±320kV (ABB 2015a)

Additionally, the Northern Pass Project is a proposed 187-mile transmission line project from Quebec to New Hampshire. Northern Pass has proposed that approximately 153 miles of the transmission would be a ± 300kV HVDC transmission line, including a total of approximately 60 miles of underground transmission. One of the alternatives evaluated for the Northern Pass Project included undergrounding the full length of the line, albeit at only 1,000MW (DOE 2014b).

None of these projects is comparable to the Plains & Eastern Project in terms of capacity, voltage and length. As a result, they do not provide evidence of the feasibility of undergrounding the Project.

Only one cable project is currently under construction (Western Link, which will connect Scotland and England) that has voltage levels of ±600kV (Siemens 2015). This project involves a submarine, rather than underground, installation using mass impregnated cable technology. Even if the cable were capable of transmitting greater than its present maximum rated capability of 2,200MW, the physical characteristics of ±600kV cable render its use infeasible on land. These characteristics include:

- Cable diameter of 5 inches
- Cable length per spool of approximately 3,400 feet
- Weight per spool of over 66 tons

These characteristics would present unreasonable barriers to constructing the Plains and Eastern Project underground. The transportation and material handling of cable spools of such weight and complexity result in many restrictions and challenges during construction, including:

- Because the maximum current rating of available cable will not deliver 4,000MW, each electrical pole would require at least two cables (for a total of at least four cables for the bi-pole configuration). Such conductors would be significantly physically larger than the conductor planned for the Project (requiring a 5-inch-diameter conductor on approximately 4,500 spools weighing 66 tons each) and could not be directly buried. Such conductors must be mechanically protected using a buried duct bank, conduit, or tunnel. Frequent access points would require abovegrade structures to allow for splicing, monitoring, and maintenance. The delivery of these spools to the construction sites, some of which are remote, would require heavy-haul trucks and could result in significant impacts for the construction of access roads and traffic. These requirements make the application of mass impregnated cables for undergrounding highly impractical—and likely impossible.
- Burying cables also would result in significant environmental impacts resulting from open trenching, horizontal directional drilling, and blasting (where necessary).
- Depending on the soil characteristics (conductivity and heat resistance), cooling stations, transition vaults, and splice vaults would be required. For example, the proposed Champlain Hudson Power Express Project requires multiple cooling stations, transition vaults, and splice vaults to make possible the burial of the terrestrial portions of that project. In the case of the Champlain Hudson Power Express Project, transition and splice vaults are precast reinforced concrete facilities that can typically measure 35 feet long by 9 feet wide and 8 feet deep. The Champlain Hudson Power Express Project is expected to require an estimated 400 splices for approximately 134 miles of terrestrial cable (DOE 2014a).
- Because four cables would be required for the bi-pole configuration, the Plains and Eastern Project could require more than 8,600 splices. In addition, cooling stations included an aboveground building measuring approximately 8 feet by 8 feet by 16 feet would be necessary. A cooling station would consist of a chiller unit and pumping system used to circulate chilled water (DOE 2014a).

The time, materials handling, and potential environmental impact of burying (including possible need for cooling stations and need for multiple transition stations) make the risks of undergrounding the Plains and Eastern Project extremely high and, even if successful, would not achieve the objectives of the Project. Ultimately, as was stated earlier in this section, underground electric transmission cable technology is not commercially available at the very high voltage and capacity levels (i.e., ±600kV and 3,500MW to 4,000MW) planned for the Project.

While there is research underway for underground high-voltage transmission cable technology that could conceivably be applied to the voltage and capacity levels of the Project, this research has yet to produce commercially available, proven technology, and DOE does not foresee that such technology will become available within the time frame for construction of the Project. Because such technology is not available, the costs for implementing underground HVDC technology of the voltage and capacity proposed for the Project are unknown.

In summary, based on current information, even if such technology were to become available, other constraints would make it infeasible to install a conductor (i.e., the transmission line) of this voltage and capacity underground. Such conductors cannot be directly buried. They must be mechanically protected by being installed within a buried duct bank, conduit, or tunnel. Frequent access points would be required from the surface into these duct banks, conduits, or tunnels to allow for splicing, monitoring, and maintenance. Heat dissipation from the underground conductors would be a significant challenge to the installation. Also, the large insulation requirements would result in extreme weights for an underground conductor relative to an overhead conductor, so only short segments could be installed at any one time, significantly increasing the cost and time required for completing the construction. The diagnosis and repair of outages could be time-consuming, which would affect emergency response times, could result in additional ground disturbance and excavation to locate and repair the problems.

2.4.4.3 Local Generation and Distribution

During public scoping, commenters suggested utilizing distributed generation as an alternative to the Applicant Proposed Project. Distributed generation involves the use of small-scale power generation technologies that are usually installed at or near the location to the load being served by the generated power. Distributed generation does not require long-range transmission lines. Distributed generation systems range in size from approximately 5 kilowatts to 10MW, in contrast to utility-scale generation that ranges from 10MW to more than 1,000MW per site. Examples of distributed generation resource technologies include residential and roof-top photovoltaic, energy storage devices, microturbines, and fuel cells.

This alternative was eliminated from further analysis because Section 1222 of the EPAct does not authorize the Secretary of Energy to participate with other entities in distributed generation, and the alternative does not meet the DOE-issued RFP for new or upgraded transmission projects. As such, the alternative would not meet the purpose and need for agency action because distributed generation as studied by DOE does not meet the utility-scale generation required. DOE has determined that distributed generation would not meet the need of utility-scale generation and would still require the Project to meet the needs of the agency's goal. DOE has established policies and programs related to distributed generation (see http://www.energy.gov/eere/slsc/renewable-energy-distributed-generation-policies-and-programs).

2.4.4.4 Energy Conservation Programs

During public scoping, commenters suggested energy conservation programs as an alternative to the Applicant Proposed Project. Commenters suggested that mandatory conservation and demand response programs be used to eliminate the need for more generation and transmission. This alternative would include regulated energy use at the consumer level to decrease the overall energy demand. This alternative was eliminated from detailed consideration because Section 1222 of the EPAct does not authorize the Secretary of Energy to participate with other entities in energy conservation programs. As such, the alternative would not meet the purpose and need for agency action because energy conservation programs, as studied by DOE, would not meet the utility-scale generation required.

DOE has determined that energy conservation programs would not meet the need of utility-scale generation and would still require the Project to meet the needs of the agency's goal. DOE has established policies and programs related to energy conservation programs (see: http://www.energy.gov/eere/efficiency).

2.5 Connected Actions

Connected actions are those that are "closely related" to the proposal. Actions are considered connected if they automatically trigger other actions which may require environmental impact statements, cannot or will not proceed unless other actions have been taken previously or simultaneously, or are interdependent parts of a larger action and depend on the larger action for their justification (40 CFR 1508.25). Connected actions are analyzed together with the Applicant Proposed Project and DOE Alternatives in this EIS.

2.5.1 Wind Energy Generation

The construction and operations and maintenance of reasonably foreseeable wind power facilities are evaluated as connected actions in the Plains & Eastern EIS. Wind power facilities that would interconnect with the Project are anticipated to be located in parts of the Oklahoma Panhandle and Texas Panhandle within an approximate 40-mile radius of the western converter station. As identified in Section 2.1.2.3, the Applicant based the 40-mile radius assumption on preliminary studies of engineering constraints and wind resource data, industry knowledge, and economic feasibility. The Applicant anticipates that these wind energy generators will be the primary customers using the transmission capacity of the Plains & Eastern transmission line. To achieve full utilization of the 3,500MW delivery capacity of the Applicant Proposed Project, the Applicant anticipates actual wind farm build-out to be approximately 4,000MW. With the addition of the Arkansas converter station alternative, the Applicant anticipates the delivery capacity of the Project to increase to 4,000MW, and associated wind farm build-out to be approximately 4,550MW (Clean Line 2014b). The Oklahoma Panhandle region contains an excellent wind resource (DOE 2011). An analysis of the wind resource in Oklahoma's Panhandle region by the National Renewable Energy Laboratory shows that large areas of wind resources with average annual wind speeds greater than 8 meters/second are prevalent in that part of the state (NREL 2011).

Neither the Applicant nor DOE knows the exact location of wind power facilities that would be connected to the Project. However, it is reasonably foreseeable that future wind farms would be located in a reasonable proximity to the Project's Oklahoma converter station and in areas with high wind resource potential and suitable land use(s). This EIS provides an analysis of potential impacts from wind development within an area of an approximate 40-mile radius of the Oklahoma converter station. Clean Line identified 12 Wind Development Zones (WDZs) in its *Wind Generation Technical Report* (Clean Line 2014b) based on available wind resources and existing land uses within the 40-mile radius. Table 2.5-1 presents the size and potential maximum generation capacity for each WDZ analyzed in this EIS for potential wind energy generation. Figures 2.1-2 and 2.1-17a in Appendix A provide illustrations of the WDZs in relation to the locations of the various Project components.

Table 2.5-1:
Size and Potential Maximum Generation Capacity of Wind Development Zones

WDZ	Approximate Total Size (acres)	Potentially Suitable Areas for Wind Development (acres)	Approximate Maximum Wind Development (megawatts)
A	109,000	101,000	800
B	125,000	108,000	900
C	160,000	123,000	1,000

Table 2.5-1:
Size and Potential Maximum Generation Capacity of Wind Development Zones

WDZ	Approximate Total Size (acres)	Potentially Suitable Areas for Wind Development (acres)	Approximate Maximum Wind Development (megawatts)
D	69,000	43,000	300
E	47,000	43,000	300
F	112,000	82,000	700
G	186,000	159,000	1,300
H	116,000	67,000	500
I	105,000	85,000	700
J	92,000	44,000	400
K	92,000	84,000	700
L	165,000	144,000	1,200

Where construction and operations and maintenance of individual wind power facilities require permits or authorizations, site-specific environmental review, possibly including NEPA review, may be conducted prior to the construction and operations and maintenance of individual wind farm projects.

2.5.2 Related Substation and Transmission Upgrades

In addition to the transmission lines and related facilities analyzed as part of the Project, the EIS also analyzes facility additions and upgrades to existing third-party transmission systems that would be required to enable the Project to transmit power. The additions and upgrades in Oklahoma and Tennessee are evaluated as connected actions in the EIS.

Oklahoma

The Applicant Proposed Project includes construction and operations and maintenance of a converter station in Texas County, Oklahoma. The Oklahoma converter station would be interconnected to the existing transmission system. This interconnection is necessary to enable the AC to DC conversion process within the Oklahoma converter station. The interconnection between the proposed Oklahoma converter station and the SPS system would be controlled to a nominal value of zero (0) MW; meaning that there would be no net energy exchange. Based on the SPS analysis, a new substation would be necessary to accommodate the interconnection due to space constraints at the existing 345kV Hitchland Substation. To alleviate these space constraints, SPS has proposed a new substation nearby, tentatively named “Optima.” This new substation, which represents the connected action, would be located within a few miles of the Oklahoma converter station in Texas County, Oklahoma, within the area identified on Figure 2.1-3 in Appendix A as the AC Interconnection Siting Area. Additional background and details are provided in Section 2.2.1.1.

Arkansas

A DOE Alternative would include construction and operations and maintenance of an intermediate converter station in Arkansas to enable injection and delivery of up to 500MW of power into the Arkansas electrical grid. Clean Line selected the Arkansas Nuclear One-Pleasant Hill 500kV Point of Interconnection in an attempt to avoid the need for additional upgrades to the surrounding transmission system and to accommodate a 500MW injection. MISO performed a feasibility study of the request and delivered results to Clean Line in February 2014. The purpose of this feasibility study was to identify the cost to Clean Line to enter into the Definitive Planning Phase, which consists of several steps that include a system impact study and an interconnection facilities study. These studies would begin to identify the upgrades required to MISO's system, if any, and the next steps for Clean Line to proceed with the Project. If, in the future, network upgrades were identified, they would likely be similar to those discussed for TVA below.

Tennessee

The Applicant Proposed Project includes construction and operations and maintenance of a converter station in Shelby County, Tennessee to enable injection of up to 3500MW of power into the Shelby Substation. As described in Section 2.2.1.3, TVA completed its Interconnection SIS to determine whether any upgrades (or modifications) to its transmission system would be necessary to protect grid reliability while accommodating Clean Line's request for interconnection at 3500MW. The upgrades within Shelby Substation (also referred to as direct assignment facilities) are analyzed in this EIS as part of the Applicant Proposed Project.

TVA's Interconnection SIS has identified the following connected actions as necessary to enable the injection of 3500MW from the Plains & Eastern Clean Line: (a) upgrades to existing infrastructure and (b) construction of a new 500kV AC transmission line, approximately 37 miles long, in western Tennessee, including necessary modifications to existing substations on the terminal ends of the new line. Upgrades to existing infrastructure would include upgrading terminal equipment at three existing 500kV substations and six existing 161kV substations; making appropriate upgrades to increase heights on 16 existing 161kV transmission lines to increase line ratings; and replacing the conductors on eight existing 161kV transmission lines. Most upgrades to existing transmission lines would occur in central and western Tennessee.

TVA's Interconnection SIS estimates that completion of all network upgrades would take 8 years to complete after TVA completes the facilities study. TVA anticipates tiering from this EIS when completing its review of potential environmental impacts of the upgrades as required by NEPA. TVA would evaluate both upgrades to existing infrastructure and construction of a new 500kV transmission line under their NEPA procedures. It is likely that upgrades to existing infrastructure would fall under categories of actions that are expected to result in few, if any, environmental impacts. TVA would likely evaluate potential impacts associated with a new 500kV AC transmission line under a separate NEPA review once the location and design have been identified. For these reasons, and because specific route information regarding the new transmission line and the specific locations for many of the upgrades to existing transmission lines is not available, these actions are not analyzed in detail in this EIS, but are discussed qualitatively in the connected action section in Chapter 3 for each resource.

TVA 500kV transmission lines are typically constructed on ROWs at least 175 feet in width and with self-supporting galvanized laced-steel structures between 85 and 125 feet tall. The distance between structures, which varies with terrain, is typically about 1,000 feet. Final structure heights, conductor span length, and conductor vertical clearance would be determined in accordance with the NESC. The electrical conductors would consist of three sets of three cables bundled in a triangular configuration, suspended beneath the structure crossarms by paired insulators arranged in a "V" shape. Ground wires, which may carry communication circuits, would be placed on the two highest points of the structures to provide lightning protection. Tower foundations are normally a laced-steel grillage, one per leg, buried in the earth. ROW easement acquisition and construction and operations and maintenance methods would generally be similar to those described for transmission lines in Sections 2.1.3, 2.1.4, and 2.1.5.

The total length of multiple existing transmission lines that could require some degree of upgrade is approximately 350 miles; most of these lines are located in central and western Tennessee. However, the upgrades would likely not be necessary along the full length of each line; i.e., the total length of existing transmission lines requiring modification would be less than 350 miles. The detailed identification of the necessary upgrades to each transmission line and construction of a new transmission line (as discussed above) is the subject of an interconnection facilities study, which should be completed in 2016. More detail regarding the typical upgrade activities is provided below.

This EIS assumes that impacts to resources would not occur where the existing terminal equipment at substations would be upgraded; these existing substations are assumed to have permanent access roads that would be used for upgrades, and upgrade activities would not increase the overall footprints of disturbance. The EIS evaluates the following likely upgrades to existing transmission lines:

1. Removing physical objects that interfere with line clearance
2. Replacing and/or modifying existing structures to increase clearance
3. Installing intermediate structures
4. Replacing the existing conductor with another that can accommodate higher power flows
5. Modifying the existing conductor to increase ground clearance
6. Adding fill rock or dirt around the base of existing structures
7. Working with the local power companies to modify their lines where they cross under TVA's lines

The various modification/upgrade activities are described in more detail below.

Typical modifications to existing conductors, installations of intermediate structures, additions of structure extensions, or replacements of existing structures are performed with standard transmission line construction and maintenance equipment such as crane trucks, bulldozers, bucket or boom trucks, and forklifts. Disturbance is usually limited to an approximate 100-foot radius around a transmission line structure.

Modifications to existing conductors include: conductor slides, cuts, and/or installation of floating deadends to increase ground clearance by increasing the height of conductor where it sags to its minimum clearance, or "belly," between structures. A slide involves relocating the conductor clamp on the adjacent structure a certain distance toward the area of concern (i.e., "sliding" the clamp). A cut involves cutting the conductor, removing a small piece of it, and then splicing the conductor ends back together. A floating deadend shortens the vertical (or "suspension") insulator string that attaches a conductor to a "suspension" (or "tangent") structure to raise the height of its conductor. A suspension structure is one that is designed to provide primarily vertical support for a conductor, but not to take the full tension of the conductor, which would require that the structure also provide significant horizontal support.

If the existing conductor is not rated to carry the new electrical load required for the transmission line, the conductor must be replaced. Reels of replacement conductor are delivered to various staging areas along the transmission line ROW and temporary H-frame clearance poles are installed at road crossings to reduce interference with traffic. Bucket trucks are utilized for worker access to the insulators supporting the conductors. Pulleys are attached to the insulators at the conductor clamp points. The new conductor is connected to the old conductor and pulled down the line through the pulleys. A bulldozer and specialized tensioning equipment is used to pull conductors to the proper tension. Workers then clamp the wires to the insulators and remove the pulleys. The length of continuous conductor wire replaced in a single "pull" varies and is limited to a maximum of 5 miles. Pull point locations depend on the type of structures supporting the conductor as well as the length of conductor being installed. Pull points are typically located along the most accessible path on the ROW (adjacent to road crossings or existing access roads). The area of disturbance at each pull point typically ranges from 200 to 300 feet along the line ROW.

Rock or soil "surcharge" is sometimes added to the base of a transmission structure when height and/or loading modifications are made to the structure. These modifications can create uplift on the structure foundation, therefore requiring the surcharge to maintain structure stability, particularly during inclement weather conditions or high conductor loading. The surcharge is typically delivered to structures by dump trucks and placed around the structure base using tracked equipment. Ground disturbance is typically limited to the immediate vicinity of the structure.

Transmission line upgrade activities are planned in a manner to maximize the use of existing access roads and to avoid non-essential stream crossings and activities in wetlands. Other sensitive environmental resources are also avoided to the extent practicable. Where necessary, standard erosion control measures such as the installation of silt fences are implemented. After the completion of the activity, the disturbed area is revegetated using native or non-invasive, low-growing plant species in appropriate areas. Areas such as pastures, agricultural fields, and lawns are restored to their former condition.

2.6 Summary of Impacts by Resource

The impacts analyzed in Chapter 3 of this EIS are summarized in Tables 2.6-1, 2.6-2, and 2.6-3. Table 2.6-1 provides a summary of potential environmental impacts from construction and operations of the proposed converter stations, including the Arkansas Converter Station Alternative Siting Area and AC interconnection. Table 2.6-2 provides a summary of the potential environmental impacts of construction and operations of the AC collection system. These impacts are provided as a range of impacts that could occur among the thirteen different AC collection system routes. Table 2.6-3 provides a summary of the potential environmental impacts of construction and operations of the HVDC transmission line, including any specific difference in impacts between the Applicant Proposed Route and the HVDC alternative routes. Unless specifically identified, potential impacts would be expected to be similar for the Applicant Proposed Route and the HVDC alternative routes.

Chapter 3 also provides the potential environmental impacts for each resource area that could occur from decommissioning of the Project components. Generally, the impacts of decommissioning the Project would be similar to those presented for construction. The Applicant would follow the same general and resource-specific EPMs during decommissioning that would be implemented during construction. In addition, the Applicant would develop a Decommissioning Plan prior to any decommissioning actions for review and approval by the applicable state and federal agencies.

Impacts are presented for the following resource categories: Agriculture; Air Quality and Climate Change; Electrical Environment; Environmental Justice; Geology, Paleontology, Minerals, and Soils; Groundwater; Health, Safety, and Intentional Destructive Acts; Historic and Cultural Resources; Land Use; Noise; Recreation; Socioeconomics; Special Status Wildlife and Fish, Aquatic Invertebrate, and Amphibian Species; Surface Water; Transportation; Vegetation Communities and Special Status Plant Species; Visual Resources; Wetlands, Floodplains, and Riparian Areas; and Wildlife and Fish.

Impacts in the table are presented in terms of direct, indirect, temporary, short-term, long-term, and permanent impacts for each resource area. Direct impacts occur at the same time and place as the Project. Indirect impacts are effects that may occur later in time, or further away from the Project, but are still reasonably foreseeable. Impacts are also characterized by time frame: temporary, short-term, long-term, or permanent. Temporary impacts would occur during construction, with the resource returning to preconstruction conditions once construction is complete. Short-term impacts would continue beyond the completion of construction and last from 2 to 5 years, depending on the resource affected. Long-term impacts would last beyond 5 years and could extend for the life of the Project; these impacts pertain to resources requiring longer recovery periods to return to preconstruction conditions. Permanent impacts are those that would be expected to continue even after decommissioning of the Project.

Table 2.6-1:
Summary of Potential Environmental Impacts—Converter Stations and AC Interconnections

RESOURCE	IMPACT
AGRICULTURAL RESOURCES	
Oklahoma Converter Station and AC Interconnection Siting Areas	Construction The Oklahoma converter station would be located on undeveloped rangeland; approximately 95% of the land cover in the siting area is grassland/herbaceous. Construction of the converter station would convert 45 to 60 acres of rangeland to a utility land use. During construction, an additional 5 to 10 acres would be used as temporary laydown areas for equipment. An additional 4.24 acres of rangeland would be converted to access roads (2.42 acres long term, 1.82 acres temporary). The Oklahoma AC interconnection would be approximately 3 miles long. The agricultural land cover in the representative ROW is currently composed of 58 acres of grasslands. Work in the ROW would include assembly of transmission structures, wire splicing, and tensioning or pulling. Outside the ROW, two additional tensioning or pulling sites would be required. A 25-acre multi-use construction yard space required for the Oklahoma AC interconnection would be shared with that of the HVDC line. During construction, assembly areas for the pole structures (either lattice or tubular structures) would be required, as would wire splicing sites and tensioning or pulling sites. Within the 65.5-acre ROW, an assembly area of 150 feet wide by 150 feet long for each structure would be required. Assuming five to seven structures per mile, the assembly areas would take up to 10.7 acres within the ROW. Approximately two wire splicing sites, each 100 feet by 100 feet (0.2 acre), would be used within the ROW during construction. Approximately four tensioning or pulling sites, 150 feet wide by 600 feet long, also would be required within the ROW, although it is estimated that 1 acre of the total will be located outside the ROW (2.0 acres each, minus 1 acre, for a total of 7 acres). Tensioning or pulling sites would be located partially outside the ROW at locations where the line turns more than 8 degrees. These sites are estimated at 1 acre. A total of approximately 74 acres would be required for the Oklahoma Converter Station (including access roads) and approximately 19 acres would be required for the Oklahoma AC interconnection during construction. Construction may affect livestock control and distribution if a gate is left open or a fence is damaged. Vehicular access during construction would increase the likelihood of livestock injury or death from collisions. Access controls (e.g., cattle guards, fences, gates) would be installed, maintained, repaired, replaced, or restored as required by regulation, road authority, or as agreed to by landowner (EPM GE-8). Operations and Maintenance Once construction has been completed, only the 45- to 60-acre converter station, the AC interconnection pole structures, and a 20-foot-wide paved access road would remain; all other temporary construction areas would be returned to their previous use, primarily rangeland. Approximately 45 acres would be fenced. Within the AC interconnection ROW (200 feet wide), only the transmission structures would remain with a total footprint of up to less than 1 acre. All other land in the ROW could be returned to previous land uses, primarily grazing. Roads not otherwise needed for maintenance and operations would be restored to preconstruction conditions.
Tennessee Converter Station and AC Interconnection Siting Areas	Construction The land cover in the Tennessee Converter Station Siting Area is approximately 50.7% agricultural land cover (30.6 percent pasture/hay and 20.1 percent cultivated crops). No center-pivot irrigation or other irrigation infrastructure is known to occur. Although the exact location has not yet been determined, construction of this converter station would convert 45 to 60 acres of currently undeveloped land to a utility land use. During construction, an additional 5 to 10

Table 2.6-1:
Summary of Potential Environmental Impacts—Converter Stations and AC Interconnections

RESOURCE	IMPACT
	acres would be used as temporary laydown areas for equipment. An additional 4.24 acres of rangeland would be converted to access roads (2.42 acres long term, 1.82 acres temporary). The Tennessee AC interconnection would be located entirely within the converter station siting area and entirely contained within the converter station footprint and the Shelby Substation footprint. All tensioning or pulling for ties between the Shelby Substation and Tennessee converter station (if necessary) would be contained within the footprint of both stations. No temporary construction areas would be needed, and the multi-use construction yard for the Tennessee AC interconnection would share construction yard space with the Tennessee converter station and would be contained within the footprint of the converter station. Construction may affect livestock control and distribution if a gate is left open or a fence is damaged. Vehicular access during construction would increase the likelihood of livestock injury or death from collisions. Access controls (e.g., cattle guards, fences, gates) would be installed, maintained, repaired, replaced, or restored as required by regulation, road authority, or as agreed to by landowner (EPM GE-8). Approximately 74 acres would be required for the Tennessee converter station (including access road) during construction; it is anticipated that any temporary construction areas would be contained within the footprint of the Tennessee Converter Station and the Shelby Substation. Operations and Maintenance Once construction has been completed, only the 45- to 60-acre converter station, the AC interconnection, and 20-foot-wide paved access road would remain; all other temporary construction areas would be returned to their previous use, primarily cultivated crops and pasture/hay. Approximately 45 acres would be fenced.
Arkansas Converter Station Alternative and AC Interconnection Siting Areas	Construction The land cover in the Arkansas Converter Station Alternative Siting Area is composed of approximately 96 acres (26.7%) pasture/hay and approximately 16 acres (4.5%) grassland/herbaceous land cover. The Arkansas AC interconnection would be approximately 5 miles long, and during construction, approximately 146.5 acres of currently primarily pasture/hay land cover would be temporarily converted to a utility use. Construction of the converter station and AC interconnection would directly affect livestock grazing by temporarily reducing forage in up to approximately 661.6 acres of land. If any crop land is in the construction area, crops grown in these areas would be lost and crops in adjacent areas may have reduced yields if there are disturbances to irrigation structures or in aerial spraying. The Applicant would avoid or minimize adverse effects to surface and subsurface irrigation and drainage systems (e.g., tiles). Operations and Maintenance Once construction has been completed, only the 20- to 35-acre converter station and 20-foot-wide paved access road would remain; all other temporary construction areas would be returned to their previous use, primarily rangeland. Approximately 35 acres would be fenced. A 25–35-acre site where the alternative AC transmission line would interconnect with the existing 500kV transmission line would also remain as a utility use. Although most of this land is not currently used for agricultural purposes, up to 72.2% is used as pasture/hay and 0.3% is grassland/herbaceous. If any of these lands are used for long-term structures, they would be removed from agricultural use until decommissioning. Within the Arkansas AC interconnection (150– 200 feet wide by 5 miles long), only the transmission structures and most access roads would remain. Roads not otherwise needed for maintenance and operations would be restored to preconstruction conditions.
AIR QUALITY AND CLIMATE CHANGE	
All Converter Stations and AC Interconnections	Construction Emissions for constructing each of the converter stations and AC interconnections are estimated to be approximately the same because the converter station sizes and construction processes are similar. While there would be minor temporary impacts on air quality in the vicinity of ongoing construction activities, emissions would be below National Ambient Air Quality Standards for all emissions. Operations and Maintenance The converter stations and AC interconnection would emit negligible air pollutants. Standard operations and maintenance of the converter stations and AC interconnection would not emit air pollutants, but maintenance activities would emit small amounts of pollutants associated with combustion of fossil fuels for worker vehicles and equipment.

Table 2.6-1:
Summary of Potential Environmental Impacts—Converter Stations and AC Interconnections

RESOURCE	IMPACT
ELECTRICAL ENVIRONMENT	
All Converter Stations	Construction There would be no electrical effects associated with construction of the converter stations, because these facilities would not be energized during construction. Electrical facilities need to be energized to create electrical effects such as electric and magnetic fields, audible noise, and radio and television interference. Operations and Maintenance For the converter stations, the dominant sources of electrical effects would be the AC interconnections. Some types of substation and switching station equipment can potentially be a source of electrical effects (e.g., power transformers can produce audible noise; converter equipment can produce radio noise, etc.). These effects can be reduced or eliminated by the use of filtering equipment, sound walls, and other methods, so the dominant sources of electrical effects are associated with the overhead transmission lines.
All AC Interconnections	Construction No electrical effects would be associated with construction of AC interconnections because these facilities would not be energized during construction. Oklahoma Converter Station AC Interconnection For the Oklahoma converter station AC interconnection, calculated AC electric fields would be below public guidelines at the ROW edges. However, for one of the three possible configurations (i.e., the double circuit Danube configuration), calculated electric fields at the ROW edge are above guidelines for workers with implanted medical devices. A variety of electronic devices are known to affect the operation of pacemakers and other implanted medical devices. Transmission lines have not been reported as a significant source to produce functional disturbances to these devices. The consequences of brief reversible pacemaker malfunction are mostly benign (typically the implanted device will resume a normal mode of operation if the patient moves away from the source of the interference). An exception would be an individual who has a sensitive pacer and depends on it completely for maintaining all cardiac rhythms. For such an individual, a malfunction that compromised pacemaker output or prevented the unit from reverting to the fixed pacing mode, even brief periods of interference, could be life-threatening. The precise coincidence of events (i.e., pacer model, field characteristics, biological need for full function pacing, and occupation involving work under transmission lines) would generally appear to be a rare event. Since no loading would be present, no AC magnetic field would be generated as a result of the transmission line. Calculated audible noise would be below the public guideline at the ROW edges for two of three possible configuration types (the other configuration type—double circuit monopole— is slightly higher than the public guideline). Calculated radio noise would below guidelines at which reception quality may be less than satisfactory during fair but not rainy weather conditions. While it is difficult to determine whether the TV noise level produced by a transmission line would cause unacceptable interference, new digital broadcast system technology would provide better coverage and less sensitivity to transmission line noise than analog television signals. Maximum ozone levels would be far below the EPA standard. Tennessee Converter Station AC Interconnection For the Tennessee converter station AC interconnection, transmission lines would be located entirely within the converter station and the adjacent Shelby Substation site. Therefore, most electrical effects would be limited to within these electrical stations. Arkansas Converter Station Alternative AC Interconnection For the Arkansas converter station AC interconnection, calculated AC electric fields would be below public guidelines at the ROW edges. However, for the lattice configuration, calculated electric fields within the ROW would be slightly above the transmission line ROW guidelines. For all configurations, calculated electric fields would exceed the American Conference of Governmental Industrial Hygienists (ACGIH) guideline for workers with implanted medical devices within the ROW and at most ROW edges. Calculated AC magnetic fields would be below public guidelines at the ROW edges for both configurations, as well as within the ROW for workers with implanted medical devices. Calculated audible noise would be at or above public guidelines at the ROW edges for both configurations. Calculated radio noise would be below Federal Communications Commission and Institute of

Table 2.6-1:
Summary of Potential Environmental Impacts—Converter Stations and AC Interconnections

RESOURCE	IMPACT
	Electrical and Electronic Engineers exposure guidelines during fair but not rainy weather conditions. While it is difficult to determine whether the TV noise level produced by a transmission line would cause unacceptable interference, new digital broadcast system technology should provide better coverage and less sensitivity to transmission line noise than analog television signals. Maximum ozone levels would be far below the EPA standard.
ENVIRONMENTAL JUSTICE	
All Converter Stations	Construction/Operations and Maintenance There would be no impacts to areas where no minority or low-income populations were identified. For areas where minority and/or low-income populations were identified, it is expected that any impacts would affect all populations equally.
GEOLOGY, PALEONTOLOGY, SOILS, AND MINERALS	
Oklahoma Converter Station and AC Interconnection Siting Areas	Construction Subsidence from karst is a possible geologic hazard of concern within the Oklahoma Converter Station Siting Area. Implementation of EPMs and appropriate engineering design, including geotechnical investigations, would avoid or minimize the potential impacts from karst. No known fossil bed sites were identified in the Oklahoma Converter Station Siting Area. About 40% of the siting area is located in the shallow bedrock, so grading and excavation activities could cause direct impacts to paleontological resources if fossils are at or near the ground surface in rock outcrops and/or areas of shallow bedrock. Designated Farmland. Eight% (73 acres) of the Oklahoma AC interconnection siting area consists of prime farmland. Depending on the specific siting of the AC interconnection line within this area, impacts could include exposing prime farmland to conditions of increased erosion potential, and soils with high compaction potential would be susceptible to compaction from construction vehicles and equipment. Either impact could result in a decrease in the productivity of such soils and a loss of fertile topsoil. Soil Limitations. All of the soils within the Oklahoma Converter Station and AC Interconnection Siting Areas would be susceptible to compaction and have moderate to high wind erosion potential. Bedrock or other restrictive layers are encountered within 60 inches of the ground surface in 42% of the Oklahoma converter station siting area and in 50% of the AC interconnection representative ROW. Soil Contamination. No areas of potential soil contamination were identified; therefore, no construction-related impacts are anticipated. Operations and Maintenance Impacts from geological hazards or to mineral resources are not anticipated because the area is located in an area of low seismic risk, soil liquefaction risk is expected to be low, and no mineral resources are located within the siting areas. Operation and maintenance of the converter station would have long-term impacts (lack of access to potential mineral resources) to a 45-acre fenced area and a conservative estimate of 2.4 acres associated with a new paved access road. Transmission structures would impact a conservative estimate of 0.4 acre.
Tennessee Converter Station and AC Interconnection Siting Areas	Construction The Tennessee converter station and AC interconnection would be constructed to withstand probable seismic events in the moderate to high seismic hazard zones. Soils within the Tennessee Converter Station Siting Area have high liquefaction potential, which could contribute to unstable conditions and potential structural damage during seismic events. Appropriate placement and design of Project components following completion of geologic/geotechnical investigations during engineering design would minimize risks related to soil liquefaction. The Applicant would implement EPMs to minimize the direct effects of landslides in this area of moderate susceptibility and low incidence. About 30% of the siting area is located in shallow bedrock, and blasting may be required. Impacts would be minimized by appropriate engineering design and through implementation of the Blasting Plan. Designated Farmland. Sixty-two percent (459 acres) of the siting area consists of designated farmland. Depending on the specific siting of the converter station and AC interconnection line within this area, impacts could include exposing prime farmland to conditions of increased erosion potential, and soils with high compaction potential would be susceptible to compaction from construction vehicles and equipment. Either impact could result

Table 2.6-1:
Summary of Potential Environmental Impacts—Converter Stations and AC Interconnections

RESOURCE	IMPACT
	in a decrease in the productivity of such soils and a loss of fertile topsoil. Soil Limitations. Soils susceptible to compaction and water erosion dominate the Tennessee siting area. The siting area includes 77 acres (10%) of land with steep slopes and 161 acres (22%) of land with hydric soils. Depending on the specific siting of the converter station, these areas could be avoided or impacted during construction activities. Construction could expose erosion-prone soils to conditions of increased erosion potential; and soils with high compaction potential would be susceptible to compaction from construction vehicles and equipment. Soil Contamination. One National Pollutant Discharge Elimination System (NPDES) site and one Toxics Release Inventory (TRI) site were identified in the siting area. The NPDES site indicates a stone and gravel operation where a permit was granted in 2008 for the discharge of stormwater. The TRI site is the 500kV Shelby Substation. These sites indicate a records inventory and do not raise a concern at this time in regards to areas of soil contamination. Operations and Maintenance The Project components would be operated and maintained in an area of moderate to high seismic hazard, and expected ground motions from an earthquake would be moderate to high. The Project components would be constructed to withstand probable seismic events and constructed in accordance with applicable federal and state regulations to prevent accidents and to ensure adequate protection for the public and the Project. Soils within the siting areas have high liquefaction potential. Geotechnical investigations would be completed in these areas during engineering design. Soils within the siting areas have high liquefaction potential. Geotechnical investigations would be completed in these areas during engineering design. The placement of Project components would be governed in part by site conditions, construction requirements, and EPMs, which would minimize risks related to soil liquefaction. Operations and maintenance would have long-term and impacts (lack of access to potential mineral resources) to a 45-acre fenced area and a conservative estimate of 2.4 acres would be associated with a new paved access road.
Arkansas Converter Station Alternative and AC Interconnection Siting Areas	Construction The converter station and AC interconnection would be located in an area of low to moderate seismic hazard, and one active surface fault that traverses the siting area. Nine percent of soils within the Arkansas Converter Station Siting Area have high liquefaction potential and about 47% of the soils within the AC interconnection have high liquefaction potential. To reduce impacts from seismic hazard and liquefaction, the Applicant would implement the same measures as described for the Tennessee Converter Station and AC Interconnection Siting Areas. The areas have moderate susceptibility and low incidence with respect to landslides. Potential landslide impacts would be reduced or mitigated using the same techniques as described for the Tennessee Converter Station and AC Interconnection Siting Areas. Impacts from blasting would be minimized by following provisions of the Blasting Plan, and the Applicant would train personnel in the practices, techniques, and protocols required by federal and state regulations and applicable permits to protect potential paleontological resources from grading and excavation activities. Shale gas play is located within the converter station and AC interconnection Siting Areas; three oil and gas wells were identified within the converter station Siting Area. EPMs LU-1, GE-29, and LU-4 would be implemented to minimize potential impacts to mineral resources from construction. Designated Farmland. The converter station siting area is located within 192 acres of designated farmland. The converter station would require 20 to 35 acres of land. The AC interconnection representative ROW includes 662 acres, all of which is designated farmland. Depending on the specific siting of the converter station and AC interconnect line within these areas, impacts could include exposing designated farmland to conditions of increased erosion potential, and soils with high compaction potential would be susceptible to compaction from construction vehicles and equipment. Either impact could result in a decrease in the productivity of such soils and a loss of fertile topsoil. Soil Limitations. Fifteen percent of the Arkansas Converter Station Alternative Siting Area is within lands with steep slopes (15 to 30 %). Soils with moderate to high wind and water erosion potential compose 47 and 27%, respectively, of siting area. Bedrock or other restrictive layers are encountered within 60 inches of the ground surface for 79% of the siting area. None of the AC Interconnection representative ROW is within lands with steep slopes (15 to 30%). Soils with moderate to high wind and water erosion potential compose 24 and 50%, respectively, of the AC interconnection representative ROW. Bedrock or other restrictive layers are encountered within 60 inches of the ground surface for

Table 2.6-1:
Summary of Potential Environmental Impacts—Converter Stations and AC Interconnections

RESOURCE	IMPACT
	62% of the AC interconnection representative ROW. Soil Contamination. Two sites were identified in the Arkansas Converter Station Alternative AC Interconnection Siting Area. Both sites are NPDES sites. Implementation of EPMs would minimize potential contamination of soils. Operations and Maintenance The area has moderate susceptibility and low incidence with respect to landslides. The Project components would be in an area of low to moderate seismic hazard. The soils within the siting areas have high liquefaction potential. Impacts from seismic hazards and liquefaction would be minimized utilizing the same measures as described for the Tennessee Converter Station Siting Area and AC Interconnection Siting Area. Impacts to mineral resources are not expected from operations. The converter station site would take 20 to 35 acres of designated farmland out of production. The AC transmission line ROW is estimated to temporarily impact 662 acres of designated farmland. Transmission line structures are conservatively estimated to permanently impact 0.6 acres of land.
GROUNDWATER	
All converter station siting areas	Construction Common impacts from all converter stations include (1) potential for contamination from spills or leaks of fuels and lubricants, (2) small and short-term changes in infiltration rates in areas of land disturbance, (3) minor impacts to water availability from water demands, and (4) potential damage to wells and associated piping systems in construction areas.
Oklahoma Converter Station and AC Interconnection Siting Areas	Oklahoma Converter Station No groundwaters of special interest are underneath the Oklahoma Converter Station Siting Area or the associated AC interconnection. No wells or wellhead protection area are located within the station siting area and a single industrial well, which would likely be avoided, is within the ROW of the AC interconnection. Construction would not include work below the water table. Water needed to support construction would likely come from groundwater. Water demand would not be expected to have an impact on the availability of groundwater for other uses. Operations and Maintenance No impacts on groundwater are expected.
Tennessee Converter Station and AC Interconnection Siting Areas	Construction The converter station and the AC interconnection line would not be located in an area with designations of special interest. No wellhead protection area or wells occur within the siting areas. Water to support construction would be expected to come from groundwater. Construction of the converter station might not encounter groundwater. Operations and Maintenance No impacts on groundwater are expected.
Arkansas Converter Station Alternative and AC Interconnection Siting Areas	Construction The Arkansas converter station alternative and AC interconnection siting areas would be located over an area that has no principal aquifer. No wellhead protection area or wells are present in the siting areas. Water to support construction would likely not come from groundwater because surface water is the predominant source of water in Pope County. Construction actions could possibly encounter groundwater. Operations and Maintenance No impacts on groundwater are expected.
HEALTH, SAFETY, AND INTENTIONAL DESTRUCTIVE ACTS	
All Project Components	Construction/Operations and Maintenance The Project would introduce hazards that could affect worker and public health and safety. Natural events, external events or accidents (e.g., aircraft mishaps or fires) or intentional destructive acts or mischief could impact such infrastructure and have related effects on the health and safety of construction workers and the public. The Project would involve the transportation and handling of hazardous materials. The implementation of EPMs associated with management of hazardous materials would keep risks to a minimum.

Table 2.6-1:
Summary of Potential Environmental Impacts—Converter Stations and AC Interconnections

RESOURCE	IMPACT
HISTORIC AND CULTURAL RESOURCES	
Oklahoma Converter Station and AC Interconnection Siting Areas	Construction The Oklahoma Converter Station and AC Interconnection Siting Areas contain no previously recorded archaeological sites or other historic properties. Cultural resources surveys would be performed prior to construction of the Project to ascertain whether any unrecorded eligible properties for listing on the NRHP are present and to assess the possible impacts of construction on such resources if present. DOE establishes the timing and protocols for cultural resources surveys in the draft Programmatic Agreement (PA), developed through consultation with State Historic Preservation Offices (SHPOs), Indian Tribes, federal agencies, and Clean Line. DOE intends to execute the PA before issuing the ROD or otherwise comply with procedures set forth in 36 CFR Part 800. Operations and Maintenance No impacts have been identified.
Tennessee Converter Station and AC Interconnection Siting Areas	Construction Same as Oklahoma Converter Station and AC Interconnection Siting Areas (row above). Operations and Maintenance No impacts have been identified.
Arkansas Converter Station Alternative and AC Interconnection Siting Areas	Construction The Arkansas Converter Station Alternative and AC Interconnection Siting Areas evaluated in the Draft EIS (roughly 20,000 acres) contain 23 previously recorded archaeological sites, including 2 that have been recommended as eligible for the National Register of Historic Places (NRHP) and 21 that have no eligibility recommendation. There are also three previously recorded historic buildings, none of which has been evaluated for NRHP eligibility. The number of previously recorded cultural resources suggested a moderate to high sensitivity for the presence of sites that might have been affected by the area evaluated in the Draft EIS. The smaller Arkansas Converter Station Alternative and AC Interconnection Siting Areas evaluated in this Final EIS would have the potential to impact a much smaller subset of these historic and cultural resources. Cultural resources surveys would be performed prior to construction of the Project to ascertain whether any historic or cultural properties eligible for listing on the NRHP are present in the affected areas and to assess the possible impacts of construction on such resources if present. DOE establishes the timing and protocols for cultural resources surveys in the draft PA developed through consultation with State Historic Preservation Offices (SHPOs), Indian Tribes, federal agencies, and Clean Line. Operations and Maintenance No impacts have been identified.
LAND USE	
Oklahoma Converter Station and AC Interconnection Siting Areas	Construction The Oklahoma converter station would be located on undeveloped rangeland; approximately 95% of the land cover in the siting area is grassland/herbaceous. Construction of this converter station would convert 45 to 60 acres of rangeland to a utility land use. The Oklahoma AC interconnection would be approximately 3 miles long and would temporarily convert approximately 66 acres of primarily undeveloped rangeland to a utility land use. Operations and Maintenance After construction is complete, only the 45- to 60-acre converter station and 20-foot-wide paved access road would remain; all other temporary construction areas would be returned to their previous use, primarily rangeland. Approximately 45 acres would be fenced. Within the 3-mile-long AC interconnection ROW, only the transmission structures would remain. All other land in the ROW could return to previous land uses, primarily grazing. Access roads that are not needed for operations and maintenance of the Project would be restored.
Tennessee Converter Station and AC Interconnection	Construction The land cover in the Tennessee Converter Station Siting Area is approximately 33 percent deciduous forest, 31 percent pasture/hay, 20% cultivated crops, and 12% woody wetlands. No existing structures are known to occur. Although the exact location within the 218-acre siting area has not yet been determined, construction of this

Table 2.6-1:
Summary of Potential Environmental Impacts—Converter Stations and AC Interconnections

RESOURCE	IMPACT
Siting Areas	converter station would convert 45 to 60 acres of this land to a utility land use. Operations and Maintenance After construction is complete, only the 45- to 60-acre converter station, the AC interconnection, and 20-foot-wide paved access road would remain; all other temporary construction areas would be returned to their previous use, primarily cultivated crops and pasture/hay. Approximately 45 acres would be fenced. Access roads that are not needed for operations and maintenance of the Project would be restored.
Arkansas Converter Station Alternative	Construction The land cover in the Arkansas Converter Station Alternative Siting Area consists primarily of deciduous forest (32.8 percent), pasture/hay (26.7 percent), evergreen forest (21.9 percent), and mixed forest (10.0 percent). Although the exact location of the converter station has not yet been determined, construction of this converter station would convert 20 to 35 acres of undeveloped land to a utility land use. The Arkansas Converter Station Alternative AC Interconnection Siting Area is approximately 1,000 feet wide and the permanent ROW would be 150 to 200 feet wide and approximately 5 miles long with a total acreage of approximately 661.6 acres. During construction, approximately 477.7 acres of primarily pasture/hay land cover would be temporarily converted to industrial utility land use. Operations and Maintenance After construction is complete, only the 20- to 35-acre converter station and 20-foot-wide paved access road would remain; all other temporary construction areas would be returned to their previous use, primarily rangeland. Approximately 35 acres would be fenced. A 25- to 35-acre site where the alternative AC transmission line would interconnect with the existing 500kV transmission line would also remain as a utility land use. Within the 5-mile-long Arkansas AC interconnection ROW, only the transmission structures would remain. Access would be restricted during the performance of maintenance activities. Access roads that are not needed for operations and maintenance of the Project would be restored.
NOISE	
Oklahoma Converter Station and AC Interconnection Siting Areas	Construction Noise levels associated with individual pieces of equipment at 50 feet away would generally range between 55 and 85 dBA maximum sound level (L_{max}). Maximum instantaneous construction noise levels would range from 91 to 95 dBA equivalent sound level (L_{eq}) at 50 feet from any work site. No noise sensitive areas would be located within DOT noise threshold distances, so no exceedances of the DOT guidelines are expected. Operations and Maintenance The predicted sound level at the nearest noise sensitive area would be below the EPA environmental noise guidelines.
Tennessee Converter Station and AC Interconnection Siting Areas	Same as Oklahoma Converter Station and AC Interconnection Siting Areas (row above).
Arkansas Converter Station Alternative and AC Interconnection Siting Areas	Construction Same as Oklahoma Converter Station and AC Interconnection Siting Areas (row above). Operations and Maintenance The predicted sound level at the nearest noise sensitive area would be below the EPA environmental noise guidelines. Six noise sensitive areas (NSAs) would be located within 659 feet of the Arkansas interconnection line, which corresponds to the threshold distance to the 55 dBA L_{dn} EPA guideline threshold for the 500kV single circuit AC transmission line, assuming operating conditions that would generate the highest noise emissions. These six NSAs may experience adverse noise impacts, which are in excess of the EPA guideline threshold. However, impacts would be less under different weather conditions or if the transmission line is located at an altitude less than 3,000 feet.
RECREATION	
Oklahoma Converter Station and AC	Construction No impacts to any recreation resources are expected because there are no recreational resources in these areas.

Table 2.6-1:
Summary of Potential Environmental Impacts—Converter Stations and AC Interconnections

RESOURCE	IMPACT
Interconnection Siting Areas	Operations and Maintenance No impacts expected.
Tennessee Converter Station	Construction No impacts to any recreation resources are expected because there are no recreational resources in these areas. Operations and Maintenance No impacts expected.
Arkansas Converter Station Alternative	Construction Impacts to recreation resources are not expected from construction of the Arkansas converter station and AC interconnection siting areas because no recreational resources are within in these areas. Operations and Maintenance Impacts to recreation resources are not expected from operations and maintenance of the Arkansas converter station and AC interconnection because no recreational resources are within in the siting areas.
SOCIOECONOMICS	
Oklahoma Converter Station and AC Interconnection Siting Areas	Construction Population and community service impacts would be minor, short term, and temporary. Economic condition impacts would be positive, minor, short term, and temporary. Construction of the converter station is expected to cost approximately $250 million and employ an average of 138 workers over a 32-month construction period, resulting in estimated total employee earnings of $16.2 million. Impacts have the potential to be more substantial in Region 1, where housing resources are more limited, if construction is concurrent with construction of the HVDC transmission line and AC collection system; this potential shortage would be further exacerbated if Project construction coincides with construction of wind projects. Tax revenue impacts would be positive, short term, and temporary from sales, use, and lodging taxes. Operations and Maintenance Operations and maintenance of each of the converter stations is expected to support up to 15 workers, with total estimated annual earnings of approximately $1 million. Annual ad valorem or property tax revenues expected to be generated by the Oklahoma converter station in the first year of operation would range from $3.2 million to $4.6 million. Thereafter, ad valorem taxes would be paid annually based on an annual assessment by the responsible taxing agency.
Tennessee Converter Station and AC Interconnection Siting Areas	Construction Population and community service impacts would be minor, short term, and temporary. Economic conditions impacts would be positive, minor, short term, and temporary. Construction of the converter station is expected to cost approximately $250 million and employ an average of 138 workers over a 32-month construction period, resulting in estimated total employee earnings of $16.2 million. Tax revenue impacts would be positive, short term, and temporary from sales, use, and lodging taxes. Operations and Maintenance Operations and maintenance of each of the converter stations is expected to support up to 15 workers, with total estimated annual earnings of approximately $1 million. Clean Line has entered into a payment-in-lieu of taxes (or "PILOT") arrangement with the Economic Development Growth Engine Industrial Development Board of the City of Memphis and Shelby County for the Tennessee converter station (see Section 3.13.6.2.7.1.2).
Arkansas Converter Station Alternative and AC Interconnection Siting Areas	Construction Same as for Tennessee converter station. Operations and Maintenance Operations and maintenance of each of the converter stations is expected to support up to 15 workers, with total estimated annual earnings of approximately $1 million. Operations and maintenance of the Arkansas converter station would generate annual property or ad valorem tax revenues in Pope County. The Arkansas converter station would result in estimated annual ad valorem or property tax revenues of about $0.9 million in its first year of operation. Thereafter, ad valorem taxes would be paid annually based on an annual assessment by the responsible taxing agency.

Table 2.6-1:
Summary of Potential Environmental Impacts—Converter Stations and AC Interconnections

RESOURCE	IMPACT
SPECIAL STATUS WILDLIFE AND FISH, AQUATIC INVERTEBRATE, AND AMPHIBIAN SPECIES	
Oklahoma Converter Station and AC Interconnection Siting Areas	Construction No mortality impacts to any of the special status species are expected. Construction would disturb approximately 45 to 60 acres of grasslands and croplands at the Oklahoma converter station and associated AC interconnection. The habitat loss is unlikely to have substantial long-term direct impacts to special status wildlife populations in the area. No direct or indirect impacts to special status fish, aquatic invertebrate, and amphibian species or their habitat would occur because no waterbodies are located within the footprint of the converter station. Operations and Maintenance Because the converter station area would be a developed site with approximately 45 acres fenced, the routine presence of staff would not have any impacts to any special status wildlife species. The expected risk of collision mortality from the AC interconnection line to avian species is low. No direct or indirect impacts to special status fish, aquatic invertebrate, and amphibian species or their habitat would occur because no waterbodies are located within the footprint of the converter station.
Tennessee Converter Station and AC Interconnection Siting Areas	Construction No mortality impacts are expected to either the northern long-eared bat or Indiana bat. Potential impacts are expected to be very limited because the siting area is largely croplands and pasture land. No loss of bat habitat is expected so long as construction does not require removal of any potential roost trees that may occur in forested areas. The only special status fish or aquatic invertebrate species identified near the converter station include the pallid sturgeon (federally endangered) and blue sucker (state threatened), which occur within the Mississippi River. Although the Mississippi River is more than 10 miles from the siting area, construction activities could impact tributaries draining into the Mississippi River. If the converter station is built adjacent to Big Creek or Bull Branch. Construction activities could introduce sediment, herbicides, and/or fuel and lubricants into the aquatic system that could travel to the Mississippi River. Operations and Maintenance No impacts to either the northern long-eared bat or Indiana bat are expected. If the converter station is built adjacent to Big Creek or Bull Branch, riparian clearing maintenance, road maintenance activities, and facilities operations could result in increased risk of chemical spills and contamination and increased sedimentation that could travel to the Mississippi River.
Arkansas Converter Station Alternative and AC Interconnection Siting Areas	Construction The siting areas contain about 55% forested habitat that could potentially be used by the Indiana bat and northern long-eared bat for summer-roosting and foraging. The occurrence and use of forested habitat by the northern long-eared bat and Indiana bat, and possibly by the Ozark big-eared bat and gray bat as foraging, within the Project ROI is likely restricted to the spring through fall. To the extent that construction of the converter station and associated AC interconnection transmission lines avoids forested areas, impacts to bat habitat (i.e., removal of roost trees or temporary disturbance of roost sites) would be minimized or avoided. No bald eagle nesting or winter roost sites are known to exist within the siting areas, but any potential sites would be identified prior to construction and appropriate measures would be implemented to avoid potential impact to nests or winter roosts. No direct impacts to special status fish, aquatic invertebrate, and amphibian species or their habitat because no waterbodies are located within the footprint of the construction area or along the interconnection area. Operations and Maintenance No impacts to any of the special status bat species are expected from operations and maintenance of the facility. The vegetation in the ROW underneath the AC transmission lines would be maintained in a low stature to prevent interference with electrical conductors. Any trees removed during construction would not be allowed to regrow, including any trees that had been used as bat roost trees. The transmission lines could pose a risk to wintering bald eagles in the region, although there is no suitable habitat within the siting area that would attract eagles from surrounding wintering areas, so the potential risk of collisions with the transmission lines is considered low. No direct or indirect impacts to special status fish, aquatic invertebrate, and amphibian species or their habitat would occur because no major waterbodies are located within the footprint of the construction area or along the interconnection area.

Table 2.6-1:
Summary of Potential Environmental Impacts—Converter Stations and AC Interconnections

RESOURCE	IMPACT
SURFACE WATER	
Common impacts to all converter station and AC interconnection siting areas	Common impacts include (1) potential for runoff and receiving water contamination from spills or leaks of fuels and lubricants, (2) changes in runoff rates in areas of land disturbance, (3) possible disturbance of drainage features, including intermittent or perennial streams, from construction of facilities and access roads; and (4) impacts to water availability from water demands.
Oklahoma Converter Station and AC Interconnection Siting Areas	Construction Limited surface water features consisting of 1.6 miles of intermittent stream beds, no perennial streams, and no major waterbodies are present in the siting areas. The length of intermittent streams within the representative 200-foot-wide ROW for the AC interconnection is 0.2 mile. Water needed to support construction would likely not come from surface water. Operations and Maintenance No impacts on surface water are expected.
Tennessee Converter Station and AC Interconnection Siting Areas	Construction Limited surface water features consisting of a few drainage features, including 0.21 mile of perennial streams, 1.5 miles of intermittent streams, and no major or other waterbodies are present within the siting areas. Water needed to support the construction would likely not come from surface water. Operations and Maintenance No impacts on surface water are expected.
Arkansas Converter Station Alternative and AC Interconnection Siting Areas	Construction The converter station siting area includes no perennial streams, 0.63 mile of intermittent streams, no major waterbodies, and 2.6 acres of reservoirs, lakes, and ponds. The 200-foot-wide representative ROW for the AC interconnection would encompass 0.16 mile of perennial streams, 1.49 miles of intermittent streams, and 1.66 acres of reservoirs, lakes, and ponds. The Applicant would avoid surface waters to the extent practicable in selecting the ultimate construction site for the station. Water to support construction of the converter station and interconnection would likely come from surface water; which is expected to be obtained from a municipal provider. Operations and Maintenance No impacts on surface water are expected.
TRANSPORTATION	
Oklahoma Converter Station and AC Interconnection Siting Areas	Construction No decrease in level of service is expected for any roadway segments in the siting areas. No railroads are located in the siting areas. No impacts to airports, airstrips, or navigation aids are expected. Operations and Maintenance Negligible impacts to transportation.
Tennessee Converter Station and AC Interconnection Siting Areas	Construction Conservative modeling of construction traffic predicts a potential decrease in the level of service from A to B (9 segments) and from B to C (5 segments) for segments of the multiple roadways. Decreases from levels of service LOS-C to LOS-D are predicted for six segments of the some local roadways centered in the area of Munford, Atoka, and Millington, Tennessee. The decrease from LOS-C to LOS-D is only a one-level drop in operation level and would be minimally noticeable to motorists. The scenario that peak traffic would be distributed entirely to the roadway segments with resulting decreases to LOS-D is a bounding scenario; actual impacts to these roadway segments are expected to be less than predicted. No railroads are located within the siting area. Equipment and buildings associated with the converter station are expected to be less than 85 feet in height; these would not affect nearby airports. Operations and Maintenance Negligible impacts to transportation.

Table 2.6-1:
Summary of Potential Environmental Impacts—Converter Stations and AC Interconnections

RESOURCE	IMPACT
Arkansas Converter Station Alternative and AC Interconnection Siting Areas	Construction Construction traffic could result in decreases in the level of service from LSO-A to LOS-B for segments of the multiple roadways. All roadways would continue to operate an acceptable LOS-C or better in the converter station siting area. No railroads, airports, airstrips, or navigation aids would be affected. Operations and Maintenance Negligible impacts to transportation.
VEGETATION COMMUNITIES	
Common impacts to all converter station and AC interconnection siting areas	Construction may cause the direct impact of vegetation removal and the indirect impacts of reduction of plant vigor from mechanical damage, fragmentation, and the introduction of invasive species. Operations and maintenance of the Project would result in the continued absence of vegetation from the footprint of the facilities for the life of the Project. Operations and maintenance of the AC transmission lines for the interconnections would impact vegetation directly through mowing and pruning in the ROW and indirectly through herbicide applications that may impact non-target plant species.
Oklahoma Converter Station and AC Interconnection Siting Areas	Construction The dominant vegetation for the siting area is grassland and herbaceous cover (605 acres). Forty-five to 60 acres of land would be cleared and graded for the station facility footprint, plus an additional 5 to 10 acres of land for the overall construction. Vegetation would not be allowed to grow on these 45–60 acres for the life of the Project and during construction of the Project for the additional 5–10 acres. Clearing and grading activities for the access road would cause removal of approximately 4 acres of vegetation for the life of the Project. A maximum 200-foot-wide by 3-mile-long interconnection ROW would result in approximately 66 acres of long-term impacts, including the initial clearing of the existing vegetation. The footprint of the transmission line support structures would require less than 1 acre of long-term impact to vegetation. Operations and Maintenance Vegetation removed during the construction of the converter station or access road would not be replaced during the operations phase of the Project. Vegetation within the ROW of the AC interconnection would be maintained during the operations and maintenance phase of the Project. The projected acreage of vegetation to maintain in the AC interconnection ROW is 66 acres.
Tennessee Converter Station and AC Interconnection Siting Areas	Construction The dominant vegetation for the siting area for the Tennessee converter station includes cultivated crop lands (394 acres) and pasture/hay (195 acres). Forty-five to 60 acres of land would be cleared and graded for the station facility footprint. Vegetation would not be allowed to grow on these 45-60 acres for the life of the Project and during construction of the Project for the additional 5–10 acres. Clearing and grading activities for the access road would cause the removal of approximately 4 acres of vegetation for the life of the Project. Operations and Maintenance Vegetation removed during the construction of the converter station or access road would not be replaced during the operations and maintenance phase of the Project.
Arkansas Converter Station Alternative and AC Interconnection Siting Areas	Construction The dominant land cover type is deciduous forest (71 acres), followed by pasture/hay lands (67 acres), and cultivated crops (44 acres). There are also 12 acres of woody wetlands within the overall siting area. Twenty to 35 acres of land would be cleared and graded for the station facility footprint. Vegetation would not be allowed to grow on these 20–35 acres for the life of the Project. Clearing and grading activities for the road would cause removal of approximately 4 acres of vegetation for the life of the Project. The following impacts would be expected: • Transmission line ROW: A maximum 200 foot-wide by 5-mile-long ROW would impact 121 acres of vegetation. • Lattice or monopole structures: Approximately 1 acre of vegetation removal. • Tubular pole structures: Less than 1 acre of vegetation removal. • AC Interconnection Siting Area: A 25-35-acre site would be required for the interconnection to an existing

Table 2.6-1:
Summary of Potential Environmental Impacts—Converter Stations and AC Interconnections

RESOURCE	IMPACT
	500kV transmission line. An additional 5-acre area would be required during construction, resulting in a potential for 40 total acres of impact. The interconnection site is mostly grassland with some forested areas. Operations and Maintenance Vegetation removed during the construction of the converter station or access road would not be replaced during the operations phase of the Project. Vegetation within the ROW of the AC interconnection would be maintained during the operations and maintenance phase of the Project. The projected acreage of vegetation to maintain in the ROW is 121 acres. Vegetation removed for the interconnection site would not be replaced except for about 5 acres required only during construction.
VISUAL RESOURCES	
Oklahoma Converter Station and AC Interconnection Siting Areas	Construction Short-term visual intrusion of construction vehicles, equipment, materials, and a work force in staging areas, and final converter station location. Vehicles, heavy equipment, structure components, ancillary facility components and materials, and workers would be visible during construction and would create short-term and local contrast within the areas of the ROW for the AC interconnection. Lighting of construction yards and work areas would create temporary visual impacts to night skies. Affected viewers would be aware of the temporary nature of the Project construction impacts, which should decrease their concern about the impact. Operations and Maintenance Facilities would contrast with the rural landscape and be visible on the horizon from large distances; however, the area is already impacted by numerous vertical structures such as wind turbines and existing transmission lines. There are no notable visual resources, so visual concern is low. Overall visual impacts would be low due to existing modification to the landscape and low number of sensitive viewers.
Tennessee Converter Station and AC Interconnection Siting Areas	Construction Same as described for the Oklahoma converter station. Operations and Maintenance Two key observation points were identified for the siting area. Depending on the observation point, the Project would result in moderate or strong contrast and moderate-high visual impacts.
Arkansas Converter Station Alternative and AC Interconnection Siting Areas	Construction Short-term visual intrusion of construction vehicles, equipment, materials, and a work force in staging areas, and final converter station location. Vehicles, heavy equipment, structure components, and workers would be visible during converter station construction and modification, access and spur road clearing and grading, structure erection, and cleanup and restoration. Affected viewers would be aware of the temporary nature of the Project construction impacts, which should decrease their concern about the impact. Operations and Maintenance The surrounding landscape of the siting area is primarily rural and agricultural and other than rural residences, does not contain a high number of sensitive resources that would be impacted. When visible in the foreground, the facilities associated with the converter station would result in high contrast on the rural landscape, but given low numbers of sensitive viewers in the area, it would have an overall low-moderate impact.
WETLANDS, FLOODPLAINS, AND RIPARIAN AREAS	
Oklahoma Converter Station and AC Interconnection Siting Areas	Construction The Oklahoma Converter Station and AC Interconnection Siting Areas are dominated by grassland/herbaceous vegetation (605 acres). No wetland resources or 100-year floodplains were identified within the siting areas. Potential impacts to riparian areas are unlikely. Less than 2 miles of intermittent stream beds, no perennial streams, and no major waterbodies are present within the siting areas. Operations and Maintenance No impacts to wetlands, floodplains, or riparian areas are expected.

Table 2.6-1:
Summary of Potential Environmental Impacts—Converter Stations and AC Interconnections

RESOURCE	IMPACT
Tennessee Converter Station and AC Interconnection Siting Areas	Construction The Tennessee Converter Station and AC Interconnection Siting Areas include approximately 2.7 acres of palustrine forested wetlands. The construction effort would avoid wetlands and waters of the United States to the extent practicable. Where impacts appear unavoidable, those wetland sites would receive a formal wetland delineation and appropriate consultation with the USACE. No 100-year floodplains occur with the siting area. Only 1.5 miles of intermittent and 0.2 mile of perennial streams, and no major waterbodies are present within the siting area. Potential impacts to riparian areas are unlikely. Operations and Maintenance If wetlands and riparian areas can be avoided during construction activity, then they should also be avoided during all operations and maintenance activities.
Arkansas Converter Station Alternative and AC Interconnection Siting Areas	Construction The Arkansas Converter Station Alternative Siting Area includes 0.6 mile of intermittent streams, 43.8 acres of floodplains, and 2.6 acres of surface waterbodies (ponds/lakes). The converter station would ultimately only disturb approximately 20–35 acres of land and it is very unlikely that these 20–35 acres would be focused on the wetland resources documented within the siting area. The construction effort should avoid wetlands and waters of the United States to the extent practicable. The Arkansas AC Interconnection Siting Area is approximately 1,000 feet wide and the permanent ROW would be 150 to 200 feet wide and approximately 5 miles long with a total acreage of approximately 661.6 acres. The ROW includes 1.5 miles of intermittent streams, 0.2 mile of perennial streams, 463.8 acres of floodplains, and 1.7 acres of other surface waterbodies (ponds/lakes). Operations and Maintenance Wetlands, floodplains and riparian areas associated with perennial streams have all been documented within the siting area, but ultimately only 20-35 acres of land would be disturbed. Therefore, these resources would likely be avoided during siting and would thus incur no impacts during operations and routine maintenance.
WILDLIFE AND FISH	
Oklahoma Converter Station and AC Interconnection Siting Areas	Construction Wildlife species would be exposed to Project-related mortality or injury. Grasslands and croplands are capable of restoring to pre-disturbance levels in a short timeframe (defined as less than 5 years). As a result, the majority of Project-related impacts to grasslands and croplands habitats would be short term in nature (i.e., those areas would restore to pre-construction conditions within 5 years or less) However, some permanent loss of grassland and croplands habitats would also occur as a result of the Project’s permanent footprint. The grassland and cropland habitats found within the Oklahoma Converter Station and AC Interconnection Siting Areas are relatively common throughout the ROI; therefore, disturbance of 45–60 acres would not result in a significant impact to local wildlife. No perennial streams and no major waterbodies are located within the siting area. Coldwater Creek, a perennial stream, is within 1 mile of the siting area. Increased sedimentation is not likely to affect Coldwater Creek; however, if construction occurs near established intermittent waterways, there is potential for sediment to travel downstream and cause potential impacts to fish and aquatic invertebrate species. Operations and Maintenance Operation and maintenance activities would result in long-term impacts to the habitats. Some permanent loss of habitat would occur as a result of the Project’s permanent footprint (i.e., some areas would be encompassed permanently by Project structures such as the converter station, transmission line structures, access roads, etc.).The permanent loss of habitat is unlikely to have substantial long-term impacts to wildlife populations in the area because the type of habitats affected are common in the region and found elsewhere in the vicinity of the Project ROI. Operation and maintenance activities would not result in long-term impacts to fish and aquatic species because no major waterbodies or perennial streams are within the siting area, and downslope streams are approximately 1 mile away.

Table 2.6-1:
Summary of Potential Environmental Impacts—Converter Stations and AC Interconnections

RESOURCE	IMPACT
Tennessee Converter Station and AC Interconnection Siting Areas	Construction Croplands and pasture/hay lands are the dominant habitat types found in the siting areas. However, hardwood forests and riparian areas are also present. Croplands and pasture lands are capable of restoring to pre-disturbance levels in a short timeframe (defined as less than 5 years). As a result, the majority of Project-related impacts to these areas would be short-term in nature. However, some permanent loss of habitats would still occur as a result of the Project's permanent footprint. Furthermore, because forests and riparian areas are also present, these types of habitats could also be potentially impacted as well. Forested and riparian areas could take decades to restore to pre-construction conditions if they are disturbed or cleared. There are no major waterbodies or streams located within the siting area. The Tennessee Converter Station Siting Area and AC Interconnection Siting Area borders Big Creek, a perennial stream, listed as impaired in 2010 for aquatic resources (fish, shellfish, and wildlife values). Impacts fish and aquatic species would likely be less if the facilities were located within the croplands and pasture/hay lands, and greater if they were located in forested areas due to the effects of long-term habitat loss from vegetation clearing, the extensive time necessary for forests to regenerate to pre-disturbance conditions and provide sediment retention, shade, and cover, and the impacts associated with edge effects in forested habitats that do not provide sedimentation retention, shade, and cover. Operations and Maintenance Operation and maintenance activities would result in long-term impacts to the habitats. Some permanent loss of habitat would occur as a result of the Project's permanent footprint (i.e., some areas would be encompassed permanently by Project structures such as the converter station, transmission line structures, access roads, etc.). The permanent loss of habitat is unlikely to have substantial long-term impacts to wildlife populations in the area because the type of habitats affected are common in the region and found elsewhere in the vicinity of the Project ROI. However, species that are near or at carrying capacity may experience a reduction in population size due to this permanent loss of potential feeding and breeding A perennial stream flows adjacent and downslope along the western side of the siting areas. Additionally, a perennial stream flows through the middle of the siting area. Placement of roads and structures that could result in increased sedimentation from operations and maintenance activities could result in long-term direct and indirect impacts to fish and aquatic invertebrate species or their habitat.
Arkansas Converter Station Alternative and AC Interconnection Siting Areas	Construction The siting area contains a variety of habitats that range from forested areas to pasture lands. The Project could result in long-term impacts to wildlife habitats (due to the timeframes necessary for these forests areas to restore to pre-construction conditions). Because the pasture/hay fields that could potentially be impacted are capable of restoring to pre-disturbance levels in a short timeframe (defined as less than 5 years), most impacts to these types of habitats would be short-term in nature. However, some long-term loss of pasture/hay field habitats would still occur as a result of the Project's footprint. Impacts to wildlife would likely be less if the facilities were located within the pasture lands, and would be greater if they were located in forested areas due to the effects of long-term habitat loss, the extensive time necessary for forests to regenerate to pre-disturbance conditions, and the impacts associated with edge effects in forested habitats. Construction would not likely result in any direct impacts to fish and aquatic invertebrate species or their habitat because no waterbodies are located within the siting area. Indirect construction impacts should be minimal. However, if either siting area is upslope of any waterbodies, there is a potential for runoff to enter the waterway, causing potential indirect impacts to fish and aquatic invertebrate species. Operations and Maintenance The permanent loss of habitat is unlikely to have substantial long-term impacts to wildlife populations in the area because the type of habitats affected are common in the region and found elsewhere in the vicinity of the Project ROI. Direct impacts to fish and aquatic invertebrate species or their habitat are not expected because no waterbodies are located within the footprint of the interconnection area.

Table 2.6-2:
Summary of Potential Environmental Impacts—AC Collection System

RESOURCE	IMPACT
Agricultural Resources	Construction Cultivated crops would be directly affected by removal of vegetation and potential removal of agricultural structures such as irrigation systems, barns, and silos. Agricultural production may be temporarily diminished. The Applicant would avoid or minimize adverse effects to surface and subsurface irrigation and drainage systems (e.g., tiles). Potential impacts to cultivated crops would vary based on the design and location of the proposed transmission line structures and access roads relative to existing agricultural operations. During construction, 325 to 1,365 acres of primarily grassland and cultivated crops would be disturbed depending on which AC collection system route is constructed. Construction of the AC collection system would directly affect livestock grazing by temporarily reducing forage for livestock within areas of grassland/herbaceous and pasture land cover. Construction may affect livestock control and distribution if a gate is left open or a fence is damaged. Vehicular access during construction would increase the likelihood of livestock injury or death from collisions. Construction and operations and maintenance of the proposed transmission lines could affect the economic value of livestock production in the representative ROW by increasing ranchers' costs and decreasing available forage. The Project could affect net earnings from livestock production in the following ways: • Decreased forage from land taken out of production • Increased management costs associated with controlling additional noxious and invasive vegetation species introduced by Project construction equipment • Increased management costs associated with moving livestock around Project-related structures and easements if a landowner wishes to move livestock during the construction period Operations and Maintenance Potential impacts to cultivated crops would vary based on the design and location of the AC collection system structures and access roads relative to existing agricultural operations. Long-term disturbance would result in 1.8 to 7.8 acres of primarily grassland/herbaceous and cultivated crops depending on which AC collection system route is constructed. Most agricultural activities such as livestock grazing and cultivating crops could be returned to the ROW upon the completion of construction.
Air Quality and Climate Change	Construction Construction activities would result in air quality and greenhouse gas emissions. Emissions are not anticipated to cause or significantly contribute to a violation of an applicable ambient air quality standard or contribute substantially to an existing or projected air quality violation. Operations and Maintenance There would be negligible amounts of air pollutants from maintenance activities. Operations and maintenance of the AC collection system would not emit pollutants; however, maintenance activities would emit small amounts of pollutants associated with combustion of fossil fuels for worker vehicles and equipment.
Electrical Environment	Construction No electrical effects would be associated with construction of the AC collection system because these facilities would not be energized during construction. Operations and Maintenance Calculations with respect to electrical fields, magnetic fields, audible noise, radio noise, television noise, and ozone were performed for each of the configurations and the results are as follows: • Calculated AC electric field levels at the ROW edges would be below guidelines for public exposure (established by non-regulatory organizations such as the Institute of Electrical and Electronics Engineers [IEEE] and the International Committee on Non-Ionizing Radiation Protection [ICNIRP]). Within the ROW, calculated electric field levels would be below some guidelines for transmission line ROWs, but exceed some public exposure guidelines. For the single circuit lattice structure configuration, calculated electric field levels exceed the ACGIH guideline for workers with implanted medical devices at the ROW edges if the ROW width is only 150 feet, but comply if the width is 200 feet. • Calculated magnetic field levels at the ROW edges are below guidelines for public exposure (established by non-regulatory organizations such as the IEEE and ICNIRP) and within the ROW are below the ACGIH

Table 2.6-2:
Summary of Potential Environmental Impacts—AC Collection System

RESOURCE	IMPACT
	guideline for workers with implanted medical devices. • Calculated audible noise levels at the ROW edges are below the EPA guideline for noise. • Calculated radio noise levels at 50 feet from the outside conductor comply with the IEEE threshold during fair weather conditions but are slightly above that threshold during rainy weather. • Television noise could cause interference. No interference from corona-generated noise expected for digital signals broadcast at frequencies above 1 gigahertz from satellites. • Maximum ozone levels are far below the EPA standard. • Based on an evaluation of research and guidelines recommended by various agencies, it is unlikely that the AC collection system would pose a known threat to human health. • Overall, the likelihood of annoyance to landowners by audible noise from the line or interference with AM radio or television reception is small.
Environmental Justice	Construction/Operations and Maintenance No temporary, short-term, or long-terms impacts to low-income or minority populations are anticipated.
Geology, Paleontology, Soils, and Minerals	Construction Designated Farmland. AC Collection System Route SW-1 would impact the least amount (9 acres) of designated farmland. AC Collection System Routes E-2, NW-1, NW-2, SE-1, and SE-3 would impact the greatest amount (502 to 671 acres) of designated farmland. Soil Limitations. Depending on the AC collection system routes that are implemented, construction would result in: • Disturbance of 128 to 1,125 acres of karst and 43 to 138 acres of shallow bedrock • 127 to 1,209 acres of soils with high compaction potential • 76 to 779 acres of soils with moderate to high wind erosion potential • 0 to 46 acres of soils with slopes of 15% to 30% • Temporary disturbance to soils from access roads Soil Contamination. One facility/site with known contamination was identified within the AC Collection System Route SW-2. That location would likely be avoided. Operations and Maintenance Impacts to soils generally depend on the length and area covered by the routes, which generally correlates with the amount of access roads and ROW. Other impacts depend on farmland and soil limitation parameters that might be affected. Impacts to soils would be limited to the actual transmission line structure footprints and from occasional use of the ROW for maintenance access. Impacts from access roads might expose soils to erosion and compaction. Impacts caused by new structures would be permanent during operations and maintenance and the access impacts would be temporary and minimal.
Groundwater	Construction Common impacts among the AC collection system routes include (1) potential for contamination from spills or leaks of fuels and lubricants, (2) short-term changes in infiltration rates in areas of land disturbance, (3) minor impacts to water availability from water demands (low demand as compared to availability), and (4) potential damage to wells and associated piping systems in construction areas. The deepest foundations for transmission line structures would be in the range of 15 to 30 feet below ground. Based on the typical depths to groundwater in the five counties in which the AC collection system routes would be located, it is expected that construction of foundations for transmission line structures would not reach groundwater. Five of the representative ROWs associated with AC Collection System Routes E-1, E-2, E-3, SE-1, and SE-3 would encompass 14 to 174 acres of nutrient-vulnerable groundwater, but do not cross areas with special source groundwater. The total number of wells (private domestic, public water supply, agricultural, and industrial) within the ROWs range from 0 to 8. Operations and Maintenance No impacts to groundwater.

Table 2.6-2:
Summary of Potential Environmental Impacts—AC Collection System

RESOURCE	IMPACT
Health, Safety, and Intentional Destructive Acts	Construction/Operations and Maintenance The Project would introduce hazards that could affect worker and public health and safety. Natural events, external events or accidents (e.g., aircraft mishaps or fires) or intentional destructive acts or mischief could impact such infrastructure and have related effects on the health and safety of construction workers and the public. The Project would involve the transportation and handling of hazardous materials. The implementation of EPMs associated with management of hazardous materials would keep risks to a minimum.
Historic and Cultural Resources	Construction AC Collection System Routes NE-1, NE-2, SE-1, SE-2, and SW-1 contain no previously recorded archaeological sites or other historic properties. AC Collection System Routes E-1, E-2, E-3, and SE-3 each contain one previously recorded archaeological site that has not been evaluated for NRHP eligibility. None contain previously recorded historic buildings. AC Collection System Routes NW-1 and NW-2 each contain two previously recorded archaeological sites, neither of which has been evaluated for NRHP eligibility. AC Collection System Route NW-1 contains no previously recorded historic buildings. The NRHP-listed Tracey Woodframe Grain Elevator is located in the vicinity of AC Collection System Route NW-2. AC Collection System Route SW-2 contains three previously recorded archaeological sites, none of which have been evaluated for NRHP eligibility. The route contains no previously recorded historic properties. AC Collection System Route W-1 contains two previously recorded archaeological sites, neither of which has been evaluated for NRHP eligibility. The route contains no previously recorded historic properties. A cultural resources survey within AC collection system would be performed prior to construction of the Project to assess the possible impacts of construction on such resources if present. Depending upon circumstances, such survey(s) would be conducted in accordance with the PA. Operations and Maintenance No impacts would be expected.
Land Use	Construction The majority of the impacts to land use would be temporary. Construction would temporarily prevent the use of rangeland and cultivated crops in the ROW. Depending on the AC collection system route, disturbance of primarily grassland and cultivated crops would range from 325 to 1,365 acres. There are 0 to 2 structures present in ROWs. Operations and Maintenance Assuming 300 miles of up to seven lattice structures per mile, the operational footprint of the structures would be approximately 42 acres. An additional 3 acres would be required for six fiber optic regeneration sites. It is anticipated that all existing roads and existing roads with repairs/improvements would be retained for operations and maintenance of the Project. It is estimated that approximately 75% of the new overland roads with no improvements and 90% of the new overland roads with clearing and new bladed roads would be retained for operations and maintenance access. These roads would be up to 20 feet wide. Access roads that are not needed for operations and maintenance would be restored. All other land in the ROW could return to most previous land uses if they are compatible with operations and maintenance of the Project. Some uses may be impeded in the ROW, such as using farming equipment near the pole structures or crop-dusting planes that would not be able to approach the transmission lines. Land uses that would not be permitted in the ROW include buildings or structures, changing the grading and land contours, and some restrictions and coordination for infrastructure such as fences and irrigation lines. In addition, access would be restricted during the performance of maintenance activities. All of the tensioning or pulling areas could return to existing uses once construction has been completed.

Table 2.6-2:
Summary of Potential Environmental Impacts—AC Collection System

RESOURCE	IMPACT
Noise	Construction Depending on the route, noise sensitive areas may experience short-term and temporary elevated noise levels. The only two schools within the ROI are within AC Collection System Route E-1, located within the town of Hardesty. Operations and Maintenance Operations and maintenance would include the use of trucks, lifts, or other equipment as needed on a periodic basis along the AC collection system. Depending on the route, some noise sensitive areas could experience adverse noise impacts under certain operational and weather conditions.
Recreation	Construction Construction is not expected to permanently preclude the use of or access to any existing recreation areas or activities since no recreation resources have been identified within the representative ROW for any routes. The southern boundaries of the Optima National Wildlife Refuge (NWR) and the Optima Wildlife Management Area (WMA) are located to the north of AC Collection System Route E-1. At the closest point, the Optima NWR and the Optima WMA are approximately 1,500 feet from this route, and about 1.5 miles from the Optima lake shoreline, which is within the NWR and WMA areas. The boundaries of the Schultz Lake State Park and Schultz WMA are located to the north of AC Collection System Routes SE-1, and E-2. At the closest point, the Schultz Lake State Park and Schultz WMA are approximately 0.5 mile from the route. The boundary of the Shorb WMA is located to the north of AC Collection System Routes E-2 and SE-3. At the closest point, the Shorb WMA is located 0.16 mile to the north of the routes. Long-term indirect impacts would result from vegetation clearing and structure erection and could affect recreational visitors in adjacent recreational areas due to changes in the scenic landscapes visible from Optima NWR and WMA, Schultz Lake State Park and WMA, and Shorb WMA. Operations and Maintenance No impacts to recreation resources are anticipated from operations and maintenance of any of the AC collection system routes because no recreation resources are located within the representative ROW.
Socioeconomics	Construction Population and community service impacts would be short term and temporary. Economic condition impacts would be positive, short term, and temporary. Impacts have the potential to be more substantial in Region 1, where existing housing resources are more limited, if construction is concurrent with construction of the HVDC line and Oklahoma converter station; this potential shortage would be further exacerbated if Project construction coincides with construction of wind projects. Tax revenue impacts would be short term and temporary from sales, use, and lodging taxes, ranging from $0.2 million to $2.5 million per route alternative. Operations and Maintenance Operations and maintenance are unlikely to affect regional agricultural production and employment, but could have localized impacts. Some short-term adverse impacts on residential property values (and salability) might occur on an individual basis as a result of the Project. However, these impacts would be highly variable, individualized, and are difficult to predict. Positive tax revenue impacts (less than $1 million per route) would be expected from annual ad valorem or property taxes. Ad valorem taxes would be paid annually based on an annual assessment by the responsible taxing agency.
Special Status Wildlife and Fish, Aquatic Invertebrate, and Amphibian Species	Construction Habitat loss and fragmentation of existing grassland habitat is one of the primary threats to the lesser prairie-chicken (LEPC). The highest quality LEPC habitat (based on Crucial Habitat Assessment Tool [CHAT]-1 and CHAT-2) occurs on the eastern side of the AC collection system area. To the extent that the AC transmission lines and access roads cross contiguous areas of native grasslands, construction of the AC collection system may contribute to the loss of potential LEPC habitat. These impacts could be minimized with routes that follow existing ROWs, areas of cultivated fields, and grassland areas already fragmented by other activities that are areas of low quality prairie chicken habitat. The Sprague's pipit also uses native grasslands and could be similarly affected by loss of habitat and fragmentation. Special status fish, aquatic invertebrate, and amphibian species potentially occurring within the AC collection system routes include populations of the Arkansas River shiner. The Beaver River and Palo Duro Creek, which are

Table 2.6-2:
Summary of Potential Environmental Impacts—AC Collection System

RESOURCE	IMPACT
	crossed by several routes, may provide aquatic habitat for the Arkansas River shiner. Potential direct impacts include grading, access roads, herbicide use, and handling of fuel and lubricants where the Beaver River and Palo Duro Creek would be crossed by the routes. Operations and Maintenance Potential impacts to special status wildlife species include mortalities from collisions with transmission lines and structures and possible electrocutions, disturbance impacts from routine maintenance activity, and loss of habitat by behavioral avoidance of areas surrounding vertical structures (i.e., transmission structures and lines). There is a potential risk of mortalities to whooping cranes and golden eagles from collisions with transmission lines and structures. The prairie chicken is a low flier and typically avoids areas surrounding tall structures. Routine maintenance and inspection work is unlikely to impact special status wildlife species other than a temporary displacement while work is performed. However, any avoidance of areas by the LEPC due to the potential for increased predation rates (due to consolidation of raptors and corvids along the AC collection lines) would constitute a loss of habitat. The use of both access roads and the ROW for repair and maintenance activities could result in both direct and indirect impacts to the Arkansas River shiner or its potential habitat in the Beaver River and Palo Duro Creek. The potential application of herbicides could result in indirect impacts, and to a lesser extent, direct impacts.
Surface Water	Construction Common impacts include (1) potential for runoff and receiving water contamination from spills or leaks of fuels and lubricants, (2) short-term changes in runoff rates in areas of land disturbance, (3) possible disturbance of drainage features, including intermittent or perennial streams, from construction of access roads; and (4) impacts to water availability from water demands. Depending on the route, potential impacts could occur to the following surface water resources: (1) the 200-foot-wide ROWs contain 0 to 0.51 mile of perennial streams, 0.25 to 2.91 miles of intermittent streams, 0 to 0.18 mile of major waterbodies, and 0 to 2.61 acres of reservoirs, lakes or ponds; (2) AC Collection System Route SE-3 crosses Wolf Creek, designated a Texas ecologically unique stream segment; (3) six of the routes cross impaired water segments of Beaver River or Palo Duro Creek; and (4) the depth to water table is great enough that pumping and discharge of groundwater during construction is unnecessary. Operations and Maintenance Operations and maintenance would not impact surface water.
Transportation	Construction Only minor decreases in the level of service for area public roadways in the ROI would be expected. These decreases would be temporary. Operations and Maintenance None of the routes would result in impacts to traffic, railroads, or airports/airfields.
Vegetation Communities	Construction Impacts include the initial clearing of vegetation in the ROW and the removal of vegetation in the locations of transmission line support structures. The range of potential impacts from vegetation clearing in the ROW ranges from 325 acres to 1,365 acres. There would be 1.9 acres to 7.8 acres of permanent vegetation loss at structural foundation placements. Operations and Maintenance There would be some degree of regular mowing and trimming of vegetation in any of the routes. None of the routes have forested land cover, so there would be little to no change in the structural form of the vegetation. Depending on the route, the projected acreage of vegetation to maintain in the ROW is between 325 and 1,365 acres.
Visual Resources	Construction There would be short-term visual intrusion of construction vehicles, equipment, materials, and a work force in staging areas, along access roads, and along the new transmission line ROW. Vehicles, heavy equipment, structure components, and workers would be visible during transmission line construction and modification, access and spur road clearing and grading, structure erection, conductor stringing, and cleanup and restoration. However, disturbance from construction activities would be transient and of short duration as activities progress along the transmission line route. Affected viewers would be aware of the temporary nature of Project construction impacts, which may decrease their concern to the impact. The structures and cables (transmission lines) would cause the

Table 2.6-2:
Summary of Potential Environmental Impacts—AC Collection System

RESOURCE	IMPACT
	major long-term change in scenery. Operations and Maintenance The routes are located in a sparsely populated area in a landscape that is primarily flat agricultural lands offering open panoramic views. The region does not contain a high number of sensitive viewers or sensitive resources, so impacts would be expected to be low–moderate. The routes are located in a largely open and undeveloped landscape, and the introduction of large vertical elements such as a transmission line, would have the potential to affect viewers over a large viewing area. Thirteen viewing locations were identified for the routes.
Wetlands, Floodplains, and Riparian Areas	Construction Impacts may vary from short term to long term, and potentially there may be permanent loss of wetland acreage. Potential impacts to wetlands for the various routes range from 0 acre to 20.1 acres. Potential impacts to floodplains range from 0 to 54.6 acres. Riparian areas could be associated with surface water features, which range from 0 to 0.5 mile of perennial streams, 0.3 to 2.9 miles of intermittent streams, 0 to 0.2 mile of major waterbodies, and 0 to 2.6 acres of reservoirs, lakes, and ponds. Operations and Maintenance Impacts may result from use of heavy machinery through wetlands, floodplains, and riparian areas. These impacts can cause soil compaction and mechanical damage or removal of vegetation. These impacts are anticipated to cover a range from temporary to potentially more severe and long-term/permanent. The use of vegetation management would be necessary to protect the Project infrastructure and enhance safety. However, the trimming, mowing, or removal of vegetation can cause changes to plant diversity and function in all three ecosystem types (i.e., wetlands, floodplains, and riparian areas). Vegetation maintenance in wetlands and riparian areas should be kept to a minimum. Additionally, the use of herbicides can cause few to severe impacts to vegetation in areas where they are applied.
Wildlife and Fish	Construction/Operations and Maintenance Some routes would have an elevated risk of avian collision during the migration seasons compared to the other routes, as well as a higher potential for disturbances to important wildlife areas due to these routes proximity to important wildlife areas (i.e., Optima NWR and Optima WMA). There would be no substantial difference between the other routes considered with regard to the types of wildlife impacts that would likely occur as a result of the route location and position; however, longer routes would likely have a greater impact due to the greater length and extent of areas impacted. The length of the various AC collection system routes range from 13 to 56 miles. There is potential for mortality, injury, and disturbance to fish and aquatic invertebrates, and aquatic habitat loss and modification where waterbodies (e.g., perennial, intermittent) would be crossed by routes.

1

Table 2.6-3:
Summary of Potential Environmental Impacts—HVDC Transmission Line

RESOURCE	IMPACT
Agricultural Resources	Construction Construction could affect livestock grazing by temporarily reducing forage areas in the representative ROW. Except while access to the ROW is temporarily restricted during construction, operations, and maintenance for safety reasons, livestock would not be displaced or prohibited from grazing in pastures overlapped by the ROW during construction, unless otherwise desired by the landowner. Construction activities during which restrictions to the ROW may occur are identified in the construction sequence and timeline provided in Table 3.2-10. Croplands would be directly affected by removal of vegetation and agricultural structures such as irrigation systems, barns, and silos. Agricultural production may be temporarily diminished. Potential temporary impacts to center-pivot irrigation could occur primarily in Regions 1, 2, 6, and 7. The operation of center-pivot irrigation could be limited in construction areas. During construction, access roads, temporary work areas, and other graded areas could temporarily disrupt the slope and flow patterns of water on flood-irrigated fields. Operations and Maintenance Maintenance may occasionally disrupt agricultural activities and production on a localized basis. Potential indirect impacts to agricultural production from interference with aerial applications of fertilizer, insecticide, and herbicide,

Table 2.6-3:
Summary of Potential Environmental Impacts—HVDC Transmission Line

RESOURCE	IMPACT
	could occur. Most of the land within the ROWs could return to previous uses after construction. Restrictions on land use within the ROW would be determined based on site-specific conditions and/or in coordination with landowners. These are not blanket limitations or restrictions that would apply to every parcel potentially impacted by the Project. The continued use of the ROW for routine agricultural practices such as grading and contouring and construction of ditches would be permitted and would be compatible with reliability criteria for HVDC facilities and would not be restricted. Limitations on land uses would be described in the easement agreement; these limitations could be modified in the easement based on site-specific conditions and/or coordination with landowners. Maintenance activities may cause temporary impacts within the ROW such as damage to crops.
Air Quality and Climate Change	Construction Construction-related emissions would be below thresholds for all criteria pollutants across all alternatives. Temporary construction impacts to air quality include emissions near sensitive areas such as residences or schools for short periods of time. Locations of residences and schools are shown in Figure 1.0-2 located in Appendix A of the EIS. The only two schools within the ROI are within AC Collection System Route E-1, located within the town of Hardesty. Air quality emissions would be elevated during construction, however typically Project construction would move relatively rapidly along a given ROW, with temporary impacts lasting for only a few days or weeks in a given area. Operations and Maintenance Operations and maintenance would emit negligible air pollutants associated with combustion of fossil fuels for worker vehicles and equipment.
Electrical Environment	Construction No electrical effects would be associated with construction because the transmission line would not be energized yet. Operations and Maintenance Calculated DC electric fields are below public guidelines (such as IEEE and ICNIRP) at the ROW edges. Calculated DC electric fields also conform to occupational standards within the ROW, except for the dedicated neutral return configurations. Calculated DC magnetic fields are below public guidelines (IEEE and ICNIRP) at the ROW edges for all configurations. Calculated audible noise is below the public guideline at the ROW edges for the standard monopole and both dedicated neutral return configurations (the standard lattice configuration is slightly higher than the EPA guideline at 55.2 dBA at one of the ROW edges, but calculated audible noise levels assume a 5 percent overvoltage condition at the highest line elevation of 3,000 feet). Calculated radio noise is below Federal Communications Commission and IEEE exposure guidelines. It is unlikely that the proposed HVDC transmission line would pose a known threat to human health.
Environmental Justice	Construction/Operations and Maintenance The Project would not disproportionately impact low-income or minority populations, and where the Project does cross areas with these populations, the impacts would be the same irrespective of the economic or racial demographics of the area.
Geology, Paleontology, Soils, and Minerals	Construction/Operations and Maintenance Long-term impacts from the Project include the conversion of geology, mineral resources access, and soils resources (especially farmland) to a utility use, primarily for access roads, and transmission line pole structure locations. Impacts include potential damage to Project infrastructure and equipment from seismicity, landslides, subsidence, or soil liquefaction. Blasting may be necessary in areas of shallow bedrock. Impacts to soil resources from construction activities are associated with clearing, grading, excavation, and other activities necessary for construction that could expose erosion-prone soils to conditions of increased erosion potential; and soils with high compaction potential would be susceptible to compaction from construction vehicles and equipment. Impacts to soils would also include the potential for loss of soil productivity. Inadvertent spills of fluids used during construction, such as fuel, lubricants, antifreeze, and herbicides could directly impact soils through contamination; and excavation activities during construction might uncover previously unknown areas of contaminated soils. Seismic hazards are low for the entire Project except for the eastern portion of the ROI in Region 5 and all of Regions 6 and 7 in the area of the New Madrid Seismic Zone. Areas of high to very high soil liquefaction potential are present in the Project Regions 4, 5, 6, and 7. Subsidence from karst is a possible geologic hazard of concern within Regions 1, 2, 4, and 5. Areas of high susceptibility for landslides are present in Project Regions 4, 5, and 7.

Table 2.6-3:
Summary of Potential Environmental Impacts—HVDC Transmission Line

RESOURCE	IMPACT
	The potential for impact to oil and gas operations is greatest in Regions 4 and 5. Given the ongoing development of the Fayetteville shale, numerous oil and gas wells and other related infrastructure could be present.
Groundwater	Construction Typical construction impacts include: • Potential for Groundwater Contamination—Contamination could occur as a result of the accidental release of hazardous substances, primarily fuels and lubricants, which would be used for construction equipment and be present in construction staging or storage yards. Compliance with permit requirements and implementation of EPMs, including spill prevention and response planning, would minimize the potential for groundwater contamination. • Changes to Infiltration Rates—Soils disturbed and loosened during construction could represent areas of increased precipitation infiltration, possibly increasing local groundwater recharge rates over the short term. After construction, impermeable facility surfaces would represent areas of decreased infiltration rates over the long term. The area of impermeable surfaces resulting from the Project would be small. In accordance with the Applicant's EPMs, soils not occupied by Project facilities would be returned to pre-activity conditions, therefore resulting in *de minimis* long-term impacts to infiltration rates. • Effects on Water Availability—Water demands to support the Project could come from groundwater resources (more likely in areas where total water use is typically from groundwater sources such as Regions 1, 2, 6, and 7) and result in less groundwater being available for other uses. Water demand associated with the Project is not expected to have noticeable effects on groundwater resources beyond those resulting from existing water usage. • Physical Damage to Well Systems—Well system damage could occur as a result of direct impacts from equipment traffic or during excavations, and could also occur at locations more remote from construction if blasting was used at excavation sites. The Applicant's EPMs would minimize these occurrences and require repairs of any damages and, in the case of any damage, arrange for temporary water supply, if necessary. Pre-construction planning, working with property owners to identify well system locations, and adjusting construction sites to avoid well systems are among the actions that would be taken to minimize the potential for damaging well systems. Operations and Maintenance Potential impacts to groundwater would be very minor. The quantities of hazardous materials present (primarily fuels and lubricants in maintenance vehicles and equipment) would be much less than during construction and water demands of facilities would be limited to that required to support the small number of employees.
Health, Safety, and Intentional Destructive Acts	Construction/Operations and Maintenance Construction and operational activities for large infrastructure projects, such as a transmission line and associated facilities can pose hazards that affect worker and public health and safety. In addition, natural events, external events or accidents (e.g., aircraft mishaps or fires) or intentional destructive acts or mischief could impact such infrastructure and have related effects on the health and safety of construction workers and the public. The Project may involve the transportation and handling of hazardous materials. Management (i.e., transportation, storage, handling, use, and disposal) of such hazardous materials during the construction and operations and maintenance phases would be undertaken in a manner to avoid or minimize health and safety impacts to workers and nearby members of the public. The implementation of EPMs associated with management of hazardous materials would keep risks to a minimum. The transmission lines and associated facilities could be susceptible to natural events such as extreme weather. Based on accident statistics for the construction and operational utility industries, the estimated construction workforce Project would experience 140 non-fatal recordable incidents during the assumed 36-month construction period. Using the average construction workforce of 1,260 workers, it is estimated that there would be approximately 0.4 fatalities during the 36-month construction phase. It is likely that no fatalities would occur. During the assumed 80-year operational period of the Project, the average operations workforce would experience 2.0 non-fatal recordable incidents annually. The construction and operational impacts of the HVDC alternative routes would be roughly equivalent to those of the Applicant Proposed Project.
Historic and Cultural Resources	Construction Potential impacts would be experienced primarily during construction. Potential construction impacts to belowground (archaeological) resources could occur as a result of ground disturbances at site locations. Potential Project impacts to aboveground historic and cultural resources such as buildings and structures would most likely be limited to visual

Table 2.6-3:
Summary of Potential Environmental Impacts—HVDC Transmission Line

RESOURCE	IMPACT
	alterations in the historical setting of the resource. Such alterations would be introduced through the erection of transmission structures, and stringing of conductors. Potential Project impacts to aboveground historic and cultural resources would be long-term for the life of the Project. Construction could also cause temporary impacts to historic and cultural resources through the generation of dust, noise, and vibration, but such effects would be transient in nature. DOE establishes the timing and protocols for cultural resources surveys, evaluation of resources' eligibility for the NRHP, and assessments of Project effects, and resolution of adverse effects in the draft PA developed through consultations with SHPOs, Indian Tribes, federal agencies, and Clean Line. Compliance with the PA and related plans would enable the Project to avoid, minimize, or mitigate adverse impacts to historic and cultural resources. Operations and Maintenance Additional ground disturbance impacts to archeological resources are unlikely to occur during operations and maintenance. Once built, the Project facilities are not likely to be substantially altered through routine operations and maintenance.
Land Use	Construction Land use impacts consist primarily of the conversion of existing land uses (primarily rangeland, cropland, and pasture/hay) to a utility use. Typical temporary impacts include the use of some areas for temporary work areas and loss of access to areas in or adjacent to work areas. Construction would prevent the use of rangeland and cultivated crops in the ROW in a specific location and may change the contour of the land and affect irrigation infrastructure. Yields from cropland, pasture/hay, and timberlands could potentially also be temporarily affected in the construction areas. There are 33 structures within the representative ROW for the Application Proposed Route, including 19 agricultural structures, 4 residential structures, 3 industrial structures (oil/gas infrastructure), 3 commercial structures, 2 abandoned structures, and 2 other structures (use unknown). HVDC alternative routes with fewer structures than the corresponding links of the Applicant Proposed Route include HVDC Alternative Routes 3-A (one less industrial structure), 3-B (two agricultural structures and one commercial structure compared to one residential, two agricultural, and one industrial structures), 6-C (three fewer agricultural structures), 7-A (one less other structure [use unknown]), 7-C (one less agricultural structure), and 7-D (two fewer agricultural structures). All other HVDC alternative routes contain more structures within the representative ROW than the corresponding links of the Applicant Proposed Route. These structures may have to be permanently removed if the Project features could not avoid them, although the Applicant would continue to work with affected landowners to minimize the impact of siting the ROW on their property, including micrositing to avoid residences and other structures. Region 4, Link 3, Variation 2, compared with the Applicant Proposed Route would cross 32 percent fewer land parcels, parallel a larger percentage of existing linear infrastructure, have 8 fewer residences within 500 feet of the representative ROW, and avoid one private airstrip. The U.S. Forest Service (USFS) has expressed several concerns regarding HVDC Alternative 4-B. According to the USFS, the ROW would create linear breaks in National Forest land and could adversely affect timber production. The USFS has also stated that, in places, HVDC Route Alternative 4-B would undermine the use for which the National Forest land was originally acquired, that is conservation of natural resources. Operations and Maintenance Long-term impacts from the Project include the conversion of land to a utility use, primarily for access roads and transmission line structure locations. Most of the land within the transmission ROWs could return to previous uses after construction, although uses incompatible with the operation of the transmission line, such as tall trees for timber, would be removed permanently from the ROW. Land uses that generally may not be permitted in the ROW include buildings or structures, changes to grading and land contours such that the ground surface elevation within the ROW would change and alter the required electrical clearance, and installing fences or irrigation lines without coordination with the Applicant. Maintenance activities may cause temporary impacts within the ROW such as damage to crops.
Noise	Construction Temporary impacts include elevated sound levels at noise sensitive areas such as residences or schools for short periods of time. Locations of residences and schools are shown in Figure 1.0-2 located in Appendix A of the EIS. Sound levels would be elevated during construction of the HVDC transmission lines. Operations and Maintenance Sound from operation of the HVDC transmission lines results from corona effects, which can result in audible noise. Corona noise is greatest on HVDC transmission lines when the lines are dry. There are two noise sensitive areas

Table 2.6-3:
Summary of Potential Environmental Impacts—HVDC Transmission Line

RESOURCE	IMPACT
	expected to exceed federal guidelines near the Applicant Proposed Route in Region 3.
Recreation	Construction Construction of the Project is not expected to permanently preclude the use of or access to any existing recreation areas or activities. Temporary impacts include the use of some recreational areas for temporary work areas and loss of access to recreation areas in or adjacent to work areas. Direct short-term impacts may include noise, visual disturbance, restricted access, and diminished quality of recreational impacts that are crossed by the representative ROW. The main differences in potential recreation impacts between the Applicant Proposed Route and the HVDC alternative routes occur in Regions 3, 4, and 5. The Applicant Proposed Route Link 1 in Region 3 would not cross Lake Carl Blackwell, while corresponding Alternative Routes 3-A and 3-B could impact approximately 23 acres of the lake. The Applicant Proposed Route Link 6 could potentially impact 4 acres of the Webbers Falls Lock and Dam Reservoir lands while the corresponding HVDC alternative routes in Region 3 could potentially impact 1 acre of the Webbers Falls Lock and Dam Reservoir lands. The Applicant Proposed Route in Region 4 could potentially impact 2 acres of the Ozark Lake WMA and 4 acres of the Frog Bayou WMA, while the corresponding HVDC alternative routes in Region 4 would not. Applicant Proposed Route Link 1 in Region 4 could potentially impact 17 acres of the Webbers Falls Lock and Dam Reservoir lands. There is no HVDC alternative route to this link of the Applicant Proposed Route. The Lee Creek Variation (Applicant Proposed Route in Region 4, Link 3) would cross the Nationwide Rivers Inventory segment of Lee Creek, while the Alternative Routes 4-A and 4-B would also cross the Nationwide Rivers Inventory segment of Lee Creek. HVDC Alternative Route 4-B could impact approximately 230 acres of the Ozark National Forest, while the Applicant Proposed Routes in Region 4 would only potentially impact approximately 2 acres. The Applicant Proposed Route in Region 5 could potentially impact 77 acres of the Cherokee WMA while the alternative routes in Region 5 would not. The representative ROW for HVDC Alternative Routes 6-C and 6-D does not include any natural areas or recreational land compared to the corresponding link of the Applicant Proposed Route, which includes approximately 0.5 acre of the Singer Forest Natural Area within the St. Francis Sunken Lands WMA. Operations and Maintenance Most of the land within the HVDC transmission line ROWs could return to previous uses after construction. Recreation uses would be permitted in the ROW; however; buildings or structures, and some restrictions for infrastructure such as fences would not be permitted. Maintenance activities may cause temporary impacts within the ROW such as restricted access.
Socioeconomics	Construction Construction of the Project would generate regional economic activity through Project-related expenditures on materials and supplies. The Project would also employ construction workers who would spend much of their income locally and support jobs and incomes elsewhere in the economy. Approximately 26% of the construction workforce is expected to be hired locally (i.e., workers who normally reside within daily commuting distance of their job site), with the remaining 74% temporarily relocating to communities along the ROI for the duration of their employment. There is a potential shortage of temporary housing and RV spaces in Region 1 that would be further exacerbated if the construction schedules for the Oklahoma converter station, AC collection system, and HVDC transmission line were to overlap. This availability could be further reduced by other outside activities in the ROI such as other construction projects, community-sponsored events, and hunting and other recreational activities, as well as connected actions, specifically the development of wind generation facilities and the Optima Substation. The Applicant proposes to prepare and implement a workforce housing strategy designed to minimize potential impacts to housing availability. Some short-term adverse impacts on residential property values (and marketability) might occur on an individual basis as a result of the Project. However, these impacts would be highly variable, individualized, and are difficult to predict. Minor, short-term increases in demand from construction workers and family members temporarily relocating to local communities within the ROI are not expected to affect the levels of service provided by existing law and fire personnel, health care and medical facilities, or educational facilities. Minor increases in population resulting from operations and maintenance of the Project are also not expected to affect the provision of community services. Construction of the Applicant Proposed Route would generate sales, use, and lodging tax revenues during the construction period, with an estimated 90% of total construction costs expected to be for materials subject to sales and use tax. Total estimated state sales and use tax revenues range from \$2.1 million in Tennessee to \$34.6 million in Oklahoma; the estimated total for Arkansas would be \$32.3 million. Local spending by construction workers would

Table 2.6-3:
Summary of Potential Environmental Impacts—HVDC Transmission Line

RESOURCE	IMPACT
	also generate sales and lodging tax revenues. Substituting one or more of the HVDC alternative routes for the corresponding links of the Applicant Proposed Route would not substantially affect the regional economic impact estimates. The largest net increases in the number of people who would temporarily relocate to each region, as compared to the Applicant Proposed Route, would occur in Region 1 with the addition of 16 people (HVDC Alternative Route 1-A) and in Region 7 where 14 and 19 more people could be added (HVDC Alternative Routes 7-C and 7-A, respectively). The majority of the HVDC alternative routes would not affect the peak number of school age children temporarily relocating to the affected regions. In other cases, there would be a potential increase of one to two school-age children as compared to the Applicant Proposed Route for that region. As compared to the Applicant Proposed Route, the largest differences in estimated sales and use tax revenue that would accrue to the respective state would occur in counties in Region 5 and range from a decrease of $2.75 million (-100%) in Cleburne County, Arkansas (because an HVDC alternative route would not cross the county), to an increase of $2.55 million (100%) in Faulkner County, Arkansas. Differences in estimated sales and use tax that would be paid to each county would range from a decrease of about $0.7 million in Cleburne County, Arkansas (Region 5), to an estimated increase of $0.5 million in Shelby County, Tennessee (Region 7). Operations and Maintenance Operations would have similar, but smaller regional economic benefits than construction. Operation of Project facilities would generate ad valorem or property tax revenues in the counties where they would be located. Operation-related expenditures would generate sales and use tax revenues. Estimates of annual county tax revenues in Oklahoma range from $0.1M to $2.4M. Estimates of annual county tax revenues in Arkansas range from $0.2M to $0.6M. Estimates of annual county tax revenues in Tennessee range from $0.2M to $0.3M. These estimates are for payments that would be made in the first year of operation. Thereafter, ad valorem taxes would be paid annually based on an annual assessment by the responsible taxing agency. Substituting one of more of the HVDC alternative routes for the corresponding link of the Applicant Proposed Route would not affect estimated operations and maintenance employment for the HVDC and AC transmission lines. Potential impacts to population, economic conditions, housing, and community services from operations and maintenance related to estimated operations and maintenance employment would be the same or very similar to those described above for the Applicant Proposed Route.
Special Status Wildlife and Fish, Aquatic Invertebrate, and Amphibian Species	Construction/Operations and Maintenance Impacts to special status wildlife species in Region 1 from the Applicant Proposed Route or alternative routes include potential habitat loss and fragmentation of existing habitat of LEPC habitat mapped focal areas (CHAT-1) or connectivity zone habitat (CHAT-2) HVDC Alternative Route 2-A in Region 2 is parallel to the Cimarron River for a portion of the route. This portion of the Cimarron River is known to be used by the interior least tern. Therefore construction of this alternative route could disturb habitat or individuals. HVDC Alternative Route 3-C in Region 3 has slightly more forested land than other alternative routes or the Applicant Proposed Route and therefore could potentially impact the American burying beetle. HVDC Alternative Route 4-B in Region 4 includes forested lands and is closer to the Ozark Plateau region than other alternative routes and the Applicant Proposed Route. The Ozark Plateau region contains cave hibernacula for special status bat species. Because of the amount of forested areas, there is a potential for greater mortality impacts to the American burying beetle during construction. The increase in forested land in closer proximity to areas of caves known to be or potentially used by bats increases the potential impacts (e.g., disturbances to or loss of roost trees) to the special status bat species along this route Similarly, HVDC Alternative Route 4-D also contains more forested land than other alternative routes and the Applicant Proposed Rout in Region 4. Therefore, there could be construction impacts to the American burying beetle and the special status bat species along this route. Direct construction impacts that could potentially affect special status fish, aquatic invertebrate, and amphibian species and their habitats include vegetation clearing, grading, access roads, herbicide use, and handling of fuel and lubricants at stream and river crossings. Vegetation clearing has the potential to increase sedimentation and decrease cover. Increased sedimentation can directly or indirectly suffocate, bury, or limit feeding of fish, aquatic invertebrate, and amphibian species. Grading and access roads have the potential to increase sedimentation, decrease cover, and increase runoff. Increased runoff can alter stream and river hydrology and provide a mechanism for delivery of sediment, herbicides, and fuel and lubricants to streams and rivers. Herbicide use and handling of fuel and lubricants have the potential to concentrate in body tissues of fish, amphibians, and filter-feeding mussels, which can result in

Table 2.6-3:
Summary of Potential Environmental Impacts—HVDC Transmission Line

<table>
<tr><th>RESOURCE</th><th>IMPACT</th></tr>
<tr><td></td><td>death.
During the construction phase of the Project, all general EPMs and those specific to special status fish, aquatic invertebrates, and amphibians would be implemented to avoid or minimize impacts to special status fish aquatic invertebrates, and amphibians.
For all regions except Region 2, there would be no difference in impacts between the Applicant Proposed Route and the HVDC alternative routes. For Region 2, HVDC Alternative Route 2- has more acres of waters designated by the USFWS as critical habitat for the Arkansas River shiner within the ROI than the corresponding link of the Applicant Proposed Route. Both the HVDC Alternative Route 2-A and the corresponding of the Applicant Proposed Route cross the Cimarron River at separate locations where it is USFWS designated critical habitat, but HVDC Alternative Route 2-A is within the critical habitat for more acres.
Potential impacts in the operations and maintenance phase of the HVDC transmission line would be similar to the potential impacts in the construction phase; however, impacts would be at a lesser extent than in the construction phase, but occur throughout the life of the Project. During the operations and maintenance phase, the use of both access roads and the ROW for repair and maintenance activities could result in both direct and indirect impacts to the Arkansas River shiner or its potential habitat in the Beaver River and Palo Duro Creek. In addition, the potential application of herbicides during operations and maintenance of the Project could result in indirect impacts, and to a lesser extent, direct impacts. During the operations and maintenance phase of the Project, both general EPMs and those specific to fish aquatic invertebrates, and amphibians would be implemented to avoid or minimize impacts to special status fish, aquatic invertebrates, and amphibians.</td></tr>
<tr><td>Surface Water</td><td>Construction
Typical impacts include:
Potential for Surface Water Contamination—Contamination could occur as a result of the accidental release of hazardous substances, primarily fuels and lubricants, which would be used by construction equipment and be present in construction staging or storage yards. Permit compliance and implementation of EPMs, including spill prevention and response planning, would minimize the potential for surface water contamination.
Changes to Runoff Rates—Soils disturbed and loosened during construction could represent areas of increased precipitation infiltration, possibly decreasing local runoff rates over the short term. Surfaces compacted during construction and impermeable facility surfaces remaining after construction would represent areas of increased runoff rates. The area of impermeable surfaces resulting from the Project would be small. In accordance with the Applicant's EPMs, soils not occupied by Project facilities would be returned to pre-activity conditions, therefore resulting in de minimis long-term impacts to runoff rates.
Direct Impacts or Disturbances to Surface Water or Drainage Channels—Surface waters and drainage channels would be avoided as practicable in the placement of transmission line facilities, with transmission lines spanning such features as necessary. Access roads may not always have the same means of avoidance and would be most likely to involve disturbance of drainage features. Preplanning of the crossing methods would minimize the length of the drainage feature affected and enhance the ability to maintain flow characteristics.
Effects on Water Availability—Water demands to support the Project could come from surface water resources (more likely in areas where total water use is typically from surface water sources such as Regions 4 and 5) and result in less surface water being available for other uses. The Project's water demand is not expected to have noticeable effects on surface water resources beyond those resulting from existing water usage.
There are differences in the amount of surface water used between regions and in the numbers of surface water features within the representative ROWs for each of the HVDC alternative routes. Water demands from the Project are not expected to be a concern, primarily because the highest demand would occur during the short-term construction phase and regions with low surface water availability are areas where groundwater use already dominates. The specific locations of each structure or access road have not yet been determined; therefore, the EIS does not identify which surface water features would be completely avoided or which could be affected by Project. Areas with the greatest amount of surface water in the ROW, such as Region 3 with the most perennial streams, reservoirs, lakes, and ponds, would be the most likely to have impacted surface waters.
Operations and Maintenance
Potential impacts would be minimal. The quantities of hazardous materials present (primarily fuels and lubricants in maintenance vehicles and equipment) would be much less than during construction, herbicides used to maintain ROWs and access roads would be applied in accordance with label instructions and any federal, state, and local</td></tr>
</table>

Table 2.6-3:
Summary of Potential Environmental Impacts—HVDC Transmission Line

RESOURCE	IMPACT
	regulations to minimize the potential for spreading, and water demands of facilities would be limited to that required to support the small number of employees.
Transportation	Construction Typical temporary impacts during construction include increased traffic from workers commuting to the construction sites, as well as increased traffic from the hauling of materials and equipment to the construction sites. Construction traffic also has the potential to impact bus and emergency routes for roadways near the construction areas. Temporary travel delays involving major roads (interstate highways, federal highways, and state highways) and railroads may also occur for HVDC transmission line installation at crossings. Construction activities that take place adjacent to major roadways also have the potential to cause temporary adverse impacts to traffic from vehicles entering and leaving the roadway and could involve lane closures. Roadway pavement or other infrastructure might be damaged by heavy vehicles delivering equipment and materials to construction areas. Transmission line structures and lines could become a hazard if they are located too close to airport operations or military airspace operating areas. River traffic may be controlled, in coordination with the USACE, during the short time required to span the conductor across Project construction activities have the potential to impact river traffic at the crossings of the Arkansas and Mississippi rivers. River traffic would not be impacted during Project operations and maintenance. Potential impacts to level of service and overall impacts to transportation resources are similar between the Applicant Proposed Route and the corresponding HVDC alternative routes. Although the HVDC alternative routes would have somewhat less roadway mileage within 50 feet of the route centerline than the Applicant Proposed Route (Regions 2 and 3), this would not be expected to have any noticeable consequences to transportation resources. Impacts to airports and airstrips are generally similar for the Applicant Proposed Route and the HVDC alternative routes as both would include measures to avoid these features to the extent possible. One route variation (Region 4, Link 3, Variation 2) is being considered as an alternative to the Applicant Proposed Route and would avoid impacts to a private airstrip that would potentially be impacted by the Applicant Proposed Route. Operations and Maintenance Long-term impacts are not expected because any increase in traffic during the operations and maintenance phase would be negligible. Transportation resources would be returned to previous operating conditions following construction.
Vegetation Communities	Construction Construction may cause the direct impact of vegetation removal and the indirect impacts of reduction of plant vigor from mechanical damage, fragmentation, and the introduction of invasive species. Impacts to vegetation may also vary in duration from short-term to long-term, with some impacts potentially permanent in nature. Removal of vegetation during construction may vary across the spectrum from short-term to permanent. Short-term removals and mechanical damage to vegetation may occur in areas of temporary construction access roads, construction laydown areas, and tensioning areas. It is likely that vegetation impacts in croplands would be short-term based on the seasonal replanting of these landscapes. Long-term to permanent impacts to vegetation would involve those areas of the ROW where vegetation is removed for new access roads and transmission structural foundations. Long-term impacts are also expected through those portions of the ROW with forested land cover due to the need to minimize canopy height for line safety. Long-term impacts may also result from vegetation removal in the portions of the Project ROW dominated by shortgrass prairie due to the difficulty of revegetation in drier climatic conditions. Operations and Maintenance Operation and maintenance of the Project is likely to impact vegetation directly through mowing and pruning in the ROW, and indirectly through herbicide applications that may impact non-target plant species.
Visual Resources	Construction Construction would result in the short-term visual intrusion of construction vehicles, equipment, materials, and a work force in staging areas, along access roads, and along the new transmission line ROW. Vehicles, heavy equipment, structure components, and workers would be visible during transmission line construction and modification, access and spur road clearing and grading, structure erection, conductor stringing, and cleanup and restoration. However, disturbance from construction activities would be transient and of short duration as activities progress along the transmission line route. Affected viewers would be aware of the temporary nature of Project construction impacts as well as existing structures in the area adjacent to the Project, which may decrease their concern to the impact.

Table 2.6-3:
Summary of Potential Environmental Impacts—HVDC Transmission Line

RESOURCE	IMPACT
	Operations and Maintenance Long-term impacts from the Project include the intrusion of transmission structures, access roads and cleared ROW that may introduce contrast into the surrounding landscape setting. Visual impacts during operations and maintenance vary by region. Sensitive viewers in Regions 1, 2, and 6 that are characterized primarily by flat croplands and grasslands with scattered vegetation are anticipated to have greater visibility of the Project due to long viewing distances associated with an open landscape with panoramic views. In addition, the tall vertical geometric structures of the Project components would result in strong contrast with the relatively flat landscape with the regions. Sensitive viewers in Regions 3, 4, 5 and 7 that are characterized by varying terrain ranging from gently rolling to hilly to rugged with a greater occurrence of dense wooded areas are anticipated to have shorter viewing distances. Project components are more likely to be partially to completely screened by existing terrain and/or vegetation in all distance zones.
Wetlands, Floodplains, and Riparian Areas	Construction Potential impacts would primarily occur during construction. Short-term impacts may include mechanical damage/crushing of vegetation from use of heavy machinery, compaction of soils, sedimentation and turbidity from construction activities, alteration of hydrology from access road construction and excavations for structure foundations, contamination from herbicide runoff and from accidental spills of hazardous substances. Potential impacts are similar between the Applicant Proposed Route and the corresponding HVDC alternative routes. Some differences are apparent, however. For wetland resources, all HVDC alternative routes for Regions 2 and 3 have potential to impact more wetland acreage than the corresponding Applicant Proposed Route links in those regions. For floodplain resources, all HVDC alternative routes for Regions 2 and 7 contain more floodplain acreage and greater potential for impacts within the 200-foot-wide representative ROW as compared to Applicant Proposed Route links in those regions. Finally, all the HVDC alternative routes for Regions 2 and 4, and most of the HVDC alternative routes for Region 1 (except HVDC Alternative Route 1-C), Region 3 (except HVDC Alternative Route 3-C), and Region 6 (except HVDC Alternative Route 6-A), would cross more riparian area resources and have the potential for more impact acreage than the corresponding Applicant Proposed Route links. Operations and Maintenance The potential long-term impacts may include placement of fill at foundation footprint locations or for permanent access roads, long-term conversion of forested wetlands or riparian areas to shrubby or herbaceous cover types within the ROW, changes to hydrology from construction of permanent access roads or support structures and other ancillary infrastructure, and introduction of invasive species from construction equipment.
Wildlife and Fish	Construction Potential impacts would include direct mortality or injury of individuals from vegetation clearing, collisions with vehicles, potential exposure to hazardous materials (e.g., accidental spills and pesticides), wildfires, or increased predation rates; disturbance of suitable habitats or disruption of normal behaviors; and habitat loss or degradation (both temporary and permanent loss/degradation of habitat). Potential impacts to fish and aquatic invertebrate species would include direct mortality and injury of individuals (e.g., via crushing during crossing construction, sedimentation, potential exposure to hazardous materials, blasting); disturbance from suitable aquatic habitats or disruption of normal behaviors; aquatic habitat loss or degradation (both temporary and permanent loss/degradation of aquatic habitat); and introduction of non-native aquatic plants and animals. Operations and Maintenance Potential impacts include the fragmentation of habitats; isolation of sub-populations and loss of meta-population dynamics; degradation of habitat quality due to edge effects as well as invasive plant species; consolidation of predatory avian species along the line (e.g., raptors and corvids), and ongoing mortality of individual birds due to collision and electrocution risks. The majority of the Project would pass through and impact habitat types that contain low vegetation, which would typically recover quickly and would not need to be permanently cleared or maintained during the Project's operations and maintenance (e.g., grassland and cropland habitats). However, Regions 4 and 5, as well as Regions 3 and 7 to a lesser extent, would cross through and impact forested habitats. The Project would result in the permanent conversion of these forested habitats within the ROW to grasslands and/or shrublands (i.e., habitats that contain low vegetation types). This would constitute a permanent loss of forested habitats, as well as create a permanent edge effect along the Project's ROW in forested habitats. This could change the species composition and use of these once forested

Table 2.6-3:
Summary of Potential Environmental Impacts—HVDC Transmission Line

RESOURCE	IMPACT
	areas (i.e., transitioning to an edge habitat community). Potential impacts to fish and aquatic invertebrate species include mortality and injury of individual fish and aquatic invertebrates from sedimentation and potential exposure to hazardous materials (e.g., oils, fuels, herbicides); aquatic habitat degradation and loss from the presence of crossing structures, sedimentation, and non-native aquatic plants and animals; avoidance of aquatic habitats near project structures and roads; and temporary disturbance during maintenance activities.

2.7 Summary of Best Management Practices

As identified in Section 2.1.7, the Applicant has developed and would implement EPMs, included in Appendix F, to avoid or minimize effects to environmental resources from construction, operations and maintenance, and/or decommissioning, as appropriate. This EIS assumed the implementation of the EPMs throughout the impact analysis for each resource area in Chapter 3.

In addition, some resource sections also include best management practices (BMPs). For these resources, implementation of the EPMs would not be able to completely avoid or minimize all potential adverse effects resulting from construction, operations and maintenance, and decommissioning of the Project. In those instances, the following BMPs could be implemented to further avoid or minimize potential adverse effects. Table 2.7-1 provides a summary listing of the BMPs identified by each resource area analyzed in Chapter 3 (those resource areas that did not identify any BMPs are not included in the table). The Applicant has not committed to implementing BMPs though it is possible that certain BMPs will be required through the ROD or Participation Agreements. Additional protective measures may be identified and required as part of ongoing consultation and permitting with federal, state, and local agencies.

Table 2.7-1:
Summary of Best Management Practices

RESOURCE AREA	BEST MANAGEMENT PRACTICE
Air Quality and Climate Change	• The quantity of sulfur hexafluoride (SF_6) emissions from maintenance activities (and potential leaks in equipment) would be minimized through the use of hermetically sealed equipment, leak detection programs, and sulfur hexafluoride recycling programs. To reduce the impacts associated with blowing fugitive dust and/or under windy conditions, the following BMPs have been identified: • Stabilize spoil piles and sources of fugitive dust by implementing control measures, such as covering and/or applying water or chemical/organic dust palliative where appropriate at active and inactive sites during workdays, weekends, holidays, and windy conditions. EPA (1995) lists common sources of fugitive dust as unpaved roads, agricultural tilling operations, aggregate storage piles, and heavy construction operations; all but agricultural tilling operations would apply to the Project and require appropriate control measures. • Install wind fencing and phase grading operations where appropriate, and operate water trucks for stabilization of surfaces under windy conditions. • Prevent spillage when hauling spoil material. • In active construction areas including access roads, Limit speeds of non-earth-moving equipment to 15 miles per hour. Limit speed of earth-moving equipment to 10 mph. To mitigate emissions resulting from mobile and stationary sources, the following BMPs have been identified:

Table 2.7-1:
Summary of Best Management Practices

RESOURCE AREA	BEST MANAGEMENT PRACTICE
	• Plan construction scheduling to minimize vehicle trips. • Limit idling of heavy equipment to less than 5 minutes unless needed for the safe operation of the equipment and verify through unscheduled inspections. • Maintain and tune engines per manufacturer's specifications to perform at EPA certification levels, prevent tampering of source engines (i.e., knowingly disabling an emission control system component or element of design of a certified engine so that it no longer meets the manufacturer's specifications) and conduct unscheduled inspections to ensure these measures are followed.
Geology, Paleontology, Minerals, and Soils	• If signs of contaminated soils are uncovered during construction activities, work would be stopped in the area of potentially contaminated soils until appropriate Project representatives could be consulted.
Health, Safety, and Intentional Destructive Acts	• Develop and implement a Health and Safety Plan that describes regulatory requirements, procedures, and practices for conducting activities to help ensure a safe working environment, which for purposes of health and safety measures should include: o Fire prevention, suppression, and emergency responder contact procedures o Natural disaster and severe weather reporting and contact procedures o Law enforcement contact procedures o Procedures for addressing hazardous materials spills and other mishaps • The Applicant will develop and implement a communications program. Section 3.1.2 describes the elements of this plan, which for purposes of health and safety should include: o Liaison and public outreach activities with local airports, aviation communities, aviation regulatory bodies, and aerial agricultural spraying operations o Local media and public outreach procedures for applicable hazard communication notices.
Land Use	• In existing forested areas where temporary construction areas require tree clearing, replant with appropriate tree species and/or reclaim temporary construction areas in coordination with landowners. • In addition to EPM LU-5, make reasonable efforts to avoid displacing structures on private property.
Noise	• Investigate noise complaints in accordance with the Applicant's communications program. It is likely that blasting would be required for some tower installations; however, in these cases, a detailed Blasting Plan would be developed and implemented to avoid noise impacts. Examples of measures that could be included in the Blasting Plan to minimize blasting impacts are: • Use tamping or stemming into the collars of blast holes and smooth-wall perimeter holes (stemming is defined as inserted material, such as crushed stone, sand, or any other inert objects placed in the top of the blast hole for the purpose of confining explosive charges and limiting rock movement and air-overpressure). • Use blasting mats. • Unless otherwise coordinated with landowners and adjacent landowners, plan blasting to take place only between the hours of 10:00 am and 4:00 pm, Monday through Friday. No blasting shall take place on weekends. • Notify landowners and tenants, including owners of adjacent utilities or structures, prior to blasting. • Detailed Blasting Plans would be developed for the Project based on site-specific activities and nearby conditions.
Socioeconomics	• The Applicant will prepare and implement a workforce housing strategy that would minimize potential impacts to housing availability. This strategy would consider Project component construction schedules, workforce required, and other outside influences.
Special Status Wildlife and Fish, Aquatic Invertebrate, and Amphibian Species	DOE and the Applicant have prepared a Biological Assessment (Appendix O) of potential impacts on special status species protected under the ESA as part of the Section 7 consultation between DOE and the USFWS. The Section 7 consultation review is a parallel but separate process conducted pursuant to the requirements of ESA and the applicable implementing regulations. A Biological Opinion will be issued by USFWS prior to the ROD. Through this process, additional protective measures may be identified and adopted to avoid and/or minimize impacts to special status species.

Table 2.7-1:
Summary of Best Management Practices

RESOURCE AREA	BEST MANAGEMENT PRACTICE
Transportation	• Accommodate existing and programmed, approved, and/or funded transportation projects to the extent practicable into the final Project design and coordinate with appropriate jurisdictions to avoid or minimize disruptions to trails, streets, or drainage/irrigation structures. • In identified areas of traffic impact, conflicts between the Project traffic and background traffic such as movements of normal heavy trucks (dump trucks, concrete trucks, standard size tractor-trailers or flatbeds, etc.) would be minimized by scheduling (essential deliveries only) to the extent practicable during peak traffic hours/times and scheduling remaining heavy truck trips during off-peak traffic hours/times. • To the extent practicable, staging activities and parking of equipment and vehicles would occur primarily within private ROW on private land. • Implement the communications program described in Section 3.1.2. • The Applicant would perform mitigation to address Project structures in the vicinity of private airstrips. This BMP would require conducting specific flight plan analyses to determine whether interference with private airstrips can be avoided through micrositing within the 1,000-foot-wide corridor to the extent practicable. If impacts are unavoidable, the Applicant would develop and implement mitigation measures and/or provide compensation, in coordination with landowners. The Applicant would apply similar mitigation to private airstrips where Project structures would present a hazard within a 1:20 glide slope from each end of private airfields.
Wetlands, Floodplains, and Riparian Areas	DOE, in consultation with the USACE, has identified the following BMPs: • In addition to protection of intermittent and perennial streams, ephemeral streams would also be included in the Applicant's streamside management zones. This BMP would add to EPM W-3. • Where tree removal is necessary in the ROW, this removal would be accomplished at ground level leaving root wads in place to aid in the stabilization of soils. • Limit, to the extent practicable, the amount of vegetation removed along streambanks and minimize the disruption of natural drainage patterns. • All permanent and temporary crossings of waterbodies would be suitably culverted, bridged, or otherwise designed and constructed to maintain low flows to sustain the movement of aquatic species. The crossings would also be constructed to withstand expected high flows. The crossings would not restrict or impede the passage of normal or high flows. • Excavated trenches that are to be backfilled would separate the upper 12 inches of topsoil from the rest of the excavated material. The topsoil would be used as the final backfill.
Wildlife and Fish	For general wildlife and fish populations and habitat: • All vegetation clearing would comply with both state and federal spatial and timing windows, and would not occur during the avian breeding season applicable to each respective region. • Identify, control, and minimize the spread of non-native, invasive species and noxious weeds to the extent practicable, including ensuring that in-water equipment and vehicles are cleaned between waterbodies to minimize the chance of transferring non-native species between waterbodies. This BMP would expand EPM FVW-2.

2.8 Summary of Unavoidable Adverse Impacts

2.8.1 Definition

Unavoidable adverse impacts could occur during construction, operations and maintenance, and decommissioning of the Project. These impacts would be expected after implementation of the EPMs and those BMPs that DOE includes in a ROD or participation agreement; however, in all cases, the impacts would have been minimized through implementation of these measures. The following sections provide a brief summary of the unavoidable adverse impacts that could occur for each environmental resource area as provided in Chapter 3.

2.8.2 Agricultural Resources

Unavoidable adverse impacts could occur if the Project could not avoid agricultural structures (e.g., barns, silos, and other out/accessory buildings). Yields from lands used for crops, pasture/hay, and grazing livestock would be temporarily affected in the construction areas, and land used for transmission structures, long-term access roads, and converter stations would be removed from agricultural production until the Project was decommissioned.

2.8.3 Air Quality and Climate Change

No unavoidable adverse impacts to air quality are anticipated to result from the Project.

2.8.4 Electrical Environment

Potential unavoidable adverse impacts to the electrical environment include the electrical effects (electric and magnetic fields, radio and television noise, audible noise, ozone, and air ions) associated with the operation of overhead HVDC and/or AC transmission lines. These effects are present within, and to a more limited extent outside, the transmission line ROW. Outside the ROW, calculated electrical effects for the Project are generally limited to levels that comply with associated standards and guidelines.

2.8.5 Environmental Justice

No unavoidable adverse impacts would be disproportionately borne by low-income or minority populations as a result from the Project.

2.8.6 Geology, Paleontology, Minerals, and Soils

2.8.6.1 Geology, Paleontology, and Minerals

Appropriate engineering design and adherence to applicable design standards would reduce the risk from geological hazards, but damage to Project components could occur if a rare, major geologic event such as a large magnitude earthquake or landslide occurred.

Despite EPMs and appropriate engineering design, scientifically valuable fossils may be disturbed and lost during construction activities. If this occurred, the small loss of fossil material would be offset to a degree by material that is recovered and preserved for scientific study purposes.

Mineral resources may exist below the surface within the Project ROWs and/or converter station sites, in which case some resources could be less accessible for the life of the Project. The types of mineral resources that would be more affected are near-surface mineral material deposits (e.g., common sand, gravel, and stone). Oil and gas resources would be less affected because recovery of the resources would be possible, even with a minimum stand-off of 250 feet from the edge of the route ROWs and converter station sites using a vertically installed well, without the use of directional drilling. With directional drilling such areas could be accessed at considerable distance from the Project.

2.8.6.2 Soils

Removal of vegetation during construction grading and excavation activities could result in the exposure of soils to erosion and compaction of soils susceptible to compaction. Transmission line structures and converter station sites would permanently impact agricultural soils and remove them from productivity during construction and operations and maintenance. Access roads used during construction would temporarily remove agricultural soils from productivity, and the use of unpaved access roads during all Project phases could result in the exposure of soils to erosion and compaction. There would be potential depletion of soil productivity including erosion and loss of fertile topsoil, and potential erosion of exposed areas and compaction of areas traversed by equipment and vehicles.

2.8.7 Groundwater

Although the water needed for the Project is expected to come from municipal water systems, some of that municipal water would undoubtedly come from groundwater sources, so there would be a minor reduction in groundwater available for other uses or natural features while the construction took place.

Common materials present during construction would be considered groundwater contaminants were those materials to be spilled, leaked, or otherwise released and eventually reach groundwater. The potential for groundwater contamination is minor due to the EPMs and permitting requirements; however, the potential would not be eliminated.

2.8.8 Health, Safety, and Intentional Destructive Acts

There is a statistical possibility that accidents resulting in worker injuries and possibly death could occur during implementation of the Project. The hazardous nature of the work, the complexity of the electrical system, and the size and areal extent of the Project all would contribute to a potential for worker injuries or death and would be considered unavoidable adverse impacts. These unavoidable adverse impacts could be as a result of common personnel-involved injuries (e.g., slips, trips, or falls), hazardous materials or waste accidents, aircraft incidents, fire hazards, natural events or disasters, or intentional destructive acts.

2.8.9 Historic and Cultural Resources

The Project has the potential to cause adverse impacts to historic and cultural resources in several ways. Construction could result in the loss of archaeological resources as a result of ground disturbances resulting from excavation and related actions that remove or redistribute soils and the contents of soils. The Project could also result in the loss of historic or culturally significant buildings, structures, sites, objects, or other aboveground features and properties if it is necessary to demolish, remove, or relocate them to allow construction of Project elements such as transmission towers, access roads, work and storage yards, and substations and switching stations at their locations. In addition, the Project has the potential to cause adverse impacts by altering the setting of neighboring historic and cultural resources and those spanned by the Project through the introduction of modernistic visually prominent elements, such as transmission towers, and auditory effects such as noise associated with the transmission of high voltage electrical currents and the passage of wind through transmission wires and towers. Such effects would only be adverse if the setting of the resource substantively contributes to its historical or cultural character or significance. In addition, such adverse effects tend to fall off with the distance separating Project elements from the resource and vary with local terrain and vegetation. Project-specific cultural resource surveys, which will be implemented as part of the Section 106 PA, in conjunction with micrositing, would tend to diminish the number and magnitude of such impacts.

2.8.10 Land Use

Unavoidable adverse impacts to land uses from the Project include the removal of vegetation and conversion of primarily rangeland and cultivated crops and some forested lands and developed open space to a utility use. The Applicant Proposed Route would result in the conversion of up to approximately 2,598 acres of land to utility use for the life of the Project, including 2,345 acres for access roads, 120 acres for two converter stations, 129 acres for all pole structures, and 4 acres for fiber regeneration sites.

Under the Applicant Proposed Route, 33 structures are present in the representative ROW: 4 residences, 3 commercial structures, 19 agricultural structures, 3 industrial structures, 2 abandoned structures, and 2 other structures (use unknown). These structures may have to be removed if the Project features could not avoid them, although the Applicant will continue to work with affected landowners to minimize the impact of siting the ROW on their property, including micrositing to avoid residences and other structures. Yields from cultivated crops, pasture/hay, and timberlands would be temporarily affected in the construction areas, and uses that are incompatible with the operation of the transmission line, such as tall trees for timber, would be removed from the ROW for the life of the Project. The height of orchard trees within the ROW could be restricted for the life of the Project.

Because the locations of Project access roads are not known at this time, it is possible that the access roads could be located in such a way that small areas of agricultural land would be isolated and no longer practicable to be used for farmland or grazing, resulting in a conversion of additional land from agricultural to non-agricultural use.

If DOE opts to participate in the Project and the Project included the Arkansas converter station, an additional 73 acres would be committed to utility use, including 35 acres for the converter station, 35 acres for the new substation, 2.4 acres for access roads, and 0.7 acre for 5 miles of AC interconnect structures.

2.8.11 Noise

Temporary noise impacts from construction activities would occur along the Project ROW. It is possible that EPA guidelines could be exceeded at some noise sensitive receptors from operations and maintenance of the AC and HVDC transmission lines.

2.8.12 Recreation

Unavoidable adverse impacts include the potential loss or alteration of recreational land and recreational uses of public or private lands that are located within the transmission line ROW because public access would be restricted at structure locations. Following the completion of construction, access to the HVDC transmission line ROWs would resume consistent with access prior to construction; in some cases, opening new areas within the ROW to recreational activities (e.g., hiking trails, hunting). Impacts to the setting of public recreational lands would be minimized by the EPMs, would be unavoidable and long term, but would not be permanent in recreational areas that the Project crosses.

2.8.13 Socioeconomics

No unavoidable adverse impacts to socioeconomic resources were identified.

2.8.14 Special Status Wildlife, Fish, Aquatic Invertebrate, and Amphibian Species

2.8.14.1 Special Status Terrestrial Wildlife Species

Construction and operations and maintenance of the Project could result in the mortality of some special status wildlife species if they are present in the affected areas during these Project phases. Mortalities could include potential mortalities associated with the clearing of vegetation as well as avian collisions with Project structures during operations and maintenance. Potential mortalities would be highest if vegetation clearing was conducted during the breeding season. Construction-related disturbances could result in temporary loss of some wildlife habitats through noise and visual disturbances. Potential loss of special status wildlife habitat during operations and maintenance could result from the effects of fragmentation, edge effects, and invasive plant species. ROW maintenance in forested habitats as well as the footprint of Project structures would result in a permanent loss of mature forest habitats.

2.8.14.2 Fish, Aquatic Invertebrate, and Amphibian Species

Construction and operations and maintenance of the Project could result in the mortality and injury of some special status fish, aquatic invertebrate, and amphibian species if they are present in the affected areas during construction or operations and maintenance. Construction mortalities and injuries could result from crushing during waterbody crossings with equipment, sedimentation, potential exposure to hazardous materials, and blasting. Mortalities and injuries during operations and maintenance could result from sedimentation and potential exposure to hazardous materials. Unavoidable impacts to special status fish, aquatic invertebrate, and amphibian species and their habitat include the potential loss or alteration of aquatic habitat in streams that may require culverts or vehicle crossings, potential loss or disturbance to riparian vegetation along streams on private or public lands where the ROW is parallel and adjacent to the stream, and potential short-term sedimentation effects on aquatic resources as a result of vehicular traffic causing disturbances within or adjacent to streams.

2.8.15 Surface Water

The Project would require a moderate level of water use, and some access roads would likely traverse through or over stream channels. Sediment-laden runoff from a construction site could occur and could have adverse effects on a receiving water. The construction general permit for stormwater discharges would minimize the potential for such incidents and would keep potential adverse impacts to these surface waters to a minimum.

2.8.16 Transportation

Construction-related adverse impacts to local traffic would occur on roadways where materials and equipment are hauled to the construction areas. Construction activities associated with the crossing of roadways and railroads and potential encroachment along roadway ROWs would also result in unavoidable temporary impacts to roadways and traffic.

2.8.17 Vegetation Communities and Special Status Plant Species

Unavoidable adverse impacts to vegetation and special status plant species from the Project may include the following elements:

- Removal of vegetation in the footprints of new transmission line support structures, permanent access roads, converter stations, and other associated infrastructure
- Conversion of structural types of vegetation (e.g., forest conversion to grassland or forest to low-stature shrublands)
- Changes to plant species diversity with the general trend likely to be a diminishment of vegetation species diversity in disturbed areas
- Potential lower yields in croplands that are disturbed during construction and operations and maintenance

2.8.18 Visual Resources

Unavoidable impacts include the potential loss or alteration of sensitive views from public or private lands that are located within or adjacent to (within the foreground/middleground) the transmission line ROW or adjacent to converter station siting areas.

2.8.19 Wetlands, Floodplains, and Riparian Areas

Unavoidable adverse impacts to wetlands, floodplains, and riparian areas from construction and operations and maintenance of the Project could include:

- Removal of vegetation in the footprints of new transmission line support structures, access roads, converter stations, and other associated infrastructure, some of which may be wetland vegetation, or vegetation present in floodplains or riparian zones
- Conversion of vegetation structure (e.g., floodplain/riparian forest conversion to grassland/herbaceous or shrub/scrub land cover)
- Changes to species diversity within wetlands, floodplains, and/or riparian areas
- Changes in total cover percentage in wetland, floodplain, and riparian zone vegetation.

2.8.20 Wildlife, Fish, and Aquatic Invertebrates

2.8.20.1 Wildlife

Construction and operations and maintenance of the Project would result in the death of some wildlife species. Mortalities could result from the vegetation clearing activities as well as avian collisions with Project structures during operations. These mortality events would likely be highest if vegetation clearing is conducted during the breeding season. Construction-related disturbances to habitats would also result in temporary loss of some wildlife habitats through noise and visual disturbances. Wildlife habitat also could be lost during operations and maintenance from the effects of fragmentation, edge effects, and invasive plant species. ROW maintenance in forested habitats as well as the footprint of Project structures would result in a permanent loss of habitats.

2.8.20.2 Fish and Aquatic Invertebrates

Unavoidable impacts include the potential loss or alteration of aquatic habitat in smaller streams that may require culverts or vehicle crossings, potential loss or disturbance to riparian vegetation along streams on private or public lands where the ROW is adjacent to the stream, and potential short-term sedimentation effects on aquatic resources as a result of vehicular traffic causing disturbances within or adjacent to streams.

2.9 Summary of Irreversible and Irretrievable Commitment of Resources

2.9.1 Definition

Resources are considered irreversibly committed when, once committed to the Project, the resource would continue to be committed throughout the life of the Project but would become available again following decommissioning of the Project and restoration (if necessary). Resources are considered irretrievably committed when, once used, consumed, destroyed, or degraded during construction, operations, maintenance, or decommissioning of the Project, the resource would no longer be available for use by future generations. Such resources could not be restored, replaced, or otherwise retrieved for the life of the Project or thereafter. Examples of irretrievable types of resources include permanent conversion of wetlands and playas, or loss of cultural resources, soils, wildlife, agricultural, and socioeconomic conditions. The losses are permanent. This section provides a summary of irreversible and irretrievable commitment of resources.

2.9.2 Agricultural Resources

Upon decommissioning of the Project, all land could return to previous uses. There would be no irreversible or irretrievable commitment of agricultural resources

2.9.3 Air Quality and Climate Change

No irreversible and irretrievable commitments of air quality resources are anticipated to result from the Project.

2.9.4 Electrical Environment

No irreversible and irretrievable commitment of resources associated with electrical effects is anticipated to result from the Project.

2.9.5 Environmental Justice

No irreversible and irretrievable commitments of resources associated with environmental justice are anticipated to result from the Project.

2.9.6 Geology, Paleontology, Minerals, and Soils

2.9.6.1 Geology, Paleontology, and Minerals

There would be no irreversible and irretrievable commitments of resources regarding geologic hazards. Because paleontological resources are nonrenewable, any impacts would render the resource disturbance irreversible and the integrity of the resource irretrievable.

2.9.6.2 Soils

There would be no irreversible and irretrievable commitments of soil resources provided that all transmission line concrete foundations, converter station facilities, and access roads were removed and successful reclamation was achieved as part of decommissioning the Project.

2.9.7 Groundwater

The Project would involve a commitment of groundwater resources, but at least to some extent, those resources would be replenished by cyclic seasonal recharge. The commitment of groundwater resources would be irreversible in that it would limit, in the short term, other options for use of that resource. Over time, however, the amounts of groundwater used to support construction would be expected to have a negligible effect on groundwater resources. In sum, the groundwater resource would be renewable or recoverable, so the commitment would not be considered irretrievable.

2.9.8 Health, Safety, and Intentional Destructive Acts

The health of workers and the public are important resources that must be protected. Through the implementation of safety plans, procedures, and required design elements, irreversible commitment of these resources would be kept to a minimum.

2.9.9 Historic and Cultural Resources

Historic and cultural resources are nonrenewable, and adverse direct effects to these resources generally constitute an irreversible and irretrievable commitment of resources. Any Project-related activity that results in the destruction, significant permanent alteration, removal, or relocation of a historic or cultural resource, such as the excavation of soil at an archeological site or the demolition of a building or structure within the Project ROW is irreversible and irretrievable. Some indirect adverse visual effects, such as the removal of large trees within the Project ROW, can be regarded as essentially irreversible, because they would take hundreds of years or more to be fully restored, while other visual and auditory indirect effects, such as those resulting from the presence of transmission towers and lines, persist throughout the lifespan of the Project, until Project elements are removed during decommissioning.

2.9.10 Land Use

The use of the approximately 2,598 acres for the life of the Project would be irreversible since these areas would be converted to a utility use as transmission structures, access roads, converter stations, or fiber regeneration sites. In addition, some land use restrictions may result within the ROW depending on the limitations determined for each individual landowner's lease agreement. As discussed above, it is possible that some small areas may no longer be practicable for agricultural use depending on the location of Project access roads. Once the Project has been decommissioned, all land could return to previous uses; therefore, there would be no irretrievable commitment of land use resources.

2.9.11 Noise

With the implementation of EPMs and identified BMPs to resolve potential noise impacts to noise sensitive areas, no irreversible or irretrievable commitments of resources related to noise are anticipated.

2.9.12 Recreation

All impacts related to recreational resources would cease with the end of the Project and would not be considered an irreversible or irretrievable commitment of resources.

2.9.13 Socioeconomics

No irreversible or irretrievable commitments of socioeconomic resources were identified.

2.9.14 Special Status Wildlife, Fish, Aquatic Invertebrate, and Amphibian Species

2.9.14.1 Special Status Terrestrial Wildlife Species

The potential permanent loss or alteration of established trees in mature forests in the eastern portion of the Project (in Regions 3, 4, 5, and 7) would last throughout the life of the Project; however, gradual recovery of habitat may occur once the Project is decommissioned. As the exact state of this recovery is not known (e.g., substantial changes related to climate, land-use, and/or weeds or pathogens may occur during the assumed 80-year lifespan of the Project), and mature forests are subject to long-term climatic regimes and it is reasonable to assume that some portions of the habitat for special status wildlife species in these forests would be irreversibly and irretrievably impacted.

2.9.14.2 Special Status Fish, Aquatic Invertebrate, and Amphibian Species

The potential permanent loss or alteration of aquatic habitat in smaller streams that may require road crossings would last throughout the life of the Project; however, gradual recovery of habitat may occur once the road crossing was removed. As the exact state of this recovery is not known (e.g., substantial changes related to climate, land-use, and/or watershed hydrology may occur during the assumed 80-year lifespan of the Project), and aquatic habitat is subject to long-term climatic regimes and changes in land-use and watershed hydrology, it is reasonable to assume that some portions of the aquatic habitat for special status fish, aquatic invertebrate, and amphibian species in these smaller streams would be irreversibly and irretrievably impacted.

2.9.15 Surface Water

The commitment of surface water resources would be irreversible in that it would limit, in the short term, future options for use of that resource. Over time, however, the amounts of water used to support construction would be expected to have a negligible effect on surface water resources. In other words, the surface water resource would be renewable or recoverable, so the commitment would not be considered irretrievable.

2.9.16 Transportation

As a result of the increased traffic associated with construction of the Project, a portion of the local roadway network capacity would be lost during the construction period. This loss would be irretrievable but short term. The use of non-renewable resources and resources that cannot be recycled would occur as a result of access roadway construction. The use of these resources would be irreversible.

2.9.17 Vegetation Communities and Special Status Plant Species

Both short- and long-term disturbance to vegetation would be reconciled through appropriate application of the Project's Restoration Plan. Once the Project has been decommissioned, there is potential for all of the approximately 2,598 acres of vegetation to be recovered. Therefore, it is predicted that there would be no irreversible or irretrievable commitment of vegetation resources.

2.9.18 Visual Resources

Irreversible and irretrievable commitment of visual resources are anticipated where large trees are removed in the ROW, since trees would not be replanted or would be replanted and would result in age disparities, the effects of which would be noticeable to the casual observer.

Impacts to visual resources from the introduction of structures (e.g., transmission structures and converter stations) and vegetation clearing would be irretrievable during the life of the Project. Once the Project has been decommissioned, however, visual resources could be restored; therefore, the introduction of structures would be not result in any irreversible commitment of visual resources.

2.9.19 Wetlands, Floodplains, and Riparian Areas

The potential permanent loss or alteration of wetlands, floodplains, and riparian areas would last throughout the life of the Project; however, gradual recovery of these resources is expected after decommissioning. It is reasonable to assume that some wetlands, floodplains, and riparian areas may be irreversibly and irretrievably impacted.

2.9.20 Wildlife, Fish, and Aquatic Invertebrates

2.9.20.1 Wildlife

The potential permanent loss or alteration of wildlife habitat associated with established trees in mature forests in the eastern Project area (in Regions 3, 4, 5, and 7) would last throughout the life of the Project; however, gradual recovery of habitat may occur once the Project is decommissioned. As the exact state of this recovery is not known (e.g., substantial changes related to climate, land-use, and/or weeds or pathogens may occur during the 80-year lifespan of the Project), and mature forests are subject to long-term climatic regimes, it is reasonable to assume that some portions of the wildlife habitat in these forests would be irreversibly and irretrievably impacted.

2.9.20.2 Fish and Aquatic Invertebrates

The potential permanent loss or alteration of aquatic habitat in smaller streams that may require road crossings would last throughout the life of the Project, or at least through the duration of use of the access roads; however, gradual recovery of habitat may occur once the road crossing was removed and the stream restored to original conditions. As the exact state of this recovery is not known (e.g., substantial changes related to climate, land-use, and/or watershed hydrology may occur during the 80-year lifespan of the Project), and aquatic habitat is subject to long-term climatic regimes and changes in land-use and watershed hydrology, it is reasonable to assume that some portions of the aquatic habitat for fish and aquatic invertebrate species in these smaller streams would be irreversibly and irretrievably impacted.

2.10 Summary of Relationship between Local Short-term Uses and Long-term Productivity

2.10.1 Definition

Pursuant to NEPA regulations (40 CFR 1502.16), an EIS must consider the relationship between short-term uses of the environment and the maintenance and enhancement of long-term productivity. In this EIS, short-term impacts are those impacts expected to occur during construction. Long-term impacts are those impacts expected to occur for some time during operations and maintenance. Permanent impacts are those that would be expected to continue even after decommissioning of the Project. The potential impacts to the environment from all phases of the Project could be minimized through the implementation of the EPMs and BMPs identified in Appendix F and Section 2.7, respectively. The following sections provide a brief summary of the relationship between local short-term uses and long-term productivity for each environmental resource area as provided in Chapter 3.

2.10.2 Agricultural Resources

The conversion of primarily agricultural land to a utility use to construct and operate the Project would result in short-term use impacts. These direct effects would include the loss of crops pasture/hay and grazing land for livestock in the representative ROW as well as loss of agricultural structures. Other short-term and localized impacts include the disruption of access to local agricultural land uses during construction. The productivity of the soil in temporary construction areas may also be reduced due to compaction and soil erosion.

2.10.3 Air Quality and Climate Change

Emissions from construction of the Project are not predicted to impact sensitive receptors and also would not impact long-term productivity. While over the short-term emissions from construction would be higher in localized areas—

because the Project provides for development of non-fossil fuel energy sources over the long term—air quality would be improved in comparison to not building the Project.

2.10.4 Electrical Environment

No short-term uses or resource removal exist that would affect long-term productivity associated with electrical effects from the Project.

2.10.5 Environmental Justice

Because the EIS did not identify any disproportionately high and adverse impacts to low-income or minority populations, there would be no short-term or long-term impact to these populations.

2.10.6 Geology, Paleontology, Minerals, and Soils

2.10.6.1 Geology, Paleontology, and Minerals

No relationships exist between local short-term uses and long-term productivity for geological hazards. Short-term impacts associated with the exposure of any scientifically important fossils from Project activities would not adversely impact the long-term potential for discovery of potential fossil resources. Any short-term effects are not expected to cause long-term impairment to the productivity of mineral resources.

2.10.6.2 Soils

Overall site productivity is primarily a matter of revegetation/reclamation success and availability for agricultural or other uses. Impacts to short-term uses of soil resources would result from construction and operations and maintenance of the Project, while impacts to long-term productivity would depend on the success of the reclamation activities. Short-term impacts are associated with land areas directly affected by construction and operations and maintenance of the Project. Short-term impacts include the construction and use of access roads during the construction phase of the Project and the use of access roads for operations and maintenance. Other short-term impacts to soil resources could occur at the footprint areas of construction work areas, converter station sites, transmission line structures, fiber optic sites, and construction tensioning or pulling areas. These areas could all be returned to other productive uses following decommissioning. A decrease in the long-term productivity of soils would result if soils were not reclaimed to their existing quality condition including such characteristics as aeration, permeability, texture, salinity and alkalinity, microbial populations, fertility, and other physical and chemical characteristics that are accepted as beneficial to overall plant growth and establishment.

2.10.7 Groundwater

Groundwater required to support the Project would represent a new, short-term use of the resource, but would have negligible effect on its long-term productivity.

2.10.8 Health, Safety, and Intentional Destructive Acts

While there would be a short-term temporary increase in potential health and safety impacts associated with construction, long-term impacts in the region would not increase and would not affect the productivity of the region.

2.10.9 Historic and Cultural Resources

The impacts associated with short-term use of the environment for cultural resources would likely be minor because DOE has developed a PA that provides a protocol for the identification of historic and cultural resources, evaluation of their possible significance and eligibility to the NRHP, and assessment and resolution of potential Project effects, including, as appropriate and practicable, impact avoidance, minimization, where practicable, and mitigation. As part of the PA, DOE will require the Applicant to develop and implement plans and activities such as those described in Section 3.9.6.1.1 as needed. The draft PA is included in Appendix P. DOE intends to execute the PA prior to issuance of the ROD or otherwise comply with procedures set forth in 36 CFR Part 800. Long-term productivity would not be affected by short-term use of the environment for cultural resources because impacts from short-term use are expected to be minor.

2.10.10 Land Use

Local short-term use effects from the Project would result from the removal of vegetation and conversion of primarily agricultural and undeveloped land to a utility use. Other short-term and local impacts include the disruption to access to local land uses that may occur, such as agriculture, oil and gas development, and residences and businesses during construction. The Project is not expected to have any long-term impacts on land use productivity.

2.10.11 Noise

Construction noise would temporarily impact nearby noise sensitive areas; noise levels associated with operations and maintenance of the Project would not impact long-term productivity. Changes in sound level associated with the Project would not be expected to negatively impact current land use and activities.

2.10.12 Recreation

Some direct short-term impacts to resources such as noise or visual disturbance, or restricted access to the recreation area during construction, would likely diminish the quality of a recreational visit. Long-term productivity of recreational areas could potentially decrease in recreational areas that were crossed by the Project.

2.10.13 Socioeconomics

Potential short-term impacts to socioeconomic resources are not expected to outweigh the long-term benefits of the Project. In the long term, the Project would be expected to increase economic productivity through the delivery of renewable energy generated in the Oklahoma and Texas Panhandle regions to load-serving entities in the mid-south and southeast regions of the United States.

2.10.14 Special Status Wildlife, Fish, Aquatic Invertebrate, and Amphibian Species

2.10.14.1 Special Status Terrestrial Wildlife Species

The Project could result in a short-term disturbance to special status wildlife; however, these impacts should not affect the long-term productivity of populations of special status wildlife.

2.10.14.2 Special Status Fish, Aquatic Invertebrate, and Amphibian Species

The Project may result in a short-term disturbance to special status fish, aquatic invertebrate, and amphibian resources; however, these impacts would not likely affect the long-term productivity of populations of special status fish, aquatic invertebrate, and amphibian species.

2.10.15 Surface Water

Surface water required to support the Project would represent a new, short-term use of the resource, but would have negligible effect on its long-term productivity. Any alterations to streambeds required by access road construction would have short term impacts on the altered segment of stream, but over time the impacts would be expected to fade as natural flora and fauna reestablished and the impacted stream segments would be small.

2.10.16 Transportation

Construction of the Project would increase the short-term uses of the local roadway network during construction but would have no impact on long-term productivity because roadways would be returned to their original condition and travel conditions would neither improve nor deteriorate during the operational life of the Project.

2.10.17 Vegetation Communities and Special Status Plant Species

The impact of short-term uses on long-term productivity to vegetation resources would be limited to those areas where (1) structural foundations are left in place until decommissioning, or (2) instances where vegetation structure is altered from forested to herbaceous structural types. In this second specific case, the functions of wildlife habitat maintenance, biodiversity, and recreational opportunities could be diminished.

2.10.18 Visual Resources

Short-term vegetation management may impair long-term visual resources where trees or areas of thick vegetation are removed and take years to grow back.

2.10.19 Wetlands, Floodplains, and Riparian Areas

The Project would result in a short-term disturbance to wetlands, floodplains, and riparian areas; however, these impacts should not affect the long-term productivity of these resources.

2.10.20 Wildlife, Fish, and Aquatic Invertebrates

2.10.20.1 Wildlife

The Project may result in a short-term disturbance to wildlife resources; however, these impacts should not affect the long-term productivity of populations of wildlife resources.

2.10.20.2 Fish and Aquatic Invertebrates

The Project would result in a short-term disturbance to aquatic resources; however, these impacts should not affect the long-term productivity of populations of fish and other aquatic species. The short-term impact of introducing non-native invasive species would be negligible; however, over time, long-term productivity would be affected and species could be eliminated from their native habitat.

2.11 Summary of Impacts from Connected Actions

The following sections provide a characterization of the potential connected actions associated with the Project. Descriptions of these connected actions are provided in Section 2.5.

2.11.1 Wind Energy Generation

As described in Section 2.5.1, wind power facilities that would interconnect with the Project are anticipated to be located in parts of the Oklahoma Panhandle and Texas Panhandle within an approximate 40-mile radius of the western converter station. The Applicant anticipates future wind farm development to be between 4,000 and 4,550MW. Neither the Applicant nor DOE knows the exact location of wind power facilities that would be connected to the Project. The Applicant has identified 12 wind development zones (WDZs) based on available wind resources and existing land uses. The range of potential impacts connected to the Project from wind energy development within these WDZs is presented in Table 2.11-1.

Table 2.11-1:
Summary of Impacts from Wind Energy Generation

RESOURCE	POTENTIAL IMPACTS
Agricultural Resources	Construction Approximately 2% of land within a wind energy facility would be disturbed, typically primarily cropland and grasslands. As indicated in Section 3.2.6.8.1, assuming between 20 and 30% of the WDZs would be built-out, between 4,328 and 6,492 acres of primarily agricultural land would be temporarily affected during construction. Wind farm developers are typically able to microsite turbines and other facility components to avoid displacing or damaging agricultural structures such as irrigation equipment, barns, and silos. Operations and Maintenance Approximately 1% or less of the land for a wind energy facility would be affected or disturbed (converted to utility use for life of the Project). For the 12 WDZs, assuming 20 to 30% build-out, between 2,164 and 3,246 acres of primarily agricultural land would be affected for the life of the wind energy facilities. Agricultural uses may usually resume around the facility once construction has been completed.
Air Quality and Climate Change	Construction Minor temporary impacts from construction emissions and are not expected to contribute to substantially increased air pollutant concentrations. Operations and Maintenance Reduction in emissions of pollutants and greenhouse gases from the displacement of current fossil fuel power sources for electricity generation.
Electrical Environment	Construction/Operations and Maintenance None expected.
Environmental Justice	Construction/Operations and Maintenance None expected.
Geology, Paleontology, Soils, and Minerals	Construction Potential impacts to karst and to paleontological resources if shallow bedrock disturbed. Complete avoidance of karst is not possible, and the risk to wind farm components from subsidence would still exist. Impacts on mineral resources extraction during construction are anticipated to be minor. Specific locations of wind generation facilities are not known at this time and therefore specific impacts to designated farmland, soil limitation parameters, or contaminated soil cannot be determined. Based on the general characteristics of the WDZs, some affected soils may be susceptible to compaction or have moderate to high wind erosion potential. The remaining soil limitation characteristics are not prominent in the WDZs. Operations and Maintenance Due to the prevalence of karst in the area, the risk for subsidence does exist. Impacts from subsidence in karst areas can be avoided and minimized during engineering design. Impacts to mineral resource accessibility would not be expected if protective measures described for the construction phase were put in place, and the locations of

Table 2.11-1:
Summary of Impacts from Wind Energy Generation

RESOURCE	POTENTIAL IMPACTS
	the facilities would be designed to avoid mineral resources to the extent possible. Impacts to designated farmland, and soils within infrastructure footprints, including turbine footprint areas, collector lines, substations, met towers, operations and maintenance buildings, and access roads for the maintenance and operations of these facilities.
Groundwater	Construction Common impacts include (1) minor potential for contamination from spills or leaks of fuels and lubricants, (2) small and short-term changes in infiltration rates in areas of land disturbance that would not be expected to result in any noticeable changes in the area's natural groundwater recharge rates; (3) minor impacts to water availability from groundwater demands for soil compaction during road, substation, and wind turbine foundation construction and for dust suppression, and (4) potential damage to wells and associated piping systems in construction areas. Operations and Maintenance Groundwater use would be minor; (limited to personal needs of the few workers associated with maintenance of facilities and equipment) no notable sources of contaminants would be in use other than the typical fuels and lubricants found in vehicles and equipment, no soil disturbance would occur, no impacts expected.
Health, Safety, and Intentional Destructive Acts	Construction Lost-time accident and fatality risks to workers typical of large construction projects. Aircraft operations, including helicopter use, could pose collision risks. Operations and Maintenance Minor potential for rotor blade failure and ice buildup and throw from blades during freezing weather conditions. Impacts typically remaining within the wind generation facility site or transmission line ROW. Potential for shadow flicker and blade glint and glare to cause annoyance to workers and public within range of wind energy generation structures.
Historic and Cultural Resources	Construction Ground disturbance has the potential to disturb belowground historic and cultural (archaeological) resources if present. Direct effects to aboveground historical and cultural resources would be transient and limited, based on micrositing and application of EPM LU-5, and could include temporary increases in noise, vibration, and dust. The level of potential adverse impacts to cultural resources associated with wind energy generation would depend on the level of archaeological surveys conducted and the associated cultural resources BMPs and mitigation plans implemented by wind energy developers. Operations and Maintenance No additional impacts expected.
Land Use	Construction Disturbance of approximately 2% of land within an individual wind energy facility, typically primarily cropland and grasslands. Assuming between 20 and 30% of the WDZs would be built out, between 4,328 and 6,492 acres would be temporarily disturbed (2% of the 20% for the low end, 2% of the 30% for the high end.) Operations and Maintenance Approximately 1% of land within a wind energy facility is converted to utility use for life of the Project. For the 12 WDZs, assuming 20 to 30% build-out, between 2,164 and 3,246 acres would be disturbed (until decommissioning). Temporary construction acres would revert to their previous use. Only turbines, access roads, generation tie-lines (if necessary), substations, and operations and maintenance buildings would remain. Agricultural uses and oil/gas development may usually resume around the facility.
Noise	Construction Noise sensitive areas near wind energy facilities could experience temporary elevated sound levels from motorized construction equipment used for general construction. Operations and Maintenance Noise from operation of wind energy generation facilities would result from the operation of wind turbines, and maintenance of the wind energy developments. Because there are no site-specific plans for the wind energy development areas, it is not possible to analyze noise impacts for each potential wind energy generation development area. As wind development projects are established in the WDZs, each would be required to proceed through state, local, and other permitting efforts as applicable.

Table 2.11-1:
Summary of Impacts from Wind Energy Generation

RESOURCE	POTENTIAL IMPACTS
Recreation	Construction Noise, dust, and human activity, as well as vegetation clearing and turbine erection would cause short-term reduced access to, or enjoyment of, recreational areas. No recreational areas are present in WDZ-C, E, F, G, H, I, J, and K, so no impacts are expected in those WDZs. It is assumed that wind energy developers would likely site wind farms to avoid direct impacts to parks and municipalities. Operations and Maintenance Long-term impacts to recreation would typically be limited to changes in the visual characteristics of a recreational area.
Socioeconomics	Construction Construction would result in a range of estimated total (direct, indirect, and induced) jobs of between 8,762 and 9,910 in Region 1. Construction would also result in a range of estimated total (direct, indirect, and induced) earnings of between $435 million and $494 million. Temporary housing impacts could occur if wind generation construction is concurrent with construction of the Project in Region 1 because housing is more limited in this region. Estimated state sales and use tax revenues would range from $158 million to $161 million in Oklahoma and from $217 million to $223 million in Texas. For the three Oklahoma counties, estimated county sales and use tax revenues per facility would range from $0.9 million to $1.9 million for a 50MW facility and from $17.9 million to $35.7 million for a 1,000MW facility. Operations and Maintenance Operations and maintenance would result in a range of estimated total (direct, indirect, and induced) jobs of between 665 and 798. Operations and maintenance would also result in a range of estimated total (direct, indirect, and induced) earnings of between $32.9 million and $41.2 million. These annual impacts would occur each year for the operating life of the potential wind facilities. Positive tax revenue impacts would be expected from annual ad valorem or property taxes. For potentially affected counties in Oklahoma, the tax revenues for a single wind facility would range from $1.9 million (for a 50MW facility in Beaver County) to $36 million (for a 1,000MW facility in Texas County). For potentially affected Texas counties, the property tax revenues for a single wind facility would range from $4.3 million (for a 50MW facility in Hansford County) to $85.6 million (for a 1,000MW facility in Sherman County).
Special Status Wildlife and Fish, Aquatic Invertebrate, and Amphibian Species	Construction Potential impacts during wind farm development could include short-term disturbances to species (i.e., displacement in the vicinity of construction activity) during construction, loss of habitat from land disturbance, and potential mortality from vehicle collisions. Potentially suitable habitat for piping plover is limited; however, there is a potential for piping plover to occur during migration. LEPC and whooping crane may feed within the croplands and grasslands; however, the whooping crane occurrence is likely to be limited to migratory and stopover occurrences. The LEPC habitat within some zones is categorized as CHAT category 1 (i.e., focal area) suggesting that large areas of undeveloped, contiguous grassland/herbaceous land cover occur. The LEPC could be potentially impacted during construction of wind farms by clearing of grassland habitats for access roads, wind turbines, and electrical stations. Specifically, the potential for construction impacts to the LEPC and its habitat is greater in WDZ-D, -I, -J, -K, and -L. These WDZs occur in eastern Texas County and western Beaver County in Oklahoma and western Ochiltree County in Texas. Potential mortality and injury, disturbance, and aquatic habitat loss and modification impacts to the Arkansas darter and Arkansas River shiner could occur in WDZ-J and WDZ-K. Operations and Maintenance Migrant bald and golden eagles and whooping cranes could be at risk for mortality collisions with the turbines. Behavioral avoidance by LEPC of otherwise suitable habitat surrounding wind turbine towers could be possible. Specific impacts would be dependent on the eventual location of the wind energy facilities. Potential impacts to the Arkansas darter and Arkansas River shiner would be similar to those from construction.
Surface Water	Construction Common impacts include (1) potential for runoff and receiving water contamination from spills or leaks of fuels and lubricants, (2) small and short-term changes in runoff rates in areas of land disturbance, and (3) possible disturbance of drainage features, including intermittent or perennial streams, from construction of access roads. Operations and Maintenance

Table 2.11-1:
Summary of Impacts from Wind Energy Generation

RESOURCE	POTENTIAL IMPACTS
	Water use would be minor; no impacts expected. Compared to pre-wind farm conditions, long-term operations and maintenance of wind farms in any of the WDZs would only result in minor changes to stormwater runoff and drainage.
Transportation	Construction: Impacts to roads would be minor, short term and temporary, most roads have the potential for one-level decreases to level of service. Level of service would not decrease below LOS-C even in the unlikely scenario where 38 wind farms and the AC collection system are under construction within 1 year, which further supports the conclusion that impacts during construction would be minor and temporary. Although railroads, airports, airstrips, and navigational aids are located within the WDZs, impacts to these features from construction are not expected. Operations and Maintenance Low level of increased rural traffic from wind farm workers and their families. FAA lighting requirements would apply to the wind turbines. In addition, the heights of the turbines would require careful selection of specific turbine sites to avoid potential conflicts with airports and military airspace. In some cases, FAA notification requirements might be triggered.
Vegetation Communities	Construction Approximately 2% of land within any wind energy facility is assumed to be disturbed during construction, equating to approximately 6,492 acres of temporary disturbance. All of the potential wind generation areas are dominated by cropland and grassland land cover types. Temporary impacts during construction may result from increased dust entrainment that can settle on surrounding vegetation causing a reduction in photosynthetic capability of plants. It is also likely that there would be mowing or potential removal of vegetation in ROWs for generation tie-lines, access roads, and electrical collection lines that are placed underground. Long-term to permanent impacts may result to vegetation where it is removed to facilitate construction of substation facilities. Operations and Maintenance Approximately 1% of land within any given wind energy facility is anticipated to be impacted by maintenance and operations. This would equate to approximately 3,246 acres. Once construction has been completed, agricultural operations would be able to continue in most of the wind farm. Agricultural activities such as cultivating crops are generally permitted up to the wind turbine pads, so only a very minimal area of existing agricultural land would be permanently removed from production. Permanent access roads may change the configuration of fields for crops.
Visual Resources	Construction Short-term visual intrusion of construction vehicles, equipment, materials, and work force in staging areas, and final turbine location. Operations and Maintenance The tall, vertical wind turbines would be in strong contrast with the primarily horizontal lines of the surrounding landscape; therefore, higher impacts are anticipated where the wind turbines are located in the foreground and near middle ground in relation to sensitive viewers. In addition, the required FAA lighting would be visible for long distances and would likely attract attention when flashing. Most of the highly sensitive resources, such as the national grassland and recreation areas, however, would be located in the background distance zone, so impacts would not be as strong as turbines would not be a dominant feature at that distance.
Wetlands, Floodplains, and Riparian Areas	Construction The potential short-term impacts from construction activities for wind energy generation could include mechanical damage/crushing of wetland and riparian vegetation, compaction of soils, sedimentation and turbidity from construction activities adjacent to these resources, alteration of hydrology from access road construction, dewatering activities, and contamination from accidental spills of hazardous substances such as fuels and lubricants. The potential long-term impacts to wetlands, floodplains, and riparian resources could include removal of vegetation during excavations for structure foundations, electrical collection lines, or during permanent access road construction, conversion of forested wetlands and riparian areas to shrubby or herbaceous cover types within the ROW, changes to hydrology from permanent access roads construction, and the introduction of invasive species from construction equipment. Operations and Maintenance There would be a potential for impacts from contamination from accidental spills of hazardous substances such as fuels and lubricants, however, the potential would be less than during construction.

Table 2.11-1:
Summary of Impacts from Wind Energy Generation

RESOURCE	POTENTIAL IMPACTS
Wildlife and Fish	Construction Short-term impacts to wildlife resources during construction may include disturbance due to increased noise, dust, and traffic. Additionally, there is the potential for short-term indirect impacts to wildlife habitats as a result of the clearing of vegetation and soil disruption during construction. There is the potential for long-term direct habitat loss related to construction of a wind energy development as well as the potential for avian and bat mortalities resulting from collisions with wind turbines and blades. Potential localized aquatic habitat damage, sensory disturbance, and mortality/injury to fish and aquatic invertebrate species could occur at stream and water body crossings. Operations and Maintenance Operations and maintenance of wind energy developments are known to have direct impacts on some wildlife species, specifically avian and bat species, due to collisions with wind turbine blades, collisions and electrocutions associated with generation tie-lines, and barotrauma of bat species. Permanent habitat loss would occur due to the footprint of the wind energy facility for the life of that facility. Potential impacts to fish and aquatic invertebrate species similar to those during construction could occur during maintenance activities at stream and river crossings.

2.11.2 Optima Substation

The future Optima Substation is anticipated to be constructed on 160 acres of currently undeveloped land near an operating wind energy facility. The land cover of the site is primarily grassland/herbaceous. Any agricultural practices, such as grazing, that currently occur on the site would be converted to a utility use. The site would be partially contained within the Oklahoma AC Interconnection Siting Area. Therefore, impacts of this connected action would be similar, but of a smaller scale, to the impacts presented for the Oklahoma Converter Station and Interconnection Siting Areas. Impacts would occur primarily during construction of the substation because there would be few, if any environmental impacts associated with operations and maintenance of the substation.

2.11.3 TVA Upgrades

The required TVA upgrades would have impacts similar to the Project, but on a smaller scale, being restricted to an approximately 37-mile-long new 500kV AC transmission line in western Tennessee and upgrades to existing facilities in western and central Tennessee. The potential impacts of the required upgrades would be limited primarily to the construction phase with negligible impacts resulting from the operation of the upgraded facilities. The upgrades to existing facilities would be unlikely to result in any significant, adverse impacts since there would not likely be any additional land disturbance required beyond the existing footprint of those facilities. The specific impacts of the new transmission line would be subject to environmental review once specific locations are identified. TVA anticipates tiering from this EIS when completing its review of potential environmental impacts of the new transmission line and upgrades to existing facilities as required by NEPA.

2.12 Summary of Impacts from the No Action Alternative

Under the No Action Alternative, DOE would not participate with the Applicant in the Applicant Proposed Project or DOE Alternatives. DOE assumes for analytical purposes that the Project would not move forward and none of the potential environmental effects associated with the Project would occur. Therefore, the Project would not be constructed and no additional impacts would occur to any of the environmental resources analyzed.

2.13 Summary of Cumulative Impacts

The cumulative impacts analysis identified past, present, and reasonably future actions that could occur within the same time and place as the Project. This section identifies those cumulative impacts for both construction and operations and maintenance. Chapter 4, Cumulative Impacts, describes the identification of past, present, and reasonably foreseeable future actions in detail and provides an evaluation of potential cumulative impacts.

Impacts from Construction

Construction activities in the seven diverse regions of the Project could result in impacts to agricultural resources, changes to land uses, temporary land disturbance, increased traffic, increased air emissions, increased noise levels, intrusions into the visual landscape, and potential impacts to wildlife, fish, aquatic invertebrate, and amphibian species and vegetation, including special status species. Cumulatively, other construction activities occurring in the same time and vicinity would have similar impacts within each region. Other past, present, and reasonably foreseeable actions identified for the seven regions that could occur within the same time and place of the Project include electrical transmission lines, roadway and bridge enhancements, new road construction, oil or natural gas pipelines, wind farm developments, and two relatively large development projects in Region 7 (Great River Super Site and Green Meadows Development; see Table 4.2-1a in Chapter 4). Multiple activities occurring at the same time and vicinity would have greater impacts than just one action. If construction activities overlapped in the same area, then the construction-related impacts could be greater than for just the Project. However, with the exception of the converter stations, construction of the Project would not affect any one area for long (i.e., no more than a few weeks or months), so the short temporal overlap would limit cumulative impacts. The majority of the actions identified are transmission lines and road construction. Most of the road construction would occur on existing roadways, not disturbing new lands, and therefore would have only minor contributions to cumulative impacts from the Project. Overall, construction of the Project, when considered with past, present, and reasonably foreseeable actions, would result in the following cumulative impacts: short-term, temporary disturbance of active agricultural lands and operations; possible restrictions on existing land uses; temporary soil and vegetation disturbance; increased risk of localized water quality impacts (spills or sedimentation); increased traffic; increased air emissions and noise levels; potential shortages in temporary housing (in Region 1); visual disruptions from construction equipment and land disturbance; and potential impacts to wildlife, fish, aquatic invertebrate, and amphibian species and vegetation, including special status species. Fish special status species are the Arkansas darter, Arkansas River shiner, Ozark cavefish, Yellowcheek darter, and pallid sturgeon. The aquatic invertebrate special status species are spectaclecase, pink mucket, Neosho mucket, speckled pocketbook, scaleshell mussel, fat pocketbook, rabbitsfoot, snuffbox, and Curtis' pearlymussel. The special status amphibian is the Ozark hellbender.

Impacts from Operations and Maintenance

After completion of construction, the majority of the Project-related impacts would be minimized. Those that would continue or increase would include electrical environment (electric fields, magnetic fields, audible noise, and radio and television interference) and visual resources. The Project individually would not be considered a strong source of electric or magnetic fields. Other existing and proposed transmission lines that would be crossed by the Project would be an additional source of electric or magnetic fields at the location of the crossing. People are exposed to numerous sources of magnetic fields on a daily basis from sources like power lines, but also from electric devices in home and office environments. The research available on the health impacts of magnetic field exposure are not definitive, and no conclusions regarding the health impacts can be drawn based on what is presently known about the health impacts of magnetic fields. Looking at the occupational guidelines, calculated DC electric fields within the

ROW would be lower than 20 kilovolts per meter, except during infrequent operating conditions (such as when a main conductor bundle is de-energized for repair or maintenance) for either monopole or lattice structures, where they would be as high as 24.3 kilovolts per meter.

Long-term visual impacts from the Project include the intrusion of the converter station and associated structures and transmission structures, access roads, and cleared ROW that may introduce contrast into the surrounding landscape setting. The cumulative impacts would be of a similar nature in areas where additional transmission line actions have been identified (Regions 1, 2, and 3). Additionally, sensitive viewers in Regions 1, 2, and 6 that are characterized primarily by flat croplands and grasslands with scattered vegetation are anticipated to have greater visibility of the Project due to long viewing distances associated with an open landscape with panoramic views. A new planned section of Highway 71 would cross Link 6 of the Region 4 Applicant Proposed Route and near the Alma Key Observation Point. The visual impacts of the new section of Highway 71 would be cumulative over the long-term with those of the Project.

2.14 Agency Preferred Alternative

The proposed Plains & Eastern transmission line represents high-voltage transmission facilities that would make possible the development of valuable wind resources in the Oklahoma and Texas Panhandle regions by providing HVDC transmission capability to deliver 3,500–4,000MW of electricity to the Mid-South and Southeast regions of the United States (depending on selected alternatives). DOE has evaluated the Proposed Action of whether to participate under Section 1222 of the EPAct, acting through and in consultation with the Administrator of the Southwestern Power Administration (Southwestern), in the Applicant Proposed Project or DOE Alternatives in one or more of the following ways: designing, developing, constructing, operating, maintaining, or owning a new electric power transmission facility and related facilities located within certain states in which Southwestern operates, namely Oklahoma, Arkansas, and, possibly Texas. As identified throughout Chapter 2, there are several elements that make up the Project. These elements include:

- Applicant Proposed Project
  - Oklahoma Converter Station and AC Interconnection
  - Tennessee Converter Station and AC Interconnection
  - AC Collection System
  - HVDC Applicant Proposed Route (through Regions 1–7)
- DOE Alternatives
  - Arkansas Converter Station and AC Interconnection
  - HVDC alternative routes (through Regions 1–7)

CEQ regulations at 40 CFR 1502.14(e) require an agency to identify its preferred alternative in the Final EIS. While developing the Final EIS, DOE considered the alternatives analyzed in the Draft EIS, the comparison of potential impacts for each resource area, and input received on the Draft EIS. DOE has coordinated with the various cooperating agencies to determine the preferred alternative for each of the Project elements. The following paragraphs present the DOE preferred alternative for each of the Project elements and the bases for its identification. DOE's identification of a preferred alternative in an EIS does not guarantee that such an alternative will be the alternative selected in DOE's ROD. Rather, identification of the preferred alternative serves to give the public notice as to which alternative DOE currently favors. The ROD, which would be signed no earlier than 30 days after the EPA Notice of Availability for the Final EIS is published in the Federal Register, would document DOE's decision.

2.14.1 Participation in the Applicant Proposed Project

Based on the information presented in the Final EIS, DOE has identified participation as its preferred alternative.

Parallel with the NEPA process, DOE is evaluating Clean Line's application under Section 1222 of the EPAct. This non-NEPA evaluation includes, but is not limited to, evaluating the application against statutory criteria and technical and financial viability. An outcome of this evaluation could be a Participation Agreement between Clean Line and DOE, which would define under what conditions DOE would participate with Clean Line and, if applicable, would include any stipulations or requirements that resulted from this environmental review under NEPA.

2.14.1.1 Oklahoma Converter Station and AC Interconnection

The Applicant Proposed Project would require an AC/DC converter station at the western terminus of the transmission line. The Oklahoma Converter Station Siting Area is an approximate 620-acre area in Texas County, Oklahoma, within which the converter station and associated AC switchyard (45 to 70 acres total) and access road or roads would be sited. The construction and operations and maintenance of the Oklahoma converter station within this siting area is DOE's preferred alternative for a converter station at the western terminus of the transmission line.

The Oklahoma converter station would require a connection to the SPP electric grid. Clean Line has proposed a double-circuit 345kV AC transmission line up to 3 miles in length to interconnect the proposed converter station with a planned Xcel Energy/Southwest Public Service Company substation referred to as Optima. The construction and operations and maintenance of this interconnection is DOE's preferred alternative for connecting the proposed Oklahoma converter station to the existing electric grid.

2.14.1.2 Tennessee Converter Station and AC Interconnection

The Applicant Proposed Project would require an AC/DC converter station at the eastern terminus of the transmission line. The Tennessee Converter Station Siting Area is an approximate 220-acre area in Shelby County, Tennessee, within which the converter station and associated AC switchyard (45 to 70 acres total) and access road or roads would be sited. The AC interconnection would be a direct connection between the converter station and the existing Shelby Substation. Consistent with Section 1222 of the EPAct, DOE's participation in the Applicant Proposed Project or DOE Alternatives would be limited to states in which Southwestern operates, namely, Oklahoma, Arkansas, and, possibly, Texas, but not Tennessee. Consequently, DOE would not participate in the portions of the Applicant Proposed Project or DOE Alternatives that would be sited in Tennessee. As such, when making its decision on whether to participate in the Project under Section 1222, DOE would not select a particular converter station location in Tennessee. The alternatives analysis of the Project components in Tennessee may be relied upon, however, by other agencies with permitting or authorization decisions for the Project in Tennessee, including, but not limited to, TVA and USACE. Therefore, DOE does not have a preferred alternative for the Tennessee converter station and AC interconnection.

2.14.1.3 AC Collection System

Clean Line would construct between four and six AC collection transmission lines within a 40-mile radius from the Oklahoma converter station to collect energy from generation resources in the Oklahoma and Texas Panhandle regions. The collection system would consist of 345kV AC transmission lines that would extend from the converter station to future wind farms. These wind farms, which would likely be established in the WDZs evaluated in the EIS as connected actions, have not been established and their exact locations cannot be known at this time. DOE evaluated 13 possible route alternatives for these AC collection transmission lines to fully evaluate their potential environmental impacts. DOE's preferred alternative is for the Applicant to construct between four and six AC collection transmission lines within a 40-mile radius from the Oklahoma converter station; the specific locations of these transmission lines cannot be known at this time and would depend on the locations of future wind farms in this area.

2.14.1.4 Arkansas Converter Station and AC Interconnection

Based on comments received during the scoping period, DOE identified and evaluated an alternative converter station in Arkansas. The Arkansas converter station would be an intermediate converter station that would not replace either of the other converter stations in Oklahoma or Tennessee. This alternative converter station would be similar to, but smaller than, the Oklahoma and Tennessee converter stations and would allow the delivery of 500MW of power to the electric grid in Arkansas. The Arkansas Converter Station Siting Area is an approximate 360-acre area in Pope County, Arkansas, within which the converter station and associated AC switchyard (20 to 35 acres total) and access road or roads would be sited. The construction and operations and maintenance of the Arkansas converter station within this siting area is DOE's preferred alternative for an intermediate converter station.

The Arkansas converter station would require a connection to the existing electric grid in Arkansas. The interconnection would include an approximate 5-mile 500kV AC transmission line to an interconnection point along the existing Arkansas Nuclear One-Pleasant Hill 500kV AC transmission line. The interconnection would include a new substation (footprint of 25–35 acres) at the point where the 500kV AC interconnection line taps the existing Arkansas Nuclear One-Pleasant Hill 500kV line. The construction and operations and maintenance of this interconnection is DOE's preferred alternative for connecting the proposed Arkansas converter station to the existing electric grid.

2.14.1.5 HVDC Transmission Line Routes

There is no "impact-free" routing choice for a large transmission line. In some regions of the Project, where there are multiple resource conflicts, the HVDC alternative routes impact certain resources differently, and some alternative routes were included in the analysis to emphasize protection of one resource or land value over another. The information in Table 2.6-3 provides a summary of potential impacts for the HVDC transmission line by resource and highlights substantive differences between the Applicant Proposed Route, route variations, and HVDC alternative routes.

After EIS scoping and during the development of the Draft EIS, DOE and Clean Line entered into a Tier IV route development process for the Applicant Proposed Route and the HVDC alternative routes. This process, as documented in Section 2.3 and the DOE Alternatives Development Report (Appendix G), included the establishment of General and Technical guidelines to focus the evaluation of the various route alternatives. The General Guidelines were intended to minimize conflicts with existing resources, developed areas, and existing incompatible infrastructure; to maximize opportunities for paralleling existing compatible infrastructure; and to take into consideration land use and other factors affecting route identification. The General Guidelines included the following:

- Utilize existing linear corridors to the extent practicable
- Utilize areas with land uses/land cover that are consistent or compatible with linear utility uses, such as existing utility corridors and open lands, to the extent practicable
- Avoid existing residences
- Avoid nonresidential structures, including barns, garages, and commercial buildings
- Minimize interference with the use and operation of existing schools, known places of worship, and existing facilities used for cultural, historical, and recreational purposes
- Avoid cemeteries or known burial places
- Minimize adverse effects to economic activities (e.g., impacts to existing residences, businesses and developed areas)
- Minimize crossing of designated public resource lands, including, but not limited to, national and state forests and parks, large camps and other recreation lands, designated battlefields or other designated historic resources and sites, and state-owned wildlife management areas
- Minimize crossings of tribal trust lands and allotments
- Minimize the number and length of crossings of large lakes, major rivers, large wetland complexes, or other sensitive water resources
- Minimize adverse effects on protected species habitat and on other identified sensitive natural resources (e.g., forested areas, native prairies, and other areas as identified by Natural Heritage Commissions)
- Minimize visibility of transmission lines from residential areas and visually sensitive public locations (e.g., public parks, scenic routes or trails, and designated Wild and Scenic Rivers)
- Avoid areas of past environmental contamination to the extent practicable
- Minimize route length, circuitry, special design requirements, and impractical construction requirements

The Technical Guidelines were specific to the Project and were based on technical limitations related to the design, ROW requirements, or reliability concerns. The Technical Guidelines included the following:

- Minimize the crossing of transmission lines of 345kV or above
- Minimize paralleling corridors with more than one existing circuit of 345kV or above
- Maintain 200 feet of centerline-to-centerline separation when paralleling existing transmission lines of 345kV or above
- Maintain 150 feet of centerline-to-centerline separation when paralleling 138kV or lower voltage transmission lines
- Minimize turning angles in the transmission line greater than 65 degrees
- Minimize the length of the transmission line located on soils sloped more than 20 percent
- Minimize underbuild or double circuit arrangements with existing AC infrastructure

The route alternatives analyzed in the Draft EIS were identified based on these guidelines. A detailed discussion of the route development and basis for identification of the Applicant Proposed Route is included in Section 2.3.1 and Appendix G. To respond to public comments on the Draft EIS, DOE and Clean Line developed 23 route variations (as described in Sections 2.3.1 and 2.4.2.1 through 2.4.2.7). These route variations were developed with the intent of reducing land use conflicts or minimizing potential environmental impacts of the Applicant Proposed Route from the levels of impacts considered in the Draft EIS. In all but one instance, the route variations replaced their corresponding segments of the Applicant Proposed Route. This exception (Region 4, Applicant Proposed Route Link

3, Variation 2) was carried forward as an additional alternative for comparative analysis in this Final EIS with the corresponding segment of the Applicant Proposed Route.

Identification of the preferred route for the HVDC transmission line depends on two primary factors: 1) the Applicant Proposed Route evaluated in the Draft EIS was initially identified from among the initial route alternatives because it minimized potential environmental impacts (as detailed in Appendix G), and 2) the Applicant Proposed Route as analyzed in this Final EIS includes route variations that were developed to incorporate feedback from landowners with the intent of reducing land use conflicts and minimizing environmental impacts. Considering these factors, the Applicant Proposed Route (as presented in the Final EIS) is DOE's preferred route for the majority of the route from the Oklahoma converter station to the Arkansas/Tennessee border. Consistent with Section 1222 of the EPAct, DOE's participation in the Project would be limited to states in which Southwestern operates, namely, Oklahoma, Arkansas, and, possibly, Texas, but not Tennessee. Consequently, DOE would not participate in any portion of the Project that would be sited in Tennessee. As such, when making its decision on whether to participate in the Project under Section 1222, DOE would not select an HVDC route alternative in Tennessee. Outside Tennessee, the only exception to the Applicant Proposed Route, as DOE's preferred route, is DOE's identification of the route variation (Region 4, Applicant Proposed Route Link 3, Variation 2) mentioned above to be a segment of the preferred route. The basis for the identification of this route variation over the corresponding segment of the Applicant Proposed Route includes the following: 1) the route variation crosses 32 percent fewer land parcels (17 versus 25); 2) the route variation parallels more than twice the length of existing infrastructure, including transmission lines and roads (4.42 miles versus 1.85 miles); 3) the representative ROW of the route variation would be located within 500 feet of 8 fewer residences (1 versus 9); and 4) the route variation would avoid a private airstrip whose operations could be impacted by the Applicant Proposed Route.

Similarly, because DOE's preferred route is the route alternative with the lowest potential for environmental impacts when compared against the other HVDC route alternatives, it is also designated as the environmentally preferable route alternative. While the No Action Alternative would avoid the environmental impacts identified in the EIS, adoption of this alternative would not meet DOE's purpose and need as identified in Section 1.1, which is to implement Section 1222 of the EPAct of 2005.

As mentioned earlier, the identification of DOE's preferred route in this Final EIS is not a DOE decision on the overall HVDC route. DOE could select from any of the proposed route alternatives for that decision with one exception: the portion of HVDC Alternative Route 4-B that would intersect the Ozark National Forest in Crawford County, Arkansas, is considered non-preferred in the Final EIS for the following reasons:

- The portion of the route alternative would adversely affect sensitive resources by creating discontinuities (linear breaks) in National Forest land (Section 3.10.6).
- The portion of the route alternative would cross lands designated as High Scenic Integrity Objectives as identified in the USFS' Forest Plan (Section 3.18.6).
- Required ROW maintenance along a portion of the route alternative would adversely affect timber production (see Section 3.10.6).
- The portion of the route alternative would, in places, undermine the use for which the National Forest land was originally acquired, i.e., conservation of natural resources (Section 3.10.6).

- The portion of the route alternative would, in places, traverse steep rugged terrain that could present an increased safety hazard during construction and future maintenance of an HVDC transmission line (Section 3.8.5.3).
- The portion of the route alternative is close to the Ozark Plateau region, which contains cave hibernacula for special status bat species. The increase in forested land in this area increases the potential for impacts to the special status bat species (e.g., disturbances to or loss of roost trees) compared to routes that do not cross the Ozark National Forest (3.14.1.7).
- The portion of the route alternative would cross into the Ozark National Forest Important Bird Area (identified by National Audubon Society), potentially indirectly impacting wildlife species (Section 3.20.1.7.3).
- The interspersed land cover and land ownership along the portion of the route alternative suggests that a variety of land uses may occur along the ROW. As a result, a variety of wildlife species common to both deciduous forests and pasture/hay land covers may occur in this area, thereby potentially exposing more wildlife species to Project-related impacts compared to the Applicant Proposed Route (Section 3.20.1.7.3).
- To the extent that the portion of the route alternative might have the benefit of avoiding private land, that benefit is limited because this portion of the route alternative would also cross a large number of parcels of privately owned land within the National Forest boundary (Section 3.10.6). (Privately owned land, or inholdings, can occur inside the boundary of a National Forest. Inholdings result from private ownership of lands prior to the designation of the National Forest, which then end up grandfathered within the legally designated boundary.)

DOE would still be able to select other portions of HVDC Alternative Route 4-B as segments of the HVDC transmission line route if used in concert with other HVDC alternative routes in Region 4. For example, the western segment of HVDC Alternative Route-4B could be used with 4-A, or the eastern portion of HVDC Alternative Route 4-B could be used with either 4-A or 4-D.

3. Affected Environment and Environmental Impacts

3.1 Introduction

3.1.1 Region of Influence

The Project covers approximately 720 miles of diverse landscape and therefore is divided into seven geographic regions. These regions are discussed in Section 2.4 and were established as part of the route development and identification process and have been carried through to the environmental analysis phase of the Project so that the existing conditions and environmental impacts could be analyzed within geographic areas that have similar characteristics. Figures 2.1-17a though 2.1-17f (located in Appendix A) provide an illustration of the Project components throughout the regions. Consistent with Section 1222 of the EPAct, DOE's participation in the Project would be limited to states in which Southwestern operates; namely Oklahoma, Arkansas, and possibly Texas, but not Tennessee. Consequently, DOE will not participate in the portions of the Project that would be located in Tennessee. This EIS does, however, evaluate the environmental impacts of the Project in Tennessee.

This chapter describes the baseline environment of the areas that could be affected by the Project and analyzes the potential environmental impacts that may result from construction, operations and maintenance, and decommissioning of the Project. To examine the potential impacts of the Project components, the EIS examines the area potentially affected by the Applicant Proposed Project and the DOE Alternatives. The EIS defines the area potentially affected by the Project as the region of influence (ROI). The ROI extends beyond the physical dimensions of the HVDC and AC transmission ROWs and converter station footprints. The ROI for the Applicant Proposed Project consists of the following:

- Oklahoma Converter Station Siting Area: An approximate 620-acre area in Texas County, Oklahoma, within which the Applicant proposes to site the Oklahoma converter station and associated AC switchyard (45 to 70 acres total) and access road(s).
- Oklahoma AC Interconnection Siting Area: An approximate 870-acre corridor within which the Applicant proposes to site an AC transmission interconnection route from the Oklahoma converter station to the future Optima Substation.
- AC Collection System: Thirteen 2-mile-wide corridors in Oklahoma (Beaver, Cimarron, and Texas counties) and Texas (Hansford, Ochiltree, and Sherman counties) within which the Applicant anticipates that the AC Collection System could be sited.
- Tennessee Converter Station Siting Area: An approximate 220-acre area located in Shelby County, Tennessee, within which the Applicant proposes to site the Tennessee converter station and associated AC switchyard (45 to 70 acres total), access road(s), and the AC interconnection, which would span between the converter station and the adjacent existing Shelby Substation.
- HVDC Applicant Proposed Route: A 1,000-foot-wide corridor within which the Applicant proposes to site the ROW for the HVDC transmission line between the Oklahoma converter station and the Tennessee converter station.

The ROI for the DOE Alternatives consist of the following:

- Arkansas Converter Station Alternative Siting Area: An approximate 360-acre siting area located in Pope County, Arkansas, within which the Arkansas converter station and associated AC switchyard (25 to 45 acres total) and access road(s) could be sited.
- Arkansas AC Interconnection Siting Area: An approximate 660-acre corridor within which potential 500kV AC transmission line(s) would be sited from the Arkansas converter station to an interconnection point(s) with an existing 500kV AC transmission line. The interconnection would require a 25- to 35-acre substation near the tap with the existing Arkansas Nuclear One-Pleasant Hill 500kV AC transmission line, with another 5 acres for material staging and equipment storage.
- HVDC Alternative Routes: A series of 1,000-foot-wide corridors that DOE has proposed as alternatives to the HVDC Applicant Proposed Route within which the ROW for the HVDC transmission line could be sited.

The ROI for connected actions (described in Section 2.5) are described below:

- Wind Energy Generation ROI: Twelve Wind Development Zones (WDZs) were identified by the Applicant within approximately 40-miles of the Oklahoma Converter Station Siting Area and within parts of the Oklahoma Panhandle and Texas Panhandle These WDZs exhibit adequate wind resource and are areas within which future development of wind energy facilities would likely occur. The ROI for the 12 WDZs is approximately 1,385,000 acres in Oklahoma (Beaver, Cimarron, and Texas counties) and Texas (Hansford, Ochiltree, and Sherman counties).
- Optima Substation ROI: The future SPS Optima Substation would be constructed within approximately 160 acres of land and would be located within a few miles of the Oklahoma converter station in Texas County, Oklahoma. It would be partially located within the Oklahoma AC Interconnection Siting Area and shown on Figure 2.1-3 (located in Appendix A).
- TVA Upgrade ROI: TVA's Interconnection SIS has identified the following as necessary to accommodate the Plains & Eastern Clean Line HVDC interconnection: (a) upgrades to existing infrastructure and (b) construction of a new 500kV transmission line, approximately 37 miles long, in western Tennessee, including necessary modifications to existing substations on the terminal ends of the new line. Upgrades to existing infrastructure would include upgrading terminal equipment at three existing 500kV substations and six existing 161kV substations, making appropriate upgrades to increase heights on sixteen existing 161kV transmission lines to increase line ratings, and replacing the conductors on eight existing 161kV transmission lines (as described in Section 2.5.2). The ROI for the direct assignment facilities would occur within the Shelby Substation. The ROI for the network upgrades, and in particular TVA's future 500kV transmission line, cannot be fully determined at this time. The ROW for the 500kV transmission line would occupy about 785 acres, assuming a ROW width of 175 feet. The upgrades to existing substations are expected to take place within the current substation boundaries and the upgrades to existing transmission lines, except for potential access roads, are expected to take place within existing ROWs.

These ROIs reflect the areas of analysis for direct and indirect impacts. The ROIs defined above are the "base" or standard ROI for the analysis. These ROIs have been expanded or modified on a resource specific basis where appropriate as described in certain resource area sections below. Resources where the ROIs have been expanded or modified include Air Quality and Climate Change, Environmental Justice, Groundwater, Surface Water, Special Status Wildlife and Fish Species, Socioeconomics, Transportation, and Visual Resources. For example, the ROI for examination of socioeconomic impacts (Section 3.13) of the Project was expanded to encompass counties surrounding the Project components so that impacts on economic conditions, agriculture, housing, and community services could be evaluated.

Representative ROW within the ROI

The analyses of impacts for the HVDC Applicant Proposed Route, AC collection system, and HVDC alternative routes are based on a representative 200-foot-wide ROW (100 feet on either side of a representative centerline). Quantitative data regarding the resources that would be directly intersected by the representative 200-foot-wide ROW are used as a representative example of potential impacts from a ROW within a given ROI. The resources that could be affected by the Project vary throughout the 1,000-foot-wide corridor where the actual ROW could be located. The representative ROW does not necessarily reflect where particular resources are most or least concentrated, or an average. For example, the representative ROW avoids many homes and environmental resources, and so moving the ROW within the 1,000-foot-wide corridor could result in environmental impacts different from those described for the representative ROW.

By identifying the existing resources within a broader corridor or siting area, the analyses presented in this EIS consider the full scope of the potential impacts from siting the Project facilities anywhere within their respective siting areas or corridors. The final transmission line ROW could be located anywhere within the 1,000-foot-wide corridor identified in this Final EIS. The final location would be determined following the completion of the NEPA process, engineering design, and ROW acquisition activities. Determination of this final location is referred to as micrositing. The micrositing of a transmission line ROW and the converter stations would require detailed engineering that considers existing conditions; compliance with federal, state, and local permits and authorizations; and incorporation of all environmental protection measures (EPMs) developed by the Applicant. The potential impacts presented in this EIS would serve as one source informing the siting of the HVDC and AC transmission line ROWs and converter stations. Further, the siting of the four to six ROWs for the AC transmission lines that would be part of the AC collection system would also depend on the final locations of the wind generation projects. The specific locations of those wind farms and transmission lines to them would not be known until after completion of this EIS process (including issuance of the ROD in this agency action) and closer to the time of construction of the Project.

3.1.2 Environmental Protection Measures, Best Management Practices, and Project Plans

For the purpose of all analyses for the EIS, it is assumed that the Applicant would conduct each phase of the Project in compliance with applicable federal, state and local laws, regulations and permits related to construction, operation and decommissioning of the Project. Appendix C presents an overview of potential federal and state permits and consultation that could be required for construction of the Project. Local permits and approvals may also be required for the Project.

The Project evaluated in this EIS and described in detail in Chapter 2 incorporates EPMs developed (and that would be implemented) by the Applicant to avoid or minimize potential adverse effects resulting from construction, operations and maintenance, and decommissioning of the Project. The EPMs, listed in Appendix F, are part of the Project. Applicable EPMs are referenced in each resource section and are repeated exactly as they are stated in Appendix F. Implementation of the EPMs is assumed throughout the impact analysis for this EIS.

In some resource sections, DOE has included best management practices (BMPs) that could further avoid or minimize potential adverse impacts. For these resource areas, implementation of the EPMs would not be adequate to avoid or minimize all potential adverse effects resulting from construction, operations and maintenance, and decommissioning of the Project.

Environmental-related project plans are also listed in Appendix F. These plans would be developed and implemented by Clean Line to avoid or minimize effects to environmental resources from construction, operations and maintenance, and/or decommissioning, as appropriate. These plans include: Transportation and Traffic Management Plan; Blasting Plan; Restoration Plan; SPCCP; SWPPP; Transmission Vegetation Management Plan (TVMP); Avian Protection Plan; a Construction Security Plan; and various cultural management planning documents. In addition, Clean Line has developed elements of a communications program, elements of which could be implemented as appropriate during the construction and/or operations and maintenance phases of the Project. The initial elements of a communications program include:

- Clean Line will review and respond to all concerns and complaints from the public.
- Clean Line will publish methods for public input through various forms of media including newspaper advertisements, online social media, email or direct correspondence.
- Clean Line will establish a toll-free hotline, mailing address, email address, and an online comment submission form to receive direct input.

Should DOE decide to participate in the Project, the EPMs would be included in the ROD as part of the project and also by one or more participation agreements. In addition, the ROD or other binding federal document may include conditions of approval (e.g., BMPs or mitigation measures) imposed by DOE or other agencies that have a decision to make or a consultation responsibility (e.g., TVA, USACE, USFWS) regarding the Project. The participation agreement(s) between the Applicant and DOE would require a monitoring plan to ensure implementation of some or all such conditions of approval.

3.1.3 Impact Analyses

Impacts to each resource are discussed in terms of direct, indirect, temporary, short-term, long-term, and permanent impacts in the sections that follow. Direct impacts occur at the same time and place as the Project. Indirect impacts are effects that may occur later in time, or further away from the Project, but are still reasonably foreseeable. Impacts are also characterized by time frame: temporary, short-term, long-term, or permanent. Temporary impacts would occur during construction, with the resource returning to preconstruction conditions once construction is complete. Short-term impacts would continue beyond the completion of construction and last from 2 to 5 years, depending on the resource affected. Long-term impacts would last beyond 5 years and could extend for the life of the Project; these impacts pertain to resources requiring longer recovery periods to return to preconstruction conditions. Permanent impacts are those that would be expected to continue even after decommissioning of the Project.

3.1.4 Chapter 3 Roadmap

3.1.4.1 Organization

Each of the following sections in this chapter is organized alphabetically by the resource sections as listed in Table 3.1-1.

Table 3.1-1:
Chapter 3 Organization

Section Number	Resource
3.2	Agricultural Resources
3.3	Air Quality and Climate Change
3.4	Electrical Environment
3.5	Environmental Justice
3.6	Geology, Paleontology, Minerals, and Soils
3.7	Groundwater
3.8	Health, Safety, and Intentional Destructive Acts
3.9	Historical and Cultural Resources
3.10	Land Use
3.11	Noise
3.12	Recreation
3.13	Socioeconomics
3.14	Special Status Wildlife and Fish, Aquatic Invertebrate, and Amphibian Species
3.15	Surface Water
3.16	Transportation
3.17	Vegetation Communities and Special Status Plant Species
3.18	Visual Resources
3.19	Wetlands, Floodplains, and Riparian Areas
3.20	Wildlife, Fish, and Aquatic Invertebrates

Specific headings within each resource section include the following:

- Affected Environment
  - Regulatory background
  - Data sources
  - Region of influence
  - Affected environment by geographic region (Region 1–Region 7)
- Impacts
  - Methodology
  - Impacts associated with the Applicant Proposed Project
  - Impacts associated with the DOE Alternatives
  - Best management practices
  - Unavoidable adverse impacts
  - Irreversible and irretrievable commitment of resources
  - Relationship between local short-term uses and long-term productivity
  - Impacts from connected actions

As a result of public comments on the Draft EIS, DOE and Clean Line have developed 23 route variations for the Applicant Proposed Route. In all but one instance, Clean Line concluded that the route variations were technically feasible and expressed support for DOE's adoption of these route variations to replace the Applicant Proposed Route that was evaluated in the Draft EIS. DOE has evaluated these route variations both individually and collectively and has concluded that they do not constitute substantial changes in the Proposed Action or significant new circumstances or information relevant to environmental concerns. These route variations are described by region in Sections 2.4.2.1 through 2.4.2.7. Each route variation is described by region within the affected environment section for each resource section in Chapter 3. Potential impacts are also described for each route variation within the impacts section for each resource section in Chapter 3.

A reference CD has been provided for the reader to ensure easy access to certain reference documents used to develop this EIS. Included on the CD are the following reference documents:

- The *Alternatives Development* Report (DOE 2013), which describes the routing process that DOE and Clean Line followed to develop the Applicant Proposed Route and the DOE Alternatives evaluated in this EIS
- Resource-specific technical reports developed by Clean Line of existing environmental conditions in the ROI
- PDF files of reference works consulted during the development of this EIS that are not available on the Internet and not protected by copyright laws

3.1.4.2 Definitions

Each section contains a discussion of unavoidable adverse impacts, irreversible and irretrievable commitment of resources, and relationship between short-term uses and long-term productivity. Unavoidable adverse impacts are caused by or resulting from the Project that are adverse and cannot be avoided with implementation of EPMs, recommended BMPs, and mitigation measures.

An “irreversible commitment of resources” occurs when, once committed to the Project, the resource would continue to be committed throughout the life of the Project but would become available again following decommissioning of the Project and restoration (if necessary). An "irretrievable commitment of resources" occurs when, once used, consumed, destroyed or degraded during construction, operation, maintenance, or decommissioning of the Project, the resource would no longer be available for use by future generations. Such resources could not be restored, replaced, or otherwise retrieved for the life of the Project or thereafter. Examples of irretrievable types of resources include permanent conversion of wetlands and playas, or loss of cultural resources, soils, wildlife, agricultural, and socioeconomic conditions. The losses are permanent.

Pursuant to NEPA regulations (40 CFR 1502.16), an EIS must consider the relationship between short-term uses of the environment and the maintenance and enhancement of long-term productivity. In this EIS, short-term impacts are those impacts expected to occur during construction. Long-term impacts are those impacts expected to last beyond 5 years and could extend for the life of the Project. Permanent impacts are those that would be expected to continue even after decommissioning of the Project.

Finally, it should be noted that there are several supporting tables that summarize characteristics associated with the affected environment and environmental impacts. Values presented in the supporting tables to this chapter for acres, mileages, and percentages have been rounded to the nearest 0.1, and values between 0 and less than 0.1 were typically rounded to 0 and 0.1, respectively. Because the numbers have been rounded, summation of the values in the table may not always be exact.

Figures Presented in Appendix A

3.2 Agricultural Resources

3.2.1 Regulatory Background

Land use laws, regulations, and standards relevant to agricultural resources in the ROI are summarized in Table 3.2-1. Permits that may apply to the Project are described in Appendix C.

Table 3.2-1:
Land Use Laws, Regulations, and Standards Relevant to Agricultural Resources

Statute/Regulation	Agency	Applicability to the Project
Federal		
U.S. Department of Agriculture (USDA) Conservation Program	USDA	The USDA is authorized to provide monetary and technical support to private landowners who reserve agricultural lands for protection of wildlife, wildlife habitat, and wetlands. Contracts are made with landowners to set aside acreage for the reserve programs. These programs include the Conservation Reserve Program (CRP), administered by the Farm Service Agency (FSA), and the Grassland Reserve Program (GRP) and the Wetlands Reserve Program (WRP), both administered by the NRCS. The CRP is administered by the FSA, with the NRCS providing technical land eligibility determinations, conservation planning, and practice implementation. The FSA does not distribute the location of CRP lands without written authorization from landowners, although the number of acres enrolled in CRP in 2007 is available and presented in Tables 3.2-2 through 3.2-9.
Farmland Protection Policy Act	USDA Natural Resources Conservation Service	See Section 3.6 for further information regarding the Farmland Protection Policy Act (FPPA).

3.2.2 Data Sources

Information on cultivated crops was obtained from the USDA National Agricultural Statistics Service CropScape Map (GIS Data Source: NASS 2013). Flood control project dam locations were identified only within Oklahoma and were provided by NRCS (GIS Data Source: NRCS 2005).Section 3.10.2 provides further detail for the land cover and structure data sources that were used.

3.2.3 Region of Influence

For agricultural resources, the ROI for the Project and connected actions is the same as described in Section 3.1.1.

3.2.4 Affected Environment

The affected environment includes the agricultural practices for the ROI in Regions 1 through 7 as described below. Section 3.6 provides further discussion on the designation of prime or unique farmland and farmland of statewide importance, and Section 3.10 provides the percentage and acreage of cultivated crops for each region.

Agriculture is the predominant land use in the ROI in Regions 1 through 7. In Regions 1, 2, and 3, grassland/pasture is the primary type of agriculture. In Regions 4 and 5, pasture/hay is the primary type of agriculture, whereas cultivated crops are more prevalent in Regions 6 and 7 (Figure 3.2-1 located in Appendix A). Agricultural structures found in the ROI in Regions 1 through 7 include concentrated animal feeding operations, barns, and silos, which are distributed throughout the ROI in each region. Center-pivot, mechanically irrigated, and precision-graded fields are also found in the ROI in Regions 1 through 7. Additionally, USDA-constructed dams are located within the ROI of Regions 3 and 4 (GIS Data Source: NRCS 2005). These dams were constructed primarily for flood control.

The market values for agriculture, crops, and livestock are provided in further detail in Section 3.13. Additionally, Section 3.13 provides information on agriculture for the counties that are within the ROI, based on data from the Agricultural Census (USDA 2014a).

Several route variations to the Applicant Proposed Route in Regions 2-7 were developed in response to public comments on the Draft EIS and are described in Appendix M and summarized in Sections 2.4.2.1–2.4.2.7. Comparisons in affected environment between the Applicant Proposed Route and the route variations by Project region, including accompanying HVDC alternative route adjustments, are provided below. The variations are presented graphically in Exhibit 1 of Appendix M.

3.2.5 Regional Description

3.2.5.1 Region 1

Region 1 is referred to as the Oklahoma Panhandle Region and includes the Applicant Proposed Route and HVDC Alternative Routes I-A through I-D, as well as the Oklahoma converter station, AC interconnection, and AC collection system routes. The ROI in Region 1 traverses through five counties in Oklahoma, Beaver, Cimarron, Harper, Texas, and Woodward. The majority land use is agriculture, which includes center-pivot irrigation and pasture/hay and is interspersed with well fields. Winter wheat is the primary crop (GIS Data Source: NASS 2013). Major cultivated crops represented within the AC collection system routes, which include winter wheat, pasture/hay, corn, sorghum, cotton, and alfalfa, are shown in Figure 3.2-1a in Appendix A. Table 3.2-2 summarizes the agricultural land use profiles for the ROI in Region 1, including the number of acres actively enrolled in the CRP in from 1996 through the end of June 2015 (FSA 2014a, 2014b). Agriculture is one of the major industries in the region; the market values for agriculture, crops, and livestock are provided below.

Table 3.2-2:
ROI Profile of Agriculture—Region 1

County	State	Percent of Land Area as Farm	Acres Enrolled in CRP	Market Value of Agriculture Products Sold	Market Value of Crops Sold	Market Value of Livestock and Product Sold
Texas	Oklahoma	99%	183,637.7	$1,013,921,000	$151,942,000	$861,980,000
Beaver	Oklahoma	96%	113,708.8	$186,990,000	$32,994,000	$153,996,000
Cimarron	Oklahoma	79%	117,177.3	$376,658,000	$65,716,000	$310,943,000
Harper	Oklahoma	93%	56,115.9	$148,726,000	$13,933,000	$134,793,000
Hansford	Texas	96%	18,244.7	$783,207,000	$110,704,000	$672,503,000
Ochiltree	Texas	93%	30,812.7	$424,605,000	62,118,000	362,487,000
Sherman	Texas	99%	89,429.2	$590,356,000	$129,479,000	$460,877,000

Source: USDA (2014c, 2014e), FSA (2014a, 2014b)

Within the ROI for the Applicant Proposed Route and the HVDC alternative routes, there are 122 agricultural structures. Within the ROI for the Oklahoma Converter Station Siting Area and the representative Oklahoma AC interconnection, there are no agricultural structures. Within the 13 AC collection system routes are 1,662 agricultural structures.

No route variations were proposed in Region 1.

3.2.5.2 Region 2

Region 2 is referred to as the Oklahoma Central Great Plains Region and includes the Applicant Proposed Route and HVDC Alternative Routes 2-A and 2-B. The ROI in Region 2 traverses Woodward, Major, and Garfield counties in Oklahoma. The majority land use is rangeland and cultivated crops and includes some regions considered to be the wheat belt of Oklahoma. Major cultivated crops represented in the area, such as alfalfa, winter wheat, sorghum, corn, and canola are grown in the ROI in this region (GIS Data Source: NASS 2013) and are shown in Figure 3.2-1b in Appendix A. Table 3.2-3 summarizes the agricultural land use profiles for the ROI in Region 2, including the number of acres actively enrolled in the CRP from 1996 through the end of June 2015 (FSA 2014a).

Table 3.2-3:
ROI Profile of Agriculture—Region 2

County	State	Percent of Land Area as Farm	Acres Enrolled in CRP	Market Value of Agriculture Products Sold	Market Value of Crops Sold	Market Value of Livestock and Product Sold
Woodward	Oklahoma	90%	15,643	$116,493,000	$15,665,000	$100,828,000
Major	Oklahoma	88%	11,766.4	$105,404,000	$41,325,000	$64,079,000
Garfield	Oklahoma	98%	4,790.8	$151,786,000	$93,745,000	$58,041,000

Source: USDA (2014c), FSA (2014a)

Fifty-six agricultural structures are present within the ROI for the Applicant Proposed Route and the HVDC alternative routes.

Two route variations to the Applicant Proposed Route were developed in Region 2 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.2. The variations are illustrated on Exhibit 1 in Appendix M. These variations represent minor adjustments to the Applicant Proposed Route. The agricultural land cover within the ROI is consistent with that described above for both Link 1, Variation 1, and Link 2, Variation 2.

3.2.5.3 Region 3

Region 3 is referred to as the Oklahoma Cross Timbers Region and includes the Applicant Proposed Route and HVDC Alternative Routes 3-A through 3-E. The ROI in Region 3 traverses Garfield, Kingfisher, Logan, Payne, Lincoln, Creek, Okmulgee, and Muskogee counties in Oklahoma. The majority land use is rangeland and cultivated crops and includes areas considered to be the wheat belt of Oklahoma. Major cultivated crops represented in the area, such as alfalfa, winter wheat, sorghum, rye, and canola are grown in the ROI in this region as shown in Figure 3.2-1c in Appendix A (GIS Data Source: NASS 2013). Table 3.2-4 summarizes the agricultural land use profiles for the ROI in Region 3, including the number of acres actively enrolled in the CRP from 1996 through the end of June 2015 (FSA 2014a).

Within the ROI for the Applicant Proposed Route and the HVDC alternative routes, there are 281 agricultural structures.

Table 3.2-4:
ROI Profile of Agriculture—Region 3

County	State	Percent of Land Area as Farm	Acres Enrolled in CRP	Market Value of Agriculture Products Sold	Market Value of Crops Sold	Market Value of Livestock and Product Sold
Kingfisher	Oklahoma	98%	2,570.5	$161,825,000	$63,461,000	$98,365,000
Logan	Oklahoma	76%	1,591.5	$43,985,000	$20,751,000	$23,234,000
Payne	Oklahoma	80%	0	$34,056,000	$9,009,000	$25,046,000
Lincoln	Oklahoma	73%	274.6	$38,730,000	$10,371,000	$28,359,000
Creek	Oklahoma	56%	0	$23,524,000	$4,474,000	$19,050,000
Okmulgee	Oklahoma	67%	0	$27,139,000	$7,519,000	$19,619,000
Muskogee	Oklahoma	65%	0	$50,557,000	$21,398,000	$29,159,000

Source: USDA (2014c), FSA (2014a)

Five route variations to the Applicant Proposed Route were developed in Region 3 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.3. The variations include Link 1, Variation 2; Links 1 and 2, Variation 1; Link 4, Variation 1; Link 4, Variation 2, and Link 5, Variation 2, and they are illustrated in Exhibit 1 in Appendix M. One route adjustment in this region was made for HVDC Alternative Route 3-A to maintain an end-to-end route with the Links 1 and 2 variations. This adjustment is also illustrated in Exhibit 1 in Appendix M. These variations represent minor changes to the Applicant Proposed Route. All of the route variations generally cross the same acreage of agricultural land cover when compared with the ROI in Region 3.

3.2.5.4 Region 4

Region 4 is referred to as the Arkansas River Valley Region and includes the Applicant Proposed Route and HVDC Alternative Routes 4-A through 4-E as well as the Lee Creek Variation. The ROI in Region 4 traverses Muskogee and Sequoyah counties in Oklahoma and Crawford, Franklin, Johnson, and Pope counties in Arkansas. The majority of land uses is pasture/hay. Major cultivated crops represented in the area, such as winter wheat, soybeans, rice, corn, and sorghum are grown in the ROI in this region and are shown in Figure 3.2-1d in Appendix A (GIS Data Source: NASS 2013). Table 3.2-5 summarizes the agricultural land use profiles for the ROI in Region 4, including the number of acres actively enrolled in the CRP from 1996 through the end of June 2015 (FSA 2014a, FSA 2015a).

Table 3.2-5:
ROI Profile of Agriculture—Region 4

County	State	Percent of Land Area as Farm	Acres Enrolled in CRP	Market Value of Agriculture Products Sold	Market Value of Crops Sold	Market Value of Livestock and Product Sold
Sequoyah	Oklahoma	47%	0	$55,485,000	$12,763,000	$42,721,000
Crawford	Arkansas	32%	721.9	$67,408,000	$22,542,000	$44,866,000
Franklin	Arkansas	40%	369.2	$158,178,000	$4,267,000	$153,911,000
Johnson	Arkansas	27%	63.1	$141,042,000	$4,335,000	$136,706,000

Source: USDA (2014b, 2014c), FSA (2014a, 2015a)

Within the ROI for the HVDC Applicant Proposed Route, the Lee Creek Variation, and the HVDC alternative routes, there are 436 agricultural structures. Table 3.10-8 in Section 3.10 provides agricultural land cover within the Lee Creek Variation in the Region 4 ROI. The Lee Creek Variation contains 5.8 percent grasslands/herbaceous land.

Seven route variations to the Applicant Proposed Route were developed in Region 4 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.4. The variations are illustrated in Exhibit 1 in Appendix M. These variations represent minor adjustments to the Applicant Proposed Route. Link 3, Variation 1, would parallel parcel boundaries but otherwise generally has the same amount of agricultural land cover as the original Applicant Proposed Route Link 3. Link 3, Variation 2, generally has the same amount of agricultural land cover as the original Applicant Proposed Route Link 3, and Link 3, Variation 3, generally has the same amount of agricultural land cover as the original Applicant Proposed Route Link 3. Link 6, Variation 1, generally has the same amount of agricultural land cover as the original Applicant Proposed Route Link 6 but would parallel parcel boundaries. Link 6, Variation 2, would avoid a WRP easement but otherwise generally has the same amount of agricultural land cover as the original Applicant Proposed Route Link 6. Link 6, Variation 3, and Link 9, Variation 1, generally each have the same amount of agricultural land cover as the original Applicant Proposed Route Links 6 and 9.

3.2.5.5 Region 5

Region 5 is referred to as the Central Arkansas Region and includes the Applicant Proposed Route and HVDC Alternative Routes 5-A through 5-F. The ROI in Region 5 traverses Pope, Conway, Van Buren, Cleburne, White, and Jackson counties in Arkansas. The majority land uses include pasture/hay and cultivated crops. Approximately 4.5 percent of the ROI in Region 5 consists of cultivated crops. Section 3.10 presents detailed information on the land cover for the Project. Major cultivated crops represented in the area, such as winter wheat, soybeans, rice, and corn are grown in the ROI in this region and are shown in Figure 3.2-1e in Appendix A (GIS Data Source: NASS 2013). Table 3.2-6 summarizes the agricultural land use profiles for the ROI in Region 5. Within the ROI for the Applicant Proposed Route, the HVDC alternative routes, the Arkansas Converter Station Siting Area, the AC Interconnection Siting Area, and new substation are 218 agricultural structures. Table 3.2-6 summarizes the agricultural land use profiles for the ROI in Region 5, including the number of acres actively enrolled in the CRP from 1996 through the end of June 2015 (FSA 2015a).

Table 3.2-6:
ROI Profile of Agriculture—Region 5

County	State	Percent of Land Area as Farm	Acres Enrolled in CRP	Market Value of Agriculture Products Sold	Market Value of Crops Sold	Market Value of Livestock and Product Sold
Pope	Arkansas	29%	1,946.1	$150,102,000	$10,396,000	$139,706,000
Conway	Arkansas	53%	192	$133,581,000	10,926,000	$122,655,000
Van Buren	Arkansas	27%	0	$19,947,000	$1,067,000	$18,880,0000
Cleburne	Arkansas	42%	130.2	$47,871,000	$1,195,000	$46,675,000
Faulkner	Arkansas	43%	1,709.9	$26,257,000	$10,067,000	$16,190,000
White	Arkansas	53%	19,220.6	$100,373,000	$39,106,000	$61,267,000
Jackson	Arkansas	75%	9,960.4	$215,265,000	$196,405,000	$18,861,000

Source: USDA (2014b), FSA (2015a)

Five route variations to the Applicant Proposed Route were developed in Region 5 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.5. The variations are illustrated in Exhibit 1 in Appendix M. These variations represent minor adjustments to the Applicant Proposed Route. Link 1, Variation 2, has generally the same amount of agricultural land cover as the original Applicant Proposed Route Link 1. Link 2, Variation 2, crosses less pasture/hay than the ROI for the original Applicant Proposed Route Link 2. Links 2 and 3, Variation 1, has generally the same amount of agricultural land cover as the original Applicant Proposed Route Links 2 and 3. Additionally, a route adjustment was made for HVDC Alternative Route 5-B to maintain an end-to-end route with Links 2 and 3, Variation 1. Links 3 and 4, Variation 2, more closely parallels parcel boundaries than the original Applicant Proposed Route Links 3 and 4; a route adjustment was made for HVDC Alternative Route 5-E to maintain an end-to-end route with this proposed variation. Link 7, Variation 1, generally has the same amount of agricultural land as Link 7 of the original Applicant Proposed Route.

3.2.5.6 Region 6

Region 6 is referred to as the Cache River and Crowley's Ridge Region and includes the Applicant Proposed Route and HVDC Alternative Routes 6-A through 6-D. The majority of the land (from 70 to 80 percent of the land area) in the counties crossed by the ROI for Region 6 (Cross, and Poinsett Counties in Arkansas) is used for agriculture. See Table 3.13-9 and Table 3.2-7 for further information. The majority of the agricultural land in theses counties is irrigated cropland. Groundwater is the source for most irrigation water used in these counties. Common irrigation systems in these areas include furrow and flood systems, with overhead sprinkler (center-pivot) irrigation also present, but to a lesser extent (see Appendix H). Major cultivated crops represented in the area, such as winter wheat, soybeans, rice, and corn are grown in the ROI in this region and are shown in Figure 3.2-1f in Appendix A (GIS Data Source: NASS 2013). Rice grown in Arkansas is 100 percent irrigated. Corn requires timely irrigation to maximize its yield potential and is almost entirely irrigated in the region. The majority of cotton and soybean acres are also irrigated in the three counties crossed by the ROI in Region 6 (see Appendix H). Table 3.2-7 summarizes the agricultural land use profiles for the ROI in Region 6, including the number of acres actively enrolled in the CRP from 1996 through the end of June 2015 (FSA 2015a). Within the ROI for the Applicant Proposed Route and the HVDC alternative routes are 40 agricultural structures.

Table 3.2-7:
ROI Profile of Agriculture—Region 6

County	State	Percent of Land Area as Farm	Acres Enrolled in CRP	Market Value of Agriculture Products Sold	Market Value of Crops Sold	Market Value of Livestock and Product Sold
Cross	Arkansas	70%	11,167.3	$215,016,000	$214,685,000	$331,000
Poinsett	Arkansas	79%	2,824.5	$287,420,000	$286,746,000	$674,000

Source: USDA (2014b), FSA (2015a)

One route variation was developed to the Applicant Proposed Route in Region 6 in response to public comments on the Draft EIS. The route variation is described in Appendix M and summarized in Section 2.4.2.6. The variation is illustrated in Exhibit 1 in Appendix M. This variation represents minor adjustments to the Applicant Proposed Route. Link 2, Variation 1, generally has the same amount of agricultural land cover as the ROI for Link 2 of the original Applicant Proposed Route. Additionally, a route adjustment was made for HVDC Alternative Route 6-A to maintain an end-to-end route with the Applicant Proposed Route Link 2, Variation 1.

3.2.5.7 Region 7

Region 7 is referred to as the Arkansas Mississippi River Delta and Tennessee Region and includes the Applicant Proposed Route and HVDC Alternative Routes 7-A through 7-D. The ROI in Region 7 traverses Poinsett and Mississippi counties in Arkansas and Tipton and Shelby counties in Tennessee. The irrigated agriculture overview presented above for Jackson, Cross, and Poinsett counties in Region 6 also apply to the Arkansas counties crossed by the ROI for Region 7. Major cultivated crops represented in the area, such as corn, soybeans, winter wheat, and cotton are grown in the ROI in this region and are shown in Figure 3.2-1f in Appendix A (GIS Data Source: NASS 2013). Extensive cultivated crops have replaced the historical wetlands. Table 3.2-8 summarizes the agricultural land use profiles for the ROI in Region 6, including the number of acres actively enrolled from 1996 through the end of June 2015 (FSA 2015a, 2015b). There are also approximately 17 acres of WRP land in the ROI. Within the ROI for the Applicant Proposed Route, the HVDC alternative routes, and the Tennessee Converter Station Siting Area are 73 agricultural structures.

Table 3.2-8:
ROI Profile of Agriculture—Region 7

County[1]	State	Percent of Land Area as Farm	Acres Enrolled in CRP	Market Value of Agriculture Products Sold	Market Value of Crops Sold	Market Value of Livestock and Product Sold
Mississippi	Arkansas	81%	1,241.3	$314,647,000	$314,464,000	$183,000
Shelby	Tennessee	16%	1,637.4	$31,806,000	$29,977,000	$1,829,000
Tipton	Tennessee	58%	228	$32,027,000	34,344,000	2,683,000

1 The respective route alternatives do not go through the same counties as listed in the table above.
Source: USDA (2014b, 2014d), FSA (2015a, 2015b)

Three route variations to the Applicant Proposed Route were developed in Region 7 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.7. The variations are illustrated in Exhibit 1 in Appendix M. Applicant Proposed Route Link 1, Variation 1; Link 1, Variation 2; and Link 5, Variation 1, each generally has the same amount of agricultural land cover as the ROI for the original Applicant Proposed Route.

3.2.5.8 Connected Actions

3.2.5.8.1 Wind Energy Generation

Land cover in the WDZs is primarily cultivated crops and grassland/herbaceous. The land cover in each WDZ is summarized in Section 3.10. Existing agricultural land uses in the WDZs include irrigated and dry cultivated crops and feedlots. Agricultural structures in the WDZs include barns and silos. Additionally, rural residences are scattered on large parcels of land and generally surrounded by agricultural land uses.

Table 3.2-9 summarizes the agricultural land use profiles for the WDZs. Agriculture is one of the major industries in the counties where the WDZs are located; the market values for agriculture, crops, and livestock are provided in Table 3.2-9. Section 3.13 describes socioeconomic impacts in detail.

Table 3.10-12 presents the land cover in each respective WDZ. The number of acres enrolled in CRP in 2007 is available and presented in the table below (USDA 2014a).

Table 3.2-9:
ROI Profile of Agriculture—WDZ Analysis in Oklahoma and Texas

County	State	Percent of Land Area as Farm	Acres Enrolled in CRP	Market Value of Agriculture Products Sold	Market Value of Crops Sold	Market Value of Livestock and Product Sold
Beaver	Oklahoma	96%	113,708.8	$186,990,000	$32,994,000	$153,996,000
Cimarron	Oklahoma	79%	117,177.3	$376,658,000	$65,716,000	$310,943,000
Texas	Oklahoma	99%	183,637.7	$1,013,921,000	$151,942,000	$861,980,000
Hansford	Texas	96%	18,244.7	$783,207,000	$110,704,000	$672,503,000
Ochiltree	Texas	93%	30,802.7	$424,605,000	62,118,000	362,487,000
Sherman	Texas	99%	89,429.2	$590,356,000	$129,479,000	$460,877,000

1 Withheld to avoid disclosing data for individual farms.

Source: USDA (2014a), FSA (2014a, 2014b)

3.2.5.8.1.1 WDZ-A

The predominant land cover in WDZ-A is approximately 60.3 percent cultivated crops. Additionally, the agricultural land cover is 26.1 percent grassland/herbaceous and 0 percent pasture/hay.

3.2.5.8.1.2 WDZ-B

The predominant land cover in WDZ-B is 53.2 percent cultivated crops. Additionally, the agricultural land cover is 37.8 percent grassland/herbaceous and 0 percent pasture/hay. Central-pivot irrigation is found throughout the WDZ.

3.2.5.8.1.3 WDZ-C

The predominant land cover in WDZ-C is 52.8 percent grassland/herbaceous; the agricultural land cover is 38.8 percent cultivated crops and 0 percent is pasture/hay.

Center-pivot irrigation is found throughout the WDZ and a concentrated animal feeding operation is located in the western portion of the WDZ southeast of Stratford, Texas.

3.2.5.8.1.4 WDZ-D

The predominant land cover in WDZ-D is 69.3 percent grass and/herbaceous; the agricultural land cover is up to 17.8 percent cultivated crops and 0 percent is pasture/hay. Transmission lines and center-pivot irrigation are present in the northern and southern portions of the WDZ.

3.2.5.8.1.5 WDZ-E

The predominant land cover in WDZ-E is 57.0 percent cultivated crops; the agricultural land cover is 31.9 percent grassland/herbaceous and 0 percent is pasture/hay.

3.2.5.8.1.6 WDZ-F

The predominant land cover in WDZ-F is 67.0 percent grassland/herbaceous; the agricultural land cover is up to 25.4 percent cultivated crops and 0 percent is pasture/hay. Center-pivot irrigation is found throughout the WDZ.

3.2.5.8.1.7 WDZ-G

The predominant land cover in WDZ-G is 53.0 percent grassland/herbaceous; the agricultural land cover is up to 40.5 percent cultivated crops and 0 percent is pasture/hay. A few parcels with central-pivot irrigation are located in the northern portion of the WDZ.

3.2.5.8.1.8 WDZ-H

The predominant land cover in WDZ-H is 81.5 percent grassland/herbaceous; the agricultural land cover is 12.9 percent cultivated crops and 0 percent is pasture/hay. A few parcels have center-pivot irrigation.

3.2.5.8.1.9 WDZ-I

The predominant land cover in WDZ-I is 61.1 percent cultivated crops; the agricultural land cover is 23.8 percent is grassland/herbaceous and 0 percent is pasture/hay.

Center-pivot irrigation is found primarily in the central portion of the WDZ. Concentrated animal feeding operations are also found in the WDZ.

3.2.5.8.1.10 WDZ-J

The predominant land cover in WDZ-J is 73.6 percent grassland/herbaceous; the agricultural land cover is 12.9 percent cultivated crops and 0 percent is pasture/hay.

Some central-pivot irrigation structures are present in the central portion of the WDZ.

3.2.5.8.1.11 WDZ-K

The agricultural land cover in WDZ-K is 46.5 percent cultivated crops; the agricultural land cover is 42.2 percent grassland/herbaceous and 0 percent is pasture/hay. Existing infrastructure includes transmission lines and some scattered center-pivot irrigation.

3.2.5.8.1.12 WDZ-L

The predominant land cover in WDZ-L is 55.2 percent cultivated crops; the agricultural land cover is 28.4 percent grassland/herbaceous and 0 percent is pasture/hay. Center-pivot irrigation is found throughout the WDZ.

3.2.5.8.2 Optima Substation

The land cover in the future Optima substation location is primarily grassland/herbaceous. There are no structures or existing infrastructure on the 160-acre site, although there are roads and an operating wind farm nearby. Cultivated crops are located south of the Optima substation, while grassland/herbaceous is the predominant agricultural land cover that surrounds the Optima substation.

3.2.5.8.3 TVA Upgrades

The ROI for the direct assignment facilities (which are included in the Applicant Proposed Project) would occur within the Tennessee Converter Station Siting Area and more specifically within the Shelby Substation. The ROI for the network upgrades, and in particular TVA's future 500kV transmission line, cannot be fully determined at this time. The new 500kV line would be constructed in western Tennessee, where agricultural lands are common and cultivated crops, grassland/herbaceous, and pasture/hay are dominant land covers. The upgrades to existing facilities would mostly be in western and central Tennessee. Upgrades to existing infrastructure would include upgrading terminal equipment at three existing 500kV substations and six existing 161kV substations, making appropriate upgrades to increase heights on 16 existing 161kV transmission lines to increase line ratings, and replacing the conductors on eight existing 161kV transmission lines. Where possible, general impacts associated with the required TVA upgrades are discussed qualitatively as described below.

3.2.6 Impacts to Agricultural Resources

The majority of the land crossed by the Project is used for agriculture, including grassland/herbaceous, cultivated crops, and pasture/hay. The analysis includes the potential for direct impacts to agricultural land from construction of the Project as well as on agricultural structures such as barns or storage silos. Potential indirect impacts to agricultural production to adjacent land and from impacts to aerial applications of fertilizer, insecticide, and herbicide and socioeconomic impacts to farmers and ranchers as a result of the impacts to the agricultural land are also discussed.

Impacts to agricultural structures are discussed in Sections 3.2.6.2 and 3.2.6.3.

3.2.6.1 Methodology

To identify potential impacts to agriculture that may result from construction and operations and maintenance of the Project, the analysis of the HVDC transmission line route alternatives, the Oklahoma and Arkansas AC interconnection lines, the Tennessee, Oklahoma, and Arkansas converter stations, and the high voltage AC collection line in Oklahoma was based on a desktop review of existing land uses within a representative centerline developed for each route alternative, data from the National Land Cover Dataset, and several online research sites that are listed in Section 6.5. A 200-foot-wide representative ROW (100 feet on each side) centered on the representative centerline was developed. Section 3.10.6 presents a more detailed discussion of the specific footprint that would be affected during each phase of the Project. In the impacts discussion, the number and type of structures within the ROW are listed, although it is assumed that the displacement of structures would be avoided in the final engineering and design of the Project.

DOE has consulted with the state NRCS offices in Oklahoma, Arkansas, and Tennessee concerning impacts to farmland protected under the FPPA and has received a determination from the agencies that the transmission lines do not irreversibly convert farmland (Sagona 2014; Adams 2014). Further, this determination has been seconded by the NRCS National Leader for the FPPA. It should be noted, however, that this determination does not apply to the converter stations, the construction of which would potentially convert farmland and would require a Form AD-1006 be submitted for evaluation. The locations of access roads needed for the Project have not yet been determined; however, the Applicant would avoid placement of permanent access roads through farmland. Once the exact locations of Project components have been determined, a farmland conversion assessment would be completed by the NRCS for any remaining components for which the NRCS has not yet issued a determination. DOE is currently consulting with the NRCS to determine potential impacts to prime farmland associated with the converter stations.

Impacts to agriculture in eastern Arkansas were assessed using information from the Arkansas Delta Agricultural Economic Impact Study prepared for the Project. This agricultural economic impact study, which focuses on four counties in eastern Arkansas: Jackson (Regions 5 and 6), Cross (Region 6), Poinsett (Regions 6 and 7), and

Mississippi (Region 7), is included as Appendix J to this EIS. The study was prepared under the direction of the Applicant and independently reviewed by DOE.

The Applicant has developed a comprehensive list of EPMs to be integrated into the Project. Implementation of these EPMs is assumed throughout the impact analysis that follows for both the Applicant Proposed Project and the DOE Alternatives. Section 3.1 describes the EPMs in more detail. A complete list of EPMs for the Project is provided in Appendix F; those EPMs that are applicable to agricultural resources are listed below:

- GE-3: Clean Line will minimize clearing vegetation within the ROW, consistent with a Transmission Vegetation Management Plan filed with NERC, and applicable federal, state, and local regulations. The TVMP may require additional analysis under NEPA depending on whether and under what conditions DOE decides to participate in the Project.
- GE-7: Roads not otherwise needed for maintenance and operations will be restored to preconstruction conditions. Restoration practices may include decompacting, recontouring, and re-seeding. Roads needed for maintenance and operations will be retained.
- GE-8: Access controls (e.g., cattle guards, fences, gates) will be installed, maintained, repaired, replaced, or restored as required by regulation, road authority, or as agreed to by landowner.
- GE-9: Clean Line will avoid and/or minimize damage to drainage features and other improvements such as ditches, culverts, levees, tiles, and terraces; however, if these features or improvements are inadvertently damaged, they will be repaired and or restored.
- GE-10: Clean Line will work with landowners to repair damage caused by construction, operation, or maintenance activities of the Project. Repairs will take place in a timely manner, weather and landowner permitting.
- GE-11: Clean Line will conduct construction, operation, and maintenance activities to minimize the creation of dust. This may include measures such as limitations on equipment, speed, and/or travel routes utilized. Water, dust palliative, gravel, combinations of these, or similar control measures may be used. Clean Line will implement measures to minimize the transfer of mud onto public roads.
- GE-27: Clean Line will minimize compaction of soils and rutting through appropriate use of construction equipment (e.g., low ground pressure equipment and temporary equipment mats).
- LU-1: Clean Line will work with landowners and operators to ensure that access is maintained as needed to existing operations (e.g., to oil/gas wells, private lands, agricultural areas, pastures, hunting leases).
- LU-2: Clean Line will minimize the frequency and duration of road closures.
- LU-3: Clean Line will work with landowners to avoid and minimize impacts to residential landscaping.
- LU-4: Clean Line will coordinate with landowners to site access roads and temporary construction areas to avoid and/or minimize impacts to existing operations and structures.
- LU-5: Clean Line will make reasonable efforts, consistent with design criteria, to accommodate requests from individual landowners to adjust the siting of the ROW on their properties. These adjustments may include consideration of routes along or parallel to existing divisions of land (e.g., agricultural fields and parcel boundaries) and existing compatible linear infrastructure (e.g., roads, transmission lines, and pipelines), with the intent of reducing the impact of the ROW on private properties.
- AG-1: Clean Line will avoid or minimize adverse effects to surface and subsurface irrigation and drainage systems (e.g., tiles). Clean Line will work with landowners to minimize the placement of structures in locations that would interfere with the operation of irrigation systems.

- AG-2: Agricultural soils temporarily impacted by construction, operation, or maintenance activities will be restored to pre-activity conditions. For example, soil remediation efforts may include decompaction, recontouring, liming, tillage, fertilization, or use of other soil amendments.
- AG-3: Clean Line will consult with landowners and/or tenants to identify the location and boundaries of agriculture or conservation reserve lands and to understand the criteria for maintaining the integrity of these committed lands.
- AG-4: Clean Line will work with landowners and/or tenants to identify specialty agricultural crops or lands (e.g., certified organic crops or products that require special practices, techniques, or standards) that may require protection during construction, operation, or maintenance. Clean Line will avoid and/or minimize impacts that could jeopardize standards or certifications that support specialty croplands or farms.
- AG-5: Clean Line will work with landowners and/or tenants to consider potential impacts to current aerial spraying or application (i.e., aerial crop spraying) of herbicides, fungicides, pesticides, and fertilizers within or near the transmission ROW. Clean Line will avoid or minimize impacts to aerial spraying practices when routing and siting the transmission line and related infrastructure.
- AG-6: Clean Line will work with landowners to develop compensation for lost crop value caused by construction and/or maintenance.
- AG-7: Clean Line will work with landowners to develop a site plan for each cropland farm on which construction or maintenance is to be performed.
- GEO-1: Clean Line will stabilize slopes exposed by its activities to minimize erosion.

3.2.6.2 Impacts Associated with the Applicant Proposed Project

This section describes the potential impacts from the Project that would be common to the converter stations, AC interconnection, AC collection system routes, and Applicant Proposed Routes that are all part of the Applicant Proposed Project. Impacts from the construction, operations and maintenance, and decommissioning of the Applicant Proposed Project are discussed separately by Project component.

General Agriculture

Temporary impacts on agriculture productivity during construction could potentially occur as a result of vegetation, and soil disturbance or loss. Impacts to pasture and cultivated crops in the construction area would be temporary and would include the temporary loss of vegetation and soils. Additionally, vegetation would be lost when grading is required and along travel routes, or roads that construction equipment travel on to a construction destination, for construction vehicles and equipment. Additional impacts to soils are provided in Section 3.6.2. Figure 3.2-1a–f in Appendix A depicts agricultural lands that are located within the ROI and ROW.

Direct impacts to agricultural structures, such as barns, ponds, silos, and animal feeding operations, within the representative ROW would be minimal. The number of agricultural structures for each alternative is presented in Section 3.2.6.2.2.1. The Project could limit future expansion of existing structures in the long term since construction of new structures would be prohibited within the Project representative ROW. Potential impacts would occur in Regions 1 through 7.

Impacts to agriculture during operations and maintenance of the Project are expected to be minimal in most areas because the majority of the representative ROW could be used for grazing and cultivated crops, if it is already being used as agricultural land, once construction has been completed. Section 3.2.6.2 discusses the operation and maintenance impacts to agriculture. Maintenance of the Project facilities may occasionally disrupt agricultural activities and production on a localized basis. In addition, the transmission structures may interfere with farming equipment and the transmission lines and poles may interfere with aerial spraying of herbicides, pesticides, fungicides, and fertilizer.

DOE prepared an example construction sequence and timeline to illustrate typical construction activities that could take place on a single parcel of land being used for agricultural operations. This list of activities is provided as Table 3.2-10. Impacts to specific categories of agriculture are discussed below.

Table 3.2-10:
Typical Construction Activities on Agricultural Property

Activity	Access Typically Restricted?	Duration (Days)	Description[1]
ROW Mowing and/or Clearing	Yes	1 to 2	Mowing equipment enters from adjoining parcel and mows portions of the ROW. The area mowed would include an access path down the ROW (approximately 16 to 35 feet wide) and two areas (each 100 feet by 100 feet) for future structure construction pads. Access to the construction area is restricted during mowing operations for safety.
None	No	3 to 14	There is a period of inactivity between mowing and/or clearing (above) and the beginning of surveying and staking (below). This period may be shorter or longer depending on construction schedule.
Survey and Staking	No	15	A survey crew stakes each structure location with wooden lath.
Install Stormwater Protection Measures	No	16	According to state requirements, any stormwater protection measures (e.g., silt fences) are installed. Silt fences would be discontinuous, and would not limit livestock movement. Installation of a silt fence typically requires one or two pickup trucks with trailers, possibly a small excavator, and a small crew of workers.
Drill and Pour Foundations	Partially	17 to 19	Auger equipment drills holes for footings, rebar cages are set, concrete trucks deliver concrete to the pad, stub angles are set, and concrete is poured into holes and mold surrounding stub angles. Access is prohibited in a small area within a protective fence around foundation sites and is periodically restricted around the construction area so that trucks and other equipment can be moved safely.
None (Concrete Curing)	Partially	20 to 22	Access to ROW is not restricted, except for a small area within a protective fence around foundation sites.
Remove Concrete Forms	Partially	23	Access to ROW is not restricted, except for a small area within a protective fence around foundation sites.
None (Concrete Curing)	Partially	24 to 33	Access to ROW is not restricted, except for a small area within a protective fence around foundation sites.
Equipment Setup, Assembly, and Structure Erection	Partially	34 to 41	Structure material is delivered to each structure site with a heavy truck, structure sections are assembled, and sections are lifted by crane and set into place. Access to ROW may be periodically restricted around the construction area so that trucks, cranes, and other equipment can be moved safely.
Insulator Assemblies Fixed To Structure	Partially	42	Insulators and associated hardware are pre-assembled into strings, and the strings are then lifted by crane or lift truck and fixed to tower arms. Access to ROW is periodically restricted around the construction area so that the trucks, cranes, and other equipment can be moved safely.
None	Partially	42 to 86	There is a period of inactivity between the end of insulator installation (above) and the beginning of wire stringing (below). This period may be shorter or longer depending on location and site conditions. During this period, access to the ROW outside the structure pads is unrestricted.
Sock and Pilot Line Threading	Yes	87	A helicopter lifts a light weight sock/pilot line, which is threaded through rollers attached to the insulators. During stringing operations, access to the ROW is restricted for safety.

Table 3.2-10:
Typical Construction Activities on Agricultural Property

Activity	Access Typically Restricted?	Duration (Days)	Description[1]
Conductor Pulling and Tensioning	Yes	88 to 92	Conductor is attached to the end of the sock/pilot and pulled through. Pulling and tensioning equipment (located on other parcels in this example) ensure that the proper clearance and sag is achieved for each span of the conductor. During stringing operations, access to the ROW is restricted for safety.
Clipping In	Yes	93	Conductor is permanently attached ("clipped in") to hardware connection at the end of insulator strings using one to three bucket trucks. Access to ROW is periodically restricted around the construction area so that the trucks and other equipment can be moved safely.
None	No	94 to 122	There is a period of inactivity between the end of clipping in and the start of final restoration activities. This lag could be considerably shorter, depending on season and site conditions.

1 This list of activities is hypothetical and does not represent specific activities that would occur on any specific piece of agricultural land. Assumptions and notes include the following:
a. One-half mile (0.5 mile) of HVDC ROW on parcel.
b. Two tangent structures planned within parcel.
c. No grading required.
d. Access obtained via driving overland through the ROW from adjoining parcels with existing gates.
e. ROW has been previously surveyed and clearing boundaries have been staked.
f. Inspection and monitoring activities during construction may require intermittent access to the ROW between activities identified.
g. Breaks will occur in the construction process and the duration of these breaks may vary from the periods of time identified.

Livestock Grazing

Construction could affect livestock grazing by temporarily reducing forage areas in the representative ROW. Except while access to the ROW is temporarily restricted during construction, operations, and maintenance for safety reasons, livestock would not be displaced or prohibited from grazing in pastures overlapped by the ROW during construction, unless otherwise desired by the landowner. Construction activities during which restrictions to the ROW may occur are identified in the construction sequence and timeline provided in Table 3.2-10. Construction may affect livestock control and distribution if a gate is left open or a fence is damaged, as livestock may not be contained and may escape. Vehicular access during construction would increase the likelihood of livestock injury or death from collisions.

Once the Project has been constructed, livestock would be permitted to graze around Project features. Direct impacts to rangeland could include long-term loss of vegetation from structure foundations and permanent access roads. During Project operations, grazing land occupied by support structures, substations, or access roads would no longer be available for grazing. The acres of lands used for livestock and grazing that would be affected by the Project represent a small share of the total acres used for livestock area within the representative ROW and would result in relatively small temporary and long-term reductions in the area available for grazing within the representative ROW.

Crop Production

Construction would temporarily prevent or reduce crop production in the representative ROW. Potential impacts may extend outside the construction area due to access constraints, impacts to irrigation structures, and/or pesticide or fertilizer application practices. Access constraints could result in a diminished yield in and near the construction area if other methods of irrigation and fertilizer, insecticide, and herbicide application are not practical. Potential economic impacts related to cultivated crop impacts are discussed in Section 3.13.

During Project operations, the physical footprint of structures, substations, and access roads would displace cultivated crops. Tractors, combines, and other mechanized equipment would be required to maneuver around structures and would result in damage or destruction of crops that are growing within or around the structure footprint at the time of construction (see Appendix J). Structures and conductors could limit the aerial application of fertilizer, herbicide, and pesticide and could result in a diminished harvest. Crop production that involves mechanical irrigation, automated farming methods, or farming equipment with large spans (up to 100 feet) could also be adversely affected by the placement of overhead conductors and support structures. Production costs increase where farmers have to divert their equipment around structures, make additional passes, take additional time to maneuver, reconfigure surface drainage, skip acres, or re-treat acres.

In most cases, structures can be located strategically to allow existing pivots to continue to operate without adverse effects and interruption of agricultural activity.

Center-pivot Irrigation

Potential temporary impacts to center-pivot irrigation could occur primarily in Regions 1, 2, 6, and 7. The operation of center-pivot irrigation during construction could be limited in construction areas. Construction equipment at tensioning and pulling sites and structure work areas could prevent the movement of irrigation systems if construction occurs during the growing season, which would prevent portions of the field from being irrigated.

Project operation, schedule maintenance, and unscheduled repairs due to storm damage have the potential to damage crops and agricultural water management systems such as center-pivot irrigation. The Applicant would avoid or minimize adverse effects to surface and subsurface irrigation and drainage systems (e.g., tiles). The Applicant would work with landowners to minimize the placement of structures in locations that would interfere with the operation of irrigation systems (AG-1). Additionally, Project inspections could be performed outside areas of the fields. The Applicant would work with landowners to develop compensation for lost crop value caused by construction and/or maintenance (AG-6) and would work with landowners to develop a site plan for each cropland farm on which construction or maintenance would be performed (AG-7).

The representative 200-foot-wide ROW for the Applicant Proposed Route or HVDC alternative routes would cross agricultural fields that are irrigated by center pivots. Agricultural operations in these areas could be limited in the long term depending on the location of the transmission structures. Project components could prevent portions of fields from being irrigated by blocking the movement of the irrigation system. Direct impacts could potentially occur in Regions 1, 2, 6, and 7. The Applicant would avoid or minimize adverse effects to surface and subsurface irrigation and drainage systems (e.g., tiles). The Applicant would work with landowners to minimize the placement of structures in locations that would interfere with the operation of irrigation systems (AG-1). The resulting dryland area could be measured and the affected parties could be compensated for the decreased productivity that results (see Appendix H).

Flood Irrigation

During construction, access roads, temporary work areas, and other graded areas could temporarily disrupt the slope and flow patterns of water on flood-irrigated fields, such as rice fields in eastern Arkansas. This impact would vary depending on the location of the Project and whether it is located upslope or downslope. Soils within the representative ROW and construction area would be temporarily compacted. Construction activities could temporarily limit access to flood-irrigated fields or impair normal agricultural operations. In some cases, landowners or tenants would need to work around transmission structure construction sites when they are surveying and constructing new levees. In flooded irrigation systems, the landowners or tenants may have to move the levee to avoid the structure, which could result in the levees being out of position (see Appendix J). These direct impacts could result in a diminished yield and, dependent on the timing of construction, a loss of rice-growing opportunity inside and/or outside of the representative ROW.

During operations and maintenance, the Applicant would allow agricultural activities to resume within the ROW. Following completion of construction, the Applicant would return all slopes to preconstruction conditions as part of final reclamation so that flood irrigation can be resumed in areas that may have been previously impacted or disrupted. The presence of transmission line structures in fields would not prohibit the flow of flood water, because water can flow around structure foundations. In furrow-irrigated fields, however, structures may obstruct continuous furrows (when beds are formed, a continuous furrow is created from the top of the field to the bottom) and farmers may be required to do additional work in rows where furrows do not align with equipment. Maneuvering equipment around structures in these areas could interrupt field operations and require more time to till the field. This disruption could have a long-term impact by diminishing crop production in localized areas downhill from the water source.

Global Navigation Satellite Systems

Farming equipment often use Global Navigation Satellite Systems (GNSS) for automated steering, custom geographic seeding and fertilizing and harvest yield mapping. Regarding the issue of GNSS interference from overhead high voltage transmission lines, research performed on the impacts did not reveal a problem for the high-quality receivers used in precision agriculture or agriculture-related aviation. No effect due to transmission line on GNSS measurements was found to impact the quality of the GNSS (Bancroft et al. 2012).

Aerial Crop Spraying

Aerial crop spraying is common in the region where there is agricultural land. Aerial crop spraying is used to apply fertilizer, fungicides, or pesticides during the growing season. Aerial crop spraying is supported by a network of controlled airports and secondary airstrips. Aerial crop spraying can involve dry applications (usually fertilizer) and liquid applications of fungicides and pesticides. The typical aircraft used for aerial application is a fixed single-wing plane, which are typically equipped with digital global positioning systems or other guidance systems. Typically, liquid applications are applied from 8 feet to 12 feet above the target; while dry applications are applied from 45 feet to 70 feet above targeted land (see Appendix H).

The adjacent swath is the most common flight pattern used in crop fields, which involves the use of straight, parallel swaths to apply products in a back and forth pattern. Applicators are accustomed to turning their spray on and off to avoid overlapping or missing spots; they are also accustomed to maneuvering around obstacles in fields (see Appendix H).

Spraying operations occur 24 hours a day, depending on the time of season; nighttime operations occur when bees are pollinating crops during daylight hours. The quantity of farmed land receiving aerial crop spraying in and near the representative ROW is not known. As a result, the following analysis assumes that any dryland or irrigated farmland could receive aerial spraying.

Construction of the transmission line could reduce the area of crops that could be treated by aerial spraying. Transmission structures or construction cranes could interfere with the flight paths of aerial applications. The potential effects would vary, depending on the location of tall structures relative to crop planting patterns, and the presence of other tall structures. Aerial spraying is also sometimes used to control large-scale insect infestations on public and private land. The short-term inability to use aerial spraying could reduce productivity and cause economic effects to farming or rangeland operations. The presence of construction workers could also delay applications.

Once construction has been completed, aerial crop spraying planes could fly at a higher altitude to avoid transmission lines and structures. A common method to maneuver around obstacles in fields is to "trim" the edge of a field by flying perpendicular to the direction the field was flown. Another approach is to stop spraying as the obstacle is approached, turn at 360 degrees, fly over the obstacle, then drop back down and continue spraying. Applicators can fly beneath the lines or wires in cases where transmission lines and other wires are positioned high enough. It may be possible to spray over the top of the obstruction in situations where the transmission lines or wires are low (see Appendix H).

However, this could result in a less precise application of fertilizer, herbicide, and pesticide, and these treatments could spill into adjacent fields. Additionally, impacts associated with aerial application could extend beyond the representative ROW as a result of the need to fly over transmission lines. Although the Applicant has made efforts to site the transmission lines adjacent to existing infrastructure, impacts may still occur in these areas due to structure heights that are taller than existing structure heights and a wider area that aerial applications must avoid.

EPMs that would avoid the impacts to agriculture are discussed in Section 3.2.6.1.

3.2.6.2.1 Converter Stations and AC Interconnection Siting Areas

This section describes the impacts to agriculture from the converter stations on either end of the HVDC transmission line and their associated AC interconnection lines. Impacts from the construction, operations and maintenance, and decommissioning of the various Project components are discussed separately under each subsection. Section 3.13 provides additional information on the socioeconomic agricultural impacts.

3.2.6.2.1.1 Construction Impacts

Direct agricultural impacts during construction would consist of long-term conversion of land for the converter station and temporary conversion of land within the representative ROW for the AC interconnection line. Potential impacts to agriculture from the construction of the Oklahoma and Tennessee converter stations and their associated AC interconnection lines are discussed below. Construction of a single converter station is estimated to take 32 months.

3.2.6.2.1.1.1 Oklahoma Converter Station Siting Area and AC Interconnection Siting Area

The Oklahoma converter station would be located on undeveloped rangeland; approximately 95 percent of the land cover in the siting area is grassland/herbaceous. Construction of the converter station would convert 45 to 60 acres of rangeland to a utility land use. During construction, an additional 5 to 10 acres would be used as temporary laydown areas for equipment. An additional 4.2 acres of rangeland would be converted to access roads (2.4 acres long term, 1.8 acres temporary). Temporary construction areas that would be required outside the representative ROW include fiber optic regeneration sites, multi-use construction yards, and fly yards.

The Oklahoma AC interconnection would be approximately 3 miles long. The agricultural land cover in the representative ROW is currently composed of 58 acres of grasslands. Work in the representative ROW would include assembly of pole structures, wire splicing, and tensioning or pulling sites. A 25-acre multi-use construction yard required for the Oklahoma AC interconnection would be shared with that of the HVDC line.

During construction, assembly areas for the pole structures (either lattice or tubular structures) would be required, as would wire splicing sites and tensioning and pulling sites. Within the 65.5 acre ROW, an assembly area of 150 feet wide by 150 feet long for each structure would be required. Assuming five to seven structures per mile would be required, the assembly areas would take up to 10.7 acres within the ROW. Approximately two wire splicing sites, each 100 feet by 100 feet (0.2 acre) would be used within the ROW during construction.

Approximately four tensioning or pulling sites, 150 feet wide by 600 feet long, also would be required within the ROW, although it is estimated that 1 acre of the total would be located outside the ROW (2.0 acres each, minus 1 acre, for a total of 7 acres).

Tensioning or pulling sites would be located partially outside the ROW at locations where the line turns more than 8 degrees, estimated at 1 acre.

A total of approximately 74 acres would be required for the Oklahoma converter station (including access roads) and approximately 19 acres would be required for the Oklahoma AC interconnection during construction.

Construction may affect livestock control and distribution if a gate is left open or a fence is damaged. Vehicular access during construction would increase the likelihood of livestock injury or death from collisions. Access controls (e.g., cattle guards, fences, gates) would be installed, maintained, repaired, replaced, or restored as required by regulation, road authority, or as agreed to by landowner (GE-8).

3.2.6.2.1.1.2 Tennessee Converter Station Siting Area and AC Interconnection Tie

The land cover in the Tennessee Converter Station Siting Area is approximately 50.7 percent agricultural land cover (30.6 percent pasture/hay and 20.1 percent cultivated crops). No center-pivot irrigation or other irrigation infrastructure is known to occur. Although the exact location has not yet been determined, construction of this converter station would convert 45 to 60 acres of currently undeveloped land to a utility land use. During construction, an additional 5 to 10 acres used as temporary laydown areas for equipment. An additional 4.2 acres of rangeland would be converted to access roads (2.4 acres long term, 1.8 acres temporary).

The Tennessee AC interconnection would be entirely contained within the Tennessee converter station footprint and the Shelby Substation footprint. All tensioning and pulling for ties between the Shelby Substation and Tennessee converter station (if necessary) would be contained within the footprint of both stations. No temporary construction areas are needed, and the multi-use construction yard for the Tennessee AC interconnection would share construction yard space with the Tennessee converter station and would be contained within the footprint of the converter station.

Construction may affect livestock control and distribution if a gate is left open or a fence is damaged. Vehicular access during construction would increase the likelihood of livestock injury or death from collisions. Access controls (e.g., cattle guards, fences, gates) would be installed, maintained, repaired, replaced, or restored as required by regulation, road authority, or as agreed to by landowner (GE-8).

Approximately 74 acres would be required for the Tennessee converter station (including access road) during construction; it is anticipated that any temporary construction areas would be contained within the footprint of the Tennessee Converter Station and the Shelby Substation.

3.2.6.2.1.2 Operations and Maintenance Impacts

Maintenance of the AC interconnection lines would be similar to construction impacts, except maintenance would require shorter work duration and would be at a smaller scale. Maintenance would likely occur on an annual basis and as needed.

3.2.6.2.1.2.1 Oklahoma Converter Station Siting Area and AC Interconnection Siting Area

Once construction has been completed, only the 45- to 60-acre converter station, the AC interconnection pole structures, and a 20-foot-wide paved access road would remain; all other temporary construction areas would be returned to their previous use, primarily rangeland. Approximately 45 acres would be fenced.

Within the AC interconnection ROW (200 feet wide), only the pole structures would remain with a total footprint of up to less than 1 acre. All other land in the ROW could be returned to previous land uses, primarily grazing. Roads not otherwise needed for maintenance and operations would be restored to preconstruction conditions. Restoration practices may include decompacting, recontouring, and re-seeding. Roads needed for maintenance and operations would be retained (GE-7). During operations and maintenance, the extent to which these activities can continue to take place would be outlined in easement agreements and would be determined in cooperation with landowners based on site-specific conditions. For example, limitations on uses within the ROW could include the following:

- A prohibition on placing a building or structure within the ROW
- Restrictions on timber or the height of orchard trees within the ROW
- Restrictions on grading and land re-contouring within the ROW that would change the ground surface elevation within the ROW such that required electrical clearances are no longer maintained
- Restrictions and/or required coordination for the construction of future allowed facilities such as fences and/or irrigation lines within the ROW
- Restricted access for safety considerations where maintenance activities are being performed

Restrictions on land use within the ROW would be determined based on site-specific conditions and/or in coordination with landowners. These are not blanket limitations or restrictions that would apply to every parcel potentially impacted by the Project. The continued use of the ROW for routine agricultural practices such as grading and contouring and construction of ditches would be permitted and would be compatible with reliability criteria for HVDC and AC facilities and would not be restricted. Limitations on land uses would be described in the easement agreement; these limitations could be modified in the easement based on site-specific conditions and/or coordination with landowners.

3.2.6.2.1.2.2 Tennessee Converter Station Siting Area and AC Interconnection Tie

Once construction has been completed, only the 20- to 35-acre converter station, the AC interconnection pole structures, and 20-foot-wide paved access road would remain; all other temporary construction areas would be returned to their previous use, primarily cultivated crops and pasture/hay. Approximately 35 acres would be fenced.

Access would be restricted during the performance of maintenance activities.

3.2.6.2.1.3 Decommissioning Impacts

Potential impacts during decommissioning of the Project would be similar to those of the construction phase for all Project components. Upon completion of decommissioning, all land could be returned to preconstruction land uses described in Section 3.2.5.

3.2.6.2.2 AC Collection System

This section discusses the impacts from the AC collection system. The Applicant Proposed Project consists of 13 AC collection system routes. Of the 13 AC collection system routes, four to six 345kV AC collection transmission lines would be constructed. Each line would extend up to 40 miles from the Oklahoma converter station to points in the Oklahoma and Texas panhandles.

3.2.6.2.2.1 Construction Impacts

Construction of the AC collection system would directly affect livestock grazing by temporarily reducing forage in areas with grassland/herbaceous and pasture land cover. Construction may affect livestock control and distribution if a gate is left open or a fence is damaged. Vehicular access during construction would increase the likelihood of livestock injury or death from collisions. Access controls (e.g., cattle guards, fences, gates) would be installed, maintained, repaired, replaced, or restored as required by regulation, road authority, or as agreed to by landowner (GE-8). The Applicant would conduct construction, operation, and maintenance activities to minimize the creation of dust. This may include measures such as limitations on equipment, speed, and/or travel routes utilized. Water, dust palliative, gravel, combinations of these, or similar control measures may be used. Clean Line would implement measures to minimize the transfer of mud onto public roads (GE-11).

Cultivated crops would be directly affected by removal of vegetation and potential removal of agricultural structures such as irrigation systems, barns, and silos. Agricultural production may be temporarily diminished. The Applicant would avoid or minimize adverse effects to surface and subsurface irrigation and drainage systems (e.g., tiles). The Applicant would work with landowners to minimize the placement of structures in locations that would interfere with the operation of irrigation systems (AG-1).

The duration of construction for the complete AC collection system would be approximately 24 months from mobilization to restoration.

Livestock

Construction and operations and maintenance of the proposed transmission lines could affect the economic value of livestock production in the representative ROW by increasing ranchers' costs and decreasing available forage.

The Project could affect net earnings from livestock production in the following ways:

- Decreased forage from land taken out of production
- Increased management costs associated with controlling additional noxious and invasive vegetation species introduced by Project construction equipment
- Increased management costs associated with moving livestock around Project-related structures and easements if a landowner wishes to move livestock during the construction phase

The value of grazing land that would be affected is further discussed in Section 3.13.

Potential impacts to cultivated crops would vary based on the design and location of the proposed transmission line structures and access roads relative to existing agricultural operations. Section 3.13 further discusses the value of cultivated crops that would be affected.

For each route described below, it is assumed that the entire acreage within the ROW would be temporarily disturbed during construction, although construction would not occur on the entire length of a route at the same time.

3.2.6.2.2.1.1 Route E-1

The representative ROW is approximately 708.0 acres. Approximately 574.2 acres of grassland/herbaceous and 48.8 acres of cultivated crops would be disturbed; no pasture/hay is located within the representative ROW. One agricultural structure is located within the representative ROW.

3.2.6.2.2.1.2 Route E-2

The representative ROW is approximately 974.4 acres. Approximately 572.8 acres of grassland/herbaceous and 298.6 acres of cultivated crops would be disturbed; no pasture/hay is located within the representative ROW. No agricultural structures are present in the representative ROW that would be affected by the construction of AC Collection System Route E-2.

3.2.6.2.2.1.3 Route E-3

The representative ROW is approximately 977.5 acres. Approximately 650.3 acres of grassland/herbaceous and 105.2 acres of cultivated crops would be disturbed; no pasture/hay is located within the representative ROW. Two agricultural structures are present in the representative ROW.

3.2.6.2.2.1.4 Route NE-1

The representative ROW would disturb approximately 729.8 acres. Approximately 291.1 acres of grassland/herbaceous and 247.2 acres of cultivated crops would be disturbed; no pasture/hay is located within the representative ROW. No structures are present in the representative ROW that would be affected by the construction of AC Collection System Route NE-1.

3.2.6.2.2.1.5 Route NE-2

The representative ROW is approximately 637.4 acres. Approximately 450.2 acres of grassland/herbaceous and 50.2 acres of cultivated crops would be disturbed; no pasture/hay is located within the representative ROW. One agricultural structure is present in the representative ROW.

3.2.6.2.2.1.6 Route NW-1

The representative ROW is approximately 1,265.4 acres. Approximately 609.5 acres of grassland/herbaceous and 85.0 acres of cultivated crops would be disturbed; no pasture/hay is located within the representative ROW. One agricultural structure is present in the representative ROW.

3.2.6.2.2.1.7 Route NW-2

The representative ROW is approximately 1,365.0 acres. Approximately 629.3 acres of grassland/herbaceous and 410.9 acres of cultivated crops would be disturbed; no pasture/hay is located within the representative ROW. There are no existing agricultural structures in the representative ROW that would be affected by the construction of AC Collection System Route NW-2.

3.2.6.2.2.1.8 Route SE-1

The representative ROW is approximately 979.4 acres. Approximately 513.2 acres of grassland/herbaceous and 340.0 acres of cultivated crops would be disturbed; no pasture/hay is located within the representative ROW. No agricultural structures are present in the representative ROW that would be affected by the construction of AC Collection System Route SE-1.

3.2.6.2.2.1.9 Route SE-2

The representative ROW is approximately 325.4 acres. Approximately 169.9 acres of grassland/herbaceous and 130.6 acres of cultivated crops would be disturbed; no pasture/hay is located within the representative ROW. No agricultural structures are present in the representative ROW that would be affected by the construction of AC Collection System Route SE-2.

3.2.6.2.2.1.10 Route SE-3

The representative ROW is approximately 1,193.6 acres. Approximately 565.7 acres of grassland/herbaceous and 483.9 acres of cultivated crops would be disturbed; no pasture/hay is located within the representative ROW. No agricultural structures are present in the representative ROW that would be affected by the construction of AC Collection System Route SE-3.

3.2.6.2.2.1.11 Route SW-1

The representative ROW is approximately 325.6 acres. Approximately 312.8 acres of grassland/herbaceous would be disturbed; no cultivated crops or pasture/hay lands are located within the representative ROW. No agricultural structures are present in the representative ROW that would be affected by the construction of AC Collection System Route SW-1.

3.2.6.2.2.1.12 Route SW-2

The representative ROW is approximately 901.4 acres. Approximately 733.0 acres of grassland/herbaceous and 33.6 acres of cultivated crops would be disturbed; no pasture/hay located within the representative ROW. No agricultural structures are present in the representative ROW that would be affected by the construction of AC Collection System Route SW-2.

3.2.6.2.2.1.13 Route W-1

The representative ROW is approximately 507.8 acres. Approximately 377.0 acres of grassland/herbaceous and 47.2 acres of cultivated crops would be disturbed; no pasture/hay is located within the representative ROW. One agricultural structure is present in the representative ROW.

3.2.6.2.2.2 Operations and Maintenance Impacts

The long-term impacts by segment are discussed below for pole structures and are summarized in Table 3.10-22. No impacts are described for access roads, because the location of access roads has not yet been determined. Because the locations of access roads to the AC collection system are not known at this time, it is possible that the access roads could be located in such a way that small areas of agricultural land would be isolated and no longer practicable to be used for farmland or grazing.

Livestock

Construction and operations and maintenance of the proposed transmission lines could affect the economic value of livestock production in the ROW by increasing ranchers' costs and decreasing available forage. The Project could affect net earnings from livestock production in the following ways:

- Decrease forage from land taken out of production
- Increase management costs associated with controlling additional noxious and invasive vegetation species introduced by Project construction equipment
- Increase management costs associated with moving livestock around Project-related structures and easements if a landowner wishes to move livestock during the construction period

The value of grazing land that would be affected is further discussed in Section 3.13.

Most agricultural activities such as livestock grazing and cultivating crops could be returned to the ROW upon the completion of construction. During operations and maintenance, the extent to which these activities can continue to take place would be outlined in easement agreements and would be determined in cooperation with landowners based on site-specific conditions. For example, limitations on uses within the ROW could include the following:

- A prohibition on placing a building or structure within the ROW
- Restrictions on timber or the height of orchard trees within the ROW
- Restrictions on grading and land re-contouring within the ROW that would change the ground surface elevation within the ROW such that required electrical clearances are no longer maintained
- Restrictions and/or required coordination for the construction of future allowed facilities such as fences and/or irrigation lines within the ROW
- Restricted access for safety considerations during performance where maintenance activities are being performed

Restrictions on land use within the ROW would be determined based on site-specific conditions and/or in coordination with landowners. These are not blanket limitations or restrictions that would apply to every parcel potentially impacted by the Project. The continued use of the ROW for routine agricultural practices such as grading and contouring and construction of ditches would be permitted and would be compatible with reliability criteria for HVDC and AC facilities and would not be restricted. Limitations on land uses would be described in the easement agreement; these limitations could be modified in the easement based on site-specific conditions and/or coordination with landowners.

The long-term disturbance in the ROW is primarily grassland/herbaceous for all the routes except for AC Collection System Route NW-1. Approximately 75 percent of the ROW for AC Collection System Route NW-1 is grassland/herbaceous.

3.2.6.2.2.3 Decommissioning Impacts

Potential impacts during decommissioning of the Project would be similar to those of the construction phase for all Project components. Once decommissioning has been completed, all land could be returned to the preconstruction land uses described in Sections 3.2.4 and 3.2.5.

3.2.6.2.3 HVDC Applicant Proposed Route

This section discusses the potential impacts to agriculture of the approximate 720-mile-long transmission facility during the three phases of the Project: construction, operations and maintenance, and decommissioning. Specific EPMs developed to avoid land use impacts are described in Section 3.2.6.2.1 and are referenced in the discussion below in parentheses.

3.2.6.2.3.1 Construction Impacts

The majority of the impacts to agriculture would be temporary. Construction would prevent the uses of pasture/hay land and cultivated crops in the representative ROW as identified in Table 3.2-10, which outlines the typical construction sequence that would occur on agricultural property. Except while access to the ROW is temporarily restricted during construction for safety reasons, livestock would not be displaced or prohibited from grazing in pastures overlapped by the ROW during construction unless otherwise desired by the landowner. Construction activities, during which restrictions to the ROW may occur, are identified in the construction sequence and timeline provided in Table 3.2-10. Construction may affect livestock control and distribution if a gate is left open or a fence is damaged. Vehicular access during construction would increase the likelihood of livestock injury or death from collisions. Access controls (e.g., cattle guards, fences, gates) would be installed, maintained, repaired, replaced, or restored as required by regulation, road authority, or as agreed to by landowner (GE-8). The Applicant would make reasonable efforts, consistent with design criteria, to accommodate requests from individual landowners to adjust the siting of the ROW on their properties. These adjustments may include consideration of routes along or parallel to existing divisions of land (e.g., agricultural fields and parcel boundaries) and existing compatible linear infrastructure (e.g., roads, transmission lines, and oil and gas pipelines), with the intent of reducing the impact of the ROW on private properties (LU-5). Additionally, the Applicant would work with landowners to develop a site plan for each cropland farm on which construction or maintenance is to be performed (AG-7).

During construction, croplands would be directly affected by removal of vegetation and agricultural structures such as irrigation systems, barns, and silos. Agricultural production may be temporarily diminished. The Applicant would work with landowners to repair damage caused by construction, operation, or maintenance activities of the Project. Repairs would take place in a timely manner, weather and landowner permitting (GE-10). The Applicant would work with landowners to develop compensation for lost crop value caused by construction and/or maintenance (AG-6). In cases where agricultural structures are located within the representative ROW, the Applicant would work with landowners to microsite the location of transmission structures to avoid impacts to or relocation of these structures.

The duration of construction is expected to be approximately 36 to 42 months for the entire Project, although the duration of construction for a single HVDC segment is anticipated to be approximately 24 months from mobilization to restoration.

Impacts by region are discussed below. For each region described below, it is assumed that the entire acreage within the representative ROW would be temporarily disturbed during construction, although construction would not occur on the entire length of the representative ROW at the same time. EPMs AG-6, GE-10, and LU-4 would help to avoid or minimize impacts in each region described below.

3.2.6.2.3.1.1 Region 1

Approximately 1,742.3 acres of grassland/herbaceous and 748.8 acres of cultivated crops would be disturbed; no pasture/hay land is located within the representative ROW. One agricultural structure is present in the representative ROW of Applicant Proposed Route Link 4.

Outside the representative ROW, tensioning or pulling areas totaling approximately 100.8 acres would be required during construction. The land cover in these areas is primarily grassland/herbaceous land cover and cultivated crops.

No route variations were proposed in Region 1.

3.2.6.2.3.1.2 Region 2

Approximately 1,299.9 acres of grassland/herbaceous and 788.0 acres of cultivated crops would be disturbed; no pasture/hay land is located within the representative ROW. Two agricultural structures are present in the representative ROW of Applicant Proposed Route Link 3 that may need to be removed so that the transmission line could be built. The representative ROW would be temporarily unavailable during construction at this location.

Outside the representative ROW, tensioning or pulling areas totaling approximately 99.0 acres would be required during construction. The predominant land cover types are grassland/herbaceous and cultivated crops.

Two route variations to the Applicant Proposed Route were developed in Region 2 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.2. Link 1, Variation 1, was developed to reduce impacts to cultivated fields and structures. The variation would cross a greater acreage of agricultural land cover when compared to the original Applicant Proposed Route Link 1.

Link 2, Variation 2, would run closer to the quarter-section line that parallels parcel boundaries and would cross approximately the same acreage of agricultural land cover when compared to the original Applicant Proposed Route Link 1.

3.2.6.2.3.1.3 Region 3

Approximately 1,339.5 acres of grassland/herbaceous, 941.3 acres of pasture/hay lands, and 312.6 acres of cultivated crops would be disturbed.

Five agricultural structures (one in Link 1, one in Link 2, two in Link 4, and one in Link 6) are present in the representative ROW.

Outside the representative ROW, tensioning or pulling areas totaling approximately 379 acres would be required during construction. The predominant land cover in these areas is grassland/herbaceous.

Five route variations to the Applicant Proposed Route were developed in Region 3 in response to public comments on the Draft EIS. Link 1, Variation 2, would cross approximately the same acreage of agricultural land cover. This variation would reduce impacts to agricultural operations by avoiding the landowner's no-till cultivated cropland.

Links 1 and 2, Variation 1, would parallel parcel boundaries and would cross slightly more agricultural land cover when compared with the original Applicant Proposed Route Links 1 and 2. A route adjustment, HVDC Alternative Route 3-A, was created to maintain an end-to-end route with this variation.

Link 4, Variation 1, was identified to avoid impacts to a quarry operation and would cross slightly more agricultural land cover when compared to the original Applicant Proposed Route Link 4.

Route Link 4, Variation 2, was identified to reduce interference with a barn, cattle pens, and residence as identified by the requesting landowner. The route variation would cross less agricultural land cover when compared to the original Applicant Proposed Route Link 4.

Link 5, Variation 2, was identified to avoid a residence and would parallel a greater length of existing infrastructure. The representative ROW for this variation would cross approximately 10 fewer acres of agricultural land cover when compared to the original Applicant Proposed Route Link 5.

3.2.6.2.3.1.4 Region 4

Approximately 1,436.1 acres of pasture/hay lands, 77.5 acres of grassland/herbaceous, and 63.9 acres of cultivated crops would be disturbed. Four agricultural structures are present in the representative ROW of Applicant Proposed Route Links 6, 7, and 9 (one in Link 6, one in Link 7, and two in Link 9).

The Lee Creek Variation is 3.4 miles long. No portion of the route is parallel to existing infrastructure. The agricultural land cover in the 200-foot-wide representative ROW is 5.8 percent grassland/herbaceous.

Outside the representative ROW, tensioning or pulling areas totaling approximately 483 acres would be required during construction. The predominant land cover in these areas is pasture/hay. One agricultural structure is present in these areas. The tensioning and pulling areas would be temporarily impacted as identified in Table 3.2-10.

Seven route variations to the Applicant Proposed Route were developed in Region 4 in response to public comments on the Draft EIS.

Link 3, Variation 1, would parallel parcel boundaries and increase the distance from residences and a cemetery. The variation would cross approximately the same acreage of agricultural land cover when compared with the original Applicant Proposed Route Link 3.

Link 3, Variation 2, would avoid two airstrips, a residence, and an agri-tourism business operation while increasing the length parallel to existing infrastructure and follow existing parcel boundaries. The representative ROW of this variation would cross approximately 35 fewer acres of agricultural land cover when compared with the original Applicant Proposed Route Link 3.

Link 3, Variation 3, would cross fewer parcels, more closely follow parcel boundaries, and avoid potential impacts to known locations of protected bat species. The representative ROW of this variation would cross approximately 20 more acres of agricultural land cover when compared with the original Applicant Proposed Route Link 3.

Link 6, Variation 1, was identified to parallel parcel boundaries and to avoid existing residences in proximity to the variation. The representative ROW of this variation would cross approximately the same acreage of agricultural land cover when compared with the original Applicant Proposed Route Link 6.

Link 6, Variation 2, was identified to avoid a WRP easement and would cross approximately the same acreage of agricultural land cover when compared with the original Applicant Proposed Route Link 6.

Link 6, Variation 3, would increase the length parallel to existing infrastructure and minimize engineering constraints due to complex terrain. The representative ROW of this variation would cross approximately 2 fewer acres of agricultural land cover when compared with the original Applicant Proposed Route Link 6.

Link 9, Variation 1, would increase the distance from a residence and campground while maintaining the length parallel to existing infrastructure and minimize engineering constraints due to complex terrain. The representative ROW of this variation would cross approximately 4 additional acres of agricultural land cover when compared with the original Applicant Proposed Route Link 9.

3.2.6.2.3.1.5 Region 5

Approximately 773.4 acres of pasture/hay land, 149.3 acres of cultivated crops, and 78.5 acres of grassland/herbaceous would be disturbed. One agricultural structure is present in the representative ROW of Applicant Proposed Route Link 2.

Outside the representative ROW, tensioning or pulling areas totaling approximately 291acres would be required during construction. The land cover in these areas is primarily pasture/hay and deciduous forest.

Five route variations to the Applicant Proposed Route were developed in Region 5 in response to public comments on the Draft EIS.

Link 1, Variation 2, would decrease the number of parcels crossed and would avoid a recently constructed residence. The representative ROW for this variation would cross approximately the same acreage of agricultural land cover when compared with the original Applicant Proposed Route Link 1.

Link 2, Variation 2, was identified to reduce impacts to a commercial forestry operation. The representative ROW for this variation would cross approximately 2 additional acres of agricultural land cover when compared with the original Applicant Proposed Route Link 2.

Links 2 and 3, Variation 1, would increase the distance from a home not previously identified during route development and would reduce the number of landowners affected; it should be noted that a route adjustment was made for HVDC Alternative Route 5-B to maintain an end-to-end route with this variation. The representative ROW for this variation would cross approximately 4 additional acres of agricultural land cover when compared with the original Applicant Proposed Route Links 2 and 3.

Links 3 and 4, Variation 2, more closely parallels parcel boundaries while avoiding parcels with conservation easements and the location of a homestead structure. The representative ROW for this variation would cross approximately 4 additional acres of agricultural land cover when compared with the original Applicant Proposed Route Links 3 and 4. It should be noted that a route adjustment was made for HVDC Alternative Route 5-E to maintain an end-to-end route with this variation.

Link 7, Variation 1, would parallel parcel boundaries and would avoid a recently constructed residence. The representative ROW for this variation would cross approximately 3 additional acres of agricultural land cover when compared to the original Applicant Proposed Route Link 7.

3.2.6.2.3.1.6 Region 6

Approximately 1,060.0 acres or 79.9 percent of agricultural land (1,056.5 acres of cultivated crops, 3.1 acres of pasture/hay lands, and 0.5 acre of grassland/herbaceous) would be disturbed. The representative ROW of Link 7 includes a parcel of land enrolled in the WRP totaling approximately 0.3 acre. Five agricultural structures are present in the representative ROW of Applicant Proposed Route Links 4 and 6 (one in Link 4 and four in Link 6).

Outside the representative ROW, tensioning or pulling areas totaling approximately 115.6 acres would be required during construction. The land cover in these areas is primarily cultivated crops.

One route variation to the Applicant Proposed Route was developed in Region 6 in response to public comments on the Draft EIS. Applicant Proposed Route Link 2, Variation 1, was identified to reduce potential interference with aerial application and a water well used for crop irrigation and would parallel more parcel boundaries when compared with the original Applicant Proposed Route Link 2. The representative ROW for this variation would cross approximately 15 additional acres of agricultural land when compared with the original Applicant Proposed Route Link 2. It should be noted that a route adjustment was made for HVDC Alternative Route 6-A to maintain an end-to-end route with this variation.

3.2.6.2.3.1.7 Region 7

Approximately 729.5 acres or 69.8 percent of agricultural land (691.8 acres of cultivated crops and 36.1 acres of pasture/hay) would be disturbed; there are 1.5 acres of grassland/herbaceous in the representative ROW. The representative ROW of Link 1 includes a parcel of land enrolled in the WRP totaling approximately 2 acres. Two agricultural structures are present in the representative ROW of Applicant Proposed Route Link 5.

Outside the representative ROW, tensioning or pulling areas totaling approximately 162.4 acres would be required during construction. The land cover in these areas is primarily cultivated crops.

Three route variations to the Applicant Proposed Route were developed in Region 7 in response to public comments on the Draft EIS.

Link 1, Variation 1, was developed to reduce interference with crop irrigation and aerial application and would parallel more parcel boundaries when compared with the original Applicant Proposed Route Link 1. The representative ROW for this variation would cross approximately 5 additional acres of agricultural land cover when compared with the original Applicant Proposed Route Link 1.

Link 1, Variation 2, would cross fewer parcels and also follow parcel boundaries more closely to avoid impacts to agricultural operations, including center pivot irrigation, a precision-leveled field, and aerial application to these fields. The representative ROW for this variation would cross approximately the same acreage of agricultural land cover when compared with the original Applicant Proposed Route Link 1.

Link 5, Variation 1 was identified to avoid a proposed new home site and addresses landowner concerns about planned residential development. The variation does not result in a change of the Applicant Proposed Route 1,000-foot-wide corridor analyzed in the Draft EIS. This variation would cross approximately 1.3 acres fewer acres of pasture/hay and would cross approximately 1.2 more acres of cultivated crops when compared with the original Applicant Proposed Route Link 5.

3.2.6.2.3.2 Operations and Maintenance Impacts

Once construction has been completed, only the transmission structures, fiber optic regeneration sites, and access roads would remain. Most of the land in the ROW could be returned to previous land uses, primarily agriculture (grazing and crops). Because the locations of access roads for the HVDC transmission line are not known at this time, it is possible that the access roads could be located in such a way that small areas of agricultural land would be isolated and no longer practicable to be used for farmland or grazing.

During operations and maintenance, the extent to which these activities can continue to take place would be outlined in easement agreements and would be determined in cooperation with landowners based on site-specific conditions. For example, limitations on uses within the ROW could include the following:

- A prohibition on placing a building or structure within the ROW
- Restrictions on timber or the height of orchard trees within the ROW
- Restrictions on grading and land re-contouring within the ROW that would change the ground surface elevation within the ROW such that required electrical clearances are no longer maintained
- Restrictions and/or required coordination for the construction of future allowed facilities such as fences and/or irrigation lines within the ROW
- Restricted access for safety considerations during performance where maintenance activities are being performed

Restrictions on land use within the ROW would be determined based on site-specific conditions and/or in coordination with landowners. These are not blanket limitations or restrictions that would apply to every parcel potentially impacted by the Project. The continued use of the ROW for routine agricultural practices such as grading and contouring and construction of ditches would be permitted and would be compatible with reliability criteria for HVDC and AC facilities and would not be restricted. Limitations on land uses would be described in the easement agreement; these limitations could be modified in the easement based on site-specific conditions and/or coordination with landowners.

Livestock grazing and cultivating crops are compatible with the operations and maintenance of the Project, although there may be occasional disturbances during maintenance, which are expected to be minimal and localized in nature. Pole structures may interfere with farming equipment and aerial crop spraying, which may reduce crop yields.

The long-term impacts by region are summarized in Table 3.10-22 for pole structures. It is anticipated that all existing roads (including existing roads with repairs/improvements) would be retained for operations and maintenance of the Project. It is estimated that approximately 75 percent of the new overland roads with no improvements, 90 percent of the new overland roads with clearing, and new bladed roads would be retained for operations and maintenance access. These roads would be up to 20 feet wide and would total an estimated 1,851 acres. Access roads that are not needed for operations and maintenance of the Project would be restored (GE-7). Because the type of pole structure that would be used has not yet been determined, the impact calculations assumed lattice structures would be used for a conservative estimate of impacts. The operational footprint would be five to seven structures per mile, each measuring 28 feet by 28 feet (less than 0.02 acre). Assuming 720 miles of lattice structures were constructed, the operational footprint would be 86 acres.

Operation and maintenance impacts would not irreversibly convert prime farmland to non-agricultural uses in the representative ROW.

3.2.6.2.3.3 Decommissioning Impacts

Potential impacts during decommissioning of the Project would be similar to those of the construction phase for all Project components. Once decommissioning has been completed, all land could be returned to the preconstruction land uses described in Sections 3.2.4 and 3.2.5.

3.2.6.3 Impacts Associated with the DOE Action Alternatives

3.2.6.3.1 Arkansas Converter Station Alternative Siting Area and AC Interconnection Siting Area

3.2.6.3.1.1 Construction Impacts

The land cover in the Arkansas Converter Station Alternative Siting Area is composed of approximately 96.0 acres (26.7 percent) pasture/hay and approximately 16.0 acres (4.5 percent) grassland/herbaceous land cover.

The Arkansas AC interconnection would be approximately 5 miles long, and during construction, approximately 146.5 acres of currently primarily pasture/hay land cover would be temporarily converted to an industrial use.

Construction of the converter station and AC interconnection would directly affect livestock grazing by temporarily reducing forage in up to approximately 661.6 acres of land. A 25- to 35-acre site for a new substation where the alternative AC transmission line would interconnect with an existing 500kV transmission line would be required, and an additional 5 acres would be temporarily required during the construction phase. This substation would be located near an existing transmission line in an area that is primarily grassland.

If any crop land is in the construction area, crops grown in these areas would be lost and crops in adjacent areas may have reduced yields if there are disturbances to irrigation structures or in aerial spraying. The Applicant would avoid or minimize adverse effects to surface and subsurface irrigation and drainage systems (e.g., tiles). The Applicant would work with landowners to minimize the placement of structures in locations that would interfere with the operation of irrigation systems (AG-1). The Applicant would work with landowners and/or tenants to consider potential impacts to current aerial spraying or application (i.e., aerial crop spraying) of herbicides, fungicides, pesticides, and fertilizers within or near the transmission ROW. The Applicant would avoid or minimize impacts to aerial spraying practices when routing and siting the transmission line and related infrastructure (AG-5). The

Applicant would conduct construction, operation, and maintenance activities to minimize the creation of dust. This may include measures such as limitations on equipment, speed, and/or travel routes utilized. Water, dust palliative, gravel, combinations of these, or similar control measures may be used. The Applicant would implement measures to minimize the transfer of mud onto public roads (GE-11). Construction may affect livestock control and distribution if a gate is left open or a fence is damaged. Vehicular access during construction would increase the likelihood of livestock injury or death from collisions. Access controls (e.g., cattle guards, fences, gates) would be installed, maintained, repaired, replaced, or restored as required by regulation, road authority, or as agreed to by landowner (GE-8). Additionally, the Applicant would work with landowners to develop a site plan for each cropland farm on which construction or maintenance is to be performed (AG-7).

3.2.6.3.1.2 Operations and Maintenance Impacts

Once construction has been completed, only the 20- to 35-acre converter station and 20-foot-wide paved access road would remain; all other temporary construction areas would be returned to their previous use, primarily rangeland. Approximately 35 acres would be fenced. The 25- to 35-acre substation where the alternative AC transmission line would interconnect with the existing 500kV transmission line would also remain as a utility use. Although most of this land is not currently used for agricultural purposes, up to 72.2 percent is used as pasture/hay and 0.3 percent is grassland/herbaceous. If any of these lands are used for long-term structures, they would be removed from agricultural use until decommissioning.

Within the Arkansas AC interconnection (150–200 feet wide by 5 miles long), only the pole structures and most access roads would remain. Roads not otherwise needed for maintenance and operations would be restored to preconstruction conditions. Restoration practices may include decompacting, recontouring, and re-seeding. Roads needed for maintenance and operations would be retained. (GE-7). All other land in the ROW could be returned to previous land uses, except that only low-growing vegetation would be permitted in the ROW. Short trees (up to 25 feet in height at maturity) would be permitted adjacent to the representative ROW.

During operations and maintenance, the extent to which these activities can continue to take place would be outlined in easement agreements and would be determined in cooperation with landowners based on site-specific conditions. For example, limitations on uses within the ROW could include the following:

- A prohibition on placing a building or structure within the ROW
- Restrictions on timber or the height of orchard trees within the ROW
- Restrictions on grading and land re-contouring within the ROW that would change the ground surface elevation within the ROW such that required electrical clearances are no longer maintained
- Restrictions and/or required coordination for the construction of future allowed facilities such as fences and/or irrigation lines within the ROW
- Restricted access for safety considerations during performance where maintenance activities are being performed

Restrictions on land use within the ROW would be determined based on site-specific conditions and/or in coordination with landowners. These are not blanket limitations or restrictions that would apply to every parcel potentially impacted by the Project. The continued use of the ROW for routine agricultural practices such as grading and contouring and construction of ditches would be permitted and would be compatible with reliability criteria for HVDC and AC facilities and would not be restricted. Limitations on land uses would be described in the easement agreement; these limitations could be modified in the easement based on site-specific conditions and/or coordination with landowners.

Because 72.2 percent of the Arkansas AC interconnection ROW is composed of pasture/hay land, it is anticipated that most of this land could be returned to pasture/hay during operations because it is a compatible use. Maintenance activities would have minimal impacts on the use of pasture/hay lands. Because the locations of access roads to the converter station are not known at this time, it is possible that the access roads could be located in such a way that small areas of agricultural land would be isolated and no longer practicable to be used for grazing.

3.2.6.3.1.3 Decommissioning Impacts

Potential impacts during decommissioning of the Project would be similar to those of the construction phase for all Project components. Once decommissioning has been completed, all land could be returned to the preconstruction land uses described in Sections 3.2.4 and 3.2.5.

3.2.6.3.2 HVDC Alternative Routes

This section discusses the potential impacts to agriculture within the 200-foot-wide representative ROWs of the HVDC alternative routes during the construction, operations and maintenance, and decommissioning phases of the Project.

3.2.6.3.2.1 Construction Impacts

The types of construction impacts would be similar to those discussed for the Applicant Proposed Route (Section 3.2.6.2.3). The majority of the impacts to agriculture would be temporary. Construction would prevent the use of rangeland and cultivated crops in the representative ROW. Construction of the transmission line would directly affect livestock grazing by temporarily reducing forage for livestock from grassland/herbaceous and pasture/hay. Temporary work areas that would be required outside the representative ROW include fiber optic regeneration sites, multi-use construction yards, and fly yards. Construction may affect livestock control and distribution if a gate is left open or a fence is damaged. Vehicular access during construction would increase the likelihood of livestock injury or death from collisions.

Cultivated crops would be directly affected by removal of vegetation and agricultural structures such as irrigation systems, barns, and silos. The Applicant would work with landowners to repair damage caused by construction, operation, or maintenance activities of the Project. Repairs would take place in a timely manner, weather and landowner permitting (GE-10). The Applicant would work with landowners to develop compensation for lost crop value caused by construction and/or maintenance (AG-6) and would work with landowners to develop a site plan for each cropland farm on which construction or maintenance is to be performed (AG-7). Agricultural production may be temporarily diminished.

Impacts by region are discussed below. For each alternative route described below, it is assumed that the entire acreage within the representative ROW would be temporarily disturbed during construction, although construction would not occur on the entire length of the representative ROW at the same time.

3.2.6.3.2.1.1 Region 1

3.2.6.3.2.1.1.1 Alternative Route 1-A

HVDC Alternative Route 1-A is approximately 123 miles long and corresponds to Applicant Proposed Route Links 2, 3, 4, and 5. If this route is selected, 3,003.1 acres would be removed from existing uses, of which 2,554.3 acres (85.0 percent) are agricultural lands (grassland/herbaceous and cultivated crops). HVDC Alternative Route 1-A has a comparable percentage of agricultural land when compared to Links 2 through 5 (2,450.9 acres and 88 percent. Thirteen agricultural structures are located within the representative ROW for HVDC Alternative Route 1-A. One agricultural structure is present in the representative ROW of the original Applicant Proposed Route.

Outside the representative ROW, tensioning or pulling areas totaling approximately 165.1 acres of primarily grassland/herbaceous would be required during construction.

3.2.6.3.2.1.1.2 Alternative Route 1-B

HVDC Alternative Route 1-B is approximately 52 miles long and corresponds to Applicant Proposed Route Links 2 and 3. If this route is selected, 1,268.4 acres would be removed from existing uses. Of the 1,268.4 acres, approximately 1009.1 acres (79.6 percent) are agricultural land that consists of grassland/herbaceous and cultivated crops. HVDC Alternative Route 1-B has less agricultural land than Links 2 and 3 (1,139.6 acres and 86.6 percent). One agricultural structure is present in the ROW; conversely, no structures are present in Applicant Proposed Route Links 2 and 3.

Outside the representative ROW, tensioning or pulling areas totaling approximately 46.2 acres would be required during construction. The predominant land cover in these areas is grassland/herbaceous. No structures are present in the tensioning or pulling areas for HVDC Alternative Route 1-B.

3.2.6.3.2.1.1.3 Alternative Route 1-C

HVDC Alternative Route 1-C is approximately 52 miles long and corresponds to Applicant Proposed Route Links 2, and 3. If this route is selected, approximately 1,039.1 acres of agricultural land (grassland/herbaceous and cultivated crops) would be removed from existing uses in the representative ROW. HVDC Alternative Route 1-C has a smaller percentage of agricultural land (1,039.1 acres, or 83 percent) than the Applicant Proposed Route Links 2 and Link 3 (1,139.6 acres, or 86.6 percent). Seven agricultural structures are present in the ROW; conversely, no agricultural structures are present in Applicant Proposed Route Links 2 and 3.

Outside the representative ROW, tensioning or pulling areas totaling approximately 60 acres would be required during construction. Approximately 35.8 acres of grassland/herbaceous and 8.3 acres of cultivated crops would be required during construction. The predominant land cover is grassland/herbaceous. No structures are present in the tensioning or pulling areas for HVDC Alternative Route 1-C.

3.2.6.3.2.1.1.4 Alternative Route 1-D

HVDC Alternative Route 1-D is approximately 33.5 miles long and corresponds to Applicant Proposed Route Links 3 and 4. If this route is selected, 819.2 acres would be removed from existing uses. Of the 819.2 acres, approximately 568.9 acres of grassland/herbaceous and 113.2 acres of cultivated crops would be removed from existing uses; no pasture/hay land is present in the representative ROW. Approximately 682.1 acres (83.2 percent) of agricultural land cover are present within the ROW. HVDC Alternative Route 1-D contains a smaller percentage of agricultural land compared to Links 3 and 4 (82.8 acres or 92.8 percent). Five agricultural structures are located in the representative ROW; conversely, one agricultural structure is located in the Applicant Proposed Route Link 4.

Outside the representative ROW, tensioning or pulling areas totaling approximately 28.5 acres, approximately 18.0 acres of which are grassland/herbaceous, would be required during construction. No structures are present in the tensioning or pulling areas for HVDC Alternative Route 1-D.

3.2.6.3.2.1.2 Region 2

Table 3.10-24 presents the land cover in the ROW for each of the two HVDC alternative routes in Region 2. Each alternative route is discussed in more detail below.

3.2.6.3.2.1.2.1 Alternative Route 2-A

HVDC Alternative Route 2-A is approximately 57 miles long and corresponds to Applicant Proposed Route Link 2. If this route is selected, approximately 1,396.3 acres would be removed from existing uses. Of the 1,396.3 acres, HVDC Alternative Route 2-A would disturb approximately 1,147.7 acres (82.2 percent) of agricultural land (grassland/herbaceous, cultivated crops, and pasture/hay land). HVDC Alternative Route 2-A contains a greater percentage of agricultural land compared to Link 2 (77.0 percent). Three agricultural structures are located within ROW; conversely, no agricultural structures are present in Link 2.

Outside the representative ROW, tensioning or pulling areas totaling approximately 83.9 acres of primarily grassland/herbaceous and cultivated crops would be required during construction. The predominant land cover is grassland/herbaceous followed by cultivated crops. No structures are present in the tensioning or pulling areas for HVDC Alternative Route 2-A.

3.2.6.3.2.1.2.2 Alternative Route 2-B

HVDC Alternative Route 2-B is approximately 30 miles long and corresponds to Applicant Proposed Route Link 3.If HVDC Alternative Route 2-B is selected, approximately 727.7 acres would be removed from existing uses. Of the 727.7 acres to be removed, approximately 680.3 acres (93.5 percent) are agricultural land (cultivated crops grassland/herbaceous)—more agricultural land than Applicant Proposed Route Link 3. No pasture/hay land is present in the representative ROW. No agricultural structures are present in the representative ROW. Two agricultural structures are present in the Applicant Proposed Route Link 3.

Outside the representative ROW, tensioning or pulling areas totaling approximately 31.2 acres of primarily cultivated crops would be required during construction. The predominant land cover is cultivated crops and no structures are present.

3.2.6.3.2.1.3 Region 3

Table 3.10-25 presents the land cover in the ROW for each of the five HVDC alternative routes in Region 3. Each alternative route is discussed in more detail below.

3.2.6.3.2.1.3.1 Alternative Route 3-A

HVDC Alternative Route 3-A is approximately 38 miles long and corresponds to Applicant Proposed Route Link 1. If this route is selected, 919.1 acres would be removed from existing uses. Of the 919.1 acres to be removed, approximately 497.3 acres of grassland/herbaceous and 150.4 acres of cultivated crops and 5.1 acres of pasture/hay would be disturbed.

The agricultural land cover within the ROW for HVDC Alternative Route 3-A is approximately 71.1 percent (652.8 acres), comparable to the agricultural land cover of HVDC Applicant Proposed Route Link 1. One agricultural structure is present in the representative ROW and one agricultural structure is present within Applicant Proposed Route Link 1.

Outside the representative ROW, tensioning or pulling areas totaling approximately 39.6 acres of primarily grassland/herbaceous would be required during construction. No structures are present in the tensioning or pulling areas for HVDC Alternative Route 3-A.

As described in Appendix M and summarized in Section 2.4.2.3, a route adjustment was developed for HVDC Alternative Route 3-A to maintain an end-to-end route with Applicant Proposed Route Link 1, Variation 2, and Links 1 and 2, Variation 1. The route adjustment parallels more parcel boundaries and crosses 4 fewer acres of agricultural land cover when compared with the original HVDC Alternative Route 3-A.

3.2.6.3.2.1.3.2 Alternative Route 3-B

HVDC Alternative Route 3-B is approximately 48 miles long and corresponds to Applicant Proposed Route Links 1, 2, and 3. For HVDC Alternative Route 3-B, 1,166.6 acres would be removed from existing uses.

The agricultural land cover within the HVDC Alternative Route 3-B representative ROW is approximately 73.3 percent agricultural land (cultivated crops, grassland/herbaceous, and pasture/hay), and contains a larger percentage of agricultural land than Links 1 through 3 (69.0 percent). Two agricultural structures are present in the representative ROW. Two agricultural structures are located within the Applicant Proposed Route Links 1, 2, and 3.

Outside the representative ROW, tensioning or pulling areas totaling approximately 84.9 acres agricultural land (primarily grassland/herbaceous) would be required during construction. No agricultural structures are located within the tensioning or pulling areas for HVDC Alternative Route 3-B.

3.2.6.3.2.1.3.3 Alternative Route 3-C

HVDC Alternative Route 3-C is approximately 122 miles long and corresponds to Applicant Proposed Route Links 3, 4, 5, and 6. For HVDC Alternative Route 3-C, 2,967.5 acres would be removed from existing uses. The agricultural land cover within the representative ROW is approximately 1,980.1 acres (66.8 percent), comparable to Links 3 through 6 (64.3 percent). Seven agricultural structures are located within the representative ROW; conversely, three agricultural structures are located within the Applicant Proposed Route Links 3, 4, 5, and 6.

Outside the representative ROW, tensioning or pulling areas totaling approximately 220.8 acres (36.3 percent grassland/herbaceous and 23.7 percent pasture/hay) would be required during construction. No agricultural structures are located within the tensioning or pulling areas for HVDC Alternative Route 3-C.

3.2.6.3.2.1.3.4 Alternative Route 3-D

HVDC Alternative Route 3-D is approximately 39 miles long and corresponds to Applicant Proposed Route Links 5 and 6. If this route is selected, 958.8 acres would be removed from existing uses. The agricultural land cover within the representative ROW is approximately 734.2 acres, or 76.6 percent, of agricultural land cover (pasture/hay, grassland/ herbaceous, and cultivated crops). The percentage of agricultural land cover within the representative ROW is comparable to Links 5 and 6 (76.2 percent). Four agricultural structures are present in the representative ROW. Conversely, one agricultural structure is located in the Applicant Proposed Route Links 5 and 6.

Outside the representative ROW, tensioning or pulling areas totaling approximately 81.9 acres (46.2 percent pasture/hay) would be required during construction. The predominant land cover is pasture/hay and no structures are present.

3.2.6.3.2.1.3.5 Alternative Route 3-E

HVDC Alternative Route 3-E is approximately 8.5 miles long and corresponds to Applicant Proposed Route Link 6. If this route is selected, 207.8 acres would be removed from existing uses.

HVDC Alternative Route 3-E would disturb approximately 121.5 acres (58.5 percent) of agricultural land (pasture/hay and grassland/herbaceous) within the representative ROW. No agricultural structures are located within the representative ROW. The land cover within the representative ROW contains a higher percentage of agricultural land (58.5 percent) compared to Link 6 of the Applicant Proposed Route, which contains 51.5 percent agricultural land.

No agricultural structures are located within the representative ROW; conversely, one agricultural is located within the Applicant Proposed Route Link 6.

Outside the representative ROW, tensioning or pulling areas totaling approximately 25.2 acres of primarily pasture/hay would be required during construction. No structures are present in the tensioning or pulling areas for HVDC Alternative Route 3-E.

3.2.6.3.2.1.4 Region 4

3.2.6.3.2.1.4.1 Alternative Route 4-A

HVDC Alternative Route 4-A is approximately 58 miles long and corresponds to Applicant Proposed Route Links 3, 4, 5, and 6. HVDC Alternative Route 4-A would disturb approximately 619.3 acres (43.4 percent) of agricultural land (pasture/hay, grassland/herbaceous, and cultivated crops). The agricultural land cover within the representative ROW (43.4 percent) contains a lower percentage of agricultural land compared to Links 3 through 6 (56.7 percent). Nine agricultural structures are located within the representative ROW; conversely, one agricultural structure is located within the Applicant Proposed Route Link 6.

Outside the representative ROW, tensioning or pulling areas totaling approximately 189 acres would be required during construction. The predominant land cover, or approximately 40.3 percent of the land cover, is pasture/hay. No structures are present within these areas.

3.2.6.3.2.1.4.2 Alternative Route 4-B

HVDC Alternative Route 4-B is approximately 79 miles long and corresponds to Applicant Proposed Route Links 2–8. For HVDC Alternative Route 4-B, 1,919.9 acres would be removed from existing uses. HVDC Alternative Route 4-B would disturb approximately 594 acres of agricultural land (30.9 percent). The agricultural land cover within the representative ROW contains a lower percentage of agricultural land compared to Applicant Proposed Route Links 2–8 (55.6 percent). The majority of HVDC Alternative Route 4-B is located within the boundaries of the Ozark

National Forest. Approximately 102 acres of the federally owned land in the Ozark National Forest is within the representative ROW; 157 acres of private land within the Ozark National Forest boundary (use unknown) is within the representative ROW. Ten agricultural structures are located within the representative ROW; conversely, four agricultural structures are located within the Applicant Proposed Route Links 2–8.

Outside the representative ROW, tensioning or pulling areas totaling approximately 198.7 acres (29.0 percent pasture/hay) would be required during construction. The predominant agricultural land cover, or approximately 29.0 percent, is pasture/hay. No structures are present in the tensioning or pulling areas for HVDC Alternative Route 4-B.

3.2.6.3.2.1.4.3 Alternative Route 4-C

HVDC Alternative Route 4-C is approximately 3 miles long and corresponds to Applicant Proposed Route Link 5. For HVDC Alternative Route 4-C, 82.6 acres would be removed from existing uses. HVDC Alternative Route 4-C would disturb approximately 19.0 acres of pasture/hay and 4.8 acres of grassland/herbaceous; no cultivated crops are in the representative ROW. No agricultural structures would be removed to construct the transmission line.

The land cover within the representative ROW contains approximately 23.8 acres of agricultural land (29 percent), a percentage that is lower to Applicant Proposed Route Link 5 (28.8 percent). No agricultural structures are located within the representative ROW; similarly, no agricultural structures are present in the Applicant Proposed Route Link 5.

Outside the representative ROW, tensioning or pulling areas totaling approximately 25.9 percent pasture/hay would be required during construction. No structures are present in the tensioning or pulling areas for HVDC Alternative Route 4-C.

3.2.6.3.2.1.4.4 Alternative Route 4-D

HVDC Alternative Route 4-D is approximately 25 miles long and corresponds to Applicant Proposed Route Links 4, 5, and 6. For HVDC Alternative Route 4-D, a total of 617.6 acres would be removed from existing uses. Approximately 319.4 acres (51.7 percent) of agricultural land would be removed from existing uses.

The percentage of agricultural land cover within the representative ROW (51.7 percent) is less than Links 4–6 (58.0 percent). Seven agricultural structures are located within the representative ROW. Conversely, one agricultural structure is present in the Applicant Proposed Route Link 6.

Outside the representative ROW, tensioning or pulling areas approximately 47.2 percent pasture/hay would be required during construction. The predominant land covers are pasture/hay and deciduous forest. No structures are present in the tensioning or pulling areas for HVDC Alternative Route 4-D.

3.2.6.3.2.1.4.5 Alternative Route 4-E

HVDC Alternative Route 4-E is approximately 37 miles long and corresponds to Applicant Proposed Route Links 8 and 9. For HVDC Alternative Route 4-E, 897.2 acres would be removed from existing uses. HVDC Alternative Route 4-E would disturb approximately 410.7 acres (45.8 percent) of agricultural land cover.

The percentage of agricultural land cover (45.8 percent) within the representative ROW is lower than Links 8 and 9 (or approximately 48.6 percent). Two agricultural structures are present within the representative ROW; similarly, two agricultural structures are present in the Applicant Proposed Route Link 9.

Outside the representative ROW, tensioning or pulling areas totaling approximately 147.2 acres would be required during construction. The predominant land cover, or approximately 49.7 percent, is pasture/hay. No structures are present in the tensioning or pulling areas for HVDC Alternative Route 4-E.

3.2.6.3.2.1.5 Region 5

3.2.6.3.2.1.5.1 Alternative Route 5-A

HVDC Alternative Route 5-A is approximately 13 miles long and corresponds to Applicant Proposed Route Link 1. For HVDC Alternative Route 5-A, 308.5 acres would be removed from existing uses. HVDC Alternative Route 5-A would disturb approximately 66.6 acres (21.6 percent) agricultural land (pasture/hay and grassland/herbaceous) are in the representative ROW.

The percentage of agricultural land cover within the representative ROW is comparable to Applicant Proposed Route Link 1 (approximately 21.6 percent agricultural land). No structures are located in the representative ROW, as is the case for Applicant Proposed Route Link 1.

Outside the representative ROW, tensioning or pulling areas totaling approximately 65.4 acres would be required during construction. Only 13.4 of these acres are agricultural (grassland/herbaceous or pasture/hay) in nature. No structures are present in the tensioning or pulling areas for HVDC Alternative Route 5-A.

3.2.6.3.2.1.5.2 Alternative Route 5-B

HVDC Alternative Route 5-B is approximately 71 miles long and corresponds to Applicant Proposed Route Links 3, 4, 5, and 6. For HVDC Alternative Route 5-B, 1,732.3 acres would be removed from existing uses. HVDC Alternative Route 5-B would disturb approximately 861.5 acres, or 49.7 percent, agricultural land (740.3 acres of pasture/hay, 42.0 acres of cultivated crops, and 79.2 acres of grassland/herbaceous).

The land cover within the representative ROW contains approximately 861.5 acres (or 49.7 percent) agricultural land, which is greater than the percentage of agricultural land for Links 3 through 6 (approximately 39.4 percent). One agricultural structure is located within the representative ROW. Conversely, there are no agricultural structures located within the Applicant Proposed Route Links 3 through 6.

Outside the representative ROW, tensioning or pulling areas totaling approximately 220.9 acres would be required during construction. The predominant land cover is pasture/hay. No structures are present in the tensioning or pulling areas for HVDC Alternative Route 5-B.

As described in Appendix M and summarized in Section 2.4.2.5, a route adjustment was developed for HVDC Alternative Route 5-B to maintain an end-to-end route with Applicant Proposed Route Links 2 and 3, Variation 1. The route adjustment crosses approximately 4 additional acres of agricultural land cover when compared with the original HVDC Alternative Route 5-B.

3.2.6.3.2.1.5.3 Alternative Route 5-C

HVDC Alternative Route 5-C is approximately 9 miles long and corresponds to Applicant Proposed Route Links 6 and 7. For HVDC Alternative Route 5-C, 224.6 acres would be removed from existing uses. HVDC Alternative Route 5-C would disturb approximately 81.8 acres of agricultural land (70.9 acres of pasture/hay, 10.7 acres of grassland/herbaceous, and 0.2 acre of cultivated crops).

The land cover within the representative ROW contains approximately 81.8 acres (36.4 percent) agricultural land. Agricultural land cover within the representative ROW is higher than the percentage in Applicant Proposed Route Links 6 and 7 (32.8 percent). One agricultural structure is present in the representative ROW; conversely, no agricultural structures are present in Applicant Proposed Route Link 6.

Outside the representative ROW, tensioning or pulling areas totaling approximately 54.0 acres would be required during construction. The predominant land cover, or approximately 47.6 percent, is pasture/hay. No structures are present in the tensioning or pulling areas for HVDC Alternative Route 5-C.

3.2.6.3.2.1.5.4 Alternative Route 5-D

HVDC Alternative Route 5-D is approximately 22 miles long and corresponds to Applicant Proposed Route Link 9. For HVDC Alternative Route 5-D, 529.6 acres would be removed from existing uses. HVDC Alternative Route 5-D would disturb approximately 144.6 acres or 27.3 percent of agricultural land (cultivated crops, pasture/hay, and grassland/herbaceous.)

The percentage of agricultural land cover within the representative ROW, or 27.3 percent, is lower than the Applicant Proposed Route Link 9, which contains approximately 46.7 percent agricultural land. No agriculture structures are present in the representative ROW, as is the case in the Applicant Proposed Route Link 9.

Outside the representative ROW, tensioning or pulling areas totaling approximately 89.3 acres would be required during construction, of which approximately 21.0 percent is cultivated crops. No agricultural structures are present in the tensioning or pulling areas for HVDC Alternative Route 5-D.

3.2.6.3.2.1.5.5 Alternative Route 5-E

HVDC Alternative Route 5-E is approximately 36 miles long and corresponds to Applicant Proposed Route Links 4, 5, and 6. For HVDC Alternative Route 5-E, approximately 885.1 acres would be removed from existing uses. HVDC Alternative Route 5-E would disturb approximately 467.2 acres (or 52.7 percent) of agricultural land (pasture/hay, cultivated crops, and grassland/herbaceous). The percentage of agricultural land cover within the representative ROW is higher than Links 4–6, or 44.2 percent. One agricultural structure is present in the representative ROW. Conversely, no agricultural structures are located in the Applicant Proposed Route Links 4, 5, and 6.

Outside the representative ROW, tensioning or pulling areas totaling approximately 88.4 acres would be required during construction, of which is predominantly 45.8 percent is pasture/hay. The predominant land cover is pasture/hay. No structures are present in the tensioning or pulling areas for HVDC Alternative Route 5-E.

As described in Appendix M and summarized in Section 2.4.2.5, a route adjustment was developed for HVDC Alternative Route 5-E in response to public comments on the Draft EIS to maintain an end-to-end route with

Applicant Proposed Route Links 3 and 4, Variation 2. The route adjustment crosses approximately 3 fewer acres of agricultural land cover when compared with the original HVDC Alternative Route 5-E.

3.2.6.3.2.1.5.6 Alternative Route 5-F

HVDC Alternative Route 5-F is approximately 22 miles long and corresponds to Applicant Proposed Route Links 5 and 6. For HVDC Alternative Route 5-F, 544.5 acres would be removed from existing uses. HVDC Alternative Route 5-F would disturb approximately 258.4 acres or 47.5 percent of agricultural land (pasture/hay, cultivated crops, and grassland/herbaceous).

The percentage of agricultural land cover (47.5 percent) within the representative ROW is greater than the percentage within the Applicant Proposed Route Links 5 and 6 (32.2 percent). No agricultural structures are present in the representative ROW. No agricultural structure is present in Link 5 and one other structure is present in Link 6.

Outside the representative ROW, tensioning or pulling areas totaling approximately 52.1 acres, of which 43.2 percent is pasture/hay, would be required during construction. No structures are present in the tensioning or pulling areas for Alternative Route 5-F.

3.2.6.3.2.1.6 Region 6

3.2.6.3.2.1.6.1 Alternative Route 6-A

HVDC Alternative Route 6-A is approximately 16 miles long and corresponds to Applicant Proposed Route Links 2, 3, and 4. For HVDC Alternative Route 6-A, 395.7 acres would be removed from existing uses. HVDC Alternative Route 6-A would disturb approximately 328.6 acres or 83.0 percent of agricultural land, all of which is cultivated crops in the representative ROW. The agricultural land cover within the representative ROW is composed entirely of cultivated crops (83.0 percent), a percentage that is lower than the corresponding links 2 through 4 of the Applicant Proposed Route (87.4). No agricultural structures are located in the representative ROW; conversely, one agricultural structure is present in Link 4.

Outside the representative ROW, tensioning or pulling areas totaling approximately 62.5 acres would be required during construction. The predominant land cover, or approximately 79.7 percent, is cultivated crops. No structures are present in the tensioning or pulling areas for HVDC Alternative Route 6-A.

As described in Appendix M and summarized in Section 2.4.2.6, a route adjustment was developed for HVDC Alternative Route 6-A to maintain an end-to-end route with Applicant Proposed Route Link 2, Variation 1. The route adjustment crosses approximately 12 fewer acres of agricultural land when compared with the original HVDC Alternative Route 6-A.

3.2.6.3.2.1.6.2 Alternative Route 6-B

HVDC Alternative Route 6-B is approximately 14 miles long and corresponds to Applicant Proposed Route Link 3. HVDC Alternative Route 6-B would disturb approximately 272.1 acres (79.2 percent) of agricultural land, which is all cultivated crops, in the representative ROW. For HVDC Alternative Route 6-B, 343.7 acres would be removed from existing uses. The percentage of agricultural land cover within the representative ROW is approximately 79.2 percent, compared to 84.1 percent agricultural land in the Applicant Proposed Route Link 3. No agricultural structure is located within the representative ROW for HVDC Alternative Route 6-B and no agricultural structures are present in the Applicant Proposed Route Link 3.

Outside the representative ROW, tensioning or pulling areas totaling approximately 32.3 acres would be required during construction. The predominant land cover is cultivated crops (79.7 percent). No structures are present in the tensioning or pulling areas for Alternative Route 6-B.

3.2.6.3.2.1.6.3 Alternative Route 6-C

HVDC Alternative Route 6-C is approximately 23 miles long and corresponds to Applicant Proposed Route Links 6 and 7. For HVDC Alternative Route 6-C, approximately 565.6 acres would be removed from existing uses. HVDC Alternative Route 6-C would disturb approximately 430.6 acres (or 76.1 percent) of agricultural land (cultivated crops and pasture/hay) are present in the representative ROW. The land cover within the representative ROW contains approximately 430.6 acres or 76.1 percent of agricultural land, which is higher than the percentage in Links 6 and 7 (71.7 percent). One agricultural structure is present in the representative ROW; conversely, four agricultural structures are present in Applicant Proposed Route Link 6, and no agricultural structures are present in Link 7.

Outside the representative ROW, tensioning or pulling areas totaling approximately 50.7 acres would be required during construction. The predominant land cover, or 69.2 percent, is cultivated crops. No structures are present in the tensioning or pulling areas for Alternative Route 6-C.

3.2.6.3.2.1.6.4 Alternative Route 6-D

HVDC Alternative Route 6-D is approximately 9 miles long and corresponds to Applicant Proposed Route Link 7. For HVDC Alternative Route 6-D, 223.6 acres would be removed from existing uses. HVDC Alternative Route 6-D would disturb approximately 205.3 acres (91.8 percent) of agricultural lands, all of which is cultivated crops, in the representative ROW.

The land cover within the representative ROW contains approximately 205.3 acres or 91.8 percent agricultural land, similar to that of Applicant Proposed Route Link 7 (92.3 percent). No agricultural structures are present in the representative ROW, as is the case with the Applicant Proposed Route Link 7.

Outside the representative ROW, tensioning or pulling areas totaling approximately 17.8 acres of primarily cultivated crops or 87.8 percent, would be required during construction. The predominant land cover is cultivated crops. No structures are present in the tensioning or pulling areas for Alternative Route 6-D.

Outside the representative ROW, tensioning or pulling areas totaling approximately 17.8 acres of primarily cultivated crops, or 87.8 percent, would be required during construction.

3.2.6.3.2.1.7 Region 7

3.2.6.3.2.1.7.1 Alternative Route 7-A

HVDC Alternative Route 7-A is approximately 43 miles long and corresponds to Applicant Proposed Route Link 1. For HVDC Alternative Route 7-A, 1052.0 acres would be removed from existing uses. HVDC Alternative Route 7-A would disturb approximately 828.8 acres (78.8 percent) of agricultural lands, which the majority are cultivated crops, in the representative ROW. The land cover within the representative ROW contains approximately 78.8 percent agricultural lands, similar to that of Applicant Proposed Route Link 1 (78.1 percent). No structures are present in the representative ROW, as is the case with Applicant Proposed Route Link 1.

Outside the representative ROW, tensioning or pulling areas totaling approximately 165.9 acres of primarily cultivated crops, or 83.8 percent, would be required during construction. The predominant land cover is cultivated crops. No structures are present in the tensioning or pulling areas for HVDC Alternative Route 7-A.

3.2.6.3.2.1.7.2 Alternative Route 7-B

HVDC Alternative Route 7-B is approximately 9 miles long and corresponds to Applicant Proposed Route Links 3 and 4. For HVDC Alternative Route 7-B, 209.9 acres would be removed from existing uses. HVDC Alternative Route 7-B would disturb approximately 120.4 acres or 57.4 percent of agricultural land (cultivated crops and pasture/hay) in the representative ROW.

The land cover within the representative ROW contains approximately 57.4 percent agricultural land, which is higher than the percent of agricultural land within the Applicant Proposed Route Links 3 and 4 (52.9 percent). One agricultural structure is present in the representative ROW; no agricultural structures are located within Links 3 and 4 and would not need to be removed in Links 3 and 4.

Outside the representative ROW, tensioning or pulling areas totaling approximately 53.9 acres would be required during construction. The predominant, or approximately 52.8 percent, land cover is cultivated crops. No structures are present in the tensioning or pulling areas for HVDC Alternative Route 7-B.

3.2.6.3.2.1.7.3 Alternative Route 7-C

HVDC Alternative Route 7-C is approximately 24 miles long and corresponds to Applicant Proposed Route Links 3, 4, and 5. If this route is selected, 578.6 acres would be removed from existing uses. HVDC Alternative Route 7-C would disturb approximately 422.8 acres of agricultural land (cultivated crops and pasture/hay) in the representative ROW. The land cover within the representative ROW contains approximately 73.1 percent agricultural lands, a percentage that is higher than Applicant Proposed Route Links 3 - 5 (52.6 percent). One agricultural structure is present in the representative ROW; conversely, two agricultural structures are present in Applicant Proposed Route Link 5.

Outside the representative ROW, tensioning or pulling areas totaling approximately 112.1 acres would be required during construction. The predominant, or approximately 64.9 percent, land cover is cultivated crops. No structures are present in the tensioning or pulling areas for HVDC Alternative Route 7-C.

3.2.6.3.2.1.7.4 Alternative Route 7-D

HVDC Alternative Route 7-D is approximately 7 miles long and corresponds to Applicant Proposed Route Links 4 and 5. For HVDC Alternative Route 7-D, 159.5 acres would be removed from existing uses. HVDC Alternative Route 7-D would disturb approximately 109.0 acres or 68.3 percent of agricultural land (cultivated crops and pasture/hay) in the representative ROW. The land cover within the representative ROW is approximately 68.3 percent agricultural lands, and is higher than the percentage of agricultural lands in Applicant Proposed Route Links 4 and 5 (63.5 percent). No structures are located in the representative ROW; conversely two agricultural structures may be removed in Link 5.

Outside the representative ROW, tensioning or pulling areas totaling approximately 30.1 acres would be required during construction. The predominant, or 59.5 percent, land cover is cultivated crops. No structures exist in the tensioning or pulling areas for HVDC Alternative Route 7-D.

3.2.6.3.2.2 Operations and Maintenance Impacts

Impacts from operations and maintenance of the HVDC alternative routes would be similar to those from the Applicant Proposed Route (see Section 3.2.6.2.3). The long-term impacts by region are summarized in Table 3.10-31 for pole structures. No permanent impacts are described for access roads because the locations of the access roads have not been determined at this time. It is possible that the access roads could be located in such a way that small areas of agricultural land would be isolated and no longer practicable to be used for farmland or grazing.

3.2.6.3.2.3 Decommissioning Impacts

Potential impacts during decommissioning of the Project would be similar to those of the construction phase for all Project components. Once decommissioning has been completed, all land could be returned to the preconstruction land uses described in Sections 3.2.4 and 3.2.5.

3.2.6.4 Best Management Practices

No BMPs are identified for this section. It should be noted that the Applicant has developed a comprehensive list of EPMs for the Project. A complete list of EPMs for the Project is provided in Appendix F. The EPMs would avoid or minimize potential impacts to agricultural resources.

3.2.6.5 Unavoidable Adverse Impacts

Unavoidable adverse impacts could occur if agricultural structures (e.g., barns, silos, and other out/accessory buildings) could not be avoided. Yields from lands used for crops, pasture/hay, and grazing livestock would be temporarily affected in the construction areas, and land used for transmission structures, long-term access roads, and converter stations would be removed from agricultural production until the Project was decommissioned.

3.2.6.6 Irreversible and Irretrievable Commitment of Resources

Upon decommissioning of the Project, all land could return to previous uses. There would be no irreversible or irretrievable commitment of agricultural resources.

3.2.6.7 Relationship between Local Short-term Uses and Long-term Productivity

The conversion of primarily agricultural land to an industrial use to construct and operate the Project would result in short-term use impacts. These direct effects would include the loss of crops pasture/hay and grazing land for livestock in the representative ROW as well as loss of agricultural structures. Other short-term and localized impacts include the disruption of access to local agricultural land uses during construction. The productivity of the soil in temporary construction areas may also be reduced due to compaction and soil erosion.

The short-term impacts would be minimized, however, because of multiple EPMs incorporated into the Project:

- Clean Line will coordinate with landowners to site access roads and temporary work areas to avoid and/or minimize impacts to existing operations and structures (LU-4).
- Clean Line will make reasonable efforts, consistent with design criteria, to accommodate requests from individual landowners to adjust the siting of the ROW on their properties. These adjustments may include consideration of routes along or parallel to existing divisions of land (e.g., agricultural fields and parcel boundaries) and existing

compatible linear infrastructure (e.g., roads, transmission lines, and pipelines), with the intent of reducing the impact of the ROW on private properties (LU-5).

- Clean Line will minimize clearing vegetation within the ROW, consistent with a Transmission Vegetation Management Plan filed with NERC, and applicable federal, state, and local regulations (GE-3). The TVMP may require additional analysis under NEPA depending on whether and under what conditions DOE decides to participate in the Project.
- Clean Line will work with landowners to avoid and minimize impacts to residential landscaping (LU-3).
- Clean Line will minimize the frequency and duration of road closures (LU-2).
- Clean Line will work with landowners and operators to ensure that access is maintained as needed to existing operations (e.g., to oil/gas wells, private lands, agricultural areas, pastures, hunting leases) (LU-1).

Additional Applicant EPMs that should ensure long-term productivity of land in the representative ROW include:

- Clean Line will avoid or minimize adverse effects to surface and subsurface irrigation and drainage systems (e.g., tiles). Clean Line will work with landowners to minimize the placement of structures in locations that would interfere with the operation of irrigation systems (AG-1).
- Agricultural soils temporarily impacted by construction, operation, or maintenance activities will be restored to pre-activity conditions. For example, soil remediation efforts may include decompaction, recontouring, liming, tillage, fertilization, or use of other soil amendments (AG-2).
- Clean Line will consult with landowners and/or tenants to identify the location and boundaries of agriculture or conservation reserve lands and to understand the criteria for maintaining the integrity of these committed lands. (AG-3).
- Clean Line will work with landowners and/or tenants to identify specialty agricultural crops or lands (e.g., certified organic crops or products that require special practices, techniques, or standards) that require protection during construction, operation, or maintenance. Clean Line will avoid and/or minimize impacts that could jeopardize standards or certifications that support specialty croplands or farms (AG-4).
- Clean Line will work with landowners and/or tenants to consider potential impacts to current aerial spraying or application (i.e., aerial crop spraying) of herbicides, fungicides, pesticides, and fertilizers within or near the transmission ROW. Clean Line will avoid or minimize impacts to aerial spraying practices when routing and siting the transmission line and related infrastructure (AG-5).
- Clean Line will work with landowners to develop compensation for lost crop value caused by construction and/or maintenance (AG-6).
- Clean Line will work with landowners to develop a site plan for each cropland farm on which construction or maintenance is to be performed (AG-7).
- Clean Line will stabilize slopes exposed by its activities to minimize erosion (GEO-1).

3.2.6.8 Connected Actions

3.2.6.8.1 Wind Energy Generation

The primary existing land use in the 12 WDZs is agriculture. Sections 3.2.6.8.1.1 through 3.2.6.8.1.12 provide more detailed information on the type of agricultural land impacted by the WDZs. It is estimated that during the construction phase, approximately 2 percent of land within a wind energy facility is affected (Denholm et al. 2009). Assuming between 20 and 30 percent of the WDZs would be built-out, between 4,328 and 6,492 acres of primarily agricultural land would be temporarily affected during construction.[1] Wind farm developers are typically able to microsite turbines and other facility components to avoid displacing or damaging agricultural structures such as irrigation equipment, barns, and silos.

During the operations and maintenance phase of wind energy facilities, approximately 1 percent or less of the land is affected or disturbed. Assuming 20 to 30 percent build-out for the 12 WDZs, a total of 2,164 to 3,246 acres of primarily agricultural land would be affected for the life of the Project (1 percent of the 20 percent for the low end, 1 percent of the 30 percent for the high end). Impacts to agricultural lands and soils would be similar to those discussed above for Project components, and a typical wind energy project could include similar EPMs.

Landowners could benefit financially from a wind farm through lease payments when turbines are sited on their lands. Given their relatively small footprints, wind turbines do not substantially decrease the land available for agricultural purposes, allowing landowners to benefit financially from lease payments and agriculture. Wind lease agreements typically include provisions to minimize the losses, including minimizing soil compaction and revegetating temporary work areas. In addition, the agreements typically stipulate compensation for landowners for any losses, such as damage or loss of crops, gates, fences, landscaping and trees, irrigation, and livestock.

Once construction has been completed, agricultural operations would be able to continue in most of the wind farm. Agricultural activities such as cultivating crops and livestock grazing are generally permitted up to the wind turbine pads, so only a very minimal area of existing agricultural land would be removed from production for the life of the Project, although long-term access roads and the configuration of wind turbines may change the configuration of fields for crops and grazing.

3.2.6.8.2 Optima Substation

The future Optima substation is anticipated to be constructed on 160 acres of currently undeveloped land near an operating wind energy facility. The land cover of the site is primarily grassland/herbaceous. Any agricultural practices, such as grazing, that currently occur on the site would be converted to a utility use.

3.2.6.8.3 TVA Upgrades

The TVA upgrades, like the Project, are linear projects (except for substation modifications) with relatively small amounts of long-term of ground disturbance considering the amount of area crossed (except in forested areas where ground disturbance resulting from ROW clearing can impact large areas). Upon completion of construction, much of the affected agricultural land could return to previous uses. Much of the following discussion is only relevant to the new 500kV transmission line, or for certain upgrades associated with the 161kV transmission lines. The TVA upgrades to existing facilities (including existing transmission lines and existing substations) should have minimal impacts to agricultural resources as ground disturbance is typically limited to the immediate vicinity of the structure.

[1] Approximately 20 to 30 percent of the 1,082,000 acres suitable for wind development would be built out (or between 216,400 and 324,600 acres). During the construction phase, approximately 2 percent of the total acreage would be disturbed. For the low end of the range, 2 percent of 216,400 is 4,328 acres. For the high end, 2 percent of 324,600 is 6,492 acres.

Upgrades required to interconnect into the TVA transmission grid could involve new disturbance of agricultural lands. Potential impacts to agricultural resources for the new transmission line, upgrades to existing lines, and modifications to substations would be similar to impacts described in detail in Section 3.2.6 for the Project. Impacts during construction could involve loss of vegetation and soil at construction sites and along travel routes; possible temporary loss of the use of structures such as barns, ponds, and silos; and possible curtailment of actions such as animal feeding operations. These types of impacts likely would be short term for the new 500 kV transmission line, although it is possible that loss of the use of structures could be long term. Potential agricultural impacts associated with the required upgrades to existing TVA facilities are not anticipated to result in significant impacts to agricultural land. The degree of potential impacts associated with the new electric transmission line would depend on the types of agriculture within the existing transmission line ROW. To the extent practicable, the new 500kV transmission line would be routed to avoid interference with crop irrigation systems. For the upgrades to existing structures, ground disturbance is typically limited to the immediate vicinity of the structure.

The majority of the ROW would be disturbed during construction of the new transmission line. Areas of fully dedicated uses (e.g., sites of structures and permanent access roads) would experience longer-term impacts than ROW areas, where existing land use may continue after construction.

During operations and maintenance of the new 500kV transmission line, agricultural activities could resume to a large extent on most disturbed areas, but some constraints and limitations would be likely, such as land use limitations within ROWs, physical interference with agricultural equipment operations, and periodic loss of access during maintenance activities. These impacts are long-term impacts. Also during operations, transmission structures could affect aerial spraying activities often used in agricultural areas. This effect could involve requiring the spraying to be performed at higher altitudes resulting in more chance for overspray or drift that could affect adjoining properties, or it could eliminate aerial spraying in some areas. Effects on the economic value of livestock production could occur through a combination of decreasing forage land available and by increasing management costs of controlling noxious and invasive vegetation species introduced during construction and costs of moving livestock around project-related structures and ROWs. Anticipated effects from upgrades to existing structures, conductor, or substations would be expected to include ground disturbance that is typically limited to the immediate vicinity of the structure; no changes would be expected with the existing uses of the ROWs.

3.2.6.9 Impacts Associated with the No Action Alternative

Under the No Action Alternative, DOE assumes for analytical purposes that the Project would not be constructed. There would be no impacts on agricultural land or resources. The existing agricultural activity throughout the regions would be expected to continue.

Figures Presented in Appendix A

3.3 Air Quality and Climate Change

This section addresses potential air quality and climate change impacts from the Project and alternatives during construction, operation, and decommissioning. Emissions of air pollutants from the Project would primarily be generated from the following activities:

- Construction of on- and off-ROW access roads
- Construction of the support structure pad sites and structure erection
- Post-construction activities involved with the ongoing use and maintenance of the transmission line, converter stations, and corridor

Air quality in a given location is determined by the concentration of various pollutants in the atmosphere. Air pollutants can be divided into three categories: criteria air pollutants for which EPA has established National Ambient Air Quality Standards (NAAQS) to protect health and welfare, toxic air pollutants (chemicals and chemical classes that have carcinogenic, mutagenic, or other hazardous effects), and greenhouse gases (GHGs) (gases that have been identified as the main cause of observed global climate change) (Buizer et al. 2013).

3.3.1 Regulatory Background

3.3.1.1 Federal

Federal air pollution regulations focus largely on criteria and toxic pollutants and include provisions applicable to stationary and mobile sources.

For criteria pollutants, NAAQS represent maximum levels of background pollution that are considered safe. Primary standards protect public health, including the health of sensitive populations, such as asthmatics, children, and the elderly. Secondary standards protect public welfare, including protecting against decreased visibility and damage to animals, crops, vegetation, and buildings. Pursuant to the CAA, EPA has established NAAQS for ambient concentrations of ozone (O_3), carbon monoxide (CO), nitrogen dioxide (NO_2), sulfur dioxide (SO_2), particulate matter (PM_{10} [i.e., particulate matter 10 microns or smaller in diameter] and $PM_{2.5}$), and airborne lead. NAAQS represent maximum acceptable concentrations that generally may not be exceeded more than once per year, except the annual standards, which may never be exceeded. The federal CAA amendments of the 1990s require states to control air pollution emission sources so that NAAQS are met and maintained. An area that does not meet the NAAQS is designated as a nonattainment area on a pollutant-by-pollutant basis.

Toxic air pollutants cause or may cause cancer or other serious health effects, such as reproductive effects or birth defects, or adverse environmental and ecological effects. The Clean Air Act currently requires EPA to regulate 187 toxic air pollutants. In contrast to the geographically based approach used for criteria pollutants, for toxic air pollutants, EPA has identified major industrial sources that emit these pollutants and developed national technology-based performance standards to significantly reduce their emissions.

A substantial amount of construction activity would occur with the Project, and fuel-fired construction equipment is a mobile source of air pollution. Mobile sources of air pollution are primarily regulated at the point of manufacture (manufacturers have been required to meet increasingly stringent emissions requirements in 40 CFR Parts 86, 89, 90, 1039, and 1048) and fuels are regulated at the fuel supplier end (40 CFR Part 80 requirements apply to criteria air pollutants and toxics, and include Renewable Fuels Standard requirements to address GHG emissions). Mobile sources can also trigger the need for a General Conformity determination (40 CFR Part 93, Subpart B) if they are emitting sufficiently large quantities of an air pollutant in an area designated “nonattainment” with respect to a current NAAQS, or which was previously designated “nonattainment” with respect to a current NAAQS (and is therefore a “maintenance” area). In such areas, a federal agency must make a determination that permitting or approving an activity will conform to the state implementation plan when the total of direct and indirect emissions (of the nonattainment/maintenance pollutant, or its precursors) in that area would equal or exceed *de minimis* levels identified in 40 CFR Part 93 Subpart B, which vary depending on the pollutant and attainment status but are no higher than 100 TPY.

3.3.1.2 State

The Project would cross through portions of Oklahoma, Arkansas, Tennessee, and Texas, with each state providing regulations for air pollutant emissions. Generally each state’s ambient air quality standards are the same as the NAAQS. In addition, each state and/or locality may have specific air regulations that the potential construction activities may need to comply with or that may require the Applicant to obtain necessary permits. Specifically, in the event that any controlled burning activities would be conducted, they would be performed in accordance with all local, state, and federal requirements. These activities also would be performed in accordance with any applicable smoke management guidelines for each state and/or locality.

3.3.2 Data Sources

Data sources used to evaluate the affected environment for air quality and climate change, as well as assess air quality and climate change impacts, include the following:

- Historical meteorological data from the National Oceanic and Atmospheric Administration’s National Climatic Data Center (NCDC 2014)
- EPA AirData archived historical ambient air quality measurements (GIS Data Source: EPA 2014)
- CAA attainment designations (42 USC § 7401 et seq.)
- U.S. Global Change Research Program (USGCRP) climate assessments (USGCRP 2014)
- Clean Line-required construction equipment (Appendix F)
- Clean Line-required operational equipment (Appendix F)
- Intergovernmental Panel on Climate Change Fifth Assessment Report (IPCC 2013)
- EPA emission factors for stationary point and area sources (EPA 2008)
- EPA NONROAD2008a emissions model (EPA 2009)
- EPA Motor Vehicle Emissions Simulator (MOVES) 2010b emissions model (EPA 2012)
- EPA Air Quality Monitoring Stations (GIS Data Source: EPA 2014)

3.3.3 Region of Influence

For air quality, the ROI for the Applicant Proposed Route, DOE Alternatives, and connected actions are generally the same as Section 3.1.1. However, for criteria air pollutants, to be conservative the ROI has been extended to approximately 300–500 feet from the roadway (CARB 2005). The reason for the expansion of the ROI is to provide an added level of conservatism in the analysis of air quality impacts to sensitive areas. The ROI includes sensitive areas including residential areas and schools. Locations of residences and schools are shown in Figure 1.0-2 located in Appendix A of the EIS. The only two schools within the ROI are within AC Collection System Route E-1, located within the town of Hardesty. Appendix E lists specific air quality concerns expressed during public scoping which are evaluated for each region of the Project.

GHGs are a global issue, involving pollutants that have relatively long lifetimes in the atmosphere and that accumulate over time. Science has not yet progressed to the point where localized impacts from GHGs as a whole can be quantitatively predicted (Kerr 2013), and GHG emissions that result from construction activities by themselves are likely to have a negligible impact on current GHG concentrations because the current concentrations reflect accumulations of pollutants over time and are therefore many orders of magnitude higher than the contribution of GHGs from the Project. GHGs are primarily of interest because of the cumulative impacts (i.e., from all sources) on global climate, as will be discussed in more detail in Section 3.3.4.

3.3.4 Affected Environment

As mentioned previously, air pollutants can be divided into three classes: criteria pollutants, toxic pollutants, and GHGs. The seven air pollutants listed below are criteria pollutants for which EPA has developed NAAQS:

- SO_2
- CO
- NO_2
- O_3
- PM_{10}
- $PM_{2.5}$
- Lead and its compounds (measured as lead)

Precursors to criteria pollutants include those that cause the formation of the pollutant after they are emitted; for example, O_3 in the ambient air is predominantly formed by photochemical reactions between oxides of nitrogen (NO_x) and volatile organic compounds (VOCs).

Concentrations of pollutants in the ambient air vary over time and therefore many of the NAAQS (Table 3.3-1) are focused on statistical functions (98th percentile concentrations, 99th percentile concentrations, etc.). They also vary spatially, so a network of air quality monitoring stations is used to assess regional air quality (see Figure 3.3-1 in Appendix A) to determine whether counties should be designated as “attainment” or “nonattainment” with respect to the NAAQS. For any particular NAAQS, if an area previously designated as “nonattainment” is redesignated as “attainment,” it is classified as a “maintenance” area (i.e., the subset of attainment areas that were previously designated as nonattainment for that standard). As identified in 40 CFR 81, the entire ROI has been designated as attainment for all of the NAAQS, with the exception of Shelby County, Tennessee (containing the city of Memphis), which is designated “marginal” nonattainment for ozone and is a maintenance area for CO.

Each of the criteria pollutants listed in Table 3.3-1 except ozone are emitted directly; ozone can also be emitted directly by a few sources but is predominantly a result of reactions between NO_x—predominantly NO_2 and nitrogen oxide (NO)—and VOCs in the air, particularly in the warmer months. For this reason, criteria pollutant emissions inventories include NO_x and VOCs, even though they are not criteria pollutants themselves.

Table 3.3-1:
Criteria Pollutants, National Ambient Air Quality Standards

Air Pollutant	Averaging Period	Primary NAAQS	Secondary NAAQS
SO_2 (ppb)	1-Hour [1]	75	NA
	3-Hour	NA	500
CO (ppm)	1-Hour [2]	35	NA
	8-Hour [2]	9	NA
NO_2 (ppb)	1-Hour [3]	100	NA
	Annual	53	53
Ozone (ppm)	8-Hour [4]	0.075	0.075
PM_{10} (µg/m^3)	24-Hour [5]	150	150
$PM_{2.5}$ (µg/m^3)	24-Hour [6]	35	35
	Annual [7]	12.0	15.0
Lead (µg/m^3)	3-Month [8]	0.15	0.15

µg/m^3 = micrograms per cubic meter
ppb = parts per billion
ppm = parts per million
1 NAAQS applies to the 3-year average of the annual (99th percentile) of the daily maximum1-hour average concentration.
2 NAAQS is not to be exceeded more than once per calendar year.
3 NAAQS applies to the 3-year average of the annual (98th percentile) of the daily maximum 1-hour average concentration.
4 NAAQS applies to the 3-year average of the annual 4th highest daily maximum 8-hour average concentration.
5 Not to be exceeded more than once per year on average over 3 years.
6 NAAQS applies to the 3-year average of the annual 98th percentile 24-hour concentration.
7 NAAQS applies to the 3-year average of annual concentrations.
8 NAAQS applies to the maximum arithmetic 3-month mean.

While the scientific understanding of climate change continues to evolve, the Intergovernmental Panel on Climate Change Fifth Assessment Report has stated that warming in the of the Earth's climate is unequivocal, that continued emissions of GHGs will cause further warming and changes in all of the components of the climate system, and that limiting climate change will require substantial and sustained reductions of GHG emissions (IPCC 2013). The report also states that it is "virtually certain" that there will be more frequent hot and fewer cold temperature extremes over most land areas on daily and seasonal timescales as global mean temperatures increase, that it is "very likely" that heat waves will occur with a higher frequency and duration, that the global ocean will continue to warm during the 21st century, that global mean sea level will continue to rise during the 21st century, and that most aspects of climate change will persist for many centuries even if emissions of CO_2 are stopped (IPCC 2013). GHGs include CO_2, methane (CH_4), and nitrous oxide (N_2O). No specific "ambient standards" exist for these pollutants, but for context, total U.S. anthropogenic (human-caused) GHG emissions were 6,576 million metric tonnes carbon dioxide equivalent (CO_2e) in 2009, and 40 percent of these were from the electric power sector (EIA 2011). Unlike criteria pollutants and air toxics, GHG concentrations have been increasing over time, and are continuing to increase. Although there are not localized monitoring networks, 2011 average concentrations of CO_2, CH_4, and N_2O were 391 ppm, 1,803 parts per billion, and 324 parts per billion, respectively, meaning that they exceeded pre-industrial levels (year 1750) by about 40 percent, 150 percent, and 20 percent, respectively (IPCC 2013). The Intergovernmental Panel on Climate Change (2013) has concluded that it is "likely" (66–100 percent probability) that GHGs contributed a global mean surface warming in the range of 0.5 C to 1.3 C over the period 1951 to 2010 and "extremely likely" (95–100 percent probability) that more than half of the observed increase in global average surface temperature from 1951 to 2010 was caused by the anthropogenic increase in GHG concentrations and other anthropogenic forcings together.

In response to public comments on the Draft EIS, several route variations to the Applicant Proposed Route were developed in Regions 2–7. These route variations are described by region in Sections 2.4.2.1 through 2.4.2.7. Because none of the route variations resulted in a change to equipment, operating schedules, vehicle trips, ground disturbance areas, etc. associated with construction activities, none of the route variations would result in changes to impacts to air quality or climate change.

3.3.4.1 Meteorological Conditions

Locally, the climate of the ROI varies by state depending largely on proximity to large waterbodies and mountain ranges (NCDC 2014). The portion of the ROI in Oklahoma and the Texas Panhandle experience extreme temperature changes, especially in the winter months, from cold fronts moving west to east after crossing the Rocky Mountains. The Oklahoma and Texas panhandles represent the driest portions of the ROI. Arkansas' climate is generally warmer and more humid in the lowlands than in the mountainous regions. Arkansas rarely incurs drought conditions given the relatively consistent annual precipitation. The Shelby County, Tennessee, portion of the ROI has similar meteorological conditions to those of the Arkansas lowlands.

3.3.5 Regional Description

Tables 3.3-2 through 3.3-8 provide existing air quality monitoring data for criteria air pollutants for stations located within or in relatively close proximity to each of the regions (GIS Data Source: EPA 2014). Generally, the monitoring stations are located in populated areas and therefore the reported concentrations may be higher than those in the more rural areas where project construction is occurring. The following subsections provide a brief description of each region's topography and meteorology. Topography and meteorology affect how air moves. For example, mountainous regions can act as barriers between air pollution concentrations and other areas.

3.3.5.1 Region 1

Region 1 is referred to as the Oklahoma Panhandle Region and includes the Applicant Proposed Route and HVDC Alternative Routes I-A through I-D. The area is generally flat with temperature extremes resulting from weather patterns moving west to east after crossing the Rocky Mountains (NCDC 2014). Existing air quality monitoring for Region 1 is summarized in Table 3.3-2. Generally, the monitoring stations are sited in populated areas and, as a result, criteria pollutant levels in more rural areas of Region 1 are likely lower than those obtained by the nearest monitoring stations. Region 1 is rural in nature with limited development.

Table 3.3-2:
Criteria Pollutants, National Ambient Air Quality Standards and Existing Air Quality in Region 1

Air Pollutant	Averaging Period	Primary NAAQS	Secondary NAAQS	Nearest Ambient Monitoring Site(s)	Distance to Nearest Monitoring Station (miles)[9]	Most Recent Quality-Assured Data [10]
SO_2 (ppb)	1-Hour [1]	75	NA	Oklahoma County, OK	127	5.3
	3-Hour	NA	500			—[11]
CO (ppm)	1-Hour [2]	35	NA	Oklahoma County, OK	127	1.37
	8-Hour [2]	9	NA			0.8
NO_2 (ppb)	1-Hour [3]	100	NA	Oklahoma County, OK	127	54
	Annual	53	53			—[11]

Table 3.3-2:
Criteria Pollutants, National Ambient Air Quality Standards and Existing Air Quality in Region 1

Air Pollutant	Averaging Period	Primary NAAQS	Secondary NAAQS	Nearest Ambient Monitoring Site(s)	Distance to Nearest Monitoring Station (miles)[9]	Most Recent Quality-Assured Data [10]
Ozone (ppm)	8-Hour [4]	0.075	0.075	Dewey County, OK	40	0.074
PM_{10} ($\mu g/m^3$)	24-Hour [5]	150	150	Ford County, KS	70	58
$PM_{2.5}$ ($\mu g/m^3$)	24-Hour [6]	35	35	Oklahoma County, OK	127	20
	Annual [7]	12.0	15.0	Oklahoma County, OK	127	10
Lead ($\mu g/m^3$)	3-Month [8]	0.15	0.15	Amarillo, TX	115	EPA AirData does not publish data

$\mu g/m^3$ = micrograms per cubic meter
ppb = parts per billion
ppm = parts per million
1 NAAQS applies to the 3-year average of the annual (99th percentile) of the daily maximum1-hour average concentration.
2 NAAQS is not to be exceeded more than once per calendar year.
3 NAAQS applies to the 3-year average of the annual (98th percentile) of the daily maximum 1-hour average concentration.
4 NAAQS applies to the 3-year average of the annual 4th highest daily maximum 8-hour average concentration.
5 Not to be exceeded more than once per year on average over 3 years.
6 NAAQS applies to the 3-year average of the annual 98th percentile 24-hour concentration.
7 NAAQS applies to the 3-year average of annual concentrations.
8 NAAQS applies to the maximum arithmetic 3-month mean.
9 Distance to the nearest monitoring station was estimated from Applicant Proposed Route and HVDC alternative routes.
10 Data for 2013 have not yet been quality-assured/finalized; therefore, the data shown are for 2010–2012 (and exclude exception events per 40 CFR 50.14). The values in this column for the Seiling, Oklahoma, station data were obtained from the state's 2012 Annual Monitoring Report http://www.deq.state.ok.us/aqdnew/airreport2012/2012o3.html and for remaining sites not included in Oklahoma's annual report data were obtained from EPA AirData (GIS Data Source: EPA 2014).
11 These averages not tabulated, since highest one-hour concentrations are well below the average standard.

3.3.5.2 Region 2

Region 2 is referred to as the Oklahoma Central Great Plains Region and includes the Applicant Proposed Route and HVDC Alternative Routes 2-A through 2-B. Like Region, 1 it is generally flat with temperature extremes resulting from weather patterns moving west to east after crossing the Rocky Mountains (NCDC 2014). Existing air quality monitoring for Region 2 is provided in Table 3.3-3. Generally, the monitoring stations are sited in populated areas and, as a result, criteria pollutant levels in Region 2 may be lower than those obtained by the nearest monitoring stations. The area is rural and development is limited.

Table 3.3-3:
Criteria Pollutants, National Ambient Air Quality Standards and Existing Air Quality in Region 2

Air Pollutant	Averaging Period	Primary NAAQS	Secondary NAAQS	Nearest Ambient Monitoring Site(s)	Distance to Nearest Monitoring Station (miles)[9]	Most Recent Quality-Assured Data[10]
SO_2 (ppb)	1-Hour [1]	75	NA	Oklahoma County, OK	40	5.3
	3-Hour	NA	500			—[11]
CO (ppm)	1-Hour [2]	35	NA	Oklahoma County, OK	40	1.37
	8-Hour [2]	9	NA			0.8

Table 3.3-3:
Criteria Pollutants, National Ambient Air Quality Standards and Existing Air Quality in Region 2

Air Pollutant	Averaging Period	Primary NAAQS	Secondary NAAQS	Nearest Ambient Monitoring Site(s)	Distance to Nearest Monitoring Station (miles)[9]	Most Recent Quality-Assured Data[10]
NO_2 (ppb)	1-Hour [3]	100	NA	Oklahoma County, OK	40	54
	Annual	53	53			—[11]
Ozone (ppm)	8-Hour [4]	0.075	0.075	Dewey County, OK	9	0.074
PM_{10} (µg/m^3)	24-Hour [5]	150	150	Oklahoma County, OK	40	59

	Annual [7]	12.0	15.0	Oklahoma County, OK	40	10
Lead (µg/m^3)	3-Month [8]	0.15	0.15	Tulsa, OK	97	0.008

For table notes, see Table 3.3-2.

3.3.5.3 Region 3

Region 3 is referred to as the Oklahoma Cross Timbers Region and includes the Applicant Proposed Route and HVDC Alternative Routes 3-A through 3-E. The area, much like Regions 1 and 2, is generally flat, although at the Oklahoma-Arkansas border there are some mountainous areas coinciding with the Ouachita Mountains. Temperature extremes result from weather patterns moving west to east after crossing the Rocky Mountains (NCDC 2014). Existing air quality monitoring for Region 3 is provided in Table 3.3-4. Although all three monitoring stations show ozone concentrations in excess of the NAAQS, the area has not been redesignated as “nonattainment” for ozone.

Table 3.3-4:
Criteria Pollutants, National Ambient Air Quality Standards and Existing Air Quality in Region 3

Air Pollutant	Averaging Period	Primary NAAQS	Secondary NAAQS	Nearest Ambient Monitoring Site(s)	Distance to Nearest Monitoring Station (miles) [9]	Most Recent Quality-Assured Data[10]
SO_2 (ppb)	1-Hour [1]	75	NA	Oklahoma County, OK	29	5.3
	3-Hour	NA	500			—[11]
CO (ppm)	1-Hour [2]	35	NA	Oklahoma County, OK	29	1.37
	8-Hour [2]	9	NA			0.8
NO_2 (ppb)	1-Hour [3]	100	NA	Oklahoma County, OK	29	54
	Annual	53	53			—[11]

$PM_{2.5}$ (µg/m^3)	24-Hour [6]	35	35	Oklahoma County, OK	29	20
	Annual [7]	12.0	15.0	Oklahoma County, OK	29	10
Lead (µg/m^3)	3-Month [8]	0.15	0.15	Tulsa, OK	30	0.008

For table notes see Table 3.3-2.

3.3.5.4 Region 4

Region 4 is referred to as the Arkansas River Valley Region and includes the Applicant Proposed Route and HVDC Alternative Routes 4-A through 4-E as well as the Lee Creek Variation. The Region includes elevation changes associated with the Ouachita Mountains in the western part of the state as the Arkansas River meanders through the region, although the region is generally flat. The temperature is generally warmer in Arkansas than in Project regions to the west (NCDC 2014). Existing air quality monitoring for Region 4 is provided in Table 3.3-5. Though the Stilwell monitoring station shows ozone concentrations in excess of the NAAQS, the area is still formally classified as "attainment" for ozone and has yet to be redesignated as nonattainment for ozone.

Table 3.3-5:
Criteria Pollutants, National Ambient Air Quality Standards and Existing Air Quality in Region 4

Air Pollutant	Averaging Period	Primary NAAQS	Secondary NAAQS	Nearest Ambient Monitoring Site(s)	Distance to Nearest Monitoring Station (miles)[9]	Most Recent Quality-Assured Data[10]
SO_2 (ppb)	1-Hour [1]	75	NA	Adair County, OK	12	7.3
	3-Hour	NA	500			—[11]
CO (ppm)	1-Hour [2]	35	NA	Adair County, OK	12	0.63
	8-Hour [2]	9	NA			0.33
NO_2 (ppb)	1-Hour [3]	100	NA	Adair County, OK	12	16
	Annual	53	53			—[11]

PM_{10} (µg/m^3)	24-Hour [5]	150	150	Adair County, OK	12	87
$PM_{2.5}$ (µg/m^3)	24-Hour [6]	35	35	Adair County, OK	12	26
	Annual [7]	12.0	15.0	Adair County, OK	12	12
				Sequoyah County, OK	6	10.8
Lead (µg/m^3)	3-Month [8]	0.15	0.15	Pulaski County, AR	70	EPA AirData does not publish data

For table notes, see Table 3.3-2.

3.3.5.5 Region 5

Region 5 is referred to as the Central Arkansas Region and includes the Applicant Proposed Route and HVDC Alternative Routes 5-A through 5-F. The region is generally flat and, like Region 4, the temperature is generally warmer in Arkansas than in Project regions further west (NCDC 2014). Existing air quality monitoring for Region 5 is provided in Table 3.3-6. The Little Rock monitoring station shows ozone concentrations in excess of the NAAQS, but the area has not been redesignated as "nonattainment" for ozone. In addition, Little Rock is a highly populated area, so criteria pollutant levels in the more remote Region 5 area (rural, with limited development) are likely to be lower than those measured in Little Rock and would be included in the nonattainment area for Little Rock.

Table 3.3-6:
Criteria Pollutants, National Ambient Air Quality Standards and Existing Air Quality in Region 5

Air Pollutant	Averaging Period	Primary NAAQS	Secondary NAAQS	Nearest Ambient Monitoring Site(s)	Distance to Nearest Monitoring Station (miles)[9]	Most Recent Quality-Assured Data[10]
SO_2 (ppb)	1-Hour [1]	75	NA	Pulaski County, AR	40	10.3
	3-Hour	NA	500			—[11]
CO (ppm)	1-Hour [2]	35	NA	Pulaski County, AR	40	1.8
	8-Hour [2]	9	NA			1.47
NO_2 (ppb)	1-Hour [3]	100	NA	Pulaski County, AR	40	51
	Annual	53	53			—[11]
Ozone (ppm)	8-Hour [4]	0.075	0.075	Pulaski County, AR	40	0.078
				Newton County, AR	25	0.069
PM_{10} ($\mu g/m^3$)	24-Hour [5]	150	150	Pulaski County, AR	40	87
$PM_{2.5}$ ($\mu g/m^3$)	24-Hour [6]	35	35	Pulaski County, AR	40	26
	Annual [7]	12.0	15.0	Pulaski County, AR	40	12
Lead ($\mu g/m^3$)	3-Month [8]	0.15	0.15	Pulaski County, AR	40	EPA AirData does not publish data

For table notes, see Table 3.3-2.

3.3.5.6 Region 6

Region 6 is referred to as the Cache River and Crowley's Ridge Region and the Applicant Proposed Route and includes HVDC Alternative Routes 6-A through 6-D. The region is generally flat and, like Regions 4 and 5, the temperature is generally warmer in Arkansas than in Project regions further west (NCDC 2014). Existing air quality monitoring for Region 6 is provided in Table 3.3-7. Generally the monitoring stations are sited in populated areas and, as a result, criteria pollutant levels in Region 6 are assumed to be lower than those obtained by the monitoring stations. For example, the levels monitored at the Crittenden County, Arkansas, and Shelby County, Tennessee, stations are within the Memphis metropolitan area, which is nonattainment for criteria pollutant ozone. Region 6 is rural, located over 30 miles from the monitoring stations near Memphis; therefore, ozone emissions are thought to be lower than those provided in Table 3.3-7. The area is rural in nature with limited development.

Table 3.3-7:
Criteria Pollutants, National Ambient Air Quality Standards and Existing Air Quality in Region 6

Air Pollutant	Averaging Period	Primary NAAQS	Secondary NAAQS	Nearest Ambient Monitoring Site(s)	Distance to Nearest Monitoring Station (miles)[9]	Most Recent Quality-Assured Data[10]
SO_2 (ppb)	1-Hour [1]	75	NA	Shelby County, TN	41	12
	3-Hour	NA	500			—[11]
CO (ppm)	1-Hour [2]	35	NA	Shelby County, TN	41	2.3
	8-Hour [2]	9	NA			1.8
NO_2 (ppb)	1-Hour [3]	100	NA	Crittenden County, AR	25	46
	Annual	53	53			—[11]
Ozone (ppm)	8-Hour [4]	0.075	0.075	Crittenden County, AR	25	0.080
				Shelby County, TN	41	0.079
PM_{10} ($\mu g/m^3$)	24-Hour [5]	150	150	Shelby County, TN	41	41

Table 3.3-7:
Criteria Pollutants, National Ambient Air Quality Standards and Existing Air Quality in Region 6

	Annual [7]	12.0	15.0	Jackson County, AR	5	10
Lead (µg/m^3)	3-Month [8]	0.15	0.15	Pulaski County, AR	74	EPA AirData does not publish data

For table notes, see Table 3.3-2.

3.3.5.7 Region 7

Region 7 is referred to as the Arkansas Mississippi River Delta and Tennessee Region and includes the Applicant Proposed Route and HVDC Alternative Routes 7-A through 7-D.The region is generally flat and shares meteorological conditions similar to the lowland areas of Arkansas (NCDC 2014). Much of the area is rural in nature with limited development, although the portions closest to the Memphis area are slightly more developed. Existing air quality monitoring for Region 7 is provided in Table 3.3-8. As stated in Section 3.3.4, Shelby County, Tennessee is designated “marginal nonattainment” with respect to the current ozone NAAQS, and is also a maintenance area with respect to the carbon monoxide NAAQS.

Table 3.3-8:
Criteria Pollutants, National Ambient Air Quality Standards and Existing Air Quality in Region 7

Air Pollutant	Averaging Period	Primary NAAQS	Secondary NAAQS	Nearest Ambient Monitoring Site(s)	Distance to Nearest Monitoring Station (miles)[9]	Most Recent Quality-Assured Data[10]
SO_2 (ppb)	1-Hour [1]	75	NA	Shelby County, TN	11	12
	3-Hour	NA	500			—[11]
CO (ppm)	1-Hour [2]	35	NA	Shelby County, TN	11	2.3
	8-Hour [2]	9	NA			1.8
NO_2 (ppb)	1-Hour [3]	100	NA	Crittenden County, AR	18	46
	Annual	53	53			—[11]

$PM_{2.5}$ (µg/m^3)	24-Hour [6]	35	35	Crittenden County, AR	18	23
				Shelby County, TN	11	23
	Annual [7]	12.0	15.0	Crittenden County, AR	18	11
				Shelby County, TN	11	10
Lead (µg/m^3)	3-Month [8]	0.15	0.15	Shelby County, TN	11	EPA AirData does not publish data

For table notes, see Table 3.3-2.

3.3.5.8 Connected Actions

3.3.5.8.1 Wind Energy Generation

The WDZs are all located within the Oklahoma Panhandle and the adjacent portions of Texas; therefore, the existing air quality is the same as that discussed in Section 3.3.5.1 for Region 1.

3.3.5.8.2 Optima Substation

The future Optima Substation would be located partially located within the Oklahoma AC Interconnection Siting Area. The existing air quality is the same as discussed in Section 3.3.5.1 for Region 1.

3.3.5.8.3 TVA Upgrades

The ROI for the direct assignment facilities (which are included in the Applicant Proposed Project) would occur within the Tennessee Converter Station Siting Area and more specifically within the Shelby Substation. The ROI for the network upgrades, and in particular TVA's future 500kV transmission line, cannot be fully determined at this time. The new 500kV transmission line would be constructed in western Tennessee. The upgrades to existing facilities would mostly be in western and central Tennessee. Upgrades to existing infrastructure would include upgrading terminal equipment at three existing 500kV substations and six existing 161kV substations, making appropriate upgrades to increase heights on 16 existing 161kV transmission lines to increase line ratings, and replacing the conductors on eight existing 161kV transmission lines. With the exception of Shelby County (see Section 3.3.5.7), none of western and central Tennessee is designated as nonattainment with current NAAQS. Where possible, general impacts associated with the required TVA upgrades are discussed in the impact sections that follow.

3.3.6 Impacts to Air Quality and Climate Change

Construction and operations and maintenance of the Project would involve sources of emissions of air pollutants and GHG emissions. This section is organized as follows:

- Section 3.3.6.1 summarizes the methodology used to quantify emissions.
- Section 3.3.6.2 describes the impacts associated with the Applicant Proposed Project.
- Section 3.3.6.3 describes the impacts associated with the DOE Alternatives.
- Section 3.3.6.4 describes the BMPs for emissions minimization.
- Sections 3.3.6.5 and 3.3.6.6 discuss unavoidable adverse impacts and irreversible and irretrievable commitments of resources, respectively.
- Sections 3.3.6.7 describe the relationship between local short-term uses and long-term productivity.
- Section 3.3.6.8 discusses impacts from connected actions, i.e., the wind farms proposed to be located on the western end of the line.
- Section 3.3.6.9 discusses impacts to air quality and climate change from the No Action Alternative.

3.3.6.1 Methodology

Emissions were estimated by calculating emissions factors (e.g., pounds per horsepower-hour of construction equipment activity, pounds per vehicle mile traveled, etc.) and multiplying by activity data provided by the Applicant (Clean Line 2013). The emission calculation methods, which represent currently accepted techniques, include the following:

- Use of equations in Sections 13.2.1, 13.2.2, and 13.2.3 of EPA's AP-42 publication to estimate fugitive dust emissions from construction (e.g., access roads, transmission line construction, and converter station construction) (EPA 2006b, 2011)
- Use of EPA's NONROAD2008a model (EPA 2009) to estimate emissions from construction equipment exhaust
- Use of factors/equations in Section 11.12 of EPA's AP-42 publication (EPA 2006a) to estimate emissions from portable concrete batch plant emissions during construction
- Construction soil disturbance and wind erosion resulting in fugitive dust emissions were calculated using methods described in WRAP Fugitive Dust Handbook (Countess Environmental 2006)
- Use of EPA's MOVES2010a model (EPA 2012) to estimate vehicle exhaust emissions for worker travel and movement of supplies during construction
- All mileages for worker trip and construction equipment trip calculations were provided by the Applicant

The Applicant provided information with respect to typical pieces of construction equipment (sizes, types, and hours of operation) and on-road vehicle traffic for (a) the construction of converter stations, (b) the construction of every 40 miles of AC collection system line (which were then scaled based on actual mileage), and (c) the construction of every 140 miles of HVDC transmission line (which were then scaled based on actual mileage). Emissions expected from the operations and maintenance phase of the Project would be negligible and would consist of emissions associated with periodic maintenance activities (e.g., worker vehicle trips). Displacement of fossil fuel power production via wind energy generation is an anticipated result from the connected wind energy developments that are anticipated to result from the Project. A qualitative assessment was undertaken to assess the benefits of these developments.

The Applicant has developed a comprehensive list of EPMs that would avoid or minimize impacts to air quality. Implementation of these EPMs is assumed throughout the impact analysis that follows for both the Applicant Proposed Project and the DOE Alternatives. A complete list of EPMs for the Project is provided in Appendix F; those EPMs that would specifically minimize the potential for release or mismanagement of hazardous constituents that could result in an impact on air quality are listed below:

- GE-3: Clean Line will minimize clearing vegetation within the ROW, consistent with a Transmission Vegetation Management Plan filed with NERC, and applicable federal, state, and local regulations. The TVMP may require additional analysis under NEPA depending on whether and under what conditions DOE decides to participate in the Project.
- GE-11: Clean Line will conduct construction, operation, and maintenance activities to minimize the creation of dust. This may include measures such as limitations on equipment, speed, and/or travel routes utilized. Water, dust palliative, gravel, combinations of these, or similar control measures may be used. Clean Line will implement measures to minimize the transfer of mud onto public roads.
- GE-21: Clean Line will maintain construction equipment in good working order. Equipment and vehicles that show excessive emissions of exhaust gasses and particulates due to poor engine adjustments or other inefficient operating conditions will be repaired or adjusted.
- GE-22: Clean Line will impose speed limits during construction for access roads (e.g., to reduce dust emissions, for safety reasons, and for protection of wildlife).
- GE-25: Clean Line will turn off idling equipment when not in use.

3.3.6.2 Impacts Associated with the Applicant Proposed Project

This section describes the potential impacts from the Applicant Proposed Project that would be common to the converter stations, AC interconnection, AC collection system, and HVDC Applicant Proposed Routes.

3.3.6.2.1 Converter Stations and AC Interconnection Siting Areas

Potential impacts from construction and operations and maintenance activities of the Project, including the converter stations and AC interconnections, are described below.

3.3.6.2.1.1 Construction Impacts

Air quality construction emissions would be temporary, lasting up to 42 months for the entire Project, but only 12 months for each converter station. Construction along AC interconnection lines would be shorter duration, with construction lasting for a matter of days to weeks. Although temporary, these emissions could impact sensitive areas nearby. The construction activities that would generate emissions include land clearing, ground excavation, and cut-and-fill operations (see Appendix F for more detail regarding equipment types). The intermittent and short-term emissions generated by these activities would include dust from soil disruption and combustion emissions from the construction equipment. Emissions associated with construction equipment include PM_{10}, $PM_{2.5}$, NO_x, CO, VOCs, SO_x, GHGs, and small amounts of air toxics. Because the emissions for mobile equipment, especially equipment used over wide distances to construct transmission lines, would occur in any one location for a matter of days or weeks, they would result in minor temporary impacts on air quality in the vicinity of ongoing construction activities. Additional information about emissions from construction equipment is included in the sections that follow. Detailed emissions calculations are provided in Appendix H.

3.3.6.2.1.1.1 Converter Stations

Emissions for constructing each of the converter stations are estimated to be approximately the same because the converter station sizes and construction processes are similar. Construction of the converter stations would be completed in three stages: site preparation, foundation installation, and erection of the station. Table 3.3-9 lists the total emissions (from all three stages) for each converter stations from non-road construction equipment exhaust; it does not include emissions from the use of portable concrete batch plants, which are addressed in Section 3.3.6.2.3.

Table 3.3-9:
Converter Station Non-Road Construction Equipment Emissions (Tons per Station)

CO	NO_x	SO_2	VOC	$PM_{10}/PM_{2.5}$	CO_2e
71.2	66.9	0.1	6.9	5.3	13,806.6

Note: Emissions factors obtained from the EPA's NONROAD2008a model (EPA 2009) and $PM_{2.5}$ emissions are conservatively estimated at being equal to PM_{10} emissions. CO_2e refers to emissions of the GHGs CO_2), CH_4, and N_2O, expressed as a weighted total where the weighting is based on the global warming potential of each gas. The global warming potential for CO_2 is 1 (by definition); for CH_4, it is 25, and for N_2O, it is 298.

On-road emissions would result from movement of construction equipment and worker vehicle trips/commutes to/from the construction areas. Because the exact routing and movement of equipment and workers is unknown for each of the converter stations, emissions estimates are based on the same assumptions for each converter station under consideration and were provided by the Applicant. Table 3.3-10 provides the total estimated on-road emissions associated with construction of each converter station.

Table 3.3-10:
Converter Station On-Road Emissions (Tons per Station)

Vehicle/Equipment[1]	CO	NO_x	SO_2	VOC	$PM_{10}/PM_{2.5}$	CO_2e
Construction Equipment Transportation	7.3	5.2	0.0	0.6	0.2/0.2	2,410
Worker Trips/Commutes	7.2	0.9	0.0	0.1	0.0/0.0	738

1 Emissions factors obtained from the EPA's MOVES2010b model (EPA 2012). $PM_{10}/PM_{2.5}$ emissions include brake and tire wear.

Fugitive dust emissions would be generated by construction of each converter station. These emissions would result from both construction and commuter vehicles traveling on area paved and unpaved roadways. Additional fugitive dust emissions would result from construction ground disturbance and wind erosion during construction of each 45- to 70-acre converter station site. Table 3.3-11 provides the estimated fugitive dust calculations for each converter station (based on an assumption of 70 acres per site). Tire and brake wear are accounted for in on-road PM_{10} and $PM_{2.5}$ emissions.

Table 3.3-11:
Converter Station Fugitive Dust Emissions (Tons per Station)

Roadway Type[1]	PM_{10}	$PM_{2.5}$
Paved Roads	9.2	2.3
Unpaved Roads	15.0	1.5
Ground Disturbance and Wind Erosion	46.2	4.6

1 Emissions factors obtained via Project-anticipated vehicle miles traveled for converter stations and by implementing the guidelines in AP 42 Chapter 13 Section 13.2.1 (EPA 2006b) and AP 42 Chapter 13 Section 13.2.2 (EPA 2011). Fugitive dust calculations do not include tire and brake wear. Ground disturbance and wind erosion calculations made using WRAP Fugitive Dust Handbook guidance.

The Tennessee converter station and AC interconnection tie would be located in Shelby County, Tennessee. Shelby County is part of a three-county marginal nonattainment area for ozone (i.e., Crittenden County, Arkansas, Shelby County, Tennessee, and a portion of DeSoto County, Mississippi) and is also a CO maintenance area. If it is determined that in any calendar year emissions of either VOC or NO_x (i.e., ozone precursors) from all Project construction activities within the ozone nonattainment area exceed the General Conformity Rule *de minimis* levels of 100 tons per year (TPY) for NO_x or VOCs, or emissions of CO from Project construction activities within Shelby County exceed the General Conformity Rule threshold of 100 TPY, federal agencies are required to make determinations of general conformity with the State Implementation Plans (SIPs) in accordance with the requirements in 40 CFR Part 93, Subpart B. Construction of the converter stations could overlap with construction of the Applicant Proposed Route in Shelby County, Tennessee. Therefore, of these three nonattainment pollutants, as shown in Tables 3.3-9 and 3.3-10, CO is the pollutant emitted in the highest quantity by construction equipment at the converter station and NO_x is the pollutant emitted in the highest quantity by construction equipment for the HVDC transmission line (as described in Section 3.3.6.2.4). However, only 5 miles of Applicant Proposed Route would be constructed in Shelby County, TN. Therefore total emissions from construction of the Applicant Proposed converter station and HVDC transmission line within Shelby County, Tennessee, would be 83 tons of NO_x. These emissions estimates would be even lower as the Applicant intends to distribute these activities over an estimated 2-year construction period, such that emissions in each year would be even further below *de minimis* level of 100 TPY; therefore, a general conformity determination is not required.

3.3.6.2.1.2 Operations and Maintenance Impacts

During the operations and maintenance phase of the Project, the converter stations and AC interconnection would emit negligible air pollutants. Standard operation of the converter stations and AC interconnection would not emit air pollutants, but maintenance activities would emit small amounts of pollutants associated with combustion of fossil fuels for worker vehicles and equipment. Converter station gas insulated switchgear may contain sulfur hexafluoride, a potent GHG. However, with BMPs implemented sulfur hexafluoride emissions would be negligible to nonexistent. As a result, levels below the *de minimis* thresholds are anticipated from operation or maintenance of the converter stations and AC interconnection.

3.3.6.2.1.3 Decommissioning Impacts

Decommissioning of the Project may occur at the end of its functional usefulness. Although details of decommissioning cannot be predicted, it is generally estimated that decommissioning emissions would be similar to (or less than) those associated with construction. The Applicant would create a Decommissioning Plan before decommissioning the Project.

3.3.6.2.2 AC Collection System

Construction of the proposed AC collection system, located in Region 1, would result in air quality and GHG emissions. Construction of AC collection system would be completed in discrete stages: ROW clearing, access roads and pad construction, foundation installation, structure lacing, structure setting, wire stringing, and restoration in addition to other support of these operations such as compliance monitoring and refueling. Because the exact routing and movement of equipment and workers is unknown for each of the AC collection system route alternatives, the analyses in this section are based on the same assumptions for each alternative under consideration. Total emissions associated with construction of the AC collection system route alternatives were calculated on a combined basis for all construction phases. Table 3.3-12 lists the estimated non-road emissions of criteria pollutants and CO_2e that would be generated by each 40-mile segment of AC transmission line construction—excluding emissions from concrete batch plants (which are addressed in Section 3.3.6.2.3. Emissions would not be localized, taking place across 40-mile segments, and therefore are not anticipated to cause or significantly contribute to a violation of an applicable ambient air quality standard or contribute substantially to an existing or projected air quality violation.

Table 3.3-12:
Non-Road Construction Equipment Emissions (Tons) per 40-Mile Segment of AC Collection System

	CO	NO_x	SO_2	VOC	$PM_{10}/PM_{2.5}$	CO_2e
Non-Road Emissions	17.7	39.1	0.1	3.7	2.5	7,598.1

Note: Emissions factors obtained from the EPA's NONROAD2008a model (EPA 2009) and $PM_{2.5}$ emissions are conservatively estimated at being equal to PM_{10} emissions.

Total emissions for each AC collection system route were calculated by taking the distance of each AC transmission line, dividing by 40 miles, and multiplying by the values in Table 3.3-12. Table 3.3-13 provides the results of this analysis (excluding those associated with portable concrete batch plants) and shows that the highest emissions would be associated with AC Collection System Route NW-2 (the longest) and the lowest emissions would be associated with AC Collection System Route SW-1 (the shortest).

Table 3.3-13:
AC Collection System Routes Non-Road Construction Equipment Emissions (Tons) by Route

AC Collection	Length (miles)	Pollutant Emissions (tons)					
		CO	NOx	SO2	VOC	$PM_{10}/PM_{2.5}$	CO2e
E-1	28.9	12.4	27.4	0.0	2.6	1.8	5318.7
E-2	39.8	17.7	39.1	0.1	3.7	2.5	7598.1
E-3	40.0	17.7	39.1	0.1	3.7	2.5	7598.1
NE-1	30.1	14.2	31.3	0.0	3.0	2.0	6078.5
NE-2	26.3	12.4	27.4	0.0	2.6	1.8	5318.7
NW-1	51.9	23.0	50.9	0.1	4.8	3.3	9877.6
NW-2	56.0	24.8	54.8	0.1	5.2	3.5	10637.4
SE-1	40.3	17.7	39.1	0.1	3.7	2.5	7598.1
SE-2	13.4	5.3	11.7	0.0	1.1	0.8	2279.4
SE-3	49.1	21.2	47.0	0.1	4.4	3.0	9117.8
SW-1	13.4	5.3	11.7	0.0	1.1	0.8	2279.4
SW-2	37.0	15.9	35.2	0.1	3.3	2.3	6838.3
W-1	20.7	8.9	19.6	0.0	1.9	1.3	3799.1

On-road emissions would result from movement of construction equipment and worker vehicle trips/commutes to/from the construction areas (including those associated with transporting portable concrete batch plants). Table 3.3-14 provides the estimated on-road emissions associated with construction of each 40-mile segment of AC transmission line (including those associated with transporting portable concrete batch plants); these are substantially lower than the non-road emissions identified in Table 3.3-12.

Table 3.3-14:
AC Collection System Routes On-Road Emissions (Tons) per 40-Mile Segment

Vehicle/Equipment	CO	NO_x	SO_2	VOC	$PM_{10}/PM_{2.5}$	CO_2e
Construction Equipment Transport	2.4	5.4	0.0	0.4	0.2/0. 2	2,159
Worker Trips/Commutes	5.0	0.6	0.0	0.1	0.0/0.0	542

Notes: Emissions factors obtained from the EPA's MOVES2010b model (EPA 2012). $PM_{10}/PM_{2.5}$ emissions include brake and tire wear.

Fugitive dust emissions would result from construction of the AC transmission lines. These emissions would result from both construction and commuter vehicles traveling on area paved and unpaved roadways. Table 3.3-15 provides the fugitive dust calculations for a representative 1-mile and 40-mile segment of AC line construction (excluding those associated with use of concrete batch plants), respectively. Construction of the AC transmission line would be localized, so these representative segment lengths of transmission line ROW construction provide a range for comparative purposes. In reality, construction of any given segment of AC transmission line would generally result in ground disturbance along the ROW between 5 and 10 miles in length. Although the values are relatively high, it should be recognized that it is widely known that there are several technical issues associated with the quantification of fugitive dust and they may overstate air quality impacts. For example, although regional emissions inventories typically show fugitive dust as the predominant source of PM emissions, chemical analyses of ambient PM concentrations shows that fugitive dust is a minor contributor to ambient PM concentrations, perhaps because a large fraction of fugitive dust from roadways is not suspendable and/or transportable over long distances (Watson and

Chow 2000; Countess Environmental 2001). As a result, EPA transportation conformity regulations allow re-entrained road dust and construction-related fugitive dust to be excluded from emissions evaluations unless they have been identified as significant contributors to ambient PM concentrations.[1]

Table 3.3-15:
AC Collection System Route Fugitive Dust Emissions (Tons) per 1-mile and 40-Mile Segments

Representative Segment	Fugitive Dust Emission Source	PM_{10}	$PM_{2.5}$
1-Mile of AC Collection System Route	Paved Roads	0.1	0.0
	Unpaved Roads	1.4	0.1
	Ground Disturbance and Wind Erosion	1.3	0.1
40-Mile of AC Collection System Route	Paved Roads	5.1	1.3
	Unpaved Roads	54.0	5.4
	Ground Disturbance and Wind Erosion	640.0	64.0

Note: Emissions factors obtained via Project anticipated vehicle miles traveled for converter stations and by implementing the guidelines in AP 42 Chapter 13 Section 13.2.1 (EPA 2011) and AP 42 Chapter 13 Section 13.2.2 (EPA 2006b). Fugitive dust calculations do not include tire and brake wear. Ground disturbance and wind erosion calculations made using WRAP Fugitive Dust Handbook guidance. Forty-mile segment emissions were estimated for 12-month period and 1-mile segment emissions were estimated for 1-month duration.

Fugitive dust emissions, including wind erosion and ground disturbance, associated with construction of each of the AC collection system routes were calculated by scaling the 40-mile emissions values in Table 3.3-15 to the distance of each AC line. Table 3.3-16 provides the results of this analysis and shows that the highest fugitive dust emissions would be associated with AC Collection System Route SE-3 and the lowest would be associated with AC Collection System Route SW-1. Brake and tire wear are accounted for in on-road emissions.

Table 3.3-16:
AC Collection System Routes Fugitive Dust Emissions (Tons)

Route	Length (Miles)	PM_{10}	$PM_{2.5}$
E-1	28.9	516.3	52.3
E-2	39.8	702.1	71.0
E-3	40.0	704.2	71.2
NE-1	30.1	531.7	53.8
NE-2	26.3	467.3	47.3
NW-1	51.9	905.3	91.4
NW-2	56.0	974.8	98.4
SE-1	40.3	705.9	71.3
SE-2	13.4	249.6	25.4
SE-3	49.1	855.3	86.4
SW-1	13.4	249.7	25.4
SW-2	37.0	651.4	65.9
W-1	20.7	376.7	38.2

[1] 40 CFR Part 93 Subpart A, §93.119(f)(8), §93.122(e), §93.122(f).

3.3.6.2.2.1 Operations and Maintenance Impacts

Operations and maintenance of the AC collection system routes would result in negligible amounts of air pollutants. Standard operation of the AC transmission lines would not emit air pollutants, but maintenance activities would emit small amounts of pollutants associated with combustion of fossil fuels for worker vehicles and equipment. As a result, inconsequential impacts are anticipated from operations or maintenance of the AC collection system routes.

3.3.6.2.2.2 Decommissioning Impacts

Decommissioning of the Project—i.e., the partial and/or total removal of built structures—may occur at the end of its functional usefulness. Although details of decommissioning cannot be predicted, it is generally estimated that emissions associated with decommissioning would be similar to (or less than) those associated with construction (in part because tearing things down involves less effort than erecting them, and in part because it is assumed that decommissioning would occur many years in the future, when the engines used are likely to be lower-emitting). The Applicant would create a Decommissioning Plan before decommissioning the Project.

3.3.6.2.3 Portable Concrete Batch Plants

Access to concrete would be required at approximate 60-mile intervals along the transmission line corridor. The Applicant would use local concrete plants where possible. Construction of the Project may require the use of portable concrete batch plants. The Applicant has indicated where the haul distance exceeds 25 to 30 miles the use of portable concrete batch plants is anticipated. The construction of concrete batch plants would result in air quality and GHG emissions. Table 3.3-17 lists the estimated non-road emissions of criteria pollutants and CO_2e for each portable concrete batch plant. At this time it is unknown where each portable concrete batch plant would be required and located; however, the emission levels associated with construction of each batch plant would be negligible relative to the emissions identified in Sections 3.3.6.2.1 and 3.3.6.2.2.

Table 3.3-17:
Portable Concrete Batch Plant Non-Road Construction Equipment Emissions (Tons)

CO	NO_x	SO_2	VOC	PM_{10}/PM2.5	CO_2e
0.3	0.8	0.0	0.1	0.1	205

Note: Emissions factors obtained from the EPA's NONROAD2008a model (EPA 2009) and $PM_{2.5}$ emissions are conservatively estimated at being equal to PM_{10} emissions.

Fugitive dust emissions would result from construction of the portable concrete batch plants. These emissions would result from both construction and commuter vehicles traveling on paved and unpaved roadways and are predicted to be 0.67 ton of PM_{10} and 0.07 tons of $PM_{2.5}$. These emissions impacts would be temporary and low level, so they would be considered minor. Fugitive dust calculations do not include tire and brake wear.

Operation of each portable concrete batch plant during construction would result in emissions of particulate matter (PM_{10} and $PM_{2.5}$). The Applicant has identified that fugitive dust from (a) unloading cement and cement supplement to silos, (b) mixer loading, and (c) truck loading would all be controlled (e.g., by fabric filter for silo loading, and by water sprays, enclosures, hoods, curtains, shrouds, movable and telescoping chutes, central duct collection systems, etc.), and that the total throughput for all of the portable concrete batch plants would be approximately 3,030 tons of cement and 450 tons of cement supplement (Clean Line 2013). Like other emissions associated with construction, because they would be temporary and would result in low emissions (0.2 ton of PM_{10} and 0.02 ton of $PM_{2.5}$), impacts are expected to be minor.

On-road emissions estimates for the portable concrete batch plants (excluding fugitive dust) are included in the respective transmission line analysis (e.g., AC or HVDC).

3.3.6.2.4 HVDC Applicant Proposed Route

Air quality emissions from construction and operation would potentially result from construction of the HVDC Applicant Proposed Route.

3.3.6.2.4.1 Construction Impacts

Construction of the Applicant Proposed Route would result in criteria air pollutant and GHG emissions. Construction of the proposed HVDC transmission line would be completed in discrete stages: ROW clearing; access roads and pad construction; foundation installation; structure lacing; structure setting; wire stringing; restoration; in addition to other support of these operations such as compliance monitoring and refueling. Because the exact routing and movement of equipment and workers is unknown by region, emissions would be based on the same assumptions for each of the regions. Total emissions for each region were considered regardless of construction stage or phase. Table 3.3-18 lists the estimated non-road emissions that would be generated by each 140-mile segment of HVDC transmission line (see Section 2.1.4) construction (excluding concrete batch plant emissions). Construction of the transmission line would occur in one continuous operation, so emissions would be localized in and have been assumed to take place within 140-mile segments along the HVDC transmission line. Because the emissions would be temporary and are for mobile equipment spread out over wide distances, they would result in minor temporary impacts on air quality in the vicinity of construction activities.

Table 3.3-18:
Non-Road Construction Equipment Emissions (Tons) per 140-Mile Segment of HVDC Line
(compared to 140-mile segment of Interstate 40 for perspective)

	CO	NO_x	SO_2	VOC	PM_{10}/PM2.5	CO_2e
Construction Equipment Emissions	61.2	134.4	0.2	12.8	8.7	26,031

Note: Emissions factors obtained from the EPA's NONROAD2008a model (EPA 2009) and $PM_{2.5}$ emissions are conservatively estimated at being equal to PM_{10} emissions; Interstate 40 is assumed to have traffic volume of 20,000 vehicles per day

Total estimated emissions for the Applicant Proposed Route in each region were derived by scaling the emissions for a 140-mile segment to the length of the actual route (in miles). Table 3.3-19 provides the results of this analysis.

Table 3.3-19:
HVDC Line Alternatives Non-Road Construction Equipment Emissions (Tons) by Alternative

		Pollutant Emissions (Tons)					
Route	Length (miles)	CO	NO_x	SO_2	VOC	PM_{10}/$PM_{2.5}$	CO_2e
APR Region 1	115.46	50.5	110.8	0.2	10.5	7.2	21,468
APR Region 2	105.97	46.4	101.7	0.2	9.7	6.6	19,704
APR Region 3	161.69	70.7	155.2	0.2	14.8	10.1	30,064
APR Region 4	126.28	55.2	121.2	0.2	11.5	7.9	23,480
APR Region 5	112.8	49.3	108.2	0.2	10.3	7.0	20,974
APR Region 6	54.36	23.8	52.2	0.1	5.0	3.4	10,108
APR Region 7	42.83	18.7	41.1	0.1	3.9	2.7	7,964

Estimated on-road emissions would result from movement of construction equipment and worker vehicle trips/commutes to/from the construction areas. Table 3.3-20 provides the on-road emissions associated with construction of each 140-mile segment of the Applicant Proposed Route.

Table 3.3-20:
On-Road Construction Equipment Emissions (Tons) per 140-Mile Segment of HVDC Line

Vehicle/Equipment	CO	NO_x	SO_2	VOC	$PM_{10}/PM_{2.5}$	CO_2e
Construction Equipment	8.4	18.9	0.1	1.6	0.7/0.7	7,557
Worker Trips/Commutes	18.4	2.2	0.0	0.4	0.1/0.0	1,896

Note: Emissions factors obtained from the EPA's MOVES2010b model (EPA 2012). $PM_{10}/PM_{2.5}$ emissions include brake and tire wear. See

Fugitive dust emissions would result from construction of the Applicant Proposed Route. These emissions would result from both construction and commuter vehicles traveling on local paved and unpaved roadways. Table 3.3-21 provides the estimated fugitive dust calculations for a representative 1-mile and 140-mile segment of HVDC transmission line construction, respectively. Construction of the HVDC transmission line would be localized, so these representative segment lengths of transmission line ROW construction provide a range for comparative purposes. In reality, construction of any given segment of HVDC transmission line would generally result in ground disturbance along the ROW between five and 10 miles in length.

Table 3.3-21:
Fugitive Dust Emissions (Tons) per 140-Mile Segment of HVDC Line

Representative Segment	Fugitive Dust Emission Source	PM_{10}	$PM_{2.5}$
1-Mile of AC Collection System Route	Paved Roads	0.1	0.0
	Unpaved Roads	1.4	0.1
	Ground Disturbance and Wind Erosion	1.3	0.1
40-Mile of AC Collection System Route	Paved Roads	18.1	4.4
	Unpaved Roads	189.1	18.9
	Ground Disturbance and Wind Erosion	2,240.0	224.0

Note: Emissions factors obtained via Project anticipated vehicle miles traveled for converter stations and by implementing the guidelines in AP 42 Chapter 13 Section 13.2.1 (EPA 2011) and AP-42 Chapter 13 Section 13.2.2 (EPA 2006b). Fugitive dust calculations do not include tire and brake wear. Ground disturbance and wind erosion calculations made using WRAP Fugitive Dust Handbook guidance. 140-mile segment emissions estimated for 12 month period, 1-mile segment emissions estimated for 1-month duration.

Fugitive dust emissions for each region of the Applicant Proposed Route were calculated by taking the distance of each HVDC transmission line, dividing by 140 miles, and multiplying by the emissions shown in Table 3.3-21. Table 3.3-22 provides the results of this analysis. Tire and brake wear are accounted for in on-road emissions.

Table 3.3-22:
HVDC Line Alternatives Fugitive Dust Emissions (Tons)

Route	Length (miles)	PM_{10}	$PM_{2.5}$
APR Region 1	115.5	2,049.3	207.3
APR Region 2	106.0	2,026.4	204.9
APR Region 3	161.7	2,833.4	286.2
APR Region 4	126.3	2,232.3	225.7
APR Region 5	112.8	2,003.4	202.7

Table 3.3-22:
HVDC Line Alternatives Fugitive Dust Emissions (Tons)

Route	Length (miles)	PM_{10}	$PM_{2.5}$
APR Region 6	54.4	1,007.6	196.6
APR Region 7	42.8	809.7	82.5

3.3.6.2.4.2 Operations and Maintenance Impacts

Operations and maintenance of the Applicant Proposed Route would emit negligible amounts of air pollutants. Standard operation of the transmission lines would not emit air pollutants, but maintenance activities would result in very low level temporary emissions of pollutants associated with combustion of fossil fuels for worker vehicles and equipment. As a result, negligible impacts would be anticipated from construction or operations and maintenance of the Applicant Proposed Route.

3.3.6.2.4.3 Decommissioning Impacts

Decommissioning of the Project may occur at the end of its functional usefulness. Although details of decommissioning cannot be predicted, it is generally estimated that decommissioning emissions would be similar to (or less than) those associated with construction. The Applicant would create a Decommissioning Plan before decommissioning the Project.

3.3.6.3 Impacts Associated with the DOE Alternatives

Air quality emissions were calculated for the DOE Alternatives.

3.3.6.3.1 Arkansas Converter Station Alternative Siting Area and AC Interconnection Siting Area

Predicted air quality emissions from the construction, operations and maintenance, and decommissioning of the Arkansas converter station would be approximately the same as those described in Section 3.3.6.2.1 for each of the Applicant Proposed Project converter stations because this converter station would be of similar size and all would be constructed following the same process. Additionally, the emission estimates for the Arkansas converter station account for the new substation that would be required at the point where the 500kV AC interconnection line taps the existing Arkansas Nuclear One-Pleasant Hill 500kV line.

3.3.6.3.2 HVDC Alternative Routes

Construction and operational impacts from the HVDC alternative routes would be similar to those of the Applicant Proposed Route, the only variation being the amount of air quality emissions based on the respective length of each HVDC alternative route. Operationally, air quality emissions for each HVDC alternative route would be the same as those described in Section 3.3.6.2.4 for the Applicant Proposed Route.

3.3.6.3.2.1 Construction Impacts

The HVDC alternative routes would use the same construction approaches described in Section 3.3.6.2.4. Air quality emissions would vary with the length of each HVDC alternative route. Table 3.3-23 provides the air quality emissions for each HVDC alternative route and Table 3.3-24 provides fugitive dust emissions for each alternative. Brake and tire wear are included in on-road emissions.

3.3.6.3.2.2 Operations and Maintenance Impacts

Operations and maintenance of any of the HVDC alternative routes would emit negligible air pollutants similar to those described in Section 3.3.6.2.4 for the Applicant Proposed Route.

3.3.6.3.2.3 Decommissioning Impacts

Decommissioning of the Project would be the same as those described in Section 3.3.6.2.4 for the Applicant Proposed Route.

3.3.6.4 Best Management Practices

In addition to the EPMs developed by the Applicant the following BMPs have been identified to control fugitive dust, emissions associated with mobile and stationary sources, and potential emissions of sulfur hexafluoride.

To reduce the impacts associated with blowing fugitive dust and/or under windy conditions, the following BMPs have been identified:

- Stabilize spoil piles and sources of fugitive dust by implementing control measures, such as covering and/or applying water or chemical/organic dust palliative where appropriate at active and inactive sites during workdays, weekends, holidays, and windy conditions. EPA (1995) lists common sources of fugitive dust as unpaved roads, agricultural tilling operations, aggregate storage piles, and heavy construction operations; all but agricultural tilling operations would apply to the Project and require appropriate control measures.
- Install wind fencing and phase grading operations where appropriate, and operate water trucks for stabilization of surfaces under windy conditions.
- Prevent spillage when hauling spoil material.
- In active construction areas including access roads, Limit speeds of non-earth-moving equipment to 15 miles per hour. Limit speed of earth-moving equipment to 10 mph.

To mitigate emissions resulting from mobile and stationary sources, the following BMPs have been identified:

- Plan construction scheduling to minimize vehicle trips.
- Limit idling of heavy equipment to less than 5 minutes unless needed for the safe operation of the equipment and verify through unscheduled inspections.
- Maintain and tune engines per manufacturer's specifications to perform at EPA certification levels, prevent tampering of source engines (i.e., knowingly disabling an emission control system component or element of design of a certified engine so that it no longer meets the manufacturer’s specifications), and conduct unscheduled inspections to ensure these measures are followed.

The quantity of sulfur hexafluoride emissions from maintenance activities (and potential leaks in equipment) would be minimized through the use of hermetically sealed equipment, leak detection programs, and sulfur hexafluoride recycling programs.

3.3.6.5 Unavoidable Adverse Impacts

No unavoidable adverse impacts to air quality are anticipated to result from the Project.

3.3.6.6 Irreversible and Irretrievable Commitment of Resources

No irreversible and irretrievable commitments of air quality resources are anticipated to result from the Project.

3.3.6.7 Relationship between Local Short-term Uses and Long-term Productivity

Emissions from construction of the Project are not predicted to impact sensitive receptors and also would not impact long-term productivity. While over the short-term emissions from construction would be higher in localized areas—because the Project provides for development of non-fossil fuel energy sources over the long term—air quality would be improved in comparison to not building the Project.

3.3.6.8 Impacts from Connected Actions

3.3.6.8.1 Wind Energy Generation

The impacts from the wind energy generation facilities that would interconnect to the Project as a result of the Project being built were qualitatively assessed because precise wind energy developments have not been identified that may result after the Project is constructed. The anticipated wind energy developments are all located within the Region 1 Oklahoma Panhandle and the adjacent portions of Texas. Although site-specific layouts of wind energy generation facilities in the wind energy development zones identified in Region 1 have yet to be designed, information regarding air emissions impacts from these potential wind energy generation facilities has been provided by the Applicant (Clean Line 2014). Emissions from construction activities were calculated based on techniques similar to those that were used to analyze impacts from the Applicant Proposed Project and DOE Alternatives. The potential impacts would be more than compensated for by reductions in emissions associated with the fact that wind energy projects generate nominal emissions, such as those from maintenance activities, and the power generated by wind energy would displace power that could otherwise be generated from fuel combustion. The benefit to air quality of these wind energy developments via displacing fossil fuel energy sources would outweigh the temporary construction air quality impacts. Section 3.3.6.8.1.2 provides qualitative analysis of the air quality emissions that may be expected from wind energy developments.

3.3.6.8.1.1 Construction Impacts

Construction of wind farms would result in criteria air pollutant and GHG emissions via engines burning fossil fuels. Fugitive dust would also result from construction of wind farms. Construction equipment emissions would be intermittent and generated in relatively small areas confined to the areas of wind farm construction. Construction planners estimate that the erection of wind farms requires roughly 150,000 gallons of fuel (approximately 85 percent diesel, 15 percent gasoline) per 100MW of capacity constructed (Repholz 2014). The GHG emissions associated with construction of 4,000–4,550MW of generating capacity is therefore approximately 66,000 to 75,000 tons CO_2e;[2] the corresponding emissions of NO_x, the most prevalent criteria pollutant in the exhaust of construction equipment, would depend on the exact mix of equipment but would be in the neighborhood of 300 to 600 tons.[3] These

[2] This calculation is based on fuel heating values and GHG emission factors in 40 CFR Part 98, Subpart C.

[3] The lower end of this range is based on an average NO_x emissions rate of approximately 0.74 pound per one million British thermal units (mmBtu) of heat input for 4,000MW of generation; the higher end is based on an average NOx emissions rate of approximately 1.3 lb/mmBtu for 4,550MW of generation.

construction emissions would be temporary, and are not expected to contribute to substantially increased air pollutant concentrations.

Dust suppressants would be implemented to reduce fugitive dust emissions during construction of the wind farms. Typically, impacts related to fugitive dusts during construction of wind farms are reduced through the use of dust palliatives and through micrositing the turbines and related components in such a way to minimize or eliminate potential temporary impacts.

3.3.6.8.1.2 Operations and Maintenance Impacts

Operational impacts to air quality associated with the wind farms are expected to be beneficial, because operations and maintenance of wind farms would result in negligible emissions (Clean Line 2014), whereas much of the electricity generated today is produced with fossil fuels such as coal or natural gas. The Applicant used a commercially available simulation model (PROMOD version 10.1) to determine a best estimate of which power sources would be displaced and what the corresponding emissions reduction would be. The Applicant used the Ventyx East NERC version 9.4 root database and updated the database to reflect expected 2018 market conditions as of May/June 2013, when the simulation work began. The model updates included but were not limited to transmission upgrades to reflect ISO transmission plans, market membership changes (e.g., Entergy joining MISO), then-current natural gas forecast, and recently announced coal plant retirements. The model provided a best estimate of displaced emissions as follows: approximately 0.00058 pounds NO_x/megawatt hours (MWh), 0.0017 pounds SO_x/MWh, 0.707 pounds CO_2/MWh, and 0.0000114 pounds mercury/MWh. Using these displaced emissions rates with the range of megawatts of anticipated power production from wind energy as identified in Section 2.5.1 (4,000MW from the wind farm build-out and 4,550MW with the addition of the Arkansas converter station alternative), calculations of displaced emissions were calculated as follows:

- NO_x, 9,800 to 11,100 TPY
- SO_x 29,000 to 33,000 TPY
- CO_2e 12 to 14 million TPY
- Mercury 0.1 TPY (approximate)

These reductions in emissions occur each year, and even 1 year of emissions reduction far exceeds the combined emissions increases associated with the construction of the Project and the wind farms. Although the emissions reduction from this single project is small relative to the 7,249 million tons CO_2e (6,576 million metric tonnes) emitted by anthropogenic sources in the United States in 2009, the electric power generation sector contributes approximately 40 percent of those emissions (EIA 2011) and the implementation of lower-GHG electricity generation is therefore an important component of achieving significant GHG emissions reductions both nationally and globally. Currently, there is no methodology that would allow DOE to estimate the specific impacts (if any) this increment of climate change would produce in the vicinity of the facility or elsewhere.

3.3.6.8.2 Optima Substation

Operationally the Substation would not result in air quality impacts. Construction emissions would be similar to those for the Project or DOE alternative converter stations and therefore would not result in exceedance of the NAAQS. Therefore, no impacts to air quality are anticipated from construction of the future Optima Substation.

3.3.6.8.3 TVA Upgrades

Upgrades required to interconnect into the TVA transmission grid could involve potential impacts to air quality for the new transmission line, upgrades to existing lines, and modifications to substations. These impacts would be similar to those described in detail in Section 3.3.6 for the Project. For upgrades to or new transmission lines and modifications to substations air quality and climate change impacts of concern would be associated primarily with construction and include fugitive dust emissions and exhaust from construction equipment and vehicles. Air emissions during construction would be intermittent and short term, with anticipated minor temporary impacts on air quality near the construction activities. The TVA upgrades would be anticipated to result in negligible air quality impacts because they would be temporary and not contribute to air quality impacts on a continued basis.

If the new or upgraded transmission lines or substation modifications occur in areas classified as nonattainment with respect to any of the air quality standards, they would be subject to provisions of regulatory requirements.

The TVA upgrades would be expected to result in negligible contributions of GHGs during short-term construction activities, similar to the Project.

3.3.6.9 Impacts from the No Action Alternative

Under the No Action Alternative, DOE assumes for analytical purposes that the Project would not be constructed or operated, so no emissions would be associated with any activities related to the Project and no emissions reduction associated with the displacement of fossil-fueled power generation by the wind generation associated with the Project.

3.4 Electrical Environment

The Project includes the following electrical facilities associated with the electrical environment:

- Applicant Proposed Project:
  - A ±600kV HVDC overhead electric transmission line with the capability to deliver approximately 3,500MW (utilizing two proposed line design configurations) along a preferred route
  - Two AC/DC converter stations (one in Oklahoma and another in Tennessee)
  - One double circuit AC transmission line of up to 345kV to connect the Oklahoma converter station
  - Two 500kV AC transmission lines to connect the Tennessee converter station
  - Four to six AC transmission lines of up to 345kV for the AC Collection System in Oklahoma and Texas
- DOE Alternatives:
  - A ±600kV HVDC overhead electric transmission line utilizing alternative routes
  - One AC/DC converter station (in Arkansas)
  - One 500kV AC transmission line to connect the Arkansas converter station (if constructed)

Detailed information regarding the transmission line configurations and convertor stations can be referenced in Chapter 2. The electrical environment evaluation involves analysis of the following electrical effects:

- DC electric fields
- AC electric fields
- DC magnetic fields
- AC magnetic fields
- Audible noise
- Radio and television noise interference
- Ozone and air ions

The following sections describe each of these electrical effects and how they relate to electrical facilities such as transmission lines.

3.4.1 Electric Fields

Voltage (electrical pressure) on an object causes an electric field. Any object with an electric charge on it has a voltage at its surface, caused by the accumulation of more electrons on that surface as compared with another object or surface. The voltage effect is not limited to the surface of the object but exists in the space surrounding the object in diminishing intensity. Electric fields can exert a force on other electric charges at a distance. The change in voltage over distance is known as the electric field. The units describing an electric field are volts per meter (V/m) or thousands of volts per meter (kilovolts per meter or kV/m). These units are measures of the difference in electrical voltage that exists between two points 1 meter apart (about 3 feet apart). The electric field becomes stronger near a charged object and decreases with distance away from the object. The electric field is a vector having both magnitude and direction as shown in Figure 3.4-1.

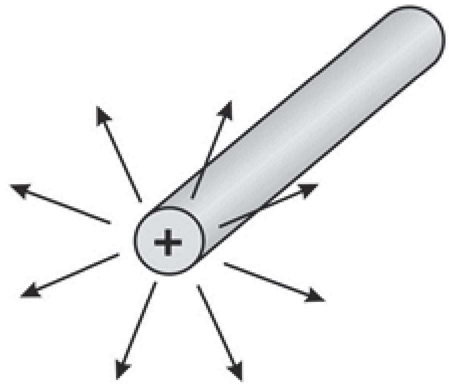

Figure 3.4-1: Electric Field around a Conductor

3.4.1.1 DC Electric Fields

Static or DC electric fields are very common phenomena. The earth creates a natural static electric field in fair weather that is a result of the 300,000 to 400,000 volt potential difference between the ionosphere and the surface of the earth (Veimeister 1972). The normal fair weather static electric field of the earth varies from month to month, reaching a maximum of about 20 percent above normal in January (when the earth is closest to the sun) and falling to about 20 percent below normal by July (when the earth is farthest from the sun). At ground level, the average value of the earth's DC electric field is approximately 120 V/m. This means that a 6-foot-tall person would have a difference in static voltage of about 220 volts between the top and bottom of their body.

Static electric fields can exist within storm clouds, where the electric potential of clouds (with respect to earth) can reach 10 to 100 million volts (Veimeister 1972). Natural static electric fields under clouds and in dust storms can reach 3 to 10kV/m (CRC 1981).

Static electric fields can also result from friction generated when someone takes off a sweater, slides across a car seat, or walks across a carpet. For example, body voltages as high as 10–16,000 volts have been measured after walking across a carpet (Chakravarti and Pontrelli 1976). It is a common occurrence that someone receives a small shock (a discharge of built-up body voltage) when touching a doorknob after walking across a carpet.

3.4.1.2 AC Electric Fields

AC electric fields are different from static DC electric fields, since AC electric fields are caused by the changing direction of electric voltage while static fields have a constant voltage direction. In the United States, AC electric power transmission lines operate at a frequency of 60 Hertz (Hz) (i.e., the voltage reverses direction at a rate of 60 cycles per second). AC transmission lines therefore create 60Hz AC electric fields, which result from the voltage on the transmission line conductors with respect to the ground.

Electric fields from a transmission line decrease with distance away from the outermost conductor, typically at a rate of approximately one divided by the distance squared ($1/d^2$). Transmission line electric fields remain relatively constant over time because the voltage of the transmission line is kept within about ±5 percent of its rated nominal voltage.

Transmission line electric fields are affected by the presence of grounded and conductive objects, as demonstrated by Figure 3.4-2. Trees and buildings, for example, can greatly reduce ground level electric fields by shielding the area near the object (Deno and Silva 1987).

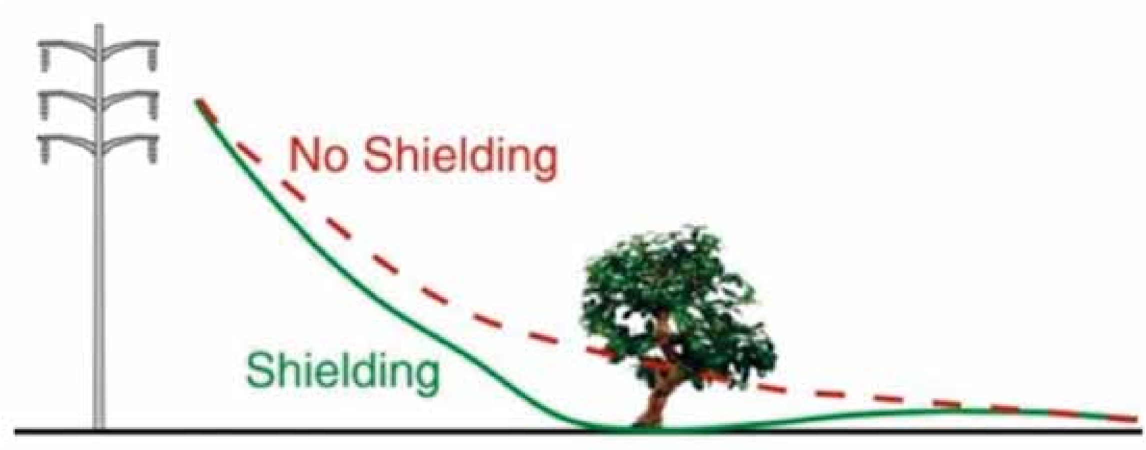

Figure 3.4-2: Electric Field Shielding Due to a Tree

Household appliances and other devices that operate on electricity also create AC electric fields. The electric field caused by small compact household appliances generally attenuates more rapidly with distance than transmission line electric fields. Appliances need not be in operation to create an electric field. Simply plugging an appliance into an electrical outlet creates an electric field around the outlet. Typical values of electric field measured 1 foot away from some common appliances are shown in Table 3.4-1.

Table 3.4-1:
Typical AC Electric Field Values for Appliances (at 12 Inches)

Appliance	Electric Field (kV/m)
Electric Blanket	0.25 [1]
Broiler	0.13
Refrigerator	0.06
Iron	0.06
Hand Mixer	0.05
Coffee Pot	0.03

1 One to 10kV/m next to blanket wires.
Source: Carstensen (1987), Enertech Consultants (1985)

3.4.2 Magnetic Fields

An electric current (the flow of electrical charges or moving electrons) in a conductor or wire creates a magnetic field. The commonly used magnetic field intensity unit of measure is the gauss (G). For most applications, the gauss is too large, so a smaller unit, the milliGauss (mG), is used for reporting magnetic field magnitudes. The milliGauss is one thousandth of a gauss.

The magnetic field is a vector quantity having magnitude and direction. The magnetic field encircles the current in the wire and the direction of the magnetic field is dependent upon the direction of current flow as shown in Figure 3.4-3.

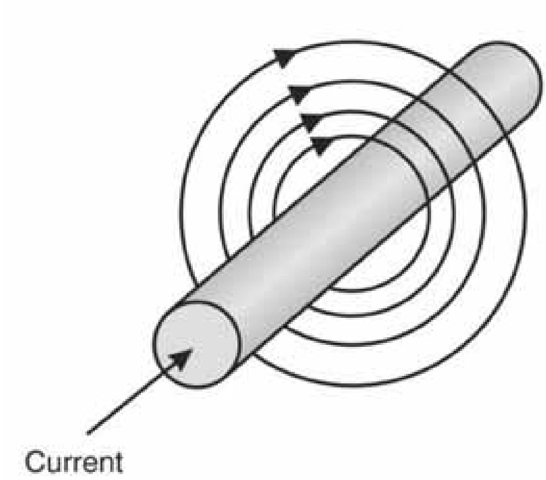

Figure 3.4-3: Magnetic Field around a Conductor

3.4.2.1 DC Magnetic Fields

Static or DC magnetic fields are very common phenomena. As a general reference, the earth has a natural static magnetic field of about 0.51 G, or 510 mG, in the Oklahoma/Arkansas/Tennessee area (Merrill and McElhinny 1983). Static magnetic fields are also found very close to everyday objects such as common refrigerator magnets (bar magnets) and radio/stereo speaker magnets (thousands of gauss field strength). Many appliances utilize DC charging current (chargeable electric razors, electric toothbrushes, electronic tablets, calculators, and other small appliances). Medical devices such as magnetic resonance imaging (MRI) machines utilize large DC magnetic fields to create scanned images (generally stronger than 10,000 G) (Olsen and Sheppard 2012).

3.4.2.2 AC Magnetic Fields

AC magnetic fields from electric power facilities and appliances differ from static (or DC) fields because they are caused by the flow of 60Hz alternating currents. Power frequency magnetic fields reverse direction at a rate of 60 cycles per second corresponding to the 60Hz operating frequency of electric power systems in the United States. Electric transmission lines therefore create 60Hz AC magnetic fields. These magnetic fields are generated by the current flowing on the transmission line conductors.

Similar to a transmission line AC electric field, the AC magnetic field typically decreases with the inverse square of the distance away from the transmission line ($1/d^2$). However, unlike AC electric fields that remain relatively constant over time, AC magnetic fields can vary considerably over time because the current on any transmission line changes in response to increasing and decreasing electrical load demands. Transmission line magnetic fields are also not easily shielded by objects, as are electric fields (EPRI 1999).

Since the magnetic field is caused by the flow of an electric current, a device must be operated to create a magnetic field. Magnetic field strengths of a large number of common household appliances were measured by the Illinois Institute of Technology Research (1984) for the U.S. Navy (Gauger 1985), and by Enertech Consultants for the Electric Power Research Institute (EPRI) (Silva et al. 1989). Typical magnetic field values for some appliances have been measured as low as 0.3mG to as high as 20,000mG (Table 3.4-2). It should be noted that anything that supplies or uses AC electrical power creates an AC magnetic field. There are other electric utility sources (e.g., distribution lines, power transformers, electrical panels, etc.), office sources (e.g., copiers, printers, computers, electric pencil sharpeners, etc.), school sources (overhead/slide projectors, aquariums, TV monitors, etc.), retail sources (e.g., refrigeration units, escalators, cash registers, etc.).

Table 3.4-2:
AC Magnetic Fields from Household Appliances

Appliance	Magnetic Field at 12 inches Away (mG)	Maximum Magnetic Field (mG)
Electric Range	3 to 30	100 to 1,200
Electric Oven	2 to 25	10 to 50
Garbage Disposal	10 to 20	850 to 1,250
Refrigerator	0.3 to 3	4 to 15
Clothes Washer	2 to 30	10 to 400
Clothes Dryer	1 to 3	3 to 80
Coffee Maker	0.8 to 1	15 to 250
Toaster	0.6 to 8	70 to 150
Crock Pot	0.8 to 1	15 to 80
Iron	1 to 3	90 to 300
Can Opener	35 to 250	10,000 to 20,000
Blender, Popper, Processor	6 to 20	250 to 1,050
Vacuum Cleaner	20 to 200	2,000 to 8,000
Portable Heater	1 to 40	100 to 1,100
Fans/Blowers	0.4 to 40	20 to 300
Hair Dryer	1 to 70	60 to 20,000
Electric Shaver	1 to 100	150 to 15,000
Fluorescent Light Fixture	2 to 40	140 to 2,000
Fluorescent Desk Lamp	6 to 20	400 to 3,500
Circular Saws	10 to 250	2,000 to 10,000
Electric Drill	25 to 35	4,000 to 8,000

Source: Gauger (1984), Silva et al. (1989)

3.4.2.3 Distinction between DC and AC Transmission Line Field Effects

Often DC transmission line and AC transmission line electrical effects are mistakenly considered as though the field effects from both types of lines are similar. The same is also true when it comes to evaluating health effect studies or potential medical device interference. For example, there are a multitude of AC magnetic field studies that have been performed related to the evaluation of health effects (such as childhood leukemia), but these results are not directly applicable to DC magnetic fields. Similarly, field effects from radio frequency sources, such as cellular telephones and smart meters, are also different from both AC and DC transmission line field effects. Therefore, it is very important to recognize these differences between DC and AC transmission line field effects as well as other higher frequency sources.

Figure 3.4-4 presents the electromagnetic spectrum arranged by increasing frequency. As shown in this figure, the static frequency of 0Hz is at the lowest end of the spectrum. The electric and magnetic fields from a DC transmission line are constant in frequency and do not alternate as other frequencies do. AC transmission lines operate at 60Hz in the United States and the fields alternate at a rate of 60 cycles per second. These fields are classified as extremely low frequency (ELF). As frequencies increase to millions or billions of Hertz, the frequency bands of AM radio, FM radio, cellular telephones, WiFi modems, microwave and satellite broadcasts, and, ultimately x-rays are reached. It is important to understand that the human body interacts differently with each of these various frequency ranges. In addition, higher frequency range fields contain higher energy levels, to the point where non-ionizing radiation crosses over into ionizing radiation (ionizing radiation is electromagnetic radiation that carries enough energy to liberate electrons from atoms or molecules).

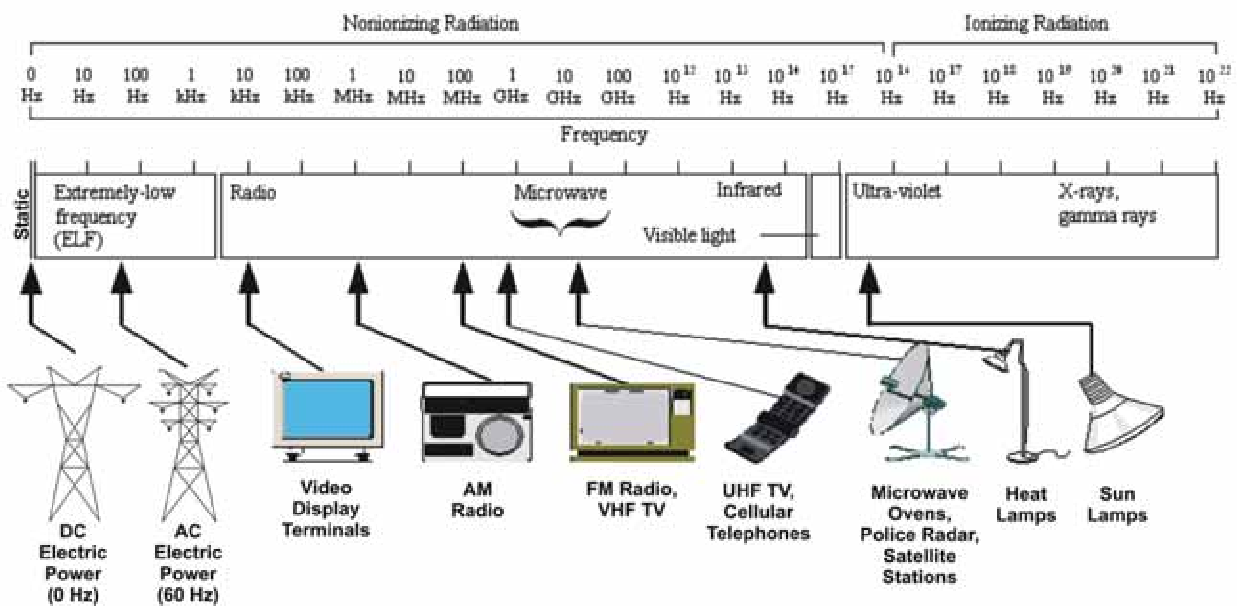

Figure 3.4-4: The Electromagnetic Spectrum

The majority of the Project consists of the ±600kV HVDC overhead electric transmission line (approximately 720 miles in length). Therefore, only DC electric and magnetic field effects would be associated with this portion of the Project (i.e., not AC field effects). In other words, only DC health effects studies would be applicable to this area of the Project.

Short segments of AC transmission line are proposed as part of the Project, and these segments would connect into convertor stations (either connecting wind farms to convertor stations or convertor stations to other substations). Only in these limited areas would AC electric and magnetic field effects be associated with this smaller portion of the Project (i.e., not DC field effects).

Within this section on the Electrical Environment, AC electric and magnetic field research is presented separately from DC electric and magnetic field research to distinguish the two topics and avoid mistakenly combining the results from these two separate and distinct subjects. Table 3.4-3 presents a summary of the sections where AC versus DC topics are found. These sections were purposefully separated from each other to minimize the misapplication of results from one section to another. For example, many of the health studies discussed in Section 3.4.11.2.1.2.2.7 for AC electric and magnetic fields are not applicable to DC transmission line effects.

Table 3.4-3:
Section Discussions for AC Versus DC Electric and Magnetic Field Electrical Effects

Topic	Section
AC Electrical Effects Research on Human Health	3.4.11.2.1.2.2.7
AC Electrical Effects Research on Pacemakers and Implanted Medical Devices	3.4.11.2.1.2.2.8
AC Electrical Effects Research on Plant and Animal Health	3.4.11.2.1.2.2.9
DC Electrical Effects Research on Human Health	3.4.11.2.3.2.6
DC Electrical Effects Research on Pacemakers and Implanted Medical Devices	3.4.11.2.3.2.7
DC Electrical Effects Research on Plant and Animal Health	3.4.11.2.3.2.8

Other health studies, such as those associated with higher radio or microwave frequencies, would not be applicable to either the DC transmission line or the AC transmission lines associated with the Project. For example, a 2013 Turkish study presented results concerning the impact of electromagnetic waves (microwaves) on epileptic seizures (Cinar et al. 2013). The study found a possible trigger effect of electromagnetic waves on seizure activity in mice, and this study was referenced in comments received on the Draft EIS out of concern over possible seizures in humans living close to the Project transmission lines. However, the study utilized electromagnetic frequencies approaching the microwave band (ranging from 100MHz to 900MHz). This frequency in no way compares to static frequency (0Hz), which is 100–900 million times higher in frequency (and almost 10 million times higher for power frequency). In fact, the paper itself cites another study (Canseven et al. 2007) that states that they “did not find any effect of 50Hz electromagnetic waves” (50Hz being the European power frequency, which is very close in frequency to the power frequency in the United States of 60Hz). There are significant differences in electric and magnetic fields associated with static frequencies (0Hz), power-frequencies (50/60Hz), and much higher frequencies (such as radio, microwave, and higher ranges).Therefore, caution must be exercised to ensure that findings associated with a particular frequency are not applied to other frequencies (even between DC and AC power frequencies).

3.4.3 Transmission Line Audible Noise

The natural phenomenon of corona can also occur on a transmission line and can create audible noise. Corona is an electrical discharge of energy that occurs on an energized surface such as a transmission line conductor (as shown in Figure 3.4-5). The electrical voltage at a specific location on an energized surface increases wherever surface irregularities occur (such as nicks on the transmission line conductor, water droplets, insects, or debris) to the point that the air surrounding that location becomes ionized and creates a tiny electrical discharge (EPRI 2010). Corona on high voltage transmission lines generates a small amount of sound or noise. The audible noise level can increase during foul weather conditions when the transmission line conductors are wet (during rain, snow, or fog) and at higher elevations. For example, water drops that collect on the surface of the conductors increase corona activity so that a crackling or humming sound may be heard near a transmission line. Audible noise decreases with distance from a transmission line.

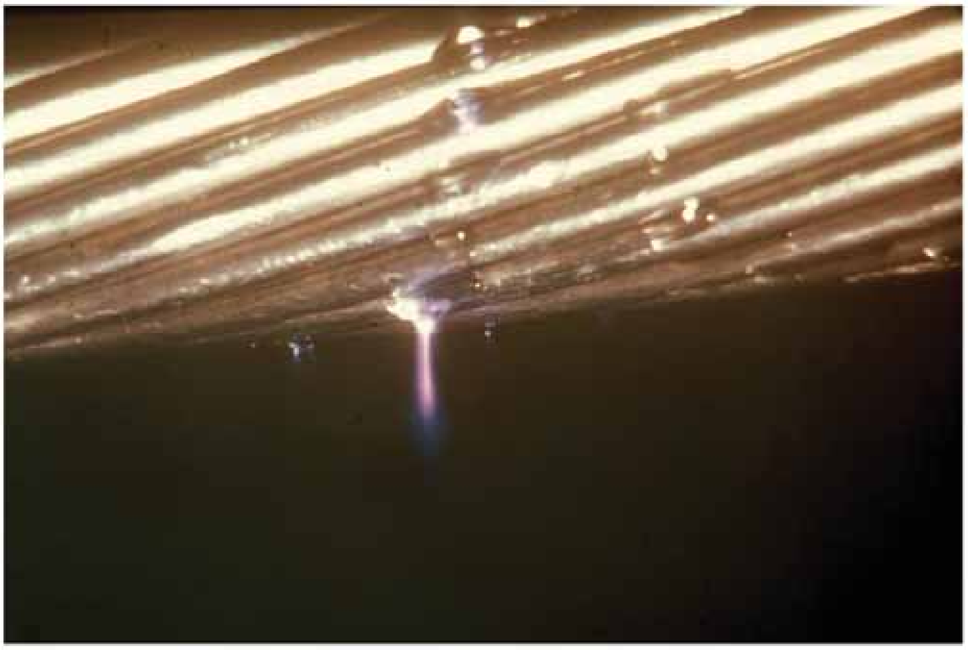

Figure 3.4-5: Close-up View of a Tiny Corona Discharge at the Surface of a Conductor

Audible noise is measured in decibels (dB), a logarithmic (i.e., dimensionless) unit that is the ratio of a sound pressure referenced to the threshold of human hearing. The apparent loudness that is attributed to sound varies not only with the sound pressure but also with the frequency (or pitch) of the sound. Since the human ear is not equally sensitive to sound at all frequencies, a specific frequency-dependent rating scale was devised (A-weighted dB scale, or dBA) to approximate the sensitivity of the human ear. This dBA scale has been chosen by most authorities for purposes of environmental noise regulation.

Typical sounds in a community may range from about 40 dBA (very quiet) to 100 dBA (very loud) or higher. Some typical noise levels range from the relative quiet of the library to the loud trains (Table 3.4-4).

Table 3.4-4:
Typical Sound Levels for Common Sources (in A-Weighted Decibels)

Source/Location	Sound Level (dBA)
Threshold of Hearing	0
Motion Picture Studio–Ambient	20
Library	35
Chicago Suburbs—nighttime minimum	40
Wind in Deciduous Trees (2–14 mph)	3–61
Falling Rain (Variable Rainfall Rates)	41–63
Tomato Field on California Farm	44
Small Town/Quiet Suburb	47–53
Private Business Office	50
Light Traffic at 100 feet Away	50

Table 3.4-4:
Typical Sound Levels for Common Sources (in A-Weighted Decibels)

Source/Location	Sound Level (dBA)
Average Residence	50
Large Retail Store	60
Accounting Office	60
Boston Inside House on Major Avenue	68
Average Traffic on Street Corner	75
Inside Sports Car (50 mph)	80
Diesel Freight Train at High Speed at 25 meters	80
Los Angeles–0.75 mile from Jet Landing	86
Loud Automobile Horn (at 1 meter)	115

Source: EPA (1974), IEEE (1974), Miller (1978)

It is important to remember that transmission line audible noise is variable and therefore is characterized using statistics that estimate the probability of a certain level of noise occurring. Statistical noise descriptors include what engineers call exceedance levels, for example, L10, L50, and L90. These descriptors indicate what percentage of time a certain noise level will be exceeded. For example, a L50 of 65 dBA indicates that 50 percent of the time, noise levels will be greater than 65 dBA at a certain location and, conversely, it could be less than 65 dBA for 50 percent of the time. Additional methods to characterize audible noise have been developed to evaluate the long-term characteristics of sound. The equivalent sound level, L_{eq}, is the average level of a varying sound over a specified period of time (EPA 1974; Keast 1980). This value is a single-number equal to the level of an equivalent constant unchanging sound.

Some government agencies have adopted a level similar to L_{eq} called the day-night averaged noise level (an equivalent day-night sound level, or L_{dn}). The L_{dn} represents a time-weighted 24-hour average noise level based on the A-weighted decibel for a variety of weather conditions. Time-weighted refers to the fact that noise occurring during certain sensitive time periods (nighttime, when other background sounds are relatively subdued) is adjusted for occurring at those times. L_{dn} includes an additional 10 dBA increase that is added to noise events occurring during the nighttime hours of 10 p.m. to 7 a.m. (because people are more sensitive to noise at night).

In most, but not all, aspects, HVDC transmission line audible noise is similar to that of HVAC transmission lines. Audible noise on HVDC lines is typically highest in fair weather or during the transition from fair to foul weather, whereas noise on HVAC lines is typically highest in foul or rainy weather (EPRI 2010). For HVAC transmission lines, the audible noise has two components: (1) a high frequency broadband noise (that distinguishes it from most common environmental noises) caused by impulsive corona, and (2) a low-frequency pure tone “hum,” at 120Hz and multiples of 120Hz, propagating laterally from the conductor (EPRI 2006c). The broadband noise spectrum extends well beyond the sonic (audible) range; i.e., beyond about 15kHz to several tens of kilohertz. The hum is a pure tone that is superimposed over the broadband noise. In different weather conditions, the relative magnitude of broadband noise and hum may be different. For example, during rain the broadband component generally dominates, whereas under icy conditions, the hum dominates. As opposed to HVAC, HVDC corona noise does not contain pure tones emerging from the broadband noise. The low frequency components of the noise (up to the 125Hz octave band) can rarely be distinguished from ambient noise, while high frequency corona noise ranges from 500Hz to 16kHz. The positive pole of a bipolar HVDC line produces more audible noise than the negative pole; in fact, audible noise generation from the negative pole is negligible. Therefore, HVDC audible noise is mostly limited to the positive conductors, unlike HVAC audible noise, where all of the conductors generate noise.

Research (EPRI 2010, 1982) has demonstrated that annoyance to HVAC transmission line audible noise is stronger than audible noise from HVDC transmission lines below 50 dBA (i.e., levels beyond the transmission line ROW). At audible noise levels lower than 50 dBA, DC audible noise was found to produce less perceived annoyance than the corresponding AC noise level. However, above 50 dBA, DC audible noise was shown to produce more annoyance than AC audible noise. As previously stated, HVDC audible noise is higher in fair weather (when people may be outside more often and no rainfall is present to mask the noise).

The laws of acoustics govern the propagation of corona-generated noise from conductors, for both the broadband and pure tone (hum) components of noise. The atmosphere, trees, and structures diminish the broadband component of the noise significantly more than the hum. If the sound has a large broad band component, different sound frequencies may attenuate at different rates, and hence the overall characteristics of the sound may change. Reflected noise by the earth has a negligible effect on the broadband noise and can be disregarded, while the ground is a good reflector of hum. Reflections from objects close to the point of interest may also have a significant effect. The pure tone hum is only slightly attenuated by air, trees, and walls. Therefore, at larger distances from the line or inside houses, the hum may become more noticeable in relation to the high-frequency random noise. Fortunately, no pure tones are present in HVDC line audible noise (which would be associated with the Project HVDC transmission line) (EPRI 2010). Altitude above sea level also affects audible noise levels. For HVAC, audible noise typically increases by about 1 dB for every 1000 feet of altitude above sea level; the same type of variation is also expected for HVDC audible noise (EPRI 2010). Audible noise calculation software typically assumes a flat, open terrain with no sound-modifying objects present (such as uneven terrain, trees, buildings, and other objects).

Electrical sparks or arcing can also create audible noise. However, during normal operation, the transmission line should not arc or spark unless there is a broken or damaged insulator or other piece of hardware. Such damage could cause very tiny arcs between the broken or damaged pieces of hardware on the transmission line itself and can be located and repaired on any modern transmission line. Trees and other growth are cleared away within the transmission line ROW to facilitate line operation and maintenance.

3.4.4 Radio and Television Noise Interference

In addition to audible noise, corona from a transmission line can also create radio and television noise. Sporadic pulses of current, such as those produced by corona and gap discharges (tiny electrical gaps between mechanically connected parts) generate electromagnetic energy over a broad range of frequencies, including the radio and television bands. Overhead transmission lines do not, as a general rule, interfere with radio or TV reception. Corona-generated radio frequency noise decreases with distance from a transmission line and also decreases with higher frequencies. (When it is a problem, it is usually for amplitude modulation [AM] radio and usually not the higher frequencies associated with TV or satellite signals.) The severity of interference depends on the strength and quality of the transmitted radio or TV signal, the quality of the radio or TV set and antenna system, and the distance between the signal receiver (radio or TV) and the transmission line. The units used for radio or TV noise are decibels referenced to 1 μV/m (or one-millionth of a volt per meter) and written as dBμV/m.

It is difficult to determine whether the radio frequency noise level produced by a transmission line will cause unacceptable interference, because the strength of the received signal, the sensitivity of the receiver, the orientation of the receiving antenna, and the ambient radio frequency noise are all important parameters in determining the degree to which noise from the transmission line may cause signal degradation. A common measure to evaluate possible interference levels is the signal-to-noise ratio (SNR): the ratio of average signal power to average noise power (for a given frequency bandwidth). Based upon listening tests, if the limit of tolerability is assessed as the point at which reception quality becomes less than satisfactory, then the radio interference level of a transmission line should be 22 dB or more below the average strength of the desired radio signal (EPRI 2006a). For television interference, an SNR of at least 30–40 dB is required if corona noise is not to cause objectionable interference (EPRI 2006a). Radio and TV noise levels caused by the proposed transmission line can be computed, but without knowing broadcast signal strengths at various locations of interest along the possible line routes, it is difficult to determine that a tolerable SNR criterion would be met.

Corona-generated noise may also potentially impact amateur radio station operators. Amateur radio operators often try to receive broadcast signals down at the lowest level of noise, so additional noise from a transmission line may impact the signal reception. In addition, there are many parameters that may influence signal reception, including the broadcast signal frequency, direction of the signal, alignment of the receiver antenna, quality of the radio station equipment, terrain variations and altitude, and especially weather conditions. Because of these various parameters, it is not feasible to precisely determine whether a particular level of transmission line radio frequency noise will cause unacceptable interference to a nearby amateur radio station operator. Transmission line owners are required to resolve interference complaints from licensed operators in accordance with the Federal Communications Commission (FCC) Rules and Regulations at 47 CFR Part 15.

An important new issue is the radio and TV conversion to digital broadcast system technology. Low levels of interference may not noticeably affect a digital receiver's performance but higher levels may break up or stop reception. In principle, the new digital signal should be less susceptible to interference than an old analog signal (Smith 2004). The quality of digital reception should be better in a given noise level and would stay good at SNRs beyond which the old analog reception is no longer viable. These results have been documented in previous studies, such as the FCC study (FCC 1999), which indicated that digital signals will provide superior coverage and immunity to impulse noise (such as noise interference from household appliances as well as power lines) than analog signals. The International Electrotechnical Commission has endorsed the Digital Radio Mondiale on-air system, which is expected to be built to be immune to atmospheric electro-magnetic interference (EMI), and therefore are highly likely to be immune to power line EMI as well (EPRI 2006a). As new digital receivers emerge for high definition television and other applications, more testing will need to be performed to determine their susceptibility to power line interference (EPRI 2006a). No interference resulting from corona-generated noise would be expected for digital signals broadcast at frequencies above 1 gigahertz (GHz) from satellites. A possible problem could be a transmission tower in the direct line-of-sight between a dish antenna and a satellite, but this could be resolved by moving the dish antenna to a different location.

Questions sometimes arise about use of GPS devices in close proximity to high voltage transmission lines. The concern is that GPS units are unable to receive a signal from the satellites and that this will negatively affect agricultural operations that require GPS. In general, interference noise must be in the same frequency band as the band in which GPS receivers operate. Transmission lines produce little to no noise in the microwave bands used by GPS systems. Research performed on this subject did not reveal a problem for the high-quality receivers used in precision agriculture or agriculture-related aviation (Silva and Olsen 2002).

There are also important differences between DC and AC radio noise. Results from laboratories, tests, and operating DC lines have shown that the highest levels of radio noise occur during fair, dry weather rather than wet weather as for AC lines. While water drops are very effective corona sources, the ionization of air near the surface of DC line conductors in wet weather is very intense and has the effect of maintaining the electric field at a relatively low level near the surface of the conductors (EPRI 2010). The positive pole of a bipolar HVDC line also produces the greatest amount of radio noise (to the extent that noise generation from the negative pole can be ignored), whereas all conductors generate noise for AC transmission lines (EPRI 2010).

3.4.5 Ozone and Air Ions

Corona from a transmission line can also create oxidants such as ozone and air ions. Ozone consists of three oxygen molecules and is measured in parts per billion (ppb). The energy emission during corona on a transmission line ionizes (electrically charges) the surrounding air, creating ozone. Air ions are also produced when high voltage corona ionizes air molecules and these are measured in ions per centimeter cubed (ions/cm^3). Negative ions are particles with one or more extra electrons (resulting in a net negative charge) while positive ions are missing one or more electrons (resulting in a net positive charge). Air ions are present throughout the earth's atmosphere and occur during weather events (thunderstorms, lightning, rain), thermal combustion (a candle flame, internal combustion engines), water droplet formation (near waterfalls or in rain), and radioactivity as shown in Table.3.4-5 (EPRI 2012; Olsen and Sheppard 2012). Several factors influence the rate of generation of these elements, the most important being the transmission line conductor characteristics, mode of corona discharge, and the ambient weather conditions—i.e., temperature, humidity, precipitation, direction and intensity of wind speed, and terrain topography. Precipitation on a conductor surface decreases the conductor surface irregularity and increases corona losses, so rainy conditions, therefore, produce one of the highest levels of ozone generation on transmission lines. The presence of water and humidity, although it increases the efficiency of ozone generation, it makes ozone decay faster than in dry weather.

Table 3.4-5:
Air Ion Concentrations for Selected Environments

Environment	Air Ion Concentration (ions/cm^3)		
	Total	Positive	Negative
Ambient (typical)	$1x10^3$ to $2x10^3$	$5x10^2$ to $1x10^3$	$5x10^2$ to $1x10^3$
Thunderstorm	$2.1x10^4$	$7x10^3$	$1.4x10^4$
Rain (increments above ambient)		$6x10^2$	$9x10^2$
Waterfall (increments above ambient)	$1.5x10^4$ to $2.7x10^4$	$2.2x10^2$ to $5.6x10^2$	$1.5x10^2$ to $5.4x10^3$
Burning Match (30 centimeters above match)	$2x10^5$ to $3x10^5$		
Cave (radioactive rock)	$15.4x10^5$	$6.7x10^5$	$6.7x10^5$
Maximum Measured Under HVDC Transmission Line (±400 and 500kV)	$3x10^5$		

Source: EPRI (2012)

Air ions are also created near HVDC transmission line conductors. Ions are formed by the ionization of air molecules (stripping away electrons from neutral air molecules to form ions) and become either positively or negatively charged. Most air ions are attracted toward the HVDC transmission line conductor of opposite polarity, but others are also directed toward the ground. If there is no wind, ions travel along the lines of electric field. In the presence of wind, air ions travel downwind until they are eventually neutralized by transferring their charge to aerosols or by coming into contact with the ground. Because aerosols have masses larger than those of air molecules, they are not as easily moved by electric field forces, and their direction is controlled primarily by the wind (the movement of space charges results in current flow).

Results of careful studies in the laboratory and measurements near transmission lines indicate that it would be unlikely that air ions and ozone from transmission lines would cause adverse health effects (EPRI 2012; NRPB 2004). Some effects have been reported, but the findings are inconsistent, and many studies have reported no effect (EPRI 2010).

3.4.6 Regulatory Background

Neither the state governments of Oklahoma, Arkansas, Tennessee, or Texas in which the Project will be constructed and operated, nor the federal government, have any statues or regulations relating to DC or AC electric and magnetic fields or radio and television interference specific to transmission lines. In the absence of any statutes or regulations, recommendations and guidelines of other state, international, and non-regulatory agencies have been consulted as an aid to the evaluation of potentially adverse impacts. The basis for some of these guidelines and recommendations and how they were developed is not always clearly defined, and not all of them represent science-based exposure limits to protect health and safety. It is also important to note that recommendations proposed to protect health and safety typically incorporate additional “safety” or “uncertainty” factors. However, the EPA has established guidelines for audible noise and ozone/air ions, which are also electrical effects associated with transmission lines.

The DOE has participated in two publications that summarize EMF: Questions and Answers About EMF, Electric and Magnetic Fields Associated with the Use of Power (NIEHS and DOE 1995) and EMF Electric and Magnetic Fields Associated with the Use of Electric Power, Questions and Answers (NIEHS and NIH 2002). These booklets contain information describing the principles of EMF, an overview of the results of major studies, and summarize the conclusions of expert review panels (additional discussion on this topic is presented in Section 3.4.11.2.1.2.2.7).

3.4.6.1 DC Electric Field Exposure Guidelines

No federal regulatory agencies or state agencies in which the Project will be operated (Oklahoma, Arkansas, Tennessee or Texas) have DC electric field exposure limits. Non-regulatory organizations have established or recommended the following DC electric field exposure limits:

- The International Committee on Electromagnetic Safety (ICES), which is a technical committee within the Institute of Electrical and Electronics Engineers (IEEE), has established a guideline of 20kV/m (thousands of volts per meter) for occupational exposure and 5kV/m for public exposure at 0Hz (ICES 2002).
- The American Conference of Governmental Industrial Hygienists (ACGIH) has established an occupational guideline of 25kV/m (ACGIH 2010), which is an industrial/occupational standard that is designed to protect workers in high field environments and not a public exposure standard. Public (non-occupational) exposure would be incidental/short-term exposure within and near the transmission line ROW. It is not clear how applicable this standard would be to construction and operation of the Project.
- The International Committee on Non-Ionizing Radiation Protection (ICNIRP) has established a guideline of 20kV/m for occupational exposure and 5kV/m for public exposure at 1Hz (ICNIRP 2010). This guideline is an international standard and is provided as an aid for DC electric field evaluation.

The consensus of these non-regulatory groups indicates that public exposure to DC electric field should be limited to 5kV/m (with occupational exposure limited to the range of 20 to 25kV/m).

3.4.6.2 AC Electric Field Exposure Guidelines

No federal regulatory agencies or state agencies in which the Project will be operated (Oklahoma, Arkansas, Tennessee or Texas) have AC electric field exposure limits. Non-regulatory organizations have established or recommended the following AC electric field exposure limits:

- The ICES, which is a technical committee within the IEEE, has established a guideline of 20kV/m for occupational exposure, 10kV/m within a transmission line ROW, and 5kV/m for public exposure (ICES 2002).
- The ACGIH has established an occupational threshold of 25kV/m, and for workers with implanted medical devices (such as cardiac pacemakers) the recommended limit is 1kV/m (ACGIH 2010). Manufacturers of implanted medical devices often provide specifications about AC electric field thresholds to patients, and these may be different from the ACGIH recommendation (additional discussion on this topic is presented in Section 3.4.11.2.1.2.2.8). The ACGIH standard is an industrial/occupational standard (which is designed to protect workers in high field environments) and not a public exposure standard. Public (non-occupational) exposure may typically be incidental/short-term exposure within and near the transmission line ROW and it is not clear how applicable this standard would be in these situations.
- Although the states of Oklahoma, Arkansas, Tennessee, and Texas do not have electric field standards for transmission lines, at least six other states have established regulations regarding electric fields (either within the ROW or at the ROW edges, as shown in Table 3.4-6) (NIEHS and NIH 2002). Within the ROW, thresholds range from 7kV/m to 11.8kV/m, depending upon the state. At the ROW edges, thresholds range from 1 to 3kV/m, depending upon the state. These regulations are engineering standards (rather than health-based standards) so that new transmission lines will have similar field levels to existing, operational transmission lines or are safety-based engineering standards to establish electric field levels to limit electric discharges that could cause a nuisance shock.
- The NESC requires that the electric field be reduced such that the largest anticipated object underneath an overhead transmission line has a current to ground of no greater than 5 milliamps (mA). High voltage transmission lines can induce a voltage, and therefore induce electric currents, in metallic objects such as a truck parked under the transmission line. The NESC therefore requires that additional ground clearance or other means shall be used to limit anticipated electric field effects to 5mA or less (IEEE 2012).
- The ICNIRP has established a guideline of 8.3kV/m for occupational exposure and 4.2kV/m for public exposure at 60Hz (ICNIRP 2010). This guideline is an international standard and is provided as an aid for AC electric field evaluation.

The consensus of these non-regulatory groups indicates that public exposure to 60Hz AC electric field should be limited to 5kV/m or less (with occupational exposure limited to the range of about 8 to 25kV/m). For occupational workers with implanted medical devices, a limit of 1kV/m has been recommended (ACGIH 2010). Specifically for a transmission line, a limit of 10kV/m has been recommended within the ROW (ICES 2002).

Table 3.4-6:
Summary of State Transmission Line Standards and Guidelines for AC Fields[1]

State	AC Electric Field		AC Magnetic Field	
	On ROW	ROW Edge	On ROW	ROW Edge
Florida*	8kV/m[a] 10kV/6 [b]	2kV/m	—	150 mG[a] (max load) 200 mG[b] (max load) 250 mG[c] (max load)
Minnesota	8kV/m	—	—	—
Montana	7kV/m[d]	1kV/m[e]	—	—
New Jersey	—	3kV/m	—	—
New York	11.8kV/m 11.0kV/m[f] 7.0kV/m[d]	1.6kV/m	—	200mG (max load)
Oregon	9kV/m	—	—	—

* ROW includes certain additional areas adjoining the ROW for Florida only
a For lines of 69–230kV
b For 500kV lines
c For 500kV lines on certain existing ROW
d Maximum for highway crossings
e Applies in residential and subdivided areas and may be waived by the landowner
f Maximum for private road crossings
Source: NIEHS and NIH (2002)

3.4.6.3 DC Magnetic Field Exposure Guidelines

No federal regulatory agencies or state agencies in which the Project will be operated (Oklahoma, Arkansas, Tennessee or Texas) have DC magnetic field exposure limits. Non-regulatory organizations have established or recommended the following DC magnetic field exposure limits:

- The ICES, which is a technical committee within the IEEE, has established a guideline of 3,530G for occupational exposure and 1,180G for public exposure at 0Hz (ICES 2002).
- The U.S. Food and Drug Administration (FDA) has established a limit of 40,000G for medical patients receiving MRI treatments and 5G for patients with pacemakers (FDA 1998).
- The ACGIH has established an occupational guideline of 20,000G for whole body exposure and 5G for persons with implanted medical devices (ACGIH 2010). Manufacturers of implanted medical devices often provide specifications about DC magnetic field thresholds to patients, which may be different from the ACGIH recommendation (additional discussion on this topic is presented in Section 3.4.11.2.3.2.7). The ACGIH standard is an industrial/occupational standard (which is designed to protect workers in high field environments) and not a public exposure standard. Public (non-occupational) exposure may typically be incidental/short-term exposure within and near the transmission line ROW and it is unclear how applicable this standard would be in these situations.

1 None of these states are locations where the Project will be constructed and operated. Field values are provided as an aid for AC electric and magnetic field evaluation.

- The ICNIRP has established a guideline of 20,000G for occupational exposure, 4,000G for public exposure, and 5G for persons with implanted medical devices (ICNIRP 2009). This is an international standard and is provided as an aid for AC electric field evaluation.

The consensus of these non-regulatory groups indicate that public exposure to DC magnetic field should be limited to the range of 1,180 to 4,000G (with occupational exposure limited to the range of 3,530 to 20,000G). For people with implanted medical devices, a limit of 5G has been recommended.

3.4.6.4 AC Magnetic Field Exposure Guidelines

No federal regulatory agencies or state agencies in which the Project will be operated (Oklahoma, Arkansas, Tennessee or Texas) have AC magnetic field exposure limits. Non-regulatory organizations have established or recommended the following AC magnetic field exposure limits:

- The ICES, which is a technical committee within the IEEE, has established a guideline of 27.1G for occupational exposure and 9.0G for public exposure to 60Hz magnetic fields (ICES 2002).
- The ACGIH has established an occupational threshold of 10 G, and for workers with implanted medical devices (such as cardiac pacemakers) the recommended limit is 1G (ACGIH 2010). Manufacturers of implanted medical devices often provide specifications about AC magnetic field thresholds to patients, which may be different from the ACGIH recommendation (additional discussion on this topic is presented in Section 3.4.11.2.1.2.2.8). The ACGIH standard is an industrial/occupational standard (which is designed to protect workers in high field environments) and not a public exposure standard. Public (non-occupational) exposure may typically be incidental/short-term exposure within and near the transmission line ROW and it is not clear how applicable this standard would be in these situations.
- Although the states of Oklahoma, Arkansas, Tennessee, and Texas do not have magnetic field standards for transmission lines, at least two other states have established regulations regarding magnetic field at the ROW edges (levels range from 150 to 250 mG, depending upon the state) as summarized in Table 3.4-6 (NIEHS and NIH 2002). These regulations are engineering standards (rather than health-based standards) so that new transmission lines will have similar field levels to existing operational transmission lines.
- The ICNIRP has established a guideline of 10G for occupational exposure and 2G for public exposure (ICNIRP 2010). This is an international standard and is provided as an aid for AC electric field evaluation.

The consensus of these non-regulatory groups indicate that public exposure to AC magnetic field should be limited to the range of 2 to 9G (2,000 to 9,000 mG) (with occupational exposure limited to the range of 10 to 27.1 G). For occupational workers with implanted medical devices, a limit of 1G has been recommended (ACGIH 2010).

3.4.6.5 Audible Noise Exposure Guidelines

Regulatory organizations have established or recommended the following audible noise exposure limit:

- The EPA has established an outdoor activity L_{dn} noise guideline of 55 dBA (EPA 1974). This value represents the sound energy averaged over a 24-hour period; it has a 10 dBA nighttime weighting (between 10:00 p.m. and 7:00 a.m.) (EPRI 2006a). The noise level is applicable to outdoor residential areas and farms and other outdoor areas where people spend time.

No other local noise ordinances establishing numerical limits were identified (Clean Line 2014a).

3.4.6.6 Radio and Television Noise Exposure Guidelines

Regulatory and non-regulatory organizations have established the following exposure limits for radio and television noise interference:

- The FCC has established that if unacceptable interference from transmission lines is present at nearby amateur radio stations (i.e. notification to an FCC representative that harmful interference is present), the owners of the transmission line are required to resolve interference complaints from licensed operators in accordance with the FCC Rules and Regulations requirements at 47 CFR Part 15.
- The IEEE established the Radio Noise Design Guide of 56 dBμV/m at a frequency of 1 million hertz (MHz) measured at 15 meters (50 feet) from the outside conductor in fair weather (IEEE 1971), which was modified by IEEE to a standard frequency of 0.5MHz by IEEE Standard 430-1986 (IEEE 1986) and corresponds to 61 dBμV/m at 0.5MHz (Olsen 2014). However, this is a design guide rating for acceptable noise performance; actual performance is dependent upon many parameters that may influence signal reception (IEEE 1971), including the broadcast signal frequency, direction of the signal, alignment of the receiver antenna, quality of the radio station equipment, terrain variations and altitude, and, especially, weather conditions.

3.4.6.7 Ozone/Air Ion Concentration Exposure Guidelines

Regulatory organizations have established the following exposure limits for ozone concentration:

- The EPA ozone standard is in terms of 8-hour average exposures to a level of 75 ppb (EPA 2008).
- The states of Oklahoma (ODEQ 2013), Arkansas (ADEQ 2014), and Tennessee (TDEC 2014) have endorsed and adopted the EPA ozone standard (EPA 2008).

3.4.7 Data Sources

Transmission line geometry and loading information was provided in the Applicant's Technical Report on the Electrical Environment Assessment of the Plains and Eastern Transmission Line Project (Clean Line 2014b).

Land use information was provided in the Applicant's Land Use and Recreation Technical Report for the Plains and Eastern Transmission Line Project (Clean Line 2013) and is also discussed in Section 3.10.

Weather information was provided by the U.S. National Oceanic and Atmospheric Administration website (http://www.noaa.gov), the Weather Underground website (http://www.wunderground.com), and the Weather Channel website (http://www.weather.com).

Locations where existing AC transmission lines are present along the proposed HVDC overhead electric transmission line route were evaluated using GIS files provided by the Applicant.

3.4.8 Region of Influence

3.4.8.1 Region of Influence for Project and DOE Alternative

The ROI associated with the Project is the transmission line ROW for the HVDC transmission line and for all AC transmission lines as described in Section 3.1.1. The precise ROW width has not yet been determined for each route section, and could vary from 150 to 200 feet in width. Certain electrical effects may extend beyond the ROW edges, so this evaluation was extended to include a distance of 200 feet beyond the maximum assumed ROW edges (which corresponds to a total of 300 feet on either side of centerline for the HVDC transmission line) and AC collection system routes.

For the AC/DC converter stations, the ROI is the potential siting areas for each converter station within which the converter station would be located (as described in Section 3.1.1). Converter stations (DC to AC) are similar to substations (AC) with respect to electrical effects such as electric and magnetic fields. The equipment associated with converter stations would not be a source of elevated fields or corona effects outside the boundaries of the proposed sites; substation and converter station equipment is typically located centrally within the site, and fields from these sources attenuate very quickly with distance away from the equipment. This equipment characteristic is recognized by IEEE in their standards (IEEE 1998), which states that: *"In a substation, the strongest fields around the perimeter fence come from the transmission and distribution lines entering and leaving the substation. The strength of fields from equipment inside the fence decreases rapidly with distance, reaching very low levels at relatively short distances beyond substation fences."* Therefore, no additional electrical field effects analysis was performed for the converter stations.

Some types of substation and switching station equipment can potentially be a source of electrical effects (for example, power transformers can produce audible noise, and converter equipment can produce radio noise, etc.). These effects can be reduced or eliminated by the use of filtering equipment, sound walls, and other methods. Computer modeling and calculations of electrical effects for the proposed converter stations were therefore not performed, except for audible noise as described in Section 3.11.6. The Applicant would use filtering equipment at each converter station if necessary to reduce noise. Therefore, no additional electrical noise effects analysis was evaluated for the converter stations.

3.4.8.2 Region of Influence for Connected Actions

The ROI for wind energy generation, the future Optima substation, and TVA upgrades is described in Section 3.1.1.

3.4.9 Affected Environment

The affected environment would include the proposed transmission line ROWs through Oklahoma, Arkansas, Tennessee, and Texas (i.e. the transmission line ROI) and the proposed converter stations. The primary electrical component of the Project is the approximately 720-mile-long ±600kV HVDC overhead electric transmission line that would be routed within each state. At each end of the DC transmission line, AC/DC converter stations are required to convert DC electricity to AC electricity for interconnection into the AC electrical grid. One double circuit AC transmission line of up to 345kV would be required to connect the Oklahoma converter station, while two 500kV AC transmission lines would be required to connect the Tennessee converter station. An additional converter station could be sited in Pope County, Arkansas, as part of the DOE alternatives. This alternative converter station would be similar to the Oklahoma and Tennessee converter stations. One 500kV AC transmission line would be required to connect the Arkansas converter station alternative to an interconnection point along an existing 500kV transmission line in Arkansas. Four to six AC transmission lines are also proposed to transport AC electrical power (the AC collection system) from wind farm generation in Oklahoma to the converter station in Oklahoma.

Detailed information regarding the transmission line configurations, convertor stations, and transmission line routes are described in Chapter 2 and in Appendix F. Several route variations to the Applicant Proposed Route in Regions 2–7 were developed in response to public comments on the Draft EIS and are described in Appendix M and summarized in Sections 2.4.2.1–2.4.2.7. The variations are presented graphically in Exhibit 1 of Appendix M. Electrical effects are associated with the type of transmission line configuration, rather than a region or particular line route. Therefore, transmission line electrical effects along a proposed route or for a route variation within a region would remain the same (assuming the transmission line configuration remains the same for the variations).

3.4.10 Regional Description

The Project (which includes the HVDC transmission line, AC collector lines, and convertor stations) would be located in Oklahoma, Arkansas, Tennessee, and Texas. Locations within these four states have been divided into seven different regions, primarily based upon the routing of the HVDC transmission line (including the Applicant proposed and alternative routes). Detailed information regarding each of the proposed transmission line routes can be referenced in Chapter 2.

Existing sources of electrical effects are present along each of the transmission line routes. These effects include static and power-frequency fields as well as radio frequency signals. Sources of these effects include existing power lines, communications equipment, and other related sources. Since the use of electricity is an integral part of our modern lifestyle, these effects are commonly found in our everyday environment and, therefore, within each of the Project regions being evaluated.

As previously discussed, static (DC) electric and magnetic fields are a common, natural phenomenon. Static electric fields are present in our environment due to the difference in voltage potential between the ionosphere and the surface of the earth. The earth's magnetic field is a natural static field, whose intensity is about 0.51 G, or 510 mG, in the Oklahoma/Arkansas/Tennessee area where the HVDC transmission line would be constructed. Many household appliances also utilize DC charging current (e.g., chargeable electric razors and electric toothbrushes). AC electric and magnetic fields exist wherever electricity is generated, transmitted, or distributed in power lines or cables or used in electrical appliances. Existing high voltage AC electric transmission lines are therefore present in power line corridors within each Project state. Overhead AC distribution lines are also commonly present along roadways and in towns, providing lower voltage electrical service directly to residents, farms, businesses, and industries in each local area. These existing power lines all produce AC electric and magnetic fields that currently contribute to the existing overall field environment. In our homes, electrical appliances are also sources of AC electric and magnetic field.

Currently, there are other high voltage DC transmission lines in operation within the United States. For example, the Pacific Intertie is an approximate 845-mile HVDC transmission line routed from the Washington/Oregon border to northern Los Angeles, California, that has been in operation since 1970. Originally operating at an electrical voltage of 400kV, the Pacific Intertie was upgraded to 500kV in 1984 and has operated at that voltage ever since.

At numerous locations within each region, the proposed HVDC transmission line is located parallel to other existing AC transmission lines. In these situations, electrical effects from existing AC transmission lines may influence effects associated with the proposed HVDC transmission line by itself (effects could be additive or subtractive). Because the HVDC transmission line route has not yet been selected, and given the numerous existing AC transmission lines present along various routes and regions, calculations of the combined electrical effects was not performed for these situations.

Electrical effects from multiple power line sources are not simply additive. For example, contributions from multiple magnetic field sources are not simply cumulative in determining the resulting magnetic field level, since magnetic fields are vectors and phasors, and thus must be added while considering both their space and time components (since AC field values from each source may not occur at precisely the same instant in time). When the vectors are in opposite directions, the fields cancel, and when the vectors are in the same direction, they add. The magnetic field at any point in space is the vector sum of the field contributions from all sources (at each instant in time). Magnetic fields from multiple sources are influenced by the distance relative to each source, the amount and direction of current flow on each source, and the configuration of the source (i.e., the arrangement of the current-carrying conductors associated with the source). Since the spatial and time components of magnetic fields from various sources are not always known, a reasonable estimation of their additive effect assumes that they will add in quadrature (the square root of the sum of the squared field components) as a "root-mean-square" (rms) value. For example, combining in quadrature a magnetic field of 10mG with a field of 5mG would equal 11.2mG (the square root of $10^2 + 5^2$) rather than 15mG if the fields were simply additive.

Audible noise is present in our environment. We experience sounds from nature (e.g. birds singing, dogs barking, thunder, etc.) as well as manmade noises (e.g. automobiles, music, human speech). Existing high voltage transmission lines may also contribute to the audible environment by creating a humming sound (resulting from the discharge of energy which that occurs on the energized surface of the transmission line conductors) within their immediate proximity. Transmission line audible noise can increase during foul weather conditions when the conductors become wet (during rain, snow, or fog) and at higher elevations. Existing high voltage AC electric transmission lines are present within each Project state, and the contribution of some transmission line audible noise is therefore also present within each region.

Existing radio frequency sources would also be present within each region of the Project. Sources such as cellular telephone antennas and microwave antennas are often located on communication towers near interstates, on tall buildings, and on power line structures. Radio and television broadcast station signals are also present within the existing environment. GPS transmitters and receivers, which utilize radio frequency and/or satellite signals, are common in automobiles, trucks, and farm equipment. In addition, equipment such as wireless routers utilize radio frequency signals to provide a communication link between computers, cellular telephones, printers, and other electronic devices. The presence of existing radio frequency signals is a very common occurrence as demonstrated by the abundance of sources that can be found in our modern society.

Within each of the following regional descriptions, the number of existing AC transmission lines present that would parallel the Project line was estimated using GIS (geographic information system) files provided by the Applicant (GIS Data Source: Clean Line 2013a, 2013b) and Tetra Tech (GIS Data Source: Tetra Tech 2014a). Radio frequency sources such as microwave and communication towers were also enumerated along the proposed HVDC routes using information provided by the FCC (GIS Data Source: FCC 2012). In evaluating the electrical effects for each region, one of the primary factors of importance would include the number of residences present along the HVDC electric transmission line route. The number of residences and other building structures were therefore also enumerated from information provided by the Applicant (GIS Data Source: Clean Line 2013a). Overall, the environment is predominantly rural agricultural land or forested land interspersed with residential areas. Detailed land use information is presented in detail in Section 3.10.

3.4.10.1 Region 1

Region 1 is referred to as the Oklahoma Panhandle Region and includes the Applicant Proposed Route, Alternative Routes 1-A through 1-D, AC collection system of up to 345kV, the Oklahoma converter station, and potentially the future Optima substation. The westernmost portion of the HVDC transmission line would be connected into the Oklahoma converter station located in Texas County, Oklahoma. The HVDC transmission line could parallel at least three other overhead AC transmission lines within this region (ranging from 69kV to 345kV in voltage). Table 3.4-7 provides the number of residences located within the ROI for the Applicant Proposed Route and HVDC alternative routes within Region 1. Table 3.4-8 provides the number of residences located within the ROI for the AC collection system. There are no residences within the ROI for the Oklahoma Converter Station Siting Area or AC Interconnection Siting Area.

3.4.10.2 Region 2

Region 2 is referred to as the Oklahoma Central Great Plains Region and includes the Applicant Proposed Route and HVDC Alternative Routes 2-A through 2-B. The HVDC transmission line could parallel at least three other overhead AC transmission lines within this region (all 115kV voltage). Table 3.4-9 provides the number of residences located within the ROI for the Applicant Proposed Route and HVDC alternative routes within Region 2.

3.4.10.3 Region 3

Region 3 is referred to as the Oklahoma Cross Timbers Region and includes the Applicant Proposed Route and HVDC Alternative Routes 3-A through 3-E. The HVDC transmission line could parallel at least eleven other overhead AC transmission lines within this region (ranging from 69kV to 345kV in voltage). Table 3.4-10 provides the number of residences located within the ROI for the Applicant Proposed Route and HVDC alternative routes within Region 3.

3.4.10.4 Region 4

Region 4 is referred to as the Arkansas River Valley Region and includes the Applicant Proposed Route and HVDC Alternative Routes 4-A through 4-E as well as the Lee Creek Variation[2]. The HVDC transmission line could parallel at least 13 other overhead AC transmission lines within this region (ranging from 69kV to 345kV in voltage). Table 3.4-11 provides the number of residences located within the ROI for the Applicant Proposed Route and HVDC alternative routes within Region 4.

3.4.10.5 Region 5

Region 5 is referred to as the Central Arkansas Region and includes the Applicant Proposed Route, HVDC Alternative Routes 5-A through 5-F, and Arkansas Converter Station Alternative Siting Area and AC Interconnection Siting Area. The HVDC transmission line could parallel at least two other overhead AC transmission lines within this region (138kV and 500kV in voltage). Table 3.4-12 provides the number of residences located within the ROI for the Applicant Proposed Route and HVDC alternative routes within Region 5. There are 152 residences within the Arkansas Converter Station Alternative Siting Area. There are 38 residences within the Arkansas AC Interconnection Siting Area.

3.4.10.6 Region 6

Region 6 is referred to as the Cache River and Crowley's Ridge Region and includes the Applicant Proposed Route and HVDC Alternative Routes 6-A through 6-D. It should be noted that the Cache/Lower White River systems are designated as a "wetlands of International Importance" under the Ramsar Convention on International Wetlands, and the Cache River is a forested wetland crossed by the ROI area. The HVDC transmission line could parallel at least one other overhead AC transmission line within this region (161kV voltage). Table 3.4-13 provides the number of residences located within the ROI for the Applicant Proposed Route and HVDC Alternative Routes within Region 6.

3.4.10.7 Region 7

Region 7 is referred to as the Arkansas Mississippi River Delta and Tennessee Region and includes the Applicant Proposed Route, Alternative Routes 7-A through 7-D, 500kV transmission collector lines, and the Tennessee converter station. The HVDC transmission line could parallel at least four other overhead AC transmission lines within this region (ranging from 161kV to 500kV in voltage). Table 3.4-14 provides the number of residences located within the ROI for the Applicant Proposed Route and HVDC alternative routes within Region 7. There are no residences within the Tennessee Converter Station Siting Area and AC Interconnection Tie.

3.4.10.8 Connected Actions

3.4.10.8.1 Wind Energy Generation

Wind energy generation facilities may be interconnected to the Project's ±600kV HVDC overhead electric transmission line to transport electricity. Electrical equipment associated with wind farms can include wind turbine generators, underground collection cables, substation with electric transformers, and AC transmission lines to connect the wind power generation to the electrical grid. Most of this equipment is located within the generation facility itself.

Wind energy generation facilities require AC transmission lines to interconnect into the electrical grid. Any generation transmission interconnection lines would be similar in size and voltage to the transmission lines associated with the AC collection system. Therefore, the regions where existing environmental conditions and the potential effects associated with these wind generation interconnection lines would be similar to the AC collection system transmission lines (Clean Line 2014b, 2014c).

3.4.10.8.2 Optima Substation

The future Optima substation would be constructed on approximately 160 acres partially within the area identified on Figure 2.1-3 as the AC interconnection siting area.

3.4.10.8.3 TVA Upgrades

The ROI for the direct assignment facilities (which are included in the Applicant Proposed Project) would occur within the Tennessee Converter Station Siting Area and more specifically within the Shelby Substation. The ROI for the network upgrades, and in particular TVA's future 500kV transmission line, cannot be determined at this time. The new 500kV transmission line would be constructed in western Tennessee. The upgrades to existing facilities would mostly be in western and central Tennessee. Upgrades to existing infrastructure would include upgrading terminal equipment at three existing 500kV substations and six existing 161kV substations, making appropriate upgrades to increase heights on 16 existing 161kV transmission lines to increase line ratings, and replacing the conductors on eight existing 161kV transmission lines. Where possible, general impacts associated with the required TVA upgrades are discussed in the impact sections that follow.

3.4.11 Electrical Environment Impacts

This section describes the electrical environment and environmental impacts associated with the AC/DC converter stations (located in Oklahoma, Arkansas, and Tennessee), the ±600kV HVDC overhead electric transmission line, the AC transmission line interconnections, and the AC transmission line collection system alternatives. The electrical effects evaluated include electric and magnetic fields, air ions and ozone, audible noise, and radio and television interference.

3.4.11.1 Methodology

Computer modeling was performed to calculate values for electrical effects associated with each of the proposed transmission line configurations. For the AC/DC converter stations, the dominant sources of electrical effects are the overhead transmission lines entering and exiting the stations. Some types of substation and switching station equipment can potentially be a source of electrical effects (for example, power transformers can produce audible noise; converter equipment can produce radio noise, etc.). These effects can be reduced or eliminated by the use of filtering equipment, sound walls, and other methods (CRC 2007), and Project converter stations are planned to be located in either rural areas or areas where other electrical substations already exist; therefore computer modeling and calculations of electrical effects for the proposed converter stations was not performed, except for audible noise as described in Section 3.11.6. Detailed calculation results are presented in Appendix I.

Two different configurations were evaluated for the proposed ±600kV HVDC overhead electric transmission line (bi-polar monopole and bi-polar lattice configurations), while nine different configurations were evaluated for the proposed AC collection system routes and converter station interconnections (five 345kV and four 500kV configurations). All of the computer modeling data related to line design configuration, conductor specifications and spacing, loading, and other parameters were provided by the Applicant (GIS Data Source: Clean Line 2013a).

Calculations were performed using the minimum midspan conductor clearance for all electrical effects except audible noise. For audible noise, calculations are performed using the minimum midspan conductor clearance plus one-third of the sag (which represents an average conductor height along the entire span between support structures) (EPRI 2006a). For transmission line corona effects, conservative assumptions for overvoltage conditions and ground elevation were used to calculate effects. Voltage levels for a high voltage transmission line are typically held relatively constant (within ±5-10 percent) while the load on the line is allowed to fluctuate with demand. A conservative overvoltage condition was assumed for all transmission lines (+5 percent for 345kV AC, +10 percent for 500kV AC, and approximately +5 percent for ±600kV DC) as cited by the Applicant (Clean Line 2014b). In addition, higher elevations accentuate corona effects, so the highest reported altitude along the Project routes (an elevation of 3,000 feet above sea level) was used. These conservative assumptions are used to calculate a maximum electrical effect value; at lower elevations, for lower voltage conditions, or for higher conductor ground clearances, the calculated electrical effects values will be lower. For AC and DC magnetic fields, two different loading conditions were modeled: average and maximum loading.

For electric and magnetic fields, calculations were performed at a height of 3.28 feet (1 meter) in accordance with IEEE Standards (IEEE 1994). For audible noise, calculations were performed at a height of 4.9 feet, which approximates the height of a human ear. For radio noise, calculations were performed at an antenna height of 6.6 feet in accordance with IEEE Standards (IEEE 1986). For television noise, calculations were performed at an antenna height of 9.8 feet. The reference frequency for the calculations is 0.5MHz for radio noise and 75MHz for TV noise. For ozone and air ions, calculations were performed at ground level (EPA 2014). Radio noise calculation results are presented for both fair and rainy weather, while television noise and ozone are presented for rainy weather only.

Environmental conditions were assumed to be at an elevation of 3,000 feet above sea level (corona effects are accentuated at higher elevations and this elevation represents the highest reported altitude along the Project routes), with a wind speed of 8.5 miles per hour (mph) and rain rate of 0.1 inch/hour. The assumed wind speed and rain rate are calculated averages based upon 2013 monthly weather data for the cities of Oklahoma City, Little Rock, and Memphis. Audible noise calculation software typically assumes a flat, open terrain with no sound-modifying objects present (such as uneven terrain, trees, buildings, and other objects). For electrical effects associated with the ±600kV HVDC overhead electric transmission line, the EPRI Transmission Line Workstation software program Version 3.0 (specifically the ACDC Line module) was used to perform the computer modeling (EPRI 1996, 2006b). For electrical effects associated with the AC transmission line collection system alternatives and interconnections, three different software programs were used for calculations. For electric and magnetic fields, the EPRI EMFWorkstation 2013 software program was used (EPRI 2013b). For audible noise, the EMFWorkstation software Version 2.51 (specifically the ENVIRO Version 3.52 module) was used to calculate L_{dn} noise levels (EPRI 1997). For all other electrical effects, the Bonneville Power Administration Corona and Field Effects software program was used (BPA 1977).

The Applicant has developed a comprehensive list of EPMs that is provided in Appendix F. Since these EPMs would be adopted, calculations assume the use of these EPMs throughout the impact analysis that follows for both the Applicant Proposed Project and the DOE alternatives.

For electrical effects, EPMs will involve the use of line design configurations and conductor types to reduce effects at and beyond the ROW edges. The Applicant has proposed using “optimal phasing” for the proposed AC transmission collection lines to reduce EMF at the ROW edges for double circuit configurations (Clean Line 2014a).

Optimal phasing takes into account the direction of current flow in all circuits to determine the appropriate phasing sequence for maximizing magnetic field reduction. For double circuit (or multiple circuit) lines located together on the same support structure (or in close proximity to one another), the overall magnetic field generated from the lines will be dependent upon the arrangement of each circuit's phase sequence (among other parameters). Circuits can be arranged so that the phase sequence for one circuit is placed adjacent to the same phase sequence of the other circuit. This situation is often called "like phasing." Circuits can also be arranged so that the phase sequence for one circuit is placed adjacent to the opposite phase sequence of the other circuit. This situation is often called "unlike phasing" (or "cross-phasing," "reverse phasing," or "low reactance phasing"). This phasing arrangement can be applied to double (or multi-circuit) transmission and/or distribution lines, or transmission lines with a lower voltage underbuild. For magnetic field reduction, the "unlike" method works best when current flow in the adjacent circuits is equal in magnitude and direction. If the current flow in adjacent circuits is in the opposite direction, then the "like" phasing method works best for magnetic field reduction.

Of the EPMs presented in Appendix F, three would specifically apply to electrical effects: GE-17, GE-18, and GE-19. GE-17 and GE-18 relate to audible noise, radio noise, and television interference by maintaining tension on insulator assemblies, protection of the conductor surface from damage during construction, inspection and repair/replace damaged equipment, and consideration of conductor size, quantity, and bundle configurations in designing the transmission line. GE-19 relates to grounding of conductive objects within the ROW to reduce the potential for induced voltage and currents on these objects.

3.4.11.2 Impacts Associated with the Applicant Project

3.4.11.2.1 Converter Stations and AC Interconnection Siting Areas

This section describes the electrical effects associated with the two applicant proposed converter stations and the AC transmission line interconnections associated with those stations. Electrical effects would only be present during operation and maintenance of these facilities. Electrical facilities need to be energized to create electrical effects such as electric and magnetic fields, audible noise, and radio and television interference. Electrical effects would not be present during the construction and decommissioning phases of the Project.

Existing facilities are present within these siting areas, some of which already create electrical effects within the environment. Table 3.4-15 presents the number of existing AC transmission lines that parallel proposed interconnection routes to the two converter stations as well as nearby communication facilities (which are existing radio-frequency sources) within a 1,000-foot-wide corridor for each proposed route alternative. Table 3.4-15 also presents a summary of the number of existing building structures (residences, agricultural buildings, churches, and schools) within the same 1,000-foot-wide corridor for each siting area.

Table 3.4-15:
Occurrence of Existing Facilities within the Applicant Proposed Converter Station and AC Interconnection Siting Areas

DC Transmission Interconnection Route	Parallels Existing AC Transmission Lines (Quantity and Voltage Range)	Existing Building Structures within 1,000-Foot-Wide Corridor (Residential/Agricultural/Church/School)[1]	Existing Communication Facilities Within 1,000-Foot-Wide Corridor (Quantity and Type)[2]
Oklahoma	1 (345kV)	0/0/0/0	0
Tennessee	0	11/13/0/0	2 (microwave towers)

1 GIS Data Source: Clean Line (2013a), Tetra Tech (2014a)
2 GIS Data Source: FCC (2012)

3.4.11.2.1.1 Construction Impacts

There are no electrical effects associated with construction of the converter stations or AC transmission lines, because these facilities would not be energized during construction. Electrical facilities need to be energized to create electrical effects such as electric and magnetic fields, audible noise, and radio and television interference.

3.4.11.2.1.2 Operations and Maintenance Impacts

For the Oklahoma AC/DC converter station, the dominant sources of electrical effects are the overhead transmission lines entering and exiting the station. Some types of substation and switching station equipment can potentially be a source of electrical effects (e.g., power transformers can produce audible noise; converter equipment can produce radio noise, etc.). These effects can be reduced or eliminated by the use of filtering equipment, sound walls, and other methods, so the dominant sources of electrical effects are associated with the overhead transmission lines; evaluation of electrical effects for the proposed converter stations was not performed except for audible noise as described in Section 3.11.6.

For the Tennessee AC/DC converter station, no electrical effects were evaluated because the overhead transmission lines are the dominant sources of electrical effects near the converter station, and the converter station interconnection would occur entirely within the converter station and the adjacent Shelby Substation site (i.e., no public access).

3.4.11.2.1.2.1 Oklahoma Converter Station Siting Area and AC Interconnection Siting Area

No electrical effects were evaluated for the Oklahoma converter station because overhead transmission lines are the dominant sources of electrical effects near the station.

There are three different 345kV AC transmission line configurations associated with the interconnection into the Oklahoma converter station. All three line designs are double circuit configurations (i.e., two circuits supported on a single structure). One line design is a double circuit monopole, supported on a tubular pole. The other two line designs (double circuit lattice tower and double circuit danube configuration) are each supported on lattice structures. Each transmission line configuration is located within its 150-foot-wide ROW, and would primarily provide voltage support (so very little or no loading would be present on the lines). Figures 3.4-6 through 3.4-8 present dimensioned drawings of the three representative 345kV AC transmission line configurations.

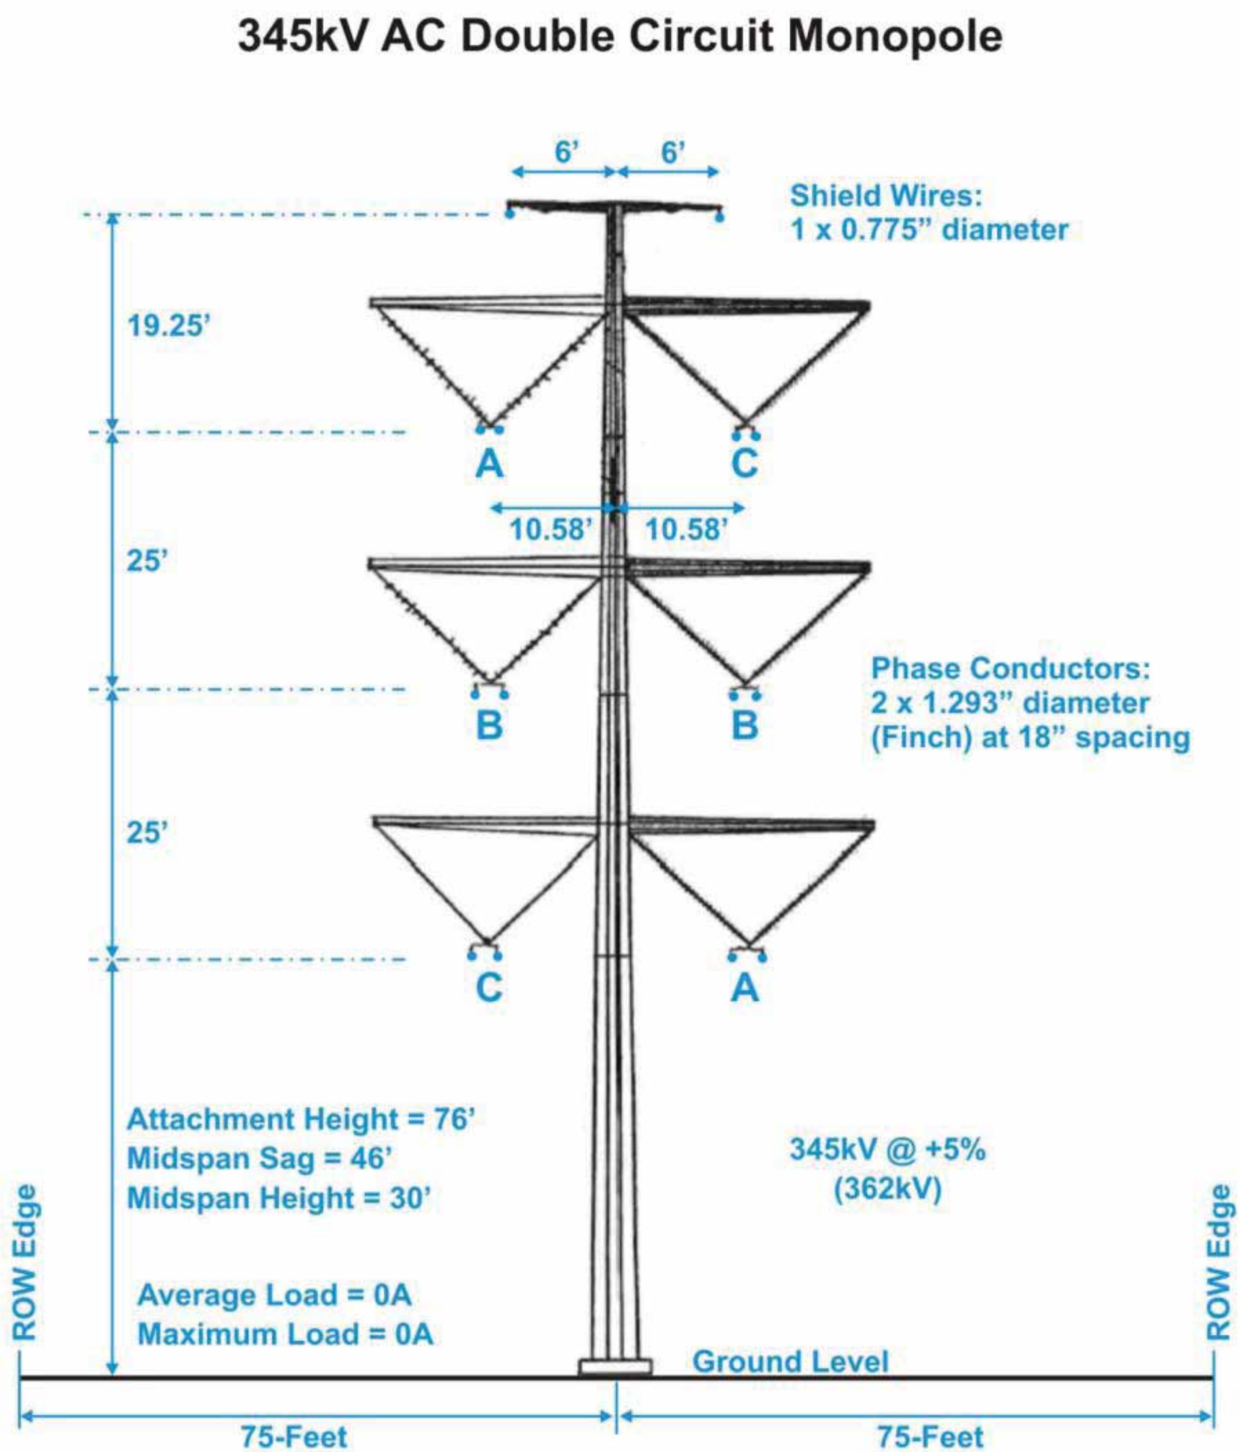

Figure 3.4-6: 345kV AC Transmission Line Double Circuit Monopole Configuration for Interconnection to Oklahoma Converter Station

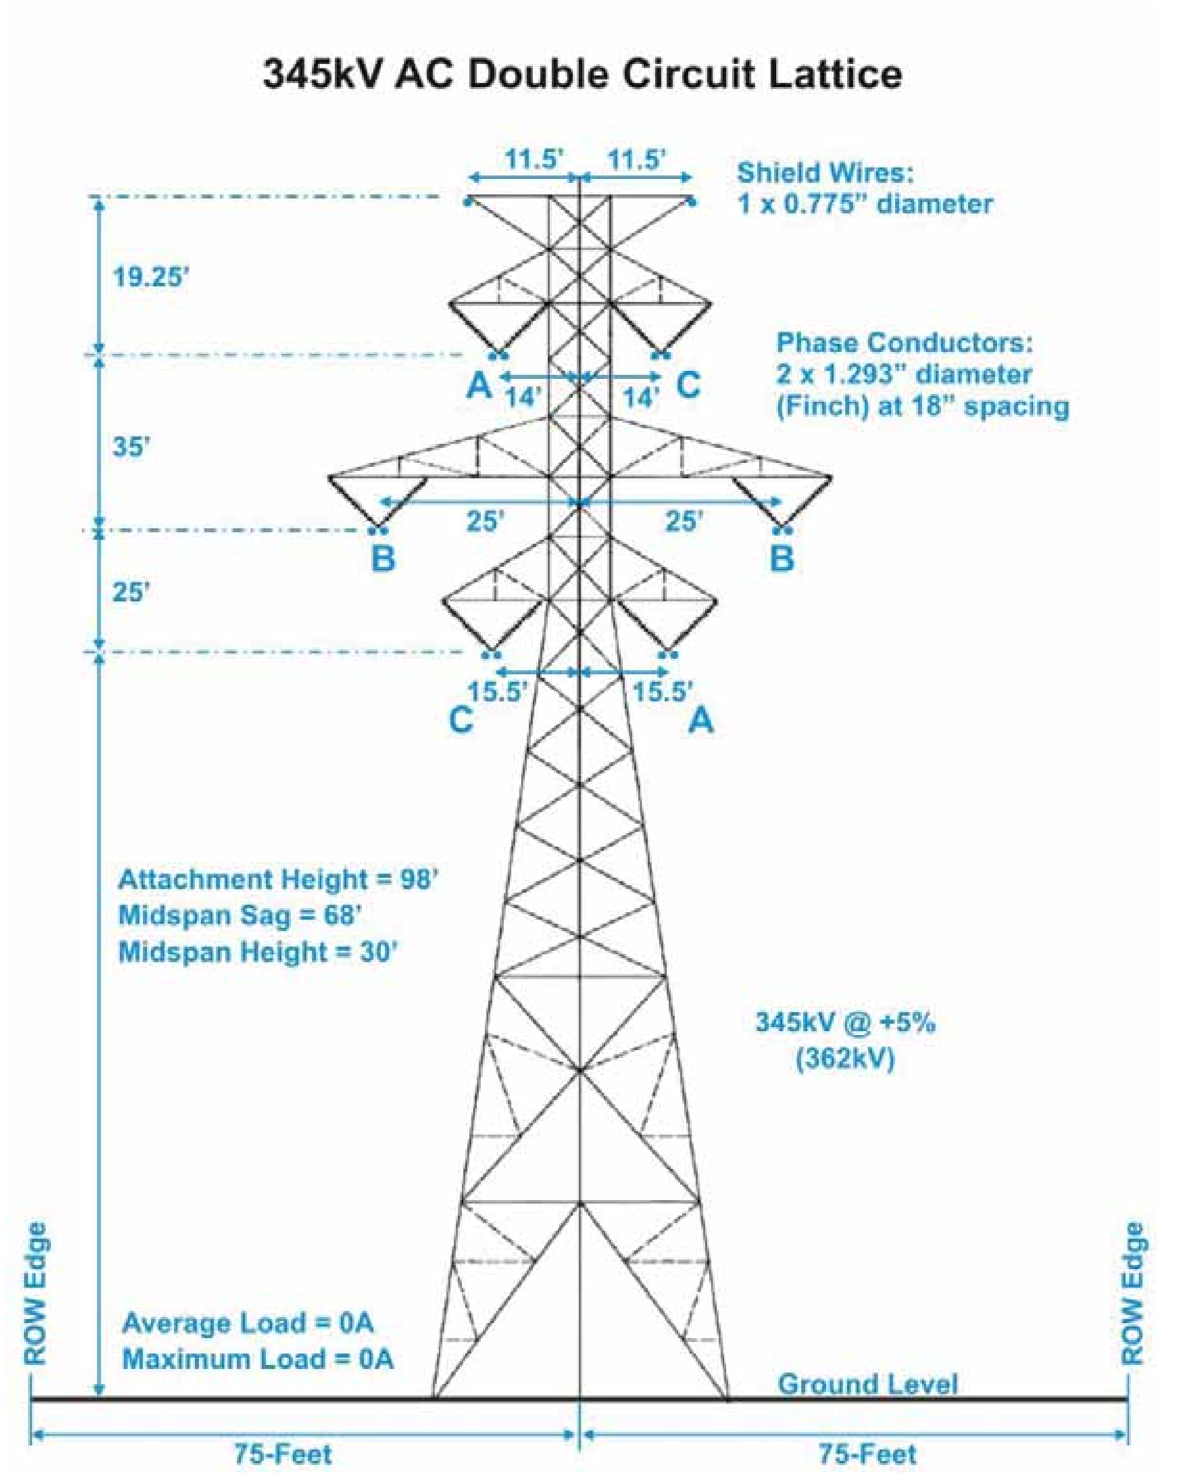

Figure 3.4-7: 345kV AC Transmission Line Double Circuit Lattice Tower Configuration for Interconnection to Oklahoma Converter Station

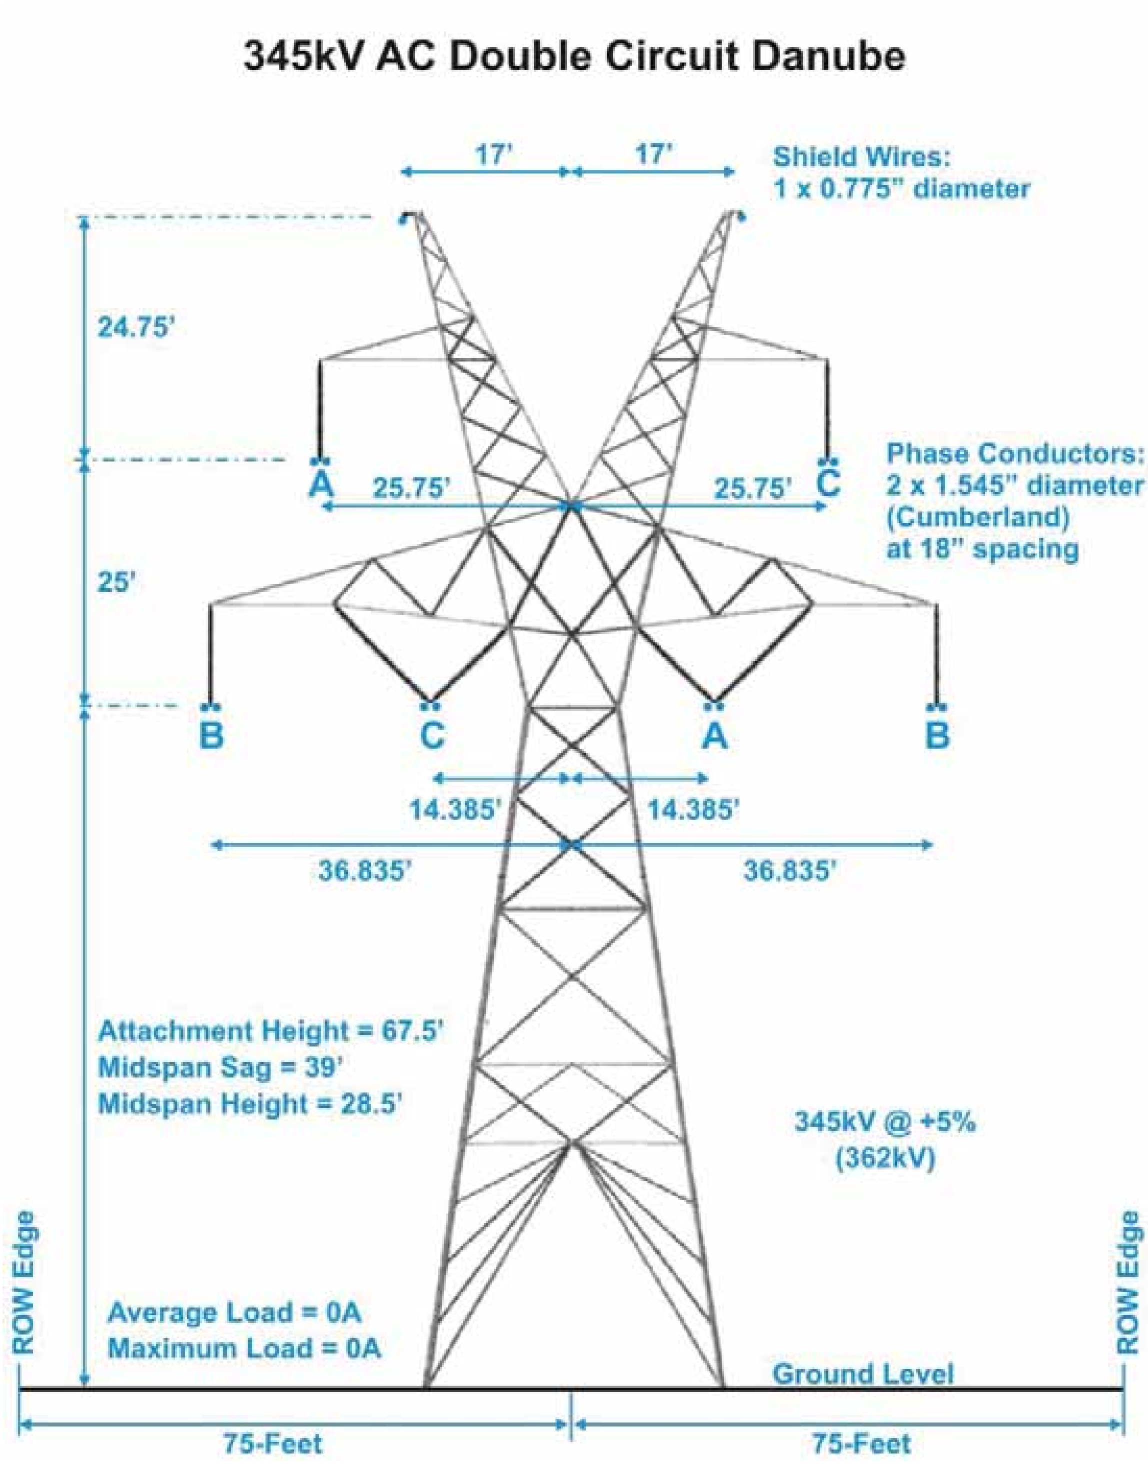

Figure 3.4-8: 345kV AC Transmission Line Double Circuit Danube Tower Configuration for Interconnection to Oklahoma Converter Station

3.4.11.2.1.2.1.1 AC Electric Field Calculation Results

AC electric field calculations were performed for the three transmission line configurations. Table 3.4-16 presents a summary of the calculated electric field at the ROW edges and for the maximum field within the ROW. Calculated field levels vary depending upon the line configuration. Figure 3.4-9 presents a graph of the calculated AC electric field for each line configuration.

Table 3.4-16:
Calculated AC Electric Field for 345kV AC Transmission Line Interconnections to Oklahoma Converter Station

345kV AC Transmission Line Configuration	Calculated AC Electric Field (kV/m)		
	ROW Edge (-75 Feet from CL)	Maximum on ROW	ROW Edge (+75 Feet from CL)
Double Circuit Monopole	0.2	4.6	0.2
Double Circuit Lattice	0.8	5.3	0.8
Double Circuit Danube	1.7	5.7	1.7

CL = Centerline; since the precise ROW width has not yet been determined, the ROI for analysis is 300 feet on either side of a representative centerline.

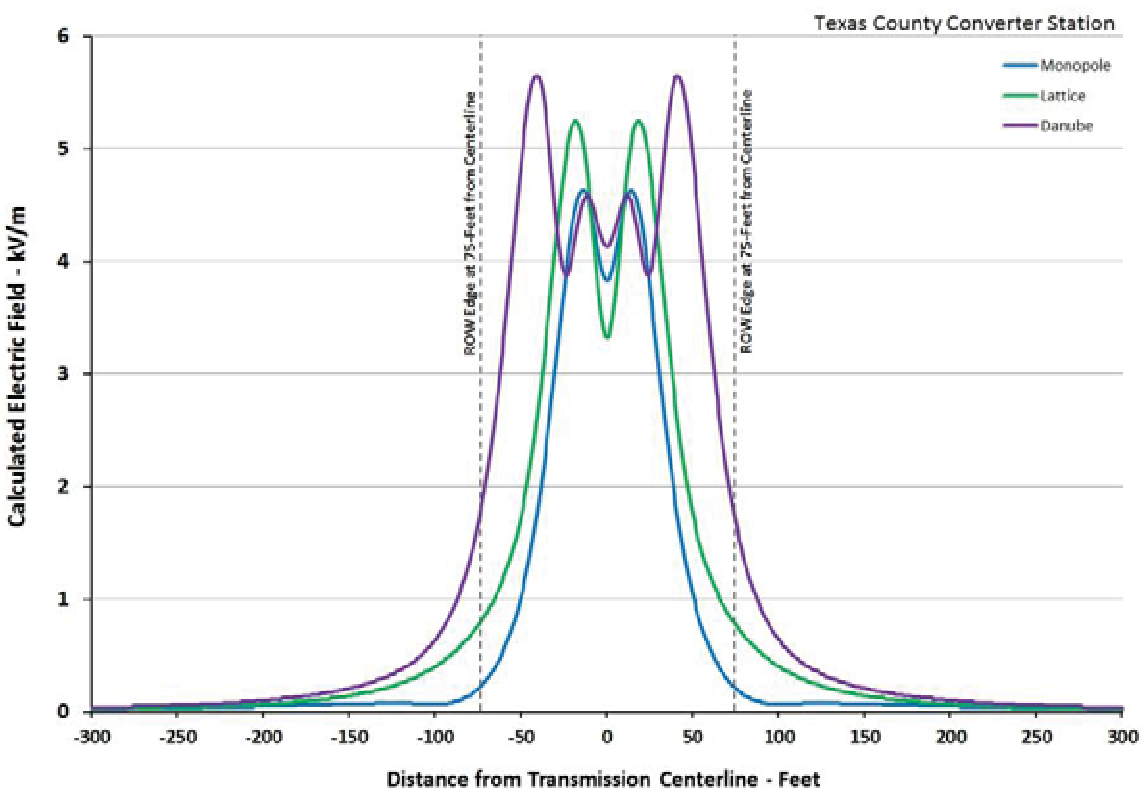

Figure 3.4-9: Calculated AC Electric Fields for 345kV AC Transmission Line Interconnections to Oklahoma Converter Station

Calculated electric field levels at the ROW edges (75 feet from centerline of the transmission line) for all of the AC transmission line interconnections are below the ICES and ICNIRP guidelines for public exposure (5kV/m and 4.2kV/m, respectively; see Section 3.4.6). Within the ROW, calculated electric field levels are below the ICES guideline of 10kV/m. For the double circuit Danube configuration, calculated electric field at the ROW edge (1.7kV/m) exceeds the ACGIH guideline of 1kV/m for workers with implanted medical devices.

3.4.11.2.1.2.1.2 AC Magnetic Field Calculation Results

The Applicant reported that there would not be any load on these transmission line interconnections (only voltage) (Clean Line 2014a). AC magnetic field calculations were therefore not performed for the three transmission line configurations because there was assumed to be no load on the transmission line. If no loading is present, no magnetic fields would be generated as a result of the transmission line.

3.4.11.2.1.2.1.3 AC Audible Noise Calculation Results

Audible noise calculations were performed for the three AC transmission line configurations. Table 3.4-17 presents a summary of the calculated day-night (L_{dn}) audible noise at the ROW edges and for the maximum noise level within the ROW. Calculated levels vary, depending upon the line configuration. Figure 3.4-10 presents a graph of the calculated audible noise for each AC transmission line configuration.

Table 3.4-17:
Calculated Audible Noise for 345kV AC Transmission Line Interconnections to Oklahoma Converter Station

345kV AC Transmission Line Configuration	Calculated Audible Noise (dBA)—L_{dn}		
	-75 Feet from CL	Maximum on ROW	+75 Feet from CL
Double Circuit Monopole	55.2	57.8	55.2
Double Circuit Lattice	52.2	54.2	52.2
Double Circuit Danube	51.0	53.6	51.0

CL = Centerline; since the precise ROW width has not yet been determined, the ROI for analysis is 300 feet on either side of a representative centerline.

Calculated audible noise levels at the ROW edges (75 feet from centerline of the transmission line) for two of the AC transmission line interconnections are at or below the EPA guideline for L_{dn} (day-night) noise of 55 dBA. The calculated audible noise level for the third (double circuit monopole) configuration is slightly higher than the EPA guideline (at 55.2 dBA), but calculated audible noise levels assume a 5 percent overvoltage condition at the highest line elevation (3,000 feet).

The sound level for a typical wilderness area is about 30 dBA, while a small town or quiet suburb is reported to be about 47–53 dBA (EPA 1974), which is similar to calculated L_{dn} noise levels from the transmission line at the ROW edge (51–55.2 dBA). The audible noise from a transmission line decreases with distance away from the line and would approach background levels within a few thousand feet of the line. During rain it may be possible to hear most high voltage AC transmission lines at close distances, but often this noise is masked by the noise of falling rain and wind.

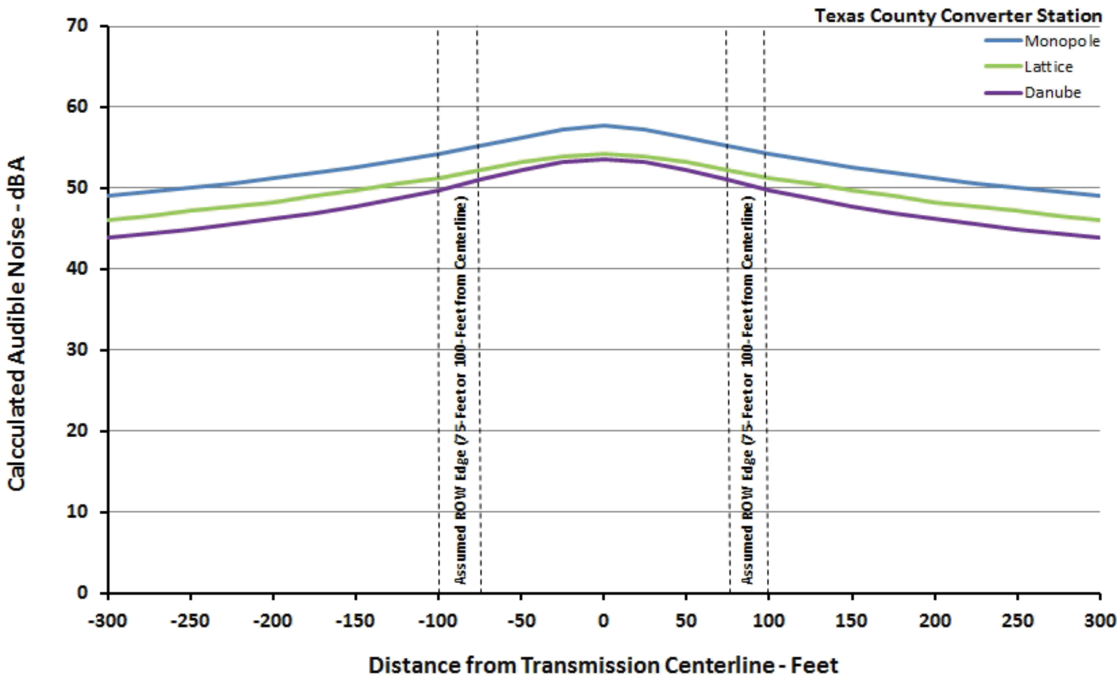

Figure 3.4-10: Calculated Audible Noise Levels (L_{dn}) for 345kV AC Transmission Line Interconnections to Oklahoma Converter Station

3.4.11.2.1.2.1.4 AC Radio Noise Calculation Results

Radio noise calculations were performed for the three AC transmission line interconnections for rainy and fair weather conditions. Table 3.4-18 presents a summary of the calculated radio noise at the ROW edges and for the maximum noise within the ROW at 500 kilohertz (kHz) for both weather conditions. Table 3.4-18 also presents calculated 500kHz radio noise at 50 feet from the outside conductor for comparison with the IEEE Standard. Calculated radio noise levels vary, depending upon the line configuration and weather conditions. As shown in Table 3.4-18, calculated radio noise levels at 50 feet from the outside conductor comply with the IEEE 61 dB:V/m threshold during fair weather conditions. Figure 3.4-11 presents a graph of the calculated radio noise levels for each AC line configuration in rainy weather, adjusted to the 500kHz reference level. Figure 3.4-12 presents a corresponding graph of the calculated radio noise levels for fair weather (adjusted to the 500kHz reference level).

Table 3.4-18:
Calculated Radio Noise for 345kV AC Transmission Line Interconnections to Oklahoma Converter Station at 500kHz

345kV AC Transmission Line Configuration	Calculated Radio Noise (dB:V/m) at 500kHz (Rainy/Fair Weather)				
	-50 Feet from Outside Conductor	ROW Edge (-75 Feet from CL)	Maximum on ROW	ROW Edge (+75 Feet from CL)	+50 Feet from Outside Conductor
Double Circuit Monopole	67.9/50.9	66.0/49.0	82.4/65.4	66.0/49.0	67.9/50.9
Double Circuit Lattice	63.3/46.3	63.3/46.3	80.0/63.0	63.3/46.3	63.3/46.3
Double Circuit Danube	61.8/44.8	65.3/48.3	77.9/60.9	65.3/48.3	61.8/44.8

CL = Centerline; since the precise ROW width has not yet been determined, the ROI for analysis is 300 feet on either side of a representative centerline.

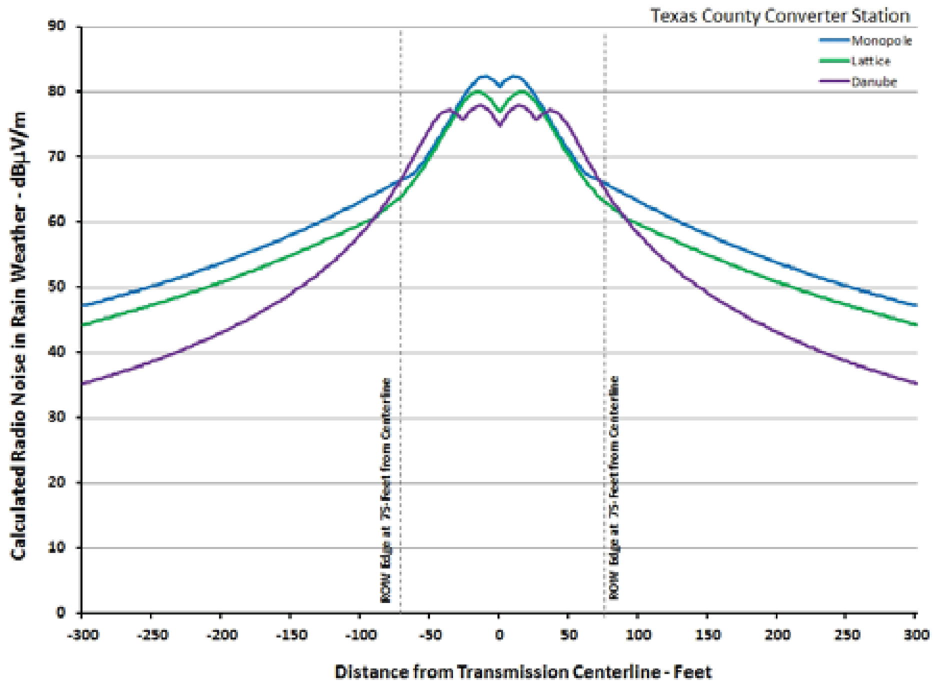

Figure 3.4-11: Calculated Radio Noise for 345kV AC Transmission Line Interconnections to Oklahoma Converter Station (Rainy Weather)

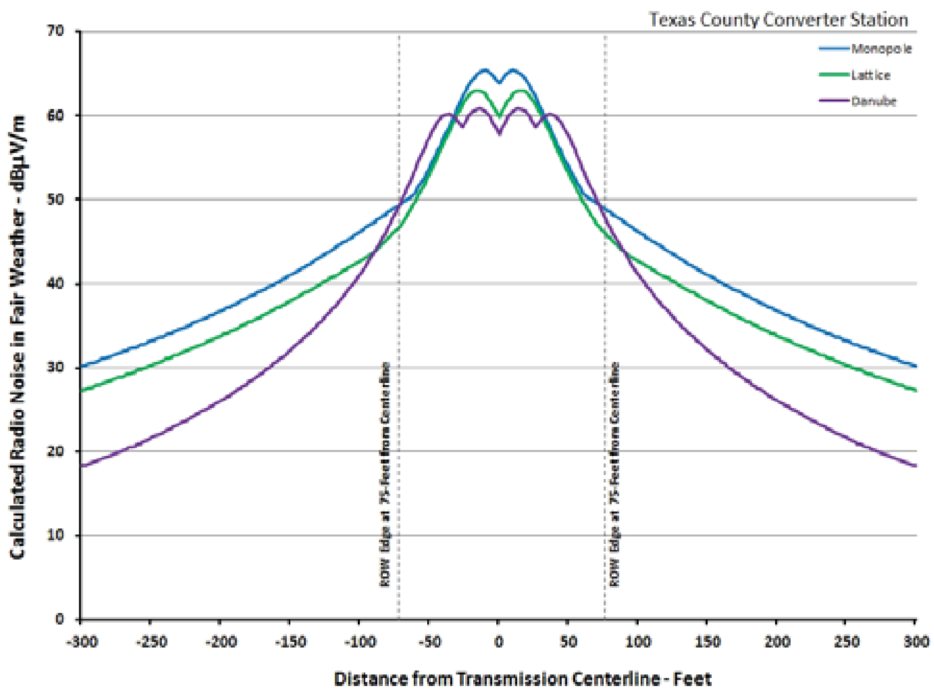

Figure 3.4-12: Calculated Radio Noise for 345kV AC Transmission Line Interconnections to Oklahoma Converter Station (Fair Weather)

It is difficult to determine whether the radio noise produced by a transmission line or any other source would cause unacceptable interference without knowing broadcast signal strengths at various locations of interest along the possible line routes. Parameters such as the strength of the received signal, the sensitivity of the receiver, the orientation and design of the receiving antenna, and ambient radio frequency noise are also important in determining the degree to which noise from any source may cause degradation of radio reception quality. Modern sources of man-made noise have grown over time and this increase has led to increasing interference in the AM broadcast band. Utilities have considerable experience in addressing complaints of interference to radio or TV reception and there are a variety of ways of mitigating interference.

For AM radio broadcasts (within 520 to 1,720kHz), coverage can be described as follows (Radio Locator 2014):

- Areas able to receive a radio station on almost any radio with moderately good to very good reception (local coverage)
- Areas where the signal of the radio station may be weak unless using a good radio or good antenna (distant coverage)
- Areas where the station signal is very weak even with a good radio and antenna, and interference may prevent reception (fringe coverage)

Radio reception from AM radio stations in fringe coverage areas may not be possible even in fair weather, regardless of the presence of radio noise sources. Reception of AM radio stations in distant coverage areas may be possible, but the potential for interference may increase near the ROW edges or within the transmission line ROW, especially during rain. Reception of AM radio stations in local coverage areas should be possible near the transmission line ROW edges, with a decreasing potential for interference with distance away from the transmission line. Rainy weather can increase interference levels.

IEEE used published listening tests of transmission line noise to create a quality-of-reception curve based upon the difference in AM radio reception quality versus the SNR—a difference between signal strength and radio noise level (previously discussed in Section 3.4.4):

- A difference of about 14 dB represents a quality of reception where background noise is very evident, but speech is easily understood
- A difference of about 20–22 dB represents a quality of reception that is fairly satisfactory but background noise is plainly evident
- A difference of about 24 dB represents a quality of reception that is very good and background noise is unobtrusive
- A difference of about 28 dB (or greater) represents an entirely satisfactory quality of reception (IEEE 1965; EPRI 2006a)

Another method for evaluating the potential for radio noise interference is based upon the IEEE Radio Noise Design Guide (IEEE 1971). This guide is intended to provide a summary of good engineering design practices that will result in a tolerable radio noise level for a proposed transmission line when placed in service. This method relates the calculated maximum surface gradient of the transmission line conductor and conductor diameter to levels of radio interference. The range of calculated maximum surface gradients for the proposed AC transmission line conductors comply with (or are less than) the established range for limiting fair weather radio noise levels in the frequency range of 150kHz to 5MHz, which includes radio broadcast frequencies.

The new digital broadcast system technology should provide improved reception and better immunity to impulse-type noise from sources such as transmission lines or vehicle ignition systems. Rather than a slowly degrading AM radio sound quality for analog systems, interference will have a threshold for performance that is essentially a go/no go proposition for digital receivers. A digital receiver can accept interference without the user noticing anything until the interference becomes so great that the reception stops. The new digital signal will be less susceptible to interference noise than an old analog signal (Smith 2004). The quality of digital reception should be better in a given noise level and would stay good beyond which the old analog reception is no longer viable. These results have been documented in previous studies, such as the FCC study (FCC 1999) that indicated that digital signals will provide improved reception and immunity to impulse noise (such as noise interference from transmission lines) than analog signals.

In 2002, the FCC selected in-band, on-channel technology as the technology AM and frequency modulation (FM) broadcasters use for digital radio broadcasting. Transition to digital radio requires broadcasters to install new equipment, and during the transition, broadcasters operate in a “hybrid” mode (broadcasting the same programming using both analog and digital signals within a single AM or FM channel). Although many stations now broadcast in digital, radio broadcasters are not required to convert to “all-digital” broadcasting at this time (FCC 2014).

FM radio stations transmit in a band of frequencies between 88MHz and 108MHz, and use a different signal modulation than AM radio which makes FM transmission immune to impulse-type noise. Transmission line corona noise, therefore, would not affect FM radio reception. FM radio is essentially a line of sight broadcast, and terrain affects FM signals.

3.4.11.2.1.2.1.5 AC Television Noise Calculation Results

Television noise calculations were performed for the three AC transmission line interconnections for rainy weather conditions. Table 3.4-19 presents a summary of the calculated television noise at the ROW edges and for the maximum noise within the ROW for the 75MHz reference level. Calculated television noise levels vary, depending upon the line configuration. Figure 3.4-13 presents a graph of the calculated television noise levels for each AC line configuration in rainy weather.

Table 3.4-19:
Calculated Television Noise for 345kV AC Transmission Line Interconnections to Oklahoma Converter Station

345kV AC Transmission Line Configuration	Calculated Television Noise (dB:V/m) at 75MHz for Rainy Weather		
	ROW Edge (-75 Feet from CL)	Maximum on ROW	ROW Edge (+75 Feet from CL)
Double Circuit Monopole	24.3	34.8	24.3
Double Circuit Lattice	22.5	32.4	22.5
Double Circuit Danube	22.4	30.2	22.4

CL = Centerline; since the precise ROW width has not yet been determined, the ROI for analysis is 300 feet on either side of a representative centerline.

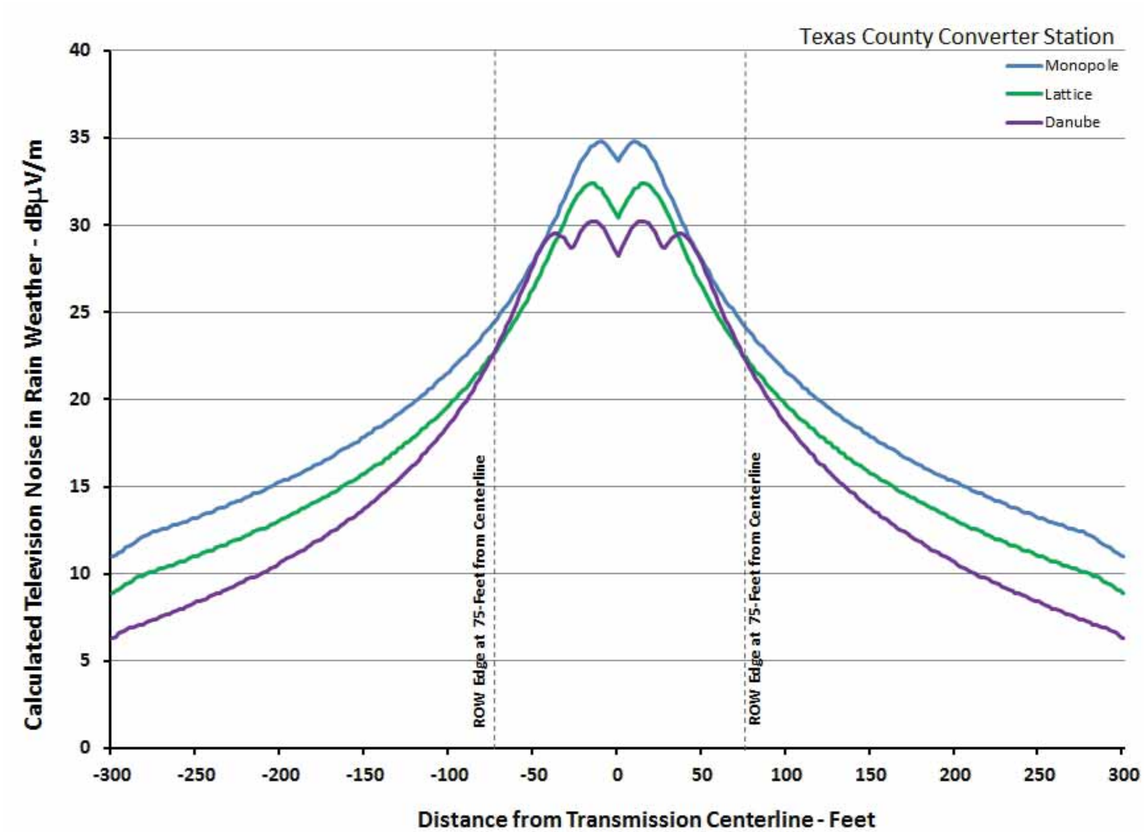

Figure 3.4-13: Calculated Television Noise for 345kV AC Transmission Line Interconnections to Oklahoma Converter Station (Rainy Weather)

As with radio noise interference, it is difficult to determine whether the television noise level produced by a transmission line would cause unacceptable interference. The new digital broadcast system technology for radio and television, however, should provide better coverage and immunity to transmission line noise than analog television signals. No interference resulting from corona-generated noise would be expected for digital signals broadcast at frequencies above 1GHz from satellites (EPRI 2006a).

3.4.11.2.1.2.1.6 Ozone Calculation Results

Ozone levels for the three AC transmission line interconnections were calculated for rainy weather conditions. Table 3.4-20 presents a summary of the calculated maximum ozone concentrations at ground level within 300 feet of the transmission centerline. Maximum ozone levels are far below the EPA standard of 75 ppb for all three line design configurations.

Table 3.4-20:
Calculated Ozone Levels for 345kV AC Transmission Line Interconnections to Oklahoma Converter Station

345kV AC Transmission Line Configuration	Calculated Ozone (ppb) Maximum within +/-300 Feet of CL
Double Circuit Monopole	0.1
Double Circuit Lattice	0.1
Double Circuit Danube	0.1

CL = Centerline; since the precise ROW width has not yet been determined, the ROI for analysis is 300 feet on either side of a representative centerline.

3.4.11.2.1.2.2 Tennessee Converter Station Siting Area and AC Interconnection Tie

No electrical effects were evaluated for the Tennessee converter station because the overhead transmission lines are the dominant sources of electrical effects near the converter station, and the converter station interconnection would occur entirely within the converter station and the adjacent Shelby Substation site (i.e., no public access).

There are two different 500kV AC transmission line configurations associated with the interconnection into the Tennessee converter station. Both line designs are double circuit configurations (i.e., two circuits supported on a single structure). One line design is a double circuit monopole and is supported on a tubular pole, while the other is a double circuit line supported on a lattice structure. Each transmission line configuration is located within a 150-foot-wide to 200-foot-wide ROW (actual ROW width has not yet been determined). Proposed loading for these lines is 1,050MW (1,212 amperes) for average loading and 1,750MW (2,021 amperes) for maximum loading. Figures 3.4-14 and 3.4.15 present dimensioned drawings of the two representative 500kV AC transmission line configurations.

3.4.11.2.1.2.2.1 AC Electric Field Calculation Results

AC electric field calculations were performed for the two transmission line configurations. Table 3.4-21 presents a summary of the calculated electric field at the ROW edges and for the maximum field within the ROW. Because the ROW width has not yet been determined, ROW edge values are provided for both possible edge locations (either 75 feet or 100 feet from the transmission centerline). Calculated field levels vary, depending upon the line configuration. Figure 3.4-16 presents a graph of the calculated AC electric field for each line configuration.

Table 3.4-21:
Calculated AC Electric Field Values for 500kV AC Transmission Line Interconnections to Tennessee Converter Station

500kV AC Transmission Line Configuration	Calculated AC Electric Field (kV/m)[1]				
	-100 Feet from CL	-75 Feet from CL	Maximum on ROW	+75 Feet from CL	+100 Feet from CL
Double Circuit Monopole	0.2	0.7	8.4	0.7	0.2
Double Circuit Lattice	1.0	1.8	9.4	1.8	1.0

CL = Centerline; since the precise ROW width has not yet been determined, the ROI for analysis is 300 feet on either side of a representative centerline.
1 Edges of the ROW have not been established and are assumed to be either 75 feet or 100 feet from centerline.

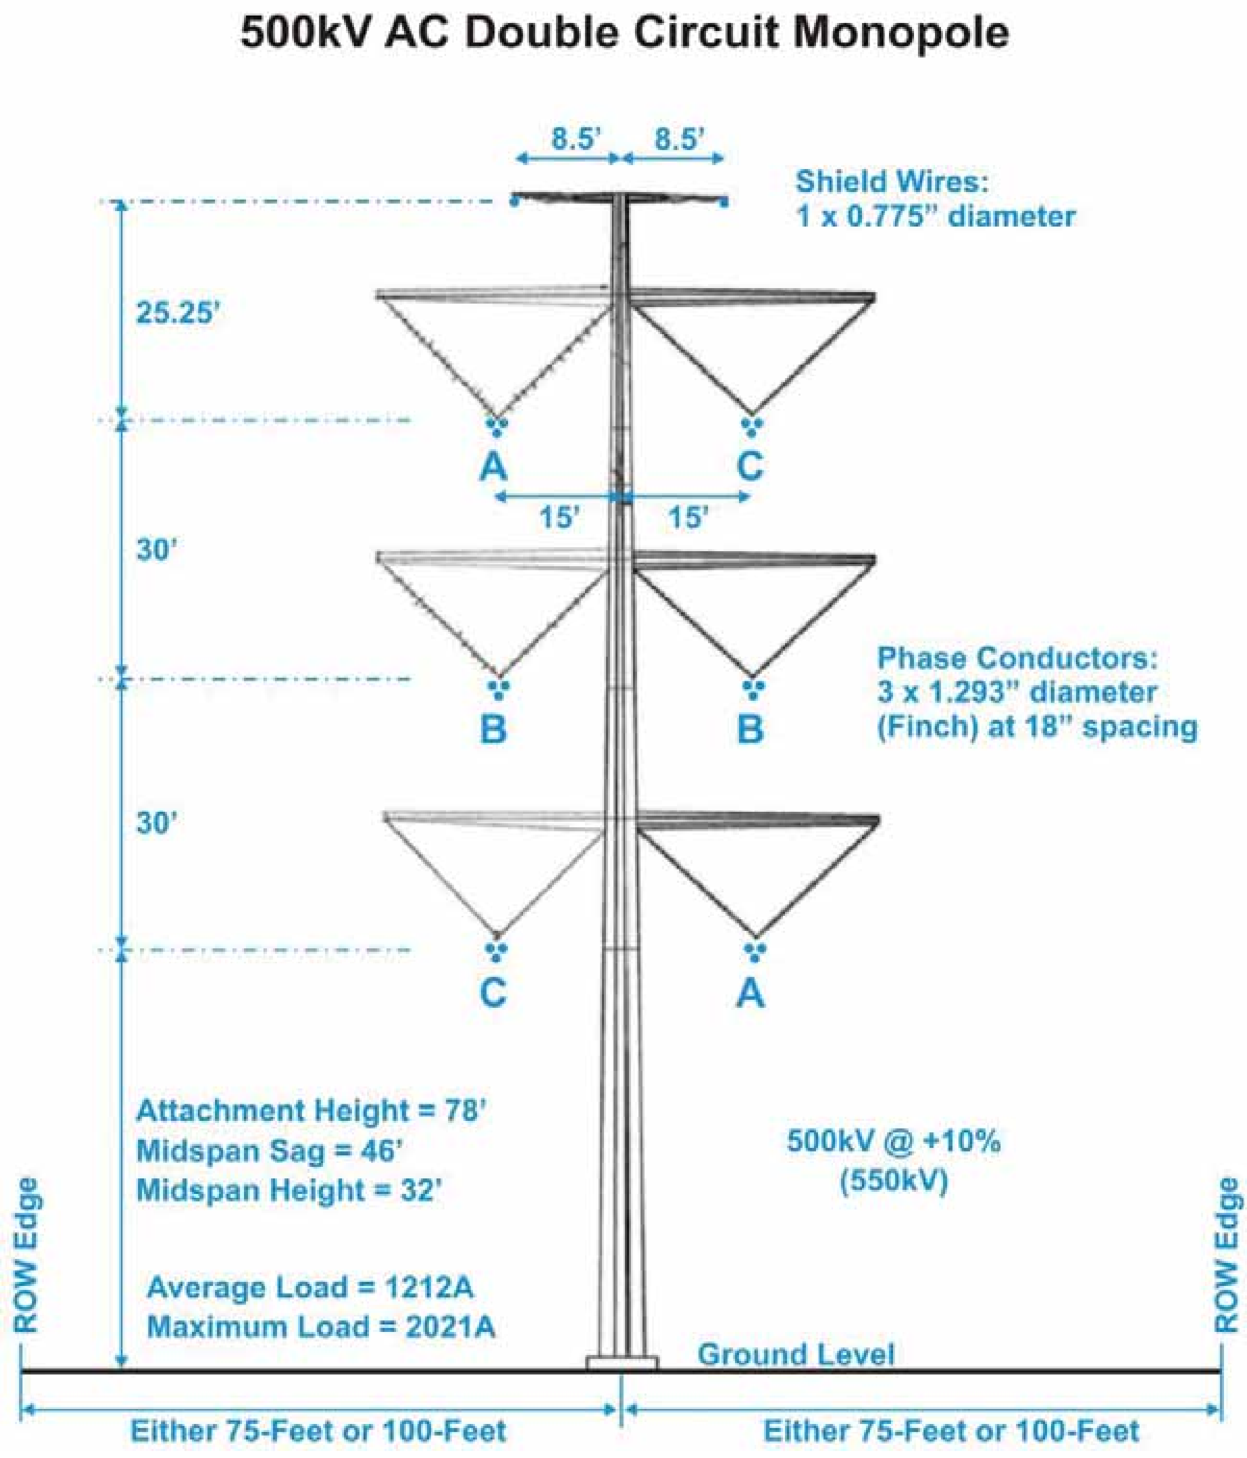

Figure 3.4-14: 500kV AC Transmission Line Double Circuit Monopole Configuration for Interconnection to Tennessee Converter Station

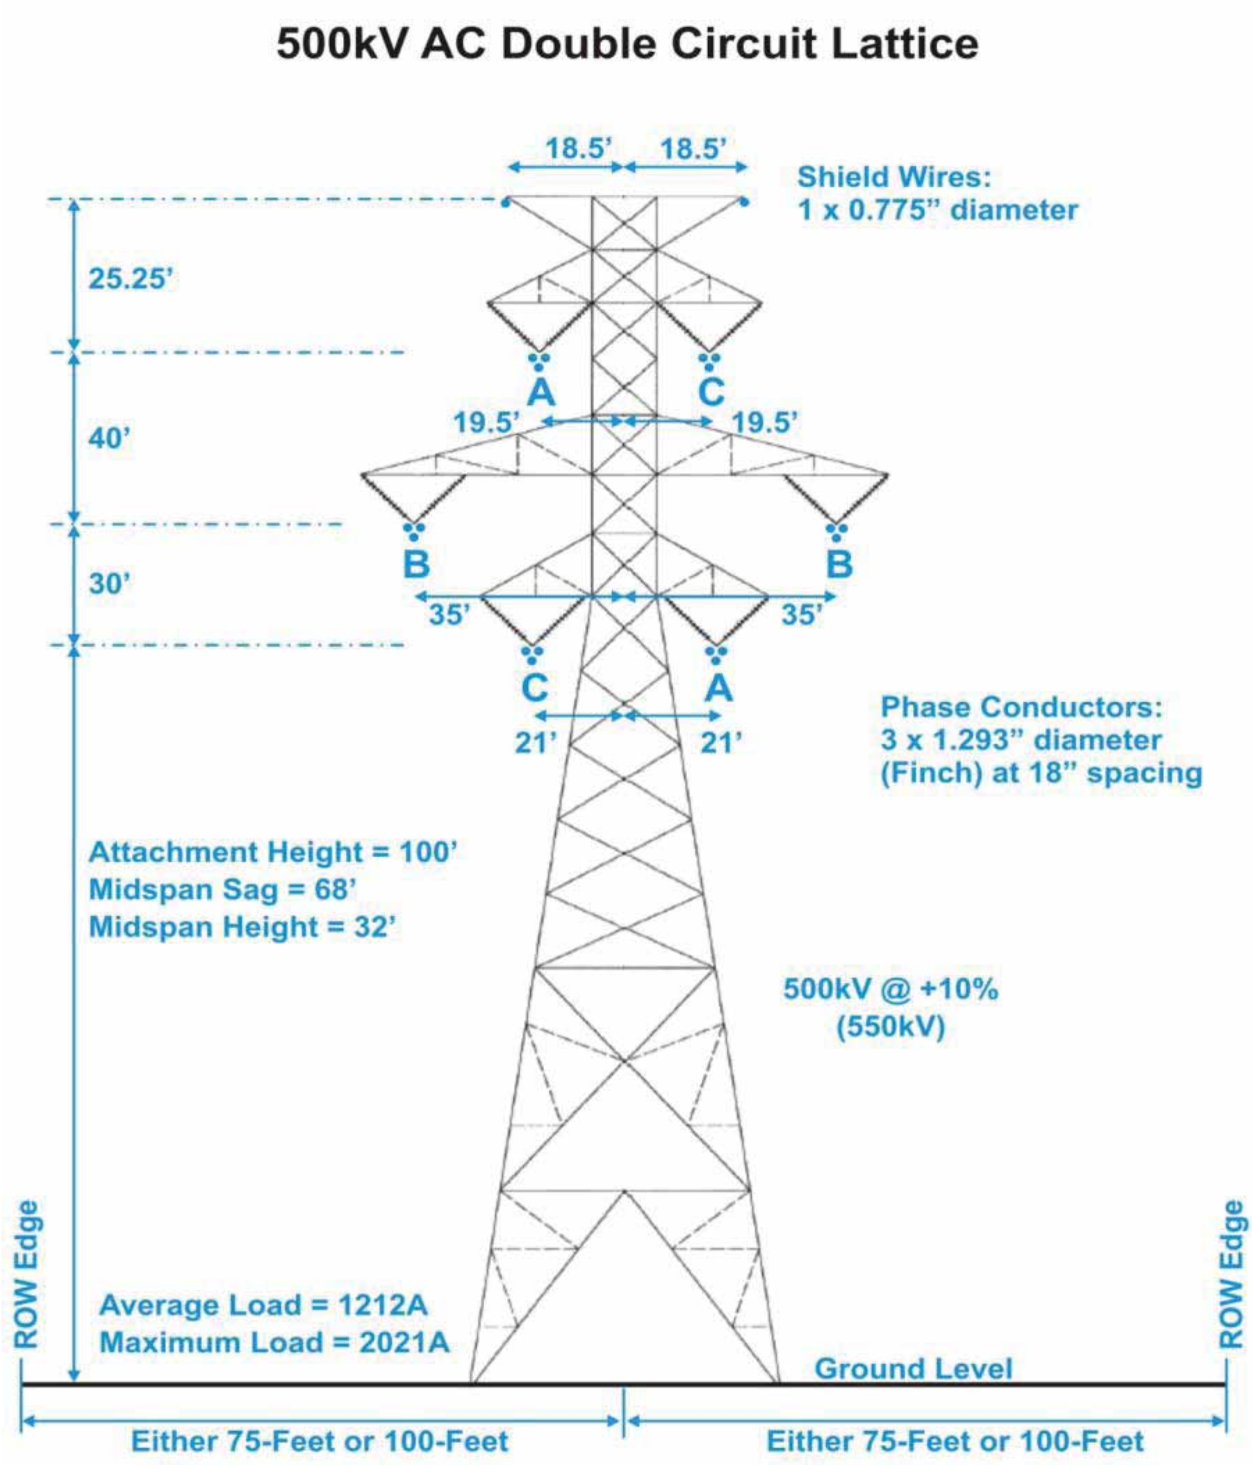

Figure 3.4-15: 500kV AC Transmission Line Double Circuit Lattice Tower Configuration for Interconnection to Tennessee Converter Station

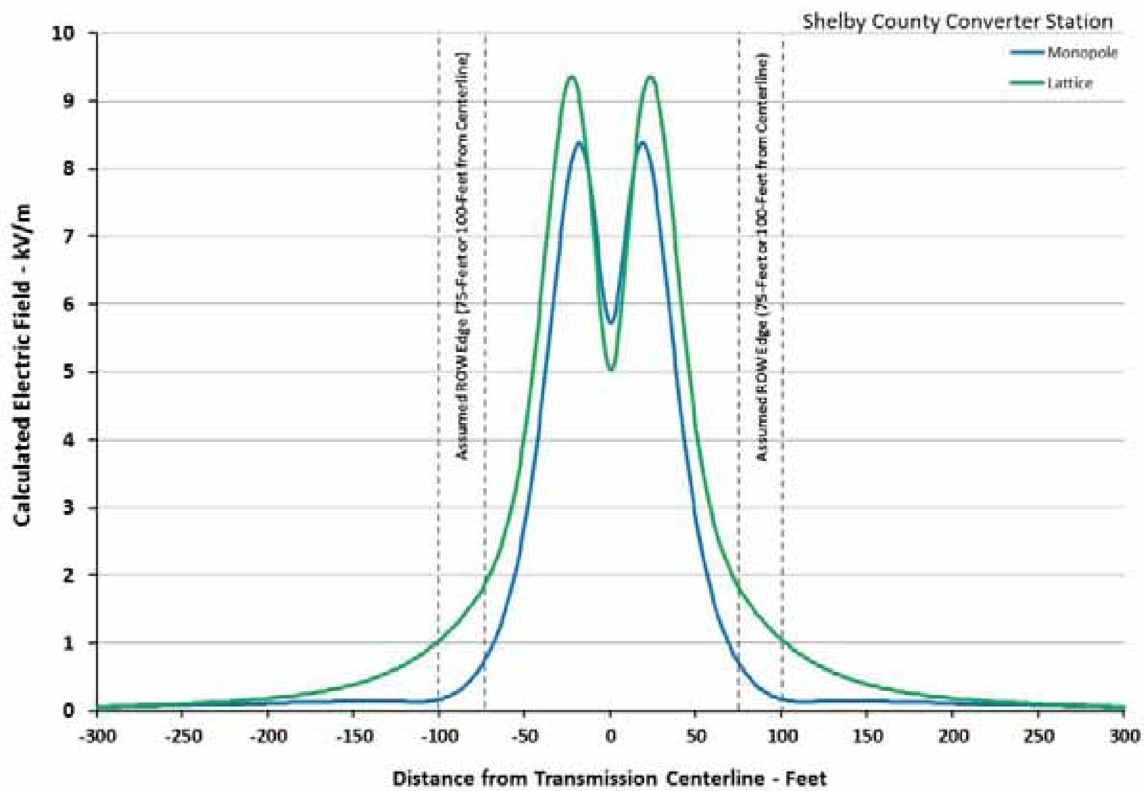

Figure 3.4-16: Calculated AC Electric Fields for 500kV AC Transmission Line Interconnections to Tennessee Converter Station

Calculated electric field levels at the ROW edges (either 75 feet or 100 feet from centerline of the transmission line) for all of the AC transmission line interconnections are below the ICES and ICNIRP guidelines for public exposure (5kV/m and 4.2kV/m respectively). Within the ROW, calculated electric field levels are below the ICES guideline of 10kV/m. For the double circuit lattice configuration, calculated electric field at the 75-foot ROW edge (1.8kV/m) exceeds the ACGIH guideline of 1kV/m for workers with implanted medical devices, but complies at the 100-foot ROW edge. Electric field effects for these transmission lines would occur primarily within the Tennessee converter station and Shelby Substation since the converter station interconnection would occur entirely within the substation site (i.e., no public access).

3.4.11.2.1.2.2.2 AC Magnetic Field Calculation Results

AC magnetic field calculations were performed for the two transmission line configurations under two different loading conditions (average and maximum loading of 1212A and 2021A respectively). Table 3.4-22 presents a summary of the calculated magnetic field at the ROW edges and for the maximum field within the ROW. Calculated field levels vary, depending upon the line configuration and loading conditions. Figure 3.4-17 presents a graph of the calculated AC magnetic field for each line configuration under average and maximum loading conditions.

Table 3.4-22:
Calculated AC Magnetic Field Values for 500kV AC Transmission Line Interconnections to Tennessee Converter Station

500kV AC Transmission Line Configuration	Calculated AC Magnetic Field (mG) for Average/Maximum Load[1]				
	-100 Feet from CL	-75 Feet from CL	Maximum on ROW	+75 Feet from CL	+100 Feet from CL
Double Circuit Monopole	17.7/29.6	32.4/54.0	178.6/297.6	32.8/54.7	18.0/30.0
Double Circuit Lattice	29.6/49.3	52.6/87.6	210.2/350.3	53.3/88.9	30.1/50.2

CL = Centerline; since the precise ROW width has not yet been determined, the ROI for analysis is 300 feet on either side of a representative centerline.
1 Edges of the ROW have not been established and are assumed to be either 75 feet or 100 feet from centerline.

Calculated magnetic field levels at the ROW edges (for either ROW width) for both AC transmission line interconnection designs are below the ICES and ICNIRP guidelines for public exposure (9,040mG and 2,000mG respectively). Calculated magnetic field levels within the ROW are also below the ACGIH guideline of 1,000mG for workers with implanted medical devices for both configurations. Magnetic field effects for these transmission lines would occur primarily within the Tennessee converter station and the Shelby Substation since the converter station interconnection would occur entirely within the substation site (i.e., no public access).

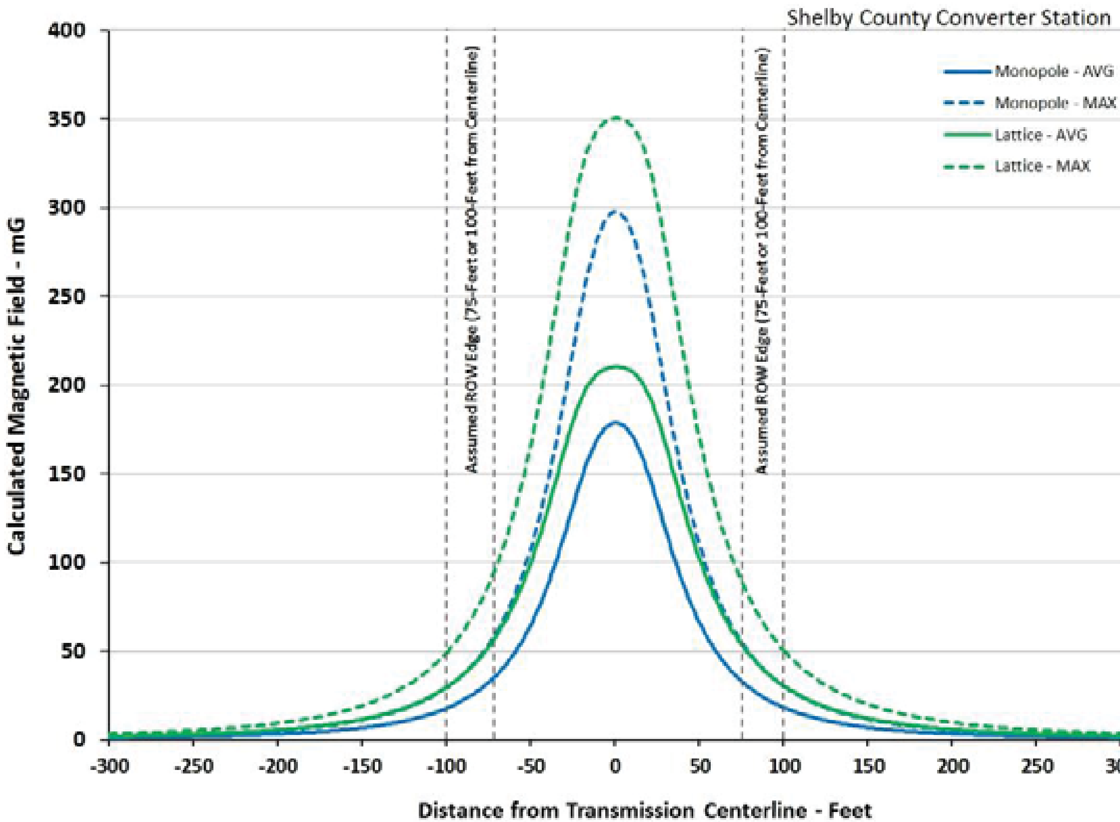

Figure 3.4-17: Calculated AC Magnetic Fields for 500kV AC Transmission Line Interconnections to Tennessee Converter Station (Average and Maximum Loading)

3.4.11.2.1.2.2.3 AC Audible Noise Calculation Results

Audible noise calculations were performed for the three AC transmission line configurations. Table 3.4-23 presents a summary of the calculated day-night (L_{dn}) audible noise at the ROW edges and for the maximum noise level within the ROW. Calculated levels vary, depending upon the line configuration. Figure 3.4-18 presents a graph of the calculated audible noise for each AC transmission line configuration.

Table 3.4-23:
Calculated Audible Noise for 500kV AC Transmission Line Interconnections to Tennessee Converter Station

500kV AC Transmission Line Configuration	Calculated Audible Noise (dBA)—L_{dn}[1]				
	-100 Feet from CL	-75 Feet from CL	Maximum on ROW	+75 Feet from CL	+100 Feet from CL
Double Circuit Monopole	60.8	61.7	64.0	61.7	60.8
Double Circuit Lattice	58.1	59.0	60.7	59.0	58.1

CL = Centerline; since the precise ROW width has not yet been determined, the ROI for analysis is 300 feet on either side of a representative centerline.
1 Edges of the ROW have not been established and are assumed to be either 75 feet or 100 feet from centerline.

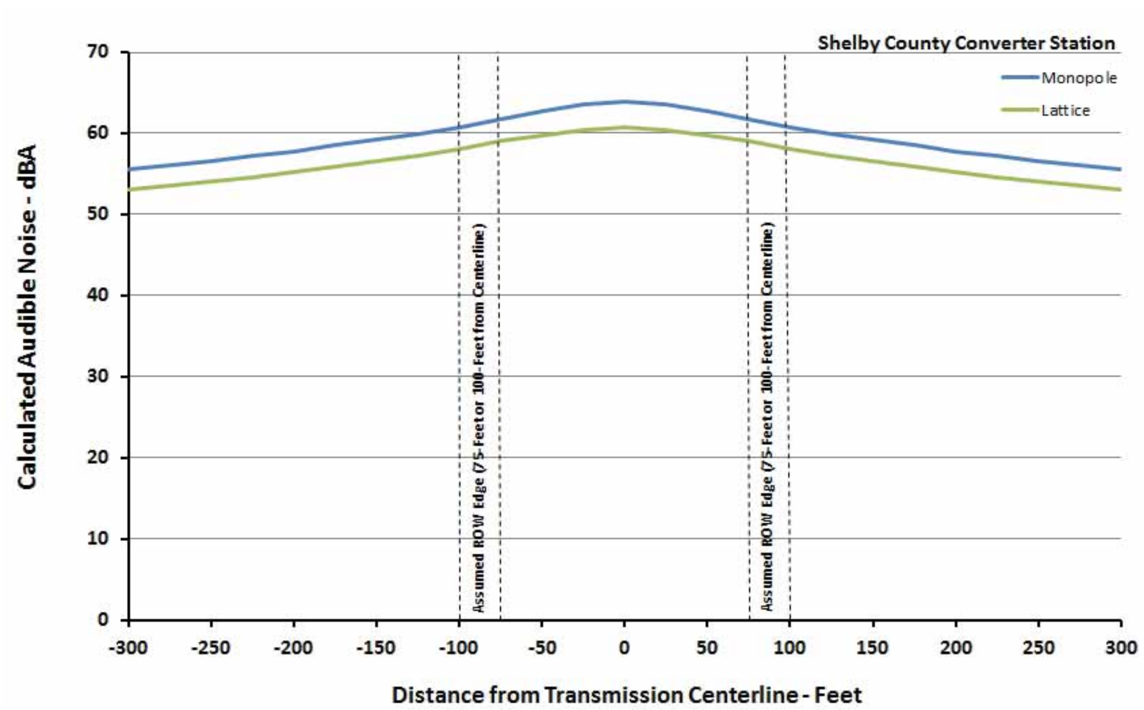

Figure 3.4-18: Calculated Audible Noise Levels (L_{dn}) for 500kV AC Transmission Line Interconnections to Tennessee Converter Station

Calculated audible noise levels at the ROW edges (either 75 feet or 100 feet from centerline of the transmission line) for all of the AC transmission line interconnections are above the EPA guideline for L_{dn} (day-night) noise of 55 dBA. Calculated audible noise levels assume a 10 percent overvoltage condition at the highest line elevation (3,000 feet). Audible noise effects for these transmission lines would occur primarily within the Tennessee converter station and the Shelby Substation since the converter station interconnection would occur entirely within the substation site (i.e., no public access).

3.4.11.2.1.2.2.4 AC Radio Noise Calculation Results

Radio noise calculations were performed for both AC transmission line interconnection designs for rainy and fair weather conditions. Table 3.4-24 presents a summary of the calculated radio noise at the ROW edges and for the maximum noise within the ROW at 500kHz for both weather conditions. Table 3.4-24 also presents calculated 500kHz radio noise at 50 feet from the outside conductor for comparison with the IEEE Standard. Calculated radio noise levels vary, depending upon the line configuration and weather conditions. As shown in Table 3.4-24, calculated radio noise levels at 50 feet from the outside conductor comply with the IEEE 61 dB:V/m threshold during fair weather conditions. Figure 3.4-19 presents a graph of the calculated radio noise levels for each AC line configuration in rainy weather, adjusted to the 500kHz reference level. Figure 3.4-20 presents a corresponding graph of the calculated radio noise levels for fair weather (adjusted to the 500kHz reference level). Radio noise interference from these transmission lines would occur primarily within the Tennessee converter station and the Shelby Substation since the converter station interconnection would occur entirely within the substation site (i.e., no public access).

Table 3.4-24:
Calculated Radio Noise for 500kV AC Transmission Line Interconnections to Tennessee Converter Station

500kV AC Transmission Line Configuration	Calculated Radio Noise (dB:V/m) at 500kHz (Rain/Fair Weather)[1]						
	-100 Feet from CL	-50 Feet from Outside Conductor	-75 Feet from CL	Maximum on ROW	+75 Feet from CL	+50 Feet from Outside Conductor	+100 Feet from CL
Double Circuit Monopole	70.5/53.5	75.4/58.4	72.9/55.9	88.8/71.8	72.9/55.9	75.4/58.4	70.5/53.5
Double Circuit Lattice	68.8/51.8	71.1/54.1	72.5/55.5	86.4/69.4	72.5/55.5	71.1/54.1	68.8/51.8

CL = Centerline; since the precise ROW width has not yet been determined, the ROI for analysis is 300 feet on either side of a representative centerline.

1 Edges of the ROW have not been established and are assumed to be either 75 feet or 100 feet from centerline.

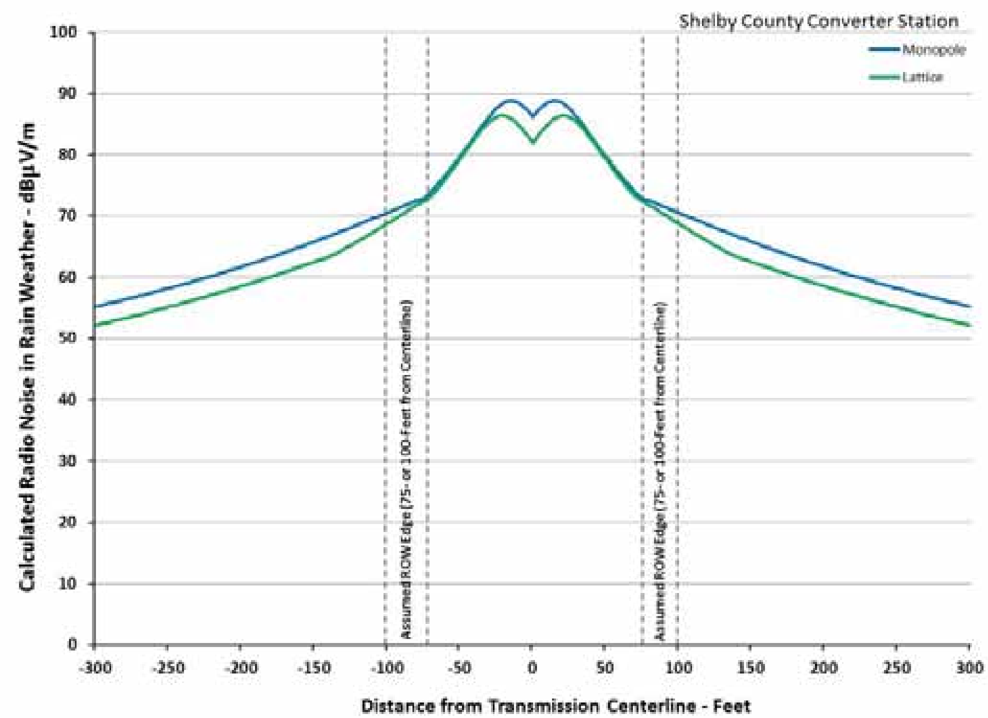

Figure 3.4-19: Calculated Radio Noise for 500kV AC Transmission Line Interconnections to Tennessee Converter Station (Rainy Weather)

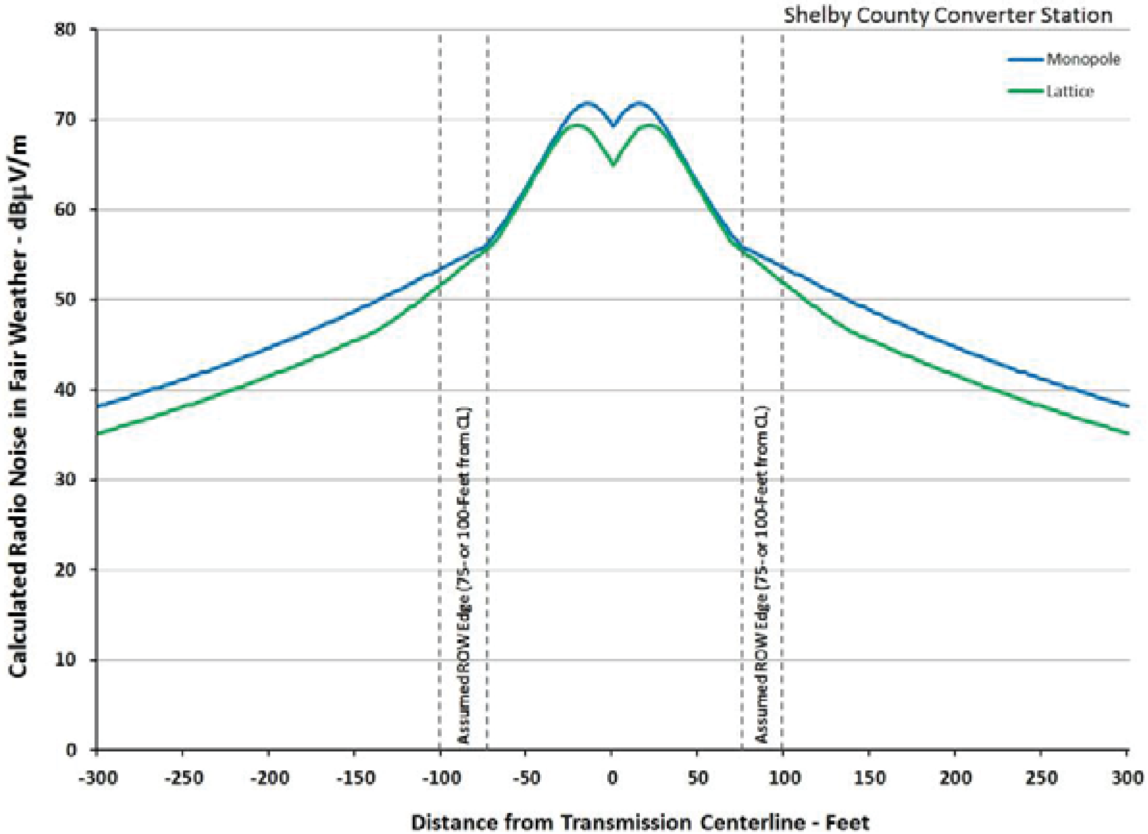

Figure 3.4-20: Calculated Radio Noise for 500kV AC Transmission Line Interconnections to Tennessee Converter Station (Fair Weather)

It is difficult to determine whether the radio noise produced by a transmission line or any other source would cause unacceptable interference without knowing broadcast signal strengths at various locations of interest along the possible line routes. Parameters such as the strength of the received signal, the sensitivity of the receiver, the orientation and design of the receiving antenna, and ambient radio frequency noise are also important in determining the degree to which noise from any source may cause degradation of radio reception quality. Section 3.4.4 presents a discussion on radio noise interference and Section 3.4.6.6 on radio noise standards.

3.4.11.2.1.2.2.5 AC Television Noise Calculation Results

Television noise calculations were performed for both AC transmission line interconnections for rainy weather conditions. Table 3.4-25 presents a summary of the calculated television noise at the ROW edges and for the maximum noise within the ROW for the 75MHz reference level. Calculated television noise levels vary, depending upon the line configuration. Figure 3.4-21 presents a graph of the calculated television noise levels for each AC line configuration in rainy weather.

Table 3.4-25:
Calculated Television Noise for 500kV AC Transmission Line Interconnections to Tennessee Converter Station

500kV AC Transmission Line Configuration	Calculated Television Noise (dB:V/m) at 75MHz for Rainy Weather[1]				
	-100 Feet from CL	-75 Feet from CL	Maximum on ROW	+75 Feet from CL	+100 Feet from CL
Double Circuit Monopole	29.3	32.0	41.2	32.0	29.3
Double Circuit Lattice	27.5	30.4	38.8	30.4	27.5

CL = Centerline; since the precise ROW width has not yet been determined, the ROI for analysis is 300 feet on either side of a representative centerline.
1 Edges of the ROW have not been established and are assumed to be either 75 feet or 100 feet from centerline

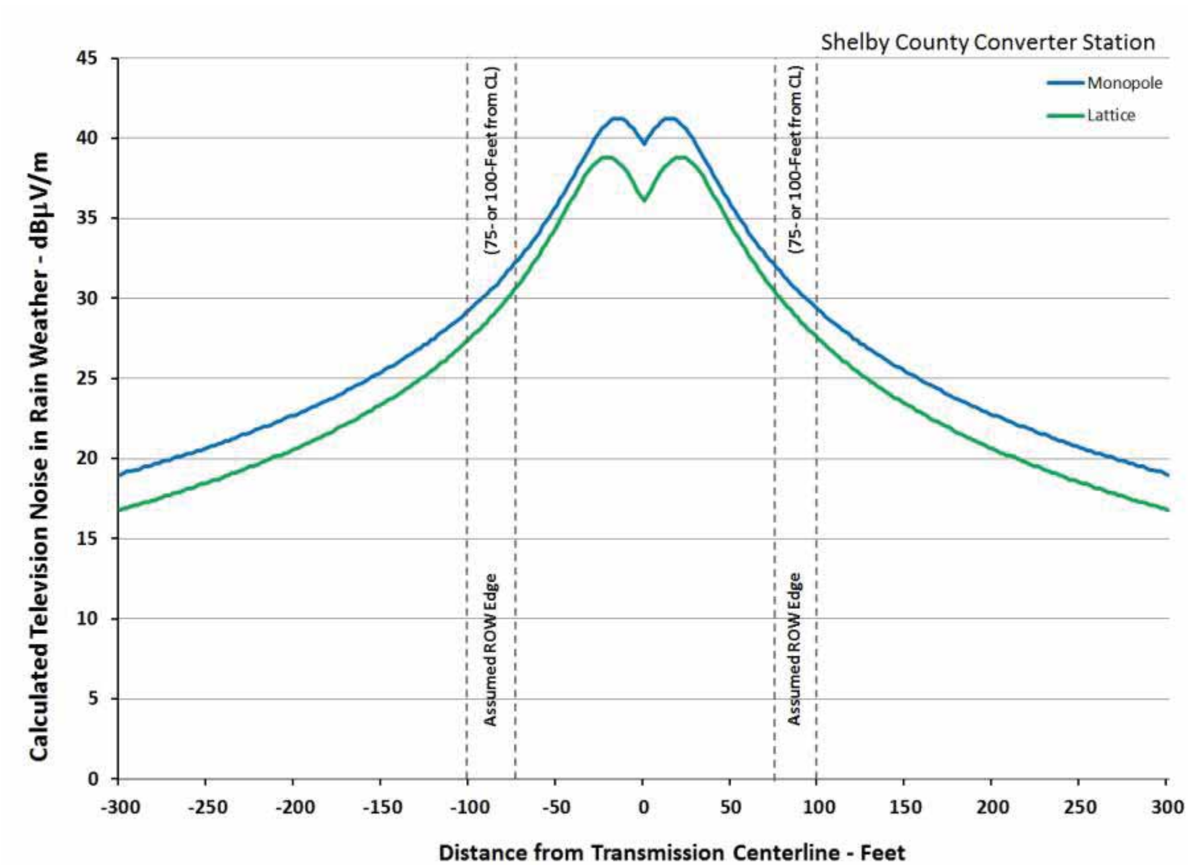

Figure 3.4-21: Calculated Television Noise for 500kV AC Transmission Line Interconnections to Tennessee Converter Station (Rainy Weather)

As with radio noise interference, it is difficult to determine whether the television noise level produced by a transmission line would cause unacceptable interference. However, the new digital broadcast system technology for radio and television should provide better coverage and immunity to transmission line noise than analog television signals. No interference resulting from corona-generated noise would be expected for digital signals broadcast at frequencies above 1GHz from satellites (EPRI 2006a). Television noise interference from these transmission lines would occur primarily within the Tennessee converter station and the Shelby Substation since the converter station interconnection would occur entirely within the substation site (i.e., no public access).

3.4.11.2.1.2.2.6 Ozone Calculation Results

Ozone levels for both AC transmission line interconnections were calculated for rainy weather conditions. Table 3.4-26 presents a summary of the calculated maximum ozone concentrations at ground level within 300 feet of the transmission centerline. Maximum ozone levels are far below the EPA standard of 75 ppb for all three line design configurations. Ozone effects from these transmission lines would occur primarily within the Tennessee converter station and the Shelby Substation since the converter station interconnection would occur entirely within the substation site (i.e., no public access).

Table 3.4-26:
Calculated Ozone Levels for 500kV AC Transmission Line Interconnections to Tennessee Converter Station

500kV AC Transmission Line Configuration	Calculated Ozone (ppb)
	Maximum within +/-300 Feet of CL
Double Circuit Monopole	0.3
Double Circuit Lattice	0.2

CL = Centerline; since the precise ROW width has not yet been determined, the ROI for analysis is 300 feet on either side of a representative centerline.

3.4.11.2.1.2.2.7 Overview of AC Electrical Effects Research on Human Health

Research has been conducted in the United States and around the world to determine whether exposure to power-frequency AC electric and magnetic fields has human health effects. This research includes epidemiological studies, laboratory studies of animals and cell tissues, and multi-disciplinary reviews (or pooled analysis). Some studies have reported a statistical association between magnetic fields and health outcomes while other studies have not. The general consensus among researchers and the medical and scientific communities is that there is insufficient evidence at this time to conclude whether magnetic fields are a cause of adverse health issues or not. The National Institute of Environmental Health Sciences (NIEHS) report to the United States Congress, at the conclusion of its multi-year EMF Rapid Program, summarized its research (NIEHS and NIH 2002). The following is an excerpt from the 1999 NIEHS report:

> *The NIEHS believes that the probability that ELF-EMF (extremely low frequency electric and magnetic field) exposure is truly a health hazard is currently small. The weak epidemiological associations and lack of any laboratory support for these associations provide only marginal, scientific support that exposure to this agent is causing any degree of harm.*

The NIEHS stated that, for most health outcomes, there is no evidence that exposure to electric and magnetic fields has adverse effects. There is some evidence from epidemiology studies that exposure to power-frequency magnetic field is associated with an increased risk for childhood leukemia. This association is difficult to interpret in the absence of reproducible laboratory evidence or a scientific explanation that links magnetic fields with childhood leukemia (NIEHS and NIH 2002).

The following discussions report on various organizations and study results concerning AC electrical effects and their conclusions:

- The International Agency for Research on Cancer (IARC) has reviewed numerous epidemiological and laboratory animal studies relevant to AC and DC fields to assess the potential for cancer causation. The epidemiology studies included residential and occupational studies of adults and children that examine the relationship between AC magnetic or electric fields and various cancers, including leukemia and brain and breast cancers. Based on its review, the IARC found limited epidemiological evidence in humans, particularly for childhood leukemia, and found that the evidence for other outcomes in adults and children, and in laboratory animals, was inadequate. A consistent relationship between adult cancer and exposure to electric or magnetic fields has not been found. Based on this evaluation of the available data, the working group classified power-frequency magnetic fields as possibly carcinogenic to humans (Group 2B) (IARC 2002). This classification is applicable only to the AC transmission line magnetic fields connecting the wind farms and other substations to converter stations. For comparison, IARC also lists coffee and pickled vegetables as Group 2B carcinogens. Power-frequency electric fields and static DC electric and magnetic fields are defined by IARC as not classifiable as to their carcinogenicity (Group 3). The proposed HVDC transmission line DC fields would be included in this Group 3 category.
- The World Health Organization (WHO) published the Environmental Health Criteria 238 (EHC 238) (WHO 2007) to address the possible health effects of exposure to AC electric and magnetic fields. The document is a thorough review of the scientific literature on the biological effects of exposure to power-frequency electric and magnetic fields to evaluate potential health risks. The Task Group was composed of international experts from a variety of scientific disciplines and organizations involved in this area and examined epidemiological, in vitro, and in vivo studies. In its assessment of the health risk posed by AC electric and magnetic fields, the Task Group concluded that (WHO 2007):

  > *Scientific evidence suggesting that every day, chronic low-intensity (above 3–4 mG) power-frequency magnetic field exposure poses a health risk is based on epidemiological studies demonstrating a consistent pattern of increased risk for childhood leukemia. Uncertainties in the hazard assessment include the role that control selection bias and exposure misclassification might have on the observed relationship between magnetic fields and childhood leukemia. In addition, virtually all of the laboratory evidence and the mechanistic evidence fail to support a relationship between low-level ELF magnetic fields and changes in biological function or disease status. Thus, on balance, the evidence is not strong enough to be considered causal, but sufficiently strong to remain a concern.*

  The information provided by the WHO is its most current statement regarding EMF information and has not changed since 2007. Comments received on the Draft EIS related concern about the WHO being under investigation for being heavily influenced by the electricity transmission industry; however, no active investigation is publicly underway. In addition, their conclusions about EMF are shared by other leading health organizations.
- Currently, the National Cancer Institute website (NCI 2015) states that “Several early epidemiological studies raised the possibility of an association between certain cancers, especially childhood cancers, and ELF-EMFs. Most subsequent studies have not shown such an association, but scientists have continued to investigate the possibility that one exists.” Additionally, NCI’s website states that no mechanism by which electric and magnetic fields could cause cancer has been identified, and animal studies have not provided any indications that EMF exposure is associated with cancer. Currently, researchers conclude that there is little evidence that exposure to EMF from power lines causes leukemia, brain tumors, or any other cancers in children. The website also states that “More recent studies, including some that considered the participant’s job title as well as measurements of their exposures, have not shown consistent findings of an increasing risk of leukemia, brain tumors, or female breast cancer with increasing exposure to magnetic fields at work.”

- The National Radiological Protection Board (NRPB; now a part of Public Health England as of April 2013) was a United Kingdom public body set up to disseminate information about the protection of mankind from radiation hazards. The NRPB later became the Advisory Group on Non-ionizing Radiation (AGNIR). The AGNIR performed an assessment of the scientific literature on potential effects of AC electric and magnetic field assessment on the information available from experimental studies on tissues, living cells and animals, and human volunteer and epidemiological studies. The AGNIR concluded that laboratory experiments have provided no good evidence that power-frequency electric and magnetic fields are capable of producing cancer, nor do human epidemiological studies suggest that they cause cancer in general. There is however some epidemiological evidence that prolonged exposure to higher levels of power-frequency magnetic field is associated with a small risk of leukemia in children. In practice, such levels of exposure are seldom encountered by the general public in the United Kingdom. In the absence of clear evidence of a carcinogenic effect in adults, or of a plausible explanation from experiments on animals or isolated cells, the epidemiological evidence is currently not strong enough to justify the firm conclusion that such fields cause leukemia in children. Unless further research indicates that the finding is due to chance or some currently unrecognized artifact, the possibility remains that intense and prolonged exposures to magnetic fields can increase the risk of leukemia in children (NRPB 2004a, 2004b).
  The BioInitiative report (2007) was prepared by a self-selected group of EMF activists and researchers and makes many claims that greatly differ from established and recognized health organizations in several countries. The purpose of this report was to *"assess scientific evidence on health impacts from EM radiation below current public exposure limits and evaluate what changes in these limits are warranted now to reduce possible public health risks in the future."* The authors of this report contend that the current procedure for developing exposure guidelines is not sufficient and should be replaced by a system that sets exposure guidelines at levels at which biological effects have been reported in some studies, but not substantiated in a rigorous review of the science or supported by other research. Based on this premise, the report proposes that significantly lower exposure levels be adopted than those that are presently considered. The conclusions in the BioInitiative report deviate substantially from those of reputable scientific organizations because they are not based on standard, scientific methods. Valid scientific conclusions are based upon weight-of-evidence reviews, which entail a systematic evaluation of the entire body of scientific evidence. This report has been criticized as not providing a valid weight-of-evidence review, since the report is a compilation of individual sections, each authored by only one to three members of the "ad hoc" group of scientists, and as a whole does not appear to be collaborative or reviewed in its entirety by the collective group. For instance, the Health Council of The Netherlands states that the report was compiled with "the selective use of scientific data" and "is not an objective and balanced reflection of the current state of scientific knowledge" (HCN 2008). Other organizations have also made similar statements. As a practical matter, the BioInitiative report implies that EMF exposure is a universal toxin and carcinogen causing many different types of diseases. This conclusion is strikingly different from what established and recognized health organizations have found.
- The California EMF Program published the results of an evaluation on scientific EMF research in 2002 (Neutra et al. 2002). Sponsored at the request of the California Public Utilities Commission and conducted by three scientists from the California Department of Health Services, these scientists reviewed numerous EMF health studies and determined a level of confidence in their opinion that a health relationship may exist from high EMF exposures (Neutra et al. 2002). The scientists evaluated these studies using a similar approach as the IARC review, in which the "quality of evidence" was evaluated. However, their evaluation focused on the epidemiology studies in particular and not as much on experimental or animal data. Based upon the guidelines developed by

the California EMF Program, each scientist expressed a level of confidence to which EMF can cause some degree of increased risk to certain specified heath conditions. These scientists concluded that the epidemiological research provided little support for an association of EMF with many of the diseases considered. For the remaining diseases (such as childhood leukemia; adult brain cancer; ALS, or amyotrophic lateral sclerosis; and miscarriages), the scientists indicated that some degree of increased risk may be present, but their confidence ratings for these conditions were not sufficient to indicate any strong certainty. In fact, these scientists report that *"there is a chance that EMFs have no effect at all"* (Neutra and Del Pizzo 2001). They also agree that EMF is not a universal carcinogen (Neutra et al. 2002). Furthermore, the scientists did not recommend that the state of California establish an EMF exposure limit.

- The 2015 EPA website (EPA 2015) states that "Scientific experiments have not clearly shown whether or not exposure to EMF increases cancer risk. There is no clear scientific evidence that electromagnetic fields affect health."
- The 2015 American Cancer Society webpage has the following statements:

  > *One study did show an increase risk of tumors and cancer that start in the C-cells of the thyroid in male rats at certain exposures. This increase risk was not seen in mice or female rats, and was not seen at the highest field strength. These inconsistencies, and the fact that these findings were not seen in the other studies, make it hard to conclude that the increased risk of tumors was really from the ELF radiation. Other studies in mice and rats looked specifically for a link between leukemia and lymphoma and exposure to ELF radiation, but no link was found.* (ACS 2015a)

  Under the American Cancer Society website section entitled "Factors with uncertain, controversial, or unproven effects on brain tumor risk:"

  > *Exposure to aspartame (a sugar substitute), exposure to electromagnetic fields from power lines and transformers, and infection with certain viruses have been suggested as possible risk factors, but most researchers agree that there is no convincing evidence to link these factors to brain tumors.* (ACS 2015b)

- In a more recent 2015 review of scientific studies, the Scientific Committee on Emerging and Newly Identified Health Risks (SCENIHR) - an agency of the European Commission - published its latest review of the scientific literature on the issue of EMF and health (SCENIHR 2015). The SCENIHR report reviewed a full multiplicity of both negative and positive scientifically plausible studies. This 2015 report, which is entitled "Potential Health Effects of Exposure to Electromagnetic Fields (EMF)," reaches a similar conclusion to its previous 2009 report (SCENIHR 2009) entitled "Health Effects of Exposure to EMF:"

  > *Overall, existing studies do not provide convincing evidence for a causal relationship between ELF MF exposure and self-reported symptoms.*
  >
  > *The new epidemiological studies are consistent with earlier findings of an increased risk of childhood leukaemia with estimated daily average exposures above 0.3 to 0.4 μT. As stated in the previous Opinions, no mechanisms have been identified and no support is existing from experimental studies that could explain these findings, which, together with shortcomings of the epidemiological studies prevent a causal interpretation.*
  >
  > *Studies investigating possible effects of ELF exposure on the power spectra of the waking EEG are too heterogeneous with regard to applied fields, duration of exposure, and number of considered leads, and statistical methods to draw a sound conclusion. The same is true for behavioural outcomes and cortical excitability.*
  >
  > *Epidemiological studies do not provide convincing evidence of an increased risk of neurodegenerative diseases, including dementia, related to power frequency MF exposure.*

> *Furthermore, they show no evidence for adverse pregnancy outcomes in relation to ELF MF. The studies concerning childhood health outcomes in relation to maternal residential ELF MF exposure during pregnancy involve some methodological issues that need to be addressed. They suggest implausible effects and need to be replicated independently before they can be used for risk assessment.* (SCENIHR 2015)

While individual scientific studies may provide support for a given hypothesis of potential health impacts, a thorough literature review is helpful in determining the scientific consensus—where one exists. Individual studies do not provide a comprehensive view of what is known in any field of science. When taken and scientifically evaluated collectively, a balanced perspective is provided. Multidisciplinary expert panels, acting on behalf of a number of national and international health and scientific agencies, and numerous health organizations have reviewed the available scientific literature regarding potential health effects of electric and magnetic fields and concluded that there are no known adverse health impacts from the electrical and magnetic fields associated with AC transmission lines. Using a systematic identification and review of the relevant literature for a specific exposure and potentially related health outcome, none of these agencies found reliable evidence of biologically harmful effects. These panels and organizations have also looked at power-frequency electric and magnetic fields, and have concluded that the association between AC magnetic fields and adverse health effects is weak.

The Precautionary Principle of risk management states that if an action or policy has a suspected risk of causing harm to the public or to the environment, in the absence of scientific consensus that the action or policy is not harmful, the burden of proof that it is not harmful falls on those taking an action. However, the scientific consensus from multidisciplinary expert panels and numerous health organizations is that there are no known adverse health impacts from the electrical and magnetic fields associated with AC transmission lines.

In addition, these health studies primarily address AC magnetic fields. While AC transmission lines are proposed as part of this Project, the main focus of the Project is the high voltage DC transmission line (approximately 720 miles in length).

If the AC electric field intensity is sufficiently large, then spark discharges due to currents induced on objects can occur. The NESC (IEEE 2012) within the United States requires that the electric field or its effects be reduced such that the largest anticipated object under a transmission line has a current to ground of no greater than 5mA. High voltage transmission lines can induce a voltage on ungrounded metallic objects such as a truck parked under the transmission line. If a path to ground is provided, such as a grounded person touching an ungrounded object, a small electric current can flow. Average adult humans can detect electric currents of about 1–2mA. Electric currents above 5mA can cause pain and startle response reactions and could be harmful under certain conditions. The NESC, therefore, requires that additional ground clearance or other means shall be used to limit electric field effects to 5mA or less.

The electric field levels from the Project are similar to other transmission lines already operating in the United States and around the world. The electric field decreases rapidly with distance away from a transmission line and electric fields from power lines are easily shielded by objects such as trees or building walls. No scientific data is available by which to conclude that transmission line electric fields have any effect on seizures. There has been some research on laboratory animals involving artificially embedded electrodes in an attempt to control seizures. However, the internal electric fields in these experiments are not like power line fields, have unusual characteristics, are at levels in tissue much higher than transmission line fields would cause, and involve use of embedded metal wires or electrodes in the test subject.

Other health studies have investigated seizures associated with higher radio and microwave frequencies, which would not be applicable to either the DC transmission line or the AC transmission lines associated with this Project. For example, a 2013 Turkish study presented results concerning the impact of electromagnetic waves (microwaves) on epileptic seizures (Cinar et al. 2013). The study found a possible trigger effect of electromagnetic waves on seizure activity in mice, and this study was raised in concern over possible seizures in humans living close to the Project transmission lines. However, the study utilized electromagnetic frequencies approaching the microwave band (ranging from 100MHz to 900MHz). This frequency in no way compares to static frequency (0Hz), which is 100–900 million times higher in frequency (and almost 10 million times higher for power frequency). In fact, the Cinar et al. cite another paper (Canseven et al. 2007) in which the authors state that they "did not find any effect of 50Hz electromagnetic waves". Therefore, caution must be exercised to ensure that findings associated with a particular frequency are not applied to other frequencies (i.e., field effects are different for different frequencies). High frequency fields, such as those associated with this seizure study, would not be applicable to either the HVDC transmission line (0Hz) or the AC transmission lines (60Hz) associated with the Project.

Studies have also been performed on electromagnetic hypersensitivity (EHS), which can include a variety of symptoms including headache, fatigue, stress, tiredness, concentration difficulties, dizziness, and sleep disturbances. The majority of studies indicate that EHS individuals cannot detect EMF exposure any more accurately than non-EHS individuals, and well-controlled double-blind studies have shown that symptoms were not correlated with EMF exposure (WHO 2005). There are also some indications that these symptoms may be due to pre-existing psychiatric conditions as well as stress reactions as a result of worrying about EMF health effects, rather than EMF exposure itself (WHO 2005).Similar results have been published in other scientific literature (Rubin et.al. 2005; Foster and Rubin 2014; Beale et. al. 1997; BioEM 2015; Mild and Sandstrom 2015).

Studies to date have not associated proximity to AC transmission lines or their electric or magnetic fields with an increased risk in autism. Hypersensitivity to noise can be one of the concerns for some children with autism. Engineers take steps in the design of transmission lines to keep noise levels low by using larger or multiple conductors for each phase and hardware with smooth and curved surfaces. In fair weather, the audible noise from a transmission line at a few thousand feet and beyond would not be possible to measure in comparison to background levels. At that distance under rainy conditions, it would be very low as well, much less than the noise of falling rain or wind.

Within the ROW, the maximum calculated AC electric field from the Project transmission lines is about 4.6 to 10.2kV/m. In this level of electric field, induced currents may create shocks from touching ungrounded metallic objects (although metal buildings and fences on or adjacent to high voltage transmission line easements are typically grounded during transmission line construction). Utilities often may supply information on living and working safely around high voltage power lines (BPA 2010, 2007).

This section is not a comprehensive review of the entire body of evidence, and excludes consideration of many other relevant published scientific studies. Scientific research utilizes epidemiology studies, animal models, and laboratory studies of basic mechanisms to scientifically evaluate a disease risk. Based upon a comprehensive review of the scientific literature, the association between AC magnetic fields and adverse health effects is weak and research is continuing. Currently, there are no U.S. state government or federal government health-based limits established for electric and magnetic fields, and where the Project is to be located, no states have any state-mandated electric and magnetic field limits.

3.4.11.2.1.2.2.8 Overview of AC Electrical Effects Research on Pacemakers and Implanted Medical Devices

Public concern has been expressed related to the electric and magnetic fields of transmission lines with the possibility of interference with cardiac pacemakers. When pacemakers detect a spurious signal of sufficient magnitude, such as an induced 60Hz current, they can change from a synchronous mode of operation to an asynchronous or fixed pacing mode of operation and then return to a synchronous mode of operation within a specified time after the signal is no longer detected. The issue is whether transmission line fields could adversely affect the pacemaker's operational mode and the resulting effect it could have on users.

For AC electric and magnetic fields, studies have determined thresholds for interference of the most sensitive units to be about 2,000 to 12,000mG for magnetic fields and about 1.5 to 2.0kV/m for electric fields. One study specifically looked at pacemaker interference under a 400kV AC transmission line (Korpinen et al. 2012). A disturbance was noted for only one device (a unipolar pacemaker) out of the 31 different types of pacemakers tested (in an electric field of 6.7–7.5kV/m and magnetic field of 24–29 mG). The pacemaker disturbance set the pace to 60 times per minute, and when the same pacemaker was configured with a bipolar lead, no disturbance was observed. The study concluded that the risk of disturbance was not deemed to be high.

The American Heart Association website lists devices with risk for pacemakers (AHA 2012), including anti-theft systems, security metal detectors, cell phones, MP3 players, and welding equipment. However, AC transmission lines are not included in the list. For implantable cardioverter defibrillators, the American Heart Association website lists low voltage power lines (typical in residential areas) as devices with little or no risk to implantable cardioverter defibrillators (ICDs) (AHA 2013).

The biological consequences of brief reversible pacemaker malfunction are mostly benign (typically the implanted device will resume a normal mode of operation if the patient moves away from the source of the interference) (Medtronic 2013a; Korpinen et al. 2012). An exception would be an individual who has a sensitive pacer and is completely dependent on it for maintaining all cardiac rhythms. For such an individual, a malfunction that compromised pacemaker output or prevented the unit from reverting to the fixed pacing mode, even brief periods of interference, could be life-threatening. The precise coincidence of events (i.e., pacer model, field characteristics, and biological need for full function pacing) would generally appear to be a rare event.

The European Committee for Electrotechnical Standardization (CENELEC) recently developed specific procedures to assess potential risks to workers with active implantable medical devices (CENELEC 2010). CENELEC has determined that these devices are expected to function without interference below a reference level of 1,000mG at 50Hz for magnetic fields (833mG at 60Hz, the frequency of the electric power system in the United States).

Medical equipment certified by the U.S. Food and Drug Administration must pass rigorous electromagnetic compatibility testing to gain approval. This assessment allows manufacturers to evaluate the compatibility performance of a medical device and demonstrate that the product achieves an appropriate level of electromagnetic immunity in environments that patients may encounter. Three of the major manufacturers of implantable medical devices recommend limits for AC electric and magnetic fields (Medtronic 2013b; Boston Scientific 2015; St. Jude Medical 2014). These three manufacturers recommend a power-frequency AC magnetic field limit in the range of 800mG to 1,600mG (depending upon the manufacturer and type of implanted device) and AC electric fields of 6 to 11.7kV/m. By comparison, the calculated EMF levels from the proposed transmission lines would be well below these levels outside of the ROW. Within the ROW, AC magnetic fields would also be below these levels. Calculated AC electric fields within the ROW range from 4.6kV/m to 10.2kV/m, depending on line voltage and configuration. These AC electric field levels are at the recommended limits from these three manufacturers.

In addition, electric fields are very easily shielded. Electric fields would generally be shielded levels (i.e., lower levels) except directly underneath the line in open areas. Riding in a vehicle, for example, the metallic body of the vehicle would provide electric field shielding for occupants inside the vehicle. Over the past decade or so, major manufacturers of pacemakers and other implantable medical devices have designed these devices to provide shielding and improved filtering from the different types of EMF that arise from many sources in our daily environments. Modern pacemakers are digital devices that are designed to filter out peripheral electrical signals and these electrical filters increase the pacemaker's ability to distinguish extraneous signals from legitimate cardiac signals. In addition, most of the pacemaker circuitry is enclosed within a metallic case that shields the device from external EMF. Based on all of these factors, no interference with medical devices would be expected due to EMF from the proposed transmission line. While a variety of electronic devices are known to affect the operation of pacemakers and other implanted medical devices, transmission lines have not been reported as a significant source to produce functional disturbances to these devices. There is a possibility that induced potentials on the leads of these devices by AC electric fields on the ROW could affect the operation of these devices, but the clinical significance of such changes appears small. Patients with implanted medical devices should observe certain precautions and need to discuss their treatment with their doctor or physician. In addition, there are a variety of different medical devices which are constantly evolving and changing. It is also impossible to quantify all of the various types of magnetic field sources encountered in people's day-to-day lives. The potential for interference to implanted devices may depend upon a variety of different parameters, including the device manufacturer, model and setting, and implantation method, among other factors. Typically implanted medical devices are set specifically for an individual by their doctor or physician within the doctor's office or medical facility. As with any implanted medical device, the user should always consult with their doctor and the device manufacturer to determine safe operational parameters for use of their specific medical device and associated medical condition.

Currently, there has been little research done on the subject of spinal cord stimulators (neurostimulation systems) and the results are mixed. EPRI reports that "there remains a paucity of information on EMI (electromagnetic interference) and neurostimulators in the literature" (EPRI 2013a). Common EMI are security systems, metal detectors, and wireless equipment. The Southern Surgical Hospital Louisiana (SSHLA 2015) states: "be mindful of high voltage power lines and other DC sources". Barrow, a neurostimulator manufacturer, says that: "yes, it is safe to be near power lines and substations" (Barrow 2015). The organization Power Over Our Pain references a device manufacturer (St. Jude Medical 2015) that states: "high voltage power lines may generate sufficient EMI to interfere if approached too closely; use caution and turn off the IPE if you feel any unusual sensations".

Manufacturers also report that "Implanted neurostimulation systems may adversely affect the operation of implanted cardiac demand pacemakers and cardioverter defibrillators" and that "an implanted cardiac device (e.g., pacemaker, defibrillator) may damage a neurostimulator" (Medtronic 2013c; St. Jude Medical 2015). One manufacturer provides information on how to approach strong EMI environments (such as a security screening device) for patients with a neurostimulator (Medtronic 2008) and states that many newer models of neurostimulators are not affected by such devices.

Some types of implanted medical devices (such as metallic stents, joint/metal replacements, etc.) do not incorporate electronic or electrical circuits and do not require power to operate. To date, no adverse interactions related to EMF exposure and metallic implants have been reliably reported or documented.

Hearing aids are another type of medical device used by people. Older hearing aids are analog and amplify all sounds in the same way. Digital hearing aids convert sound waves into digital signals using computer chips with complex amplification processing and are the most popular form of hearing aid today (FDA 2015a). Different styles of digital hearing aids include behind-the-ear, on-the-ear, in-the-ear, in-the-canal, and completely-in-the-canal designs. Other features include a telephone coil ("T-coil") setting to switch from the normal microphone setting to a setting that utilizes a coil to eliminate environmental sounds and allow better hearing during telephone conversations. Digital hearing aids operate within a frequency range of 250Hz–8kHz, which is higher than power frequency (60Hz). Interference has been observed with digital hearing aids and higher frequency sources such as cellular phones (FDA 2015b) and radar (WHO 2015). For the Project HVDC transmission line, DC magnetic field levels would be comparable to the earth's natural static magnetic field and should not create an interference issue. For AC magnetic fields, one case study (McKinnon 1994) identified power-frequency ground current on water and steam pipes which created interference only while using the T-coil setting on digital hearing aids (i.e. no interference was reported while using the normal setting). While similar issues could be present near AC transmission lines, switching from the T-coil setting to the normal setting could eliminate the interference issue. Medical devices such as digital hearing aids are constantly being redesigned and improved to be less susceptible to interference issues.

3.4.11.2.1.2.2.9 Overview of AC Electrical Effects Research on Plant and Animal Health

Research has been conducted to determine whether exposure to power-frequency AC electric and magnetic fields has environmental effects on plant or animal life. Numerous studies have examined the effect of power-frequency electric and magnetic field exposure on plant species, both forest and agricultural. For trees located near very high voltage transmission lines (above 1,200kV), needle burn occurred on trees within 100 feet of the transmission lines (these 1,200kV lines are much higher in voltage than the 345kV and 500kV lines associated with the Project). Other studies of seed germination, seedling growth, seed production, and biomass found no adverse effects due to AC electric and magnetic field exposure. Results from studies on some groups of animals did not report any effect due to electric or magnetic fields, while other studies found mixed results, with some studies indicating an effect due to electric or magnetic fields while others did not. These results were therefore inconsistent and inconclusive.

The following discussions report on various study results concerning electrical effects and their conclusions:

- Numerous studies have examined the effect of AC electric and magnetic field exposure on plant species, both forest and agricultural. Needle burn occurred on trees within 100 feet of very high voltage (above 1,200kV) transmission lines (Rogers et al. 1984). Other studies of seed germination, seedling growth, seed production, and biomass found no adverse effects due to AC electric and magnetic field exposure (Lee et al. 1996).
- The National Grid website presents the results on farm crop studies and AC transmission lines reviewed during a 1991 study (National Grid 2014b). Seven studies had findings of either no effects (five studies) or low yields and reduced germination rates in a minority of the tests (two studies). Similar effects were also reported for electric and magnetic fields and farm animals. Of eight studies, six studies reported no effects, one study reported no

major effects (but various minor effects), and one study reported some effects (National Grid 2014a). Overall, the majority of these studies found that generally there were no effects on crops or animals.

- Because of the shielding effects of trees, shrubs, grass, and the soil, ground-dwelling and underground species are largely shielded from AC electric fields under transmission lines (Deno and Silva 1987). Larger species of animals such as deer, elk, and domestic animals may have greater potential exposure to electric fields. Magnetic field exposure is unaffected by these shielding factors and all plant and animal species would experience greater exposure in the vicinity of transmission lines.
- Domestic animals grazing near transmission lines are subject to potentially higher levels of AC electric and magnetic field exposure than large game species. Two studies (Algers and Hennichs 1985; Algers and Hultgren 1987) compared the reproductive functions of pregnant cows exposed to 50Hz AC fields with unexposed animals and found no effect. Two studies (Goodwin 1975; Picton et al. 1985) monitored the behavior of big game species near a 500kV transmission line. Neither study found any effect due to AC electric or magnetic fields. In fact the Goodwin study states: "…the presence of the towers and the levels of audible noise and electric and magnetic fields recorded on the right-of-way did not influence animal behavior".
- AC electric and magnetic field effects on cellular functions in sheep, in particular immune response, have also been examined (Hefeneider et al. 2001). In a previously unpublished report, these researchers noted differences in the production of leukocyte proteins between exposed and control groups. In a replicated effort, sheep were subjected to much longer periods of electric and magnetic field exposure but found no evidence of differences in immune response.
- The studies of cows performed at McGill University in Quebec (Burchard et al. 1996, 1998, 2004) were controlled experiments designed to mimic the exposures of cows standing continuously under a 735kV AC transmission line to determine whether EMF exposure caused a biological response in dairy cows that affected milk fat percentage, dry matter intake, blood progesterone, reduction of melatonin, or changes to milk production. Two groups of eight cows were continuously exposed to 10kV/m AC electric fields and 300mG AC magnetic fields for about thirty days. The researchers concluded that EMF did cause some biological response in productivity variables for the dairy cattle, but these responses did not represent a health hazard for exposed cattle and recommended further research (Burchard et al.1996, 1998, 2004). Figure 3.4-22 presents a photograph of cows grazing under a high voltage transmission line.
- Avian species are exposed to AC electric and magnetic field during flybys of transmission lines and nesting or roosting in their vicinity. A study by Fernie et al. (2000) reported that continuous AC electric and magnetic field exposure reduced hatching and fledging success, reduced embryonic development, and increased egg size. These researchers also found effects of continuous, extended electric and magnetic field exposure on the body mass and food intake of reproducing falcons and altered melatonin levels in male falcons. However, another study of embryonic development (Beaver et al. 1994) showed no adverse impacts of magnetic field exposure. After a review of AC electric and magnetic field from transmission lines and avian species, another study (Fernie and Reynolds 2005) concluded that electric and magnetic field can affect birds but the results are not consistent or even in a consistent direction.
- Research on AC electric and magnetic field and melatonin levels in seasonal breeding species has produced inconsistent results (Wilson et al. 1981; Holmberg 1995; Kroeker et al. 1996; Vollrath et al. 1997; and Huuskonen et al. 2001). An examination of sheep and cattle exposed to electric and magnetic field from transmissions lines above 500kV showed no effect on hormone melatonin levels (Stormshak et al. 1992; Lee et al. 1993, 1995; Thompson et al. 1995; Burchard et al. 1998, 2004).

- Beehives exposed to AC electric fields of 7kV/m compared to unexposed hives were found to have adverse effects on the colonies including decreased hive weight, increased mortality, loss of the queen, and a decrease in the hive's survival (Greenberg et al. 1981). These effects were caused by induced currents and micro-shocks from the electric field, and eliminated by shielding the hive, using hives without metallic parts, or placing the hive farther away from the transmission line.
- A study of native bees was performed near high voltage AC transmission lines in Maryland, Wisconsin, and Oregon. The study evaluated larval development, floral visitation, pollination, species' diversity and abundance. No indication of negative impacts of EMF was found in any of the study areas and there continues to be no credible evidence that native bee species are harmed by EMF in terms of foraging, nesting, or behavior (Russell et al. 2013).
- A study on cattle and deer herds reported that the animals preferentially aligned themselves along the geomagnetic axis (Begall et al. 2008). Satellite images were used to obtain alignment data for herds over various regions of the earth. A second study from the same research team (Burda et al. 2009) reported this alignment was not observed for herds near AC transmission lines. However, an independent research group (Hert et al. 2011) was unable to confirm the results using the same satellite-based images. Two different statistical evaluation methods (one evaluation method tried to replicate the original study and the second tried an improved method) did not replicate the same findings.

Figure 3.4-22: Cattle Grazing Underneath a High Voltage Transmission Line

Several laboratory and field studies have investigated the potential effect of electric and magnetic fields from transmission lines on plants, such as agricultural crops, trees, and forest and woodland vegetation. No adverse biological effects were consistently observed, and none have been confirmed at exposure at levels similar to those of the Project. Other research on the health, behavior, or productivity of animals, including livestock (e.g., dairy cows, sheep, and pigs) and a variety of other species (e.g., small mammals, deer, elk, birds, and bees) has not identified any reliable effects at the field levels associated with the Project. This section was intended to provide a review of many of the relevant scientific studies which have been published and is not meant to be a comprehensive review of the entire body of evidence (many other scientific studies have been performed). Based upon a comprehensive review of the scientific literature, the association between AC magnetic fields and adverse effects to plant life and animal health is weak.

3.4.11.2.1.2.2.10 Grounding and Stray Voltage for AC Fields

Electric currents can be induced by EMFs in conductive objects near AC transmission lines. For magnetic fields, the concern is for very long objects parallel and close to the line. The majority of concern is about the potential for small electric currents to be induced by electric fields in ungrounded metallic objects very close to transmission lines. Metallic roofs, vehicles, vineyard trellises, and fences are examples of objects that can develop a small electric charge in proximity to high-voltage transmission lines. Object characteristics, degree of grounding, and electric field strength affect the amount of induced charge. An electric current can flow when an object has an induced charge and a path to ground is presented. The amount of current flow is determined by the impedance of the object to ground and the voltage induced between the object and ground. It is important to evaluate the amount of induced current that can flow because of the potential for nuisance shocks to people and animals.

Agricultural operations can occur on or near a transmission line ROW. Long fences parallel to a transmission line can present an induced current situation, especially if the fence posts are non-metallic and insulate wires from ground. This problem is solved by adequately grounding the fence with a ground rod connected to the fencing wire (usually done during power line construction or by using metal fence posts). Electric company engineers typically provide grounding guidelines for objects, including fences, close to high-voltage transmission lines.

Irrigation systems often incorporate long runs of metallic pipes that can be subject to field induction when located parallel and close to transmission lines (BPA 2007). Electric field induction is generally negligible because the irrigation pipes contact moist soil, but annoying currents could still be experienced from electric field coupling to the pipe. However, caution should be used in storing, handling, and installing irrigation pipe near power lines. While moving irrigation pipe under or near power lines, equipment should be kept in a horizontal position to keep away from the overhead wires (never oriented vertically toward the wires). Pipe runs laid at right angles to the transmission line will minimize induced currents, although such a layout may not always be feasible. If there are induction problems, they can be mitigated by grounding and/or insulating the pipe runs. For example, the possibility of nuisance shocks can be eliminated by having metallic pipes touching ground or by the use of grounding straps for activities such as unloading sections of pipe from a vehicle.

Operation of irrigation systems beneath transmission lines presents another safety concern. If the system uses a high-pressure nozzle to project a stream of water, the water may make contact with the energized transmission line conductors. Generally, the water stream consists of solid and broken portions. If the solid stream contacts an energized conductor, an electric current could flow down the water stream to someone contacting the high-pressure nozzle. Transmission line contact by the broken-up part of the water stream is unlikely to present any hazard. Guidance on safe operation of irrigation systems near transmission lines can be provided by electric utility engineers.

Contact current impacts can also be a source of concern regarding potential effects on animal health and productivity. These impacts can result from two different and separate situations: stray voltage and induced currents. The term “stray voltage” is often loosely used but generally describes a voltage between two objects where no voltage difference should exist. Small voltages can sometimes be measured between two grounded objects in different locations due to current in a grounding system. Larger voltages can be on enclosures of electrical equipment due to induced voltage or failure of insulation systems. Effects of stray voltage can occur, for example, when an animal makes contact between two different electrical system grounds (such as an on-farm neutral and an off-farm neutral). Commonly accepted sources of stray voltage on a farm include a variety of internal electrical wiring problems, as well as non-farm related problems (such as high resistance wires and connections within the lower voltage local electric distribution system). Small stray voltages may never be noticed and may be difficult to detect. Larger voltages can have impacts from barely perceptible to nuisance electric shocks. Metal electrical equipment cases are bonded to ground to prevent a shock hazard if energized conductors accidentally contact the case. In situations where this bonding is not provided or has failed, a potentially dangerous hazard of electric shock exists when energized conductors contact the case. In any place where equipment is in direct contact with a person or animal (such as electric milking machines and other conditions), stray voltages must be removed. Typically, high voltage overhead transmission lines themselves do not create stray voltage problems.

Stray voltage due to electrical systems and wiring should not be confused with induced currents, where small electric currents are induced by the electric field of a high-voltage transmission line. In this latter case, a voltage difference could be created, for example, by the electric field and different grounding between two objects. This situation can be resolved by relocating objects or animals away from under a high-voltage line, grounding conductive objects, and/or possibly shielding an area (such as a chicken wire canopy) to reduce the electric field strength locally within that area. In some rare cases, a distribution line built directly under and parallel to a high-voltage transmission line could become a source of elevated primary neutral currents. This induced current could result in high enough neutral to earth voltages that in turn might contribute to an excess of acceptable current in a cow contacting an area on an adjoining farm.

Livestock have a threshold for the perception of electrical effects. For example, in Wisconsin the “level of concern” for a cow is defined as 2 mA AC rms steady-state or 1 volt AC rms steady state (PSCW 1996). The level of concern is not a damage level but a very conservative pre-injury level, below the point where moderate avoidance behavior is likely to occur and well below where a cow’s behavior or milk production would be harmed. This finding coincides with a USDA report that states 1.0mA is the lowest threshold at which the most sensitive cows perceive shock, that levels of 1.0 to 3.0mA have no effect on milk production, a moderate behavioral response will occur at 3.0 to 6.0mA, and severe response occurs above 6.0mA (USDA 1991). Other studies have examined whether transmission line-induced currents disturb animals (IEEE 1985). One study indicated that the power-frequency current induced in a cow present in a 10kV/m field is about 0.25mA. This level of current passing through the animal’s tongue during drinking would not exceed the animal’s apparent reaction threshold. Pigs and sheep have been found similarly insensitive to the currents induced by such a field. Another study of farm animals near 745kV transmission lines was performed to determine the effects, if any, of EMFs (Amstutz and Miller 1980). This 2-year study on 11 livestock farms (beef cattle, dairy cattle, swine, and sheep) concluded that none of the farm operators indicated that they observed any health problems caused by the 765kV line.

However, another study of cattle in 1982 found that there are slight but detectable changes in cattle location patterns near energized power lines (Rogers et al. 1982). This study showed a pattern of decreased cattle use near the power line; however, it was not clear whether these changes were in response to the energized power line itself or some related factor (such as audible noise associated with the power line, perception of electric fields through hair stimulation, electric shocks to the animals from grounded objects, or simply a response to possible uneven forage production patterns over time). Overall, numerous studies have been performed related to possible EMF effects on various animals, and no consistent detectable effect has been found on, for example, health, milk production, fertility, behavior, and carcass quality. While the results of the health assessments are unclear, the interaction with induced currents would be considered an adverse impact of the proposed Project.

Besides agricultural operations and farms, electric transmission lines often share utility corridors with pipelines. In these situations, transmission line electrical effects are generally analyzed so that measures can be taken to control the induced voltage on a pipeline to meet the National Association of Corrosion Engineers guideline (NACE 2007). If an electric transmission line route parallels a pipeline, engineers for the Applicant would conduct field investigations to determine any potential safety issues or other design requirements that may result from the presence of the pipeline. The Project would then address those requirements as a part of the detailed transmission line design, including consultation with the pipeline company to determine design requirements specifically related to the presence and location of the pipeline. Crossings of pipelines by electric transmission lines are also commonplace, but are even less of a concern because of the weak magnetic-field coupling of the two systems.

Engineering constraints and obstructions, including oil and gas infrastructure, are also commonly encountered and routinely dealt with during the routing and engineering design processes for electric transmission lines. Oil and gas wells have been identified within the 1,000-foot-wide ROI. The transmission line would be designed using adequate minimum clearances so as to not restrict the movement of oilfield equipment, such as drilling rigs, workover rigs, vacuum tracks, tank trucks, and other equipment necessary to operate the oil field facilities. EPM GE-29 states that "Clean Line will work with landowners and operators of oil and gas wells, utilities, and other infrastructure to identify and verify the location of facilities and to minimize adverse impacts. Identification may include use of the One Call system and surveying of existing facilities."

The maximum calculated AC electric field from the Project transmission lines is about 4.6 to 10.2kV/m and 19.4 to 24.3kV/m for DC electric fields, which is above some public and occupational thresholds within the ROW. In this level of electric field, induced currents may create shocks from touching ungrounded metallic objects. Metal buildings and fences on or adjacent to high voltage transmission line easements are routinely grounded during construction.

3.4.11.2.1.2.2.11 Interference to Radio Frequency Equipment

Concerns are sometimes raised that transmission lines may interfere with other communication devices, such as precision agricultural equipment (which utilizes GPS signals), cellular telephones, wireless internet (Wi-Fi/modems/local area networks), computer systems, radio, satellite television systems, and other types of telecommunications equipment. However, these devices all utilize radio frequency signals that are not affected by power lines.

Research has been performed to evaluate the potential for high voltage AC power lines to affect GPS signals (Silva and Olsen 2002). The work involved theoretical analysis of GPS signals in relation to transmission lines and practical measurements at different locations in the United States directly under power lines up to 500kV and including 345kV lines. The results of the theoretical analysis indicated that it is unlikely that high voltage transmission lines can interfere with the GPS satellite signals. Evaluation was made of the potential for interference due to partial blocking of the satellite signals by overhead wires or the overhead conductors, a process called "signal scattering." The analysis showed that interference was not possible because of the small electrical size of the power line conductors relative to a GPS microwave signal wavelength and the relatively large height above ground of electrical wires. Because power line conductors are much smaller than the GPS signal wavelength, little blocking of the signals would occur when they pass around the conductors. Moreover, the conductors are high enough above the ground that any blocking is insignificant. Practical measurements were performed using a precision agriculture GPS receiver underneath the transmission lines. These measurements were performed to determine any changes in positioning accuracy or the strength of the received satellite signals while driving under power lines (both in fair and rainy weather). The practical measurements showed no effect on the received GPS signal strength due to multiple transmission lines, which was expected based on the authors original theoretical calculations.

GPS equipment is constantly improving and manufacturers design their systems for an array of sophisticated applications. In general, high-quality GPS manufacturers supply GPS units that are designed to function in the environment for which they are intended to be used. Since there are over 300,000 miles of high voltage transmission lines in the United States, GPS manufacturers can reasonably anticipate an electric power line as one part of a diverse operating environment for GPS equipment. In addition, there are continuing improvements to the GPS system itself, such as the addition of new and stronger signals for the next generation of satellites, that will enhance reception and performance.

The cell phone industry makes extensive use of GPS. GPS is used for the precise timing standards in the operation of cell phone networks and some cell phone companies use a signal modulation scheme that is similar to GPS. One practical example of successful use of GPS and microwave signals near power lines is the common practice of mounting cell phone base antennas and high accuracy GPS antennas directly onto high voltage transmission line towers throughout North America (Figures 3.4-23 and 3.4-24). This is significant, because the microwave cell phone signals from distant users are received by the base station antennas which are located on towers much closer to high voltage conductors than a tractor on the ground, for example. In addition to cell phone antennas, GPS antennas are also mounted on high voltage transmission line towers as well. The fact that the cell phone industry currently mounts its GPS and cell phone antennas on transmission line towers clearly indicates that power line interference is not a concern for the industry.

Figure 3.4-23: GPS Antennas Used by Cellular Base Stations Mounted Directly on High Voltage Transmission Line Towers

Figure 3.4-24: Examples of Cellular Antennas Installed Directly on High Voltage Transmission Lines

Other research has also been performed on the potential for interference to GPS from high voltage transmission lines, including two studies near two HVDC lines (±450kV and ±500kV) adjacent to a 230kV HVAC transmission line (Pollock and Wright 2011; Bancroft et.al. 2012). Both of these studies support the findings of the previous studies, reporting that AC and DC transmission lines did not create interference with GPS systems.

The Project will not interfere with wireless internet or cellular telephone use. WiFi and local area networks operate using radio frequency signals (2.4 to 5.9GHz range) as does cellular telephones (700MHz to 2.7GHz), and the transmission lines in the Project will operate at a frequency a billion times lower than that of these devices. Line-of-sight can be an issue if a tower structure physically blocks a transmitter and receiver. In these circumstances, either the placement of the transmitter or receiver can be moved locally to a new location where line-of-sight can be reestablished.

As of 2009, broadcast TV transmission (full power) is in digital format and the digital signal is less susceptible to interference than the old analog signal. A Federal Communications Commission study shows that digital signals provide superior immunity to impulse type noise. If TV service is provided by satellite (such as high definition TV or HDTV), the signal comes from space in microwave frequencies (4–18 billion Hz) and no interference would occur from DC or 60Hz transmission line EMF.

3.4.11.2.1.3 Decommissioning Impacts

No electrical effects would be associated with the decommissioning of the converter stations or the AC overhead transmission interconnection lines. Once decommissioned, no electrical energy would be generated that would create electrical effects such as electric and magnetic fields, audible noise, or radio and television interference.

3.4.11.2.2 AC Collection System

This section describes the electrical effects associated with AC transmission line collection system in Oklahoma and Texas. Electrical effects would only be present during operations and maintenance of these facilities. Electrical facilities need to be energized to create electrical effects such as electric and magnetic fields, audible noise, and radio and television interference. Electrical effects would not be present during the construction and decommissioning phases of the Project.

Existing facilities are present along many of the AC collection system routes, some of which already create electrical effects within the environment. Table 3.4-27 presents the number of existing AC transmission lines that parallel the AC collection system routes as well as nearby communication facilities (which are existing radio-frequency sources) within a 1,000-foot-wide corridor for each proposed route alternative. Table 3.4-27 also presents a summary of the number of existing building structures (residences, agricultural buildings, churches, and schools) within the same 1,000-foot-wide corridor for each route.

Table 3.4-27:
Occurrence of Existing Facilities along Proposed AC Collection System Routes

AC Collection System Route	Parallels Existing AC Transmission Lines (Quantity and Voltage Range)	Existing Building Structures within 1,000-Foot Corridor (Residential/ Agricultural/Church/School)[1]	Existing Communication Facilities Within 1,000-Foot-WideCorridor (Quantity and Type)[2]
E-1	1 (115kV)	193/207/1/2	3 (CT, AS)
E-2	2 (345kV)	19/73/0/0	0
E-3	0	39/162/0/0	5 (MT, PM, AS)

2 GIS Data Source: FCC (2012)

3.4.11.2.2.1 Construction Impacts

No electrical effects are associated with construction of the AC collection system routes, because these AC transmission lines would not be energized during construction. Electrical facilities must be energized to create electrical effects such as electric and magnetic fields, audible noise, and radio and television interference.

3.4.11.2.2.2 Operations and Maintenance Impacts

There are two different 345kV AC transmission line design configurations associated with the AC collection system in Oklahoma. Both line designs are single circuit configurations (i.e., one single circuit supported on a structure). The monopole line design is supported on a tubular pole, while the other design is a single circuit supported on a lattice structure. Each transmission line configuration is located within a representative 150-foot-wide to 200-foot-wide ROW (the actual ROW width has not yet been determined). Proposed loading for these lines is 570MW (945 amperes) for average loading and 950MW (1,590 amperes) for maximum loading. Figures 3.4-25 and 3.4-26 present dimensioned drawings of the two representative 345kV AC transmission line configurations.

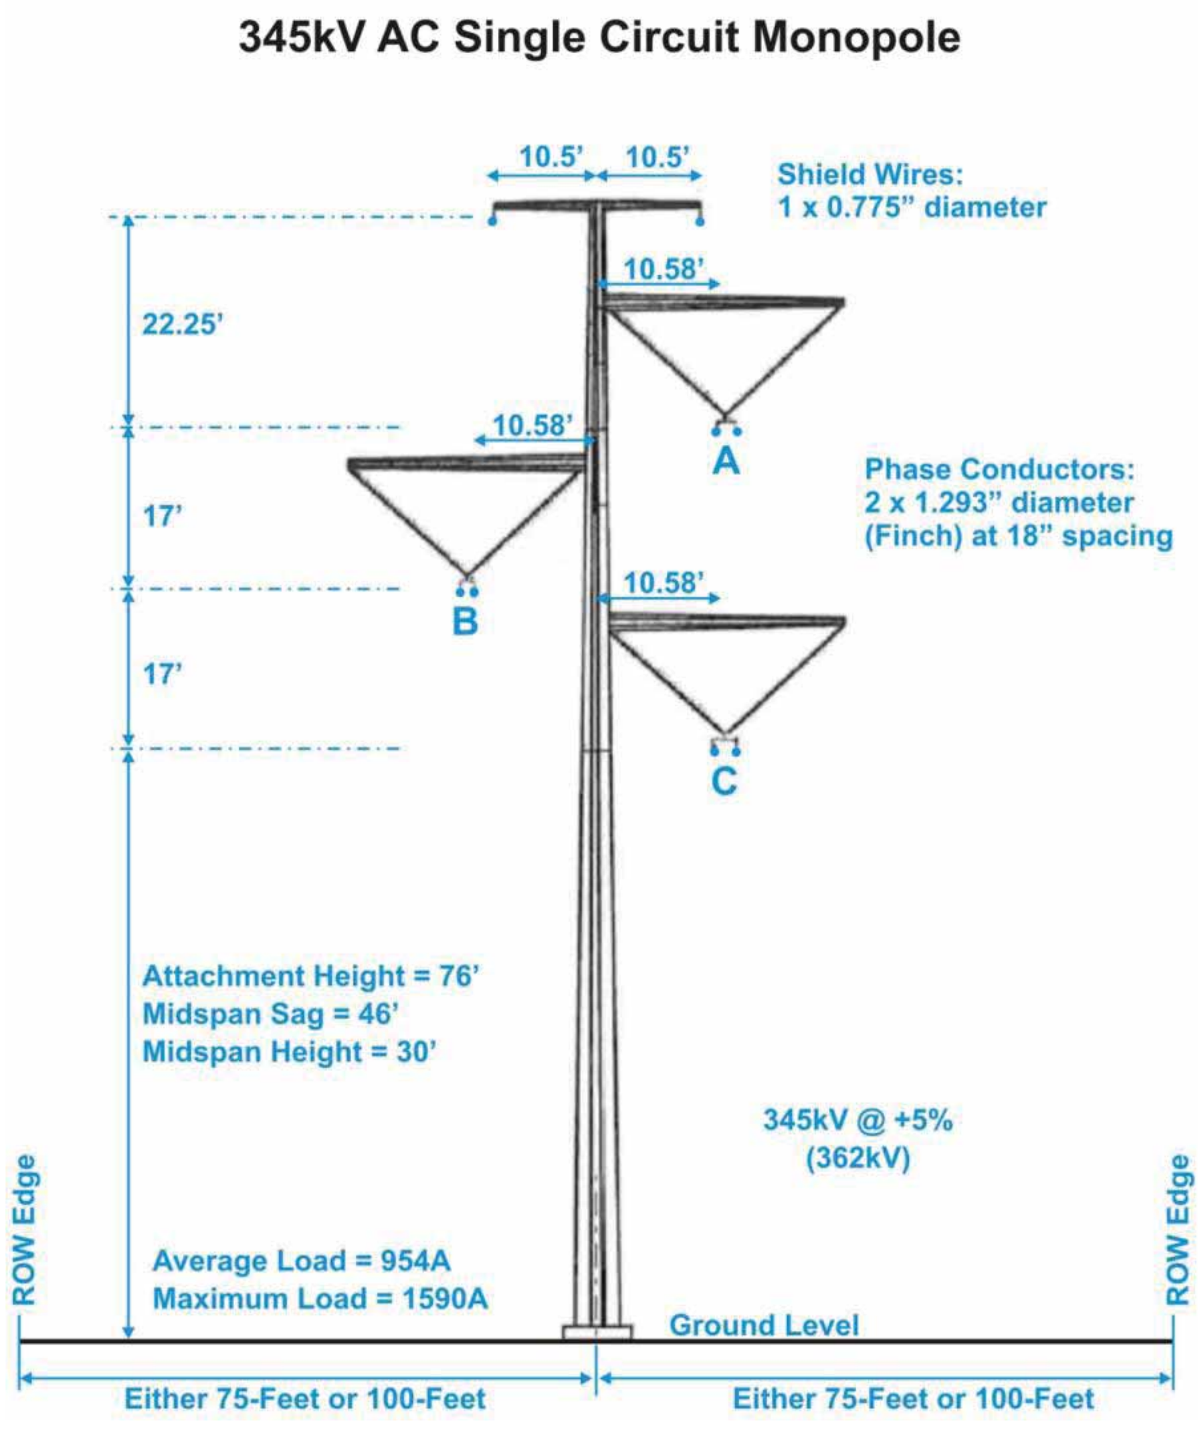

Figure 3.4-25: 345kV AC Transmission Line Single Circuit Monopole Configuration

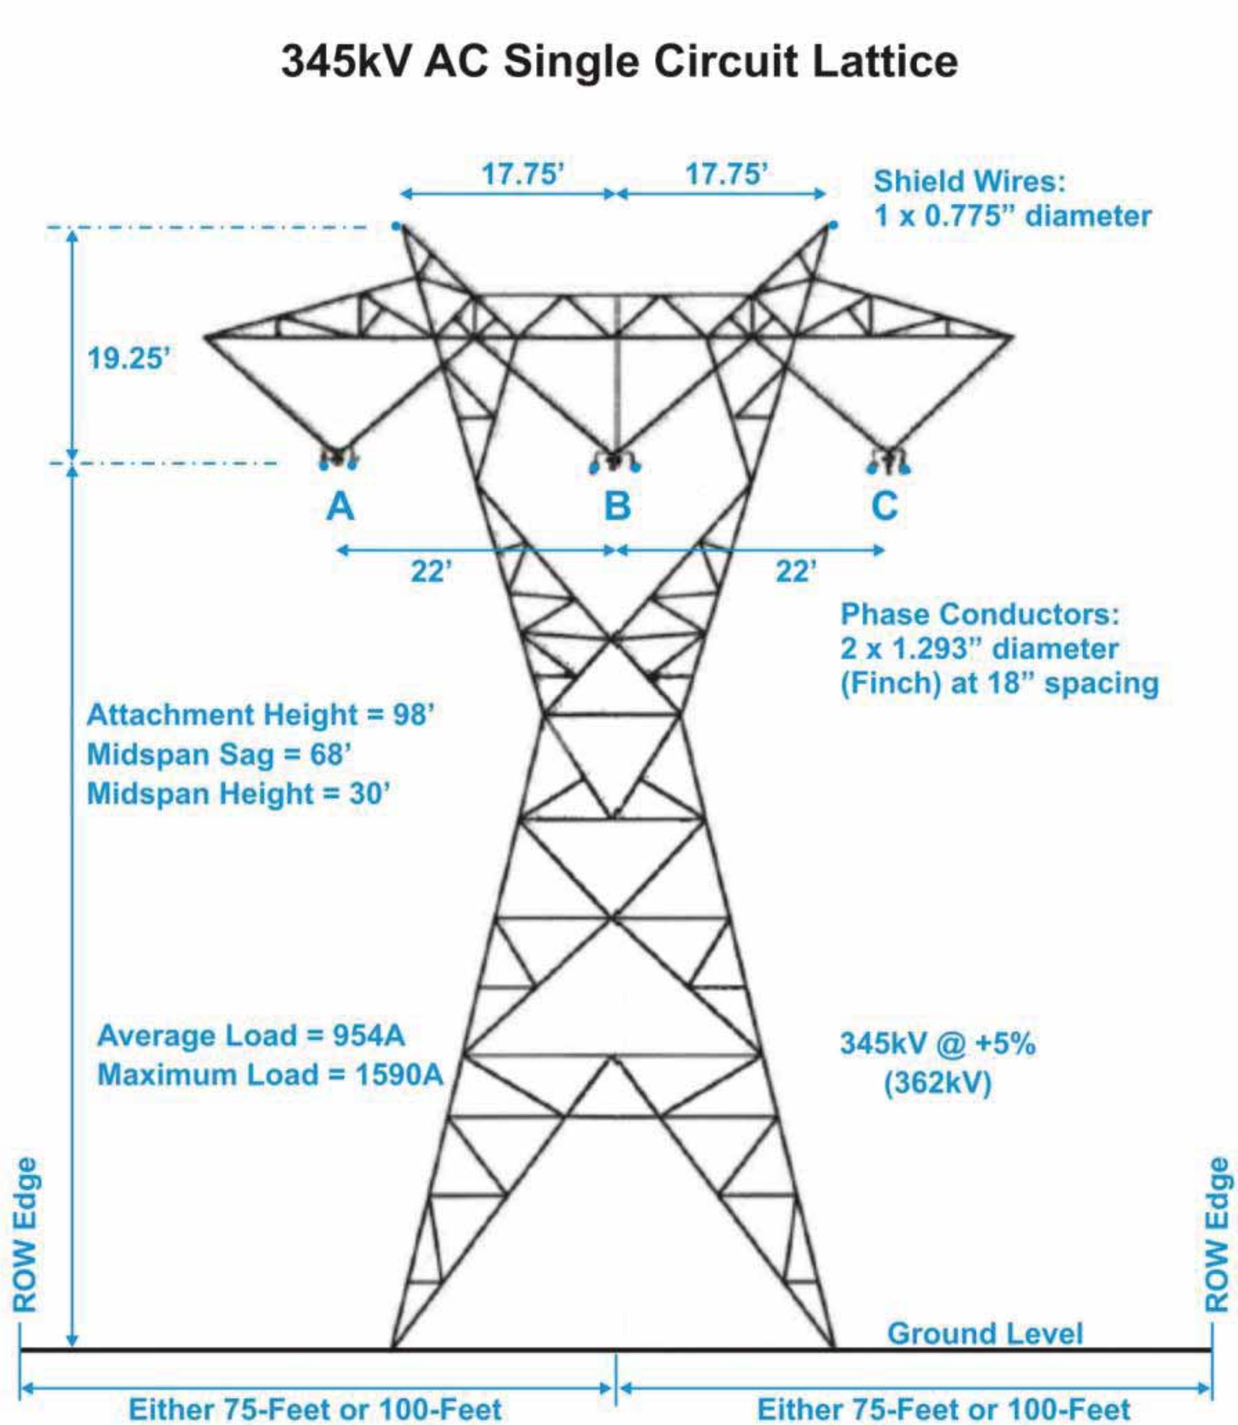

Figure 3.4-26: 345kV AC Transmission Line Single Circuit Lattice Tower Configuration

3.4.11.2.2.2.1 AC Electric Field Calculation Results

AC electric field calculations were performed for the two transmission line configurations. Table 3.4-28 presents a summary of the calculated electric field at the ROW edges and for the maximum field within the ROW. Because the ROW width has not yet been determined, ROW edge values are provided for both possible edge locations (either 75 feet or 100 feet from the transmission centerline). Calculated field levels vary, depending upon the line configuration. Figure 3.4-27 presents a graph of the calculated AC electric field for each line configuration.

Table 3.4-28:
Calculated AC Electric Field Values for 345kV AC Transmission Lines Associated with the AC Collection System Alternatives

345kV AC Transmission Line Configuration	Calculated AC Electric Field (kV/m)[1]				
	-100 Feet from CL	-75 Feet from CL	Maximum on ROW	+75 Feet from CL	+100 Feet from CL
Single Circuit Monopole	0.5	0.8	6.0	0.6	0.4
Single Circuit Lattice	0.6	1.3	6.0	1.3	0.6

CL = Centerline; since the precise ROW width has not yet been determined, the ROI for analysis is 300 feet on either side of a representative centerline.
1 Edges of the ROW have not been established and are assumed to be either 75 feet or 100 feet from centerline.

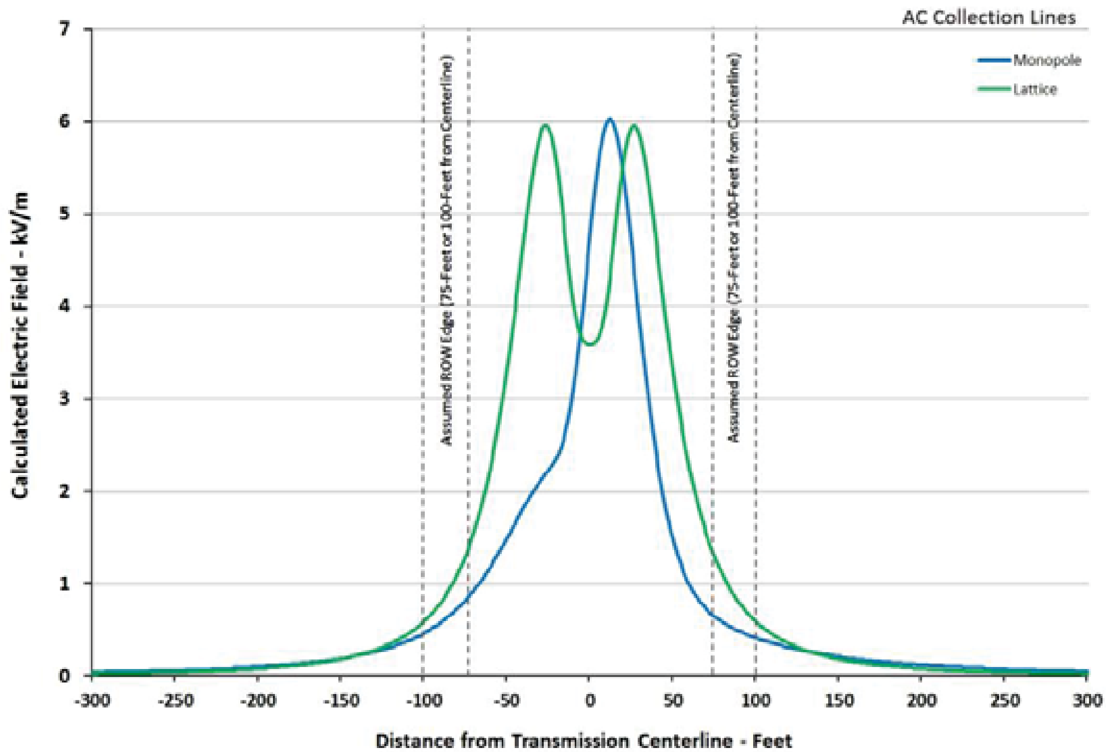

Figure 3.4-27: Calculated AC Electric Fields for 345kV AC Transmission Lines Associated with the AC Collection System

Calculated electric field levels at the ROW edges (either 75 feet or 100 feet from centerline of the transmission line) for both AC transmission line configurations are below the ICES and ICNIRP guidelines for public exposure (5kV/m and 4.2kV/m, respectively). However, the maximum electric field within the ROW exceeds both of these public standards. Within the ROW, however, calculated electric field levels are below the ICES guideline of 10kV/m for a transmission line ROW. Calculated electric fields at the ROW edge exceed the ACGIH guideline of 1kV/m for workers with implanted medical devices for the single circuit lattice configuration if the ROW width is only 150 feet (as opposed to 200 feet).

3.4.11.2.2.2.2 AC Magnetic Field Calculation Results

AC magnetic field calculations were performed for both transmission line configurations under two different loading conditions (average and maximum loading of 945 amperes and 1,590 amperes respectively). Table 3.4-29 presents a summary of the calculated magnetic field at the ROW edges and for the maximum field within the ROW. Calculated field levels vary, depending upon the line configuration and the number of circuits present. Figure 3.4-28 presents a graph of the calculated AC magnetic field for each line configuration under average and maximum loading conditions.

Calculated magnetic field levels at the ROW edges for both AC transmission line interconnection designs are below the ICES and ICNIRP guidelines for public exposure (9,040mG and 2,000mG, respectively). Calculated magnetic field levels within the ROW are also below the ACGIH guideline of 1,000mG for workers with implanted medical devices for both configurations.

Table 3.4-29:
Calculated AC Magnetic Field Values for 345kV AC Transmission Line Configurations Associated with the AC Collection System

345kV AC Transmission Line Configuration	Calculated AC Magnetic Field (mG) for Average/Maximum Load[1]				
	-100 Feet from CL	-75 Feet from CL	Maximum on ROW	+75 Feet from CL	+100 Feet from CL
Single Circuit Monopole	18.3/30.5	28.4/47.3	138.3/230.4	33.0/55.1	20.3/33.9
Single Circuit Lattice	23.1/38.5	40.2/66.9	220.3/367.1	40.7/67.8	23.5/39.2

CL = Centerline; since the precise ROW width has not yet been determined, the ROI for analysis is 300 feet on either side of a representative centerline.

1 Edges of the ROW have not been established and are assumed to be either 75 feet or 100 feet from centerline.

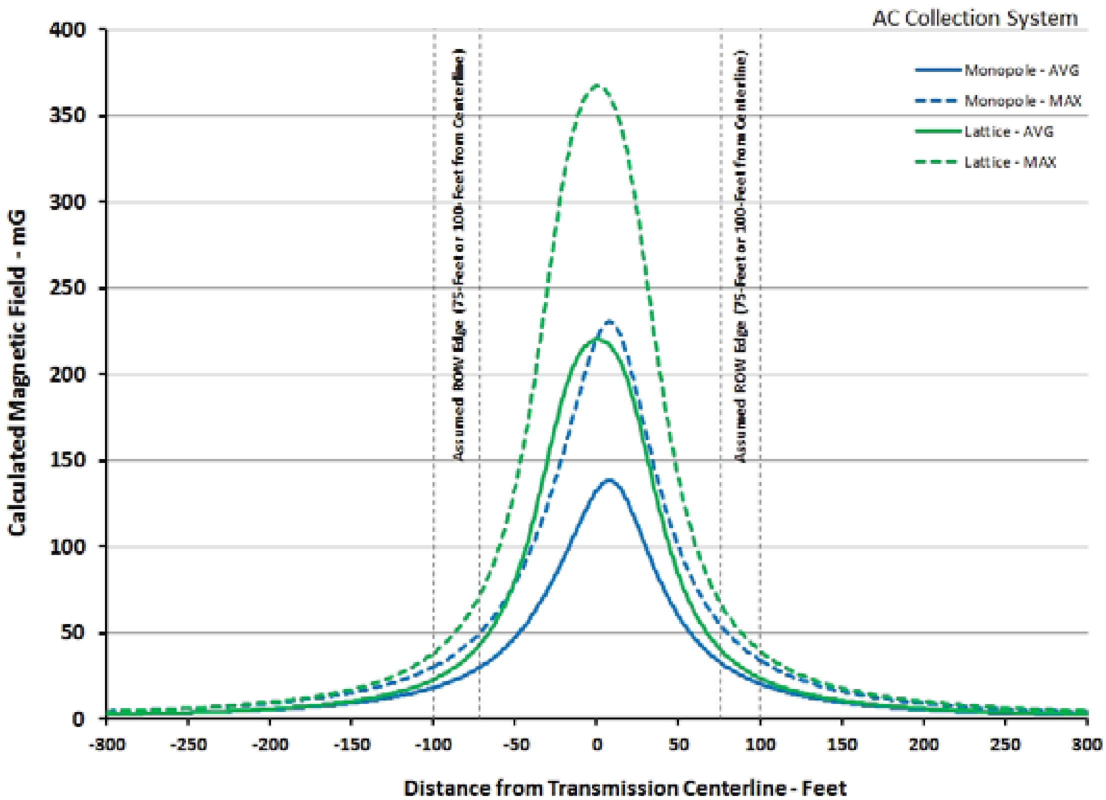

Figure 3.4-28: Calculated AC Magnetic Fields for 345kV AC Transmission Lines Associated with the AC Collection System

3.4.11.2.2.2.3 AC Audible Noise Calculation Results

Audible noise calculations were performed for both AC transmission line configurations. Table 3.4-30 presents a summary of the calculated day-night (L_{dn}) audible noise at the ROW edges and for the maximum noise level within the ROW. Calculated levels vary, depending upon the line configuration. Figure 3.4-29 presents a graph of the calculated audible noise for each AC transmission line configuration.

Table 3.4-30:
Calculated Audible Noise for 345kV AC Transmission Line Configurations Associated with the AC Collection System

345kV AC Transmission Line Configuration	Calculated Audible Noise (dBA)—L_{dn}[1]				
	-100 Feet from CL	-75 Feet from CL	Maximum on ROW	+75 Feet from CL	+100 Feet from CL
Single Circuit Monopole	47.9	48.9	51.6	49.1	48.1
Single Circuit Lattice	50.1	51.2	53.9	51.2	50.1

CL = Centerline; since the precise ROW width has not yet been determined, the ROI for analysis is 300 feet on either side of a representative centerline.

1 Edges of the ROW have not been established and are assumed to be either 75 feet or 100 feet from centerline.

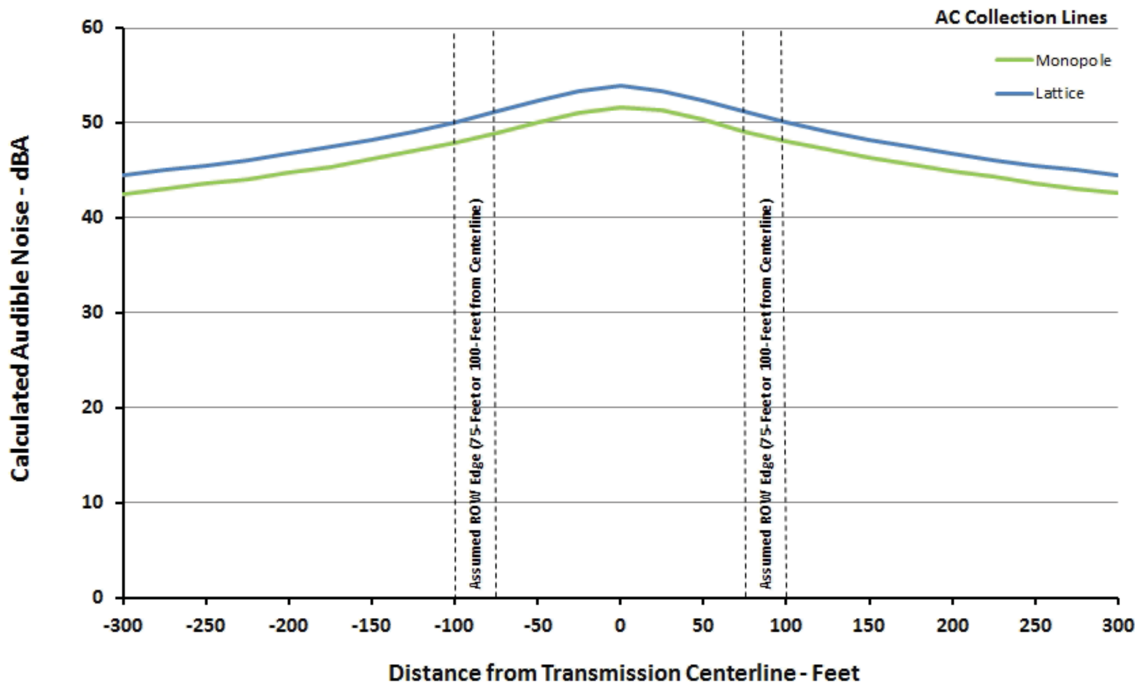

Figure 3.4-29: Calculated Audible Noise Levels (L_{dn}) for 345kV AC Transmission Lines Associated with the AC Collection System

Calculated audible noise levels at the ROW edges (either 75 feet or 100 feet from centerline of the transmission line) for all of the AC transmission line interconnections are below the EPA guideline for L_{dn} (day-night) noise of 55 dBA. Calculated audible noise levels assume a 5 percent overvoltage condition at the highest line elevation (3,000 feet).

3.4.11.2.2.2.4 AC Radio Noise Calculation Results

Radio noise calculations were performed for both AC transmission line designs for rainy and fair weather conditions. Table 3.4-31 presents a summary of the calculated radio noise at the ROW edges and for the maximum noise within the ROW at 500kHz for both weather conditions. Table 3.4-31 also presents calculated 500kHz radio noise at 50 feet from the outside conductor for comparison with the IEEE Standard. Calculated radio noise levels vary, depending upon the line configuration and weather conditions. As shown in Table 3.4-31, calculated radio noise levels at 50 feet from the outside conductor comply with the IEEE 61 dB:V/m threshold in fair weather conditions. Figure 3.4-30 presents a graph of the calculated radio noise levels for each AC line configuration in rainy weather, adjusted to the 500kHz reference level. Figure 3.4-31 presents a corresponding graph of the calculated radio noise levels for fair weather (adjusted to the 500kHz reference level).

Table 3.4-31:
Calculated Radio Noise for 345kV AC Transmission Line Configurations Associated with the AC Collection System Alternatives

345kV AC Transmission Line Configuration	Calculated Radio Noise (dB:V/m) at 500kHz (Rainy/Fair Weather)[1]						
	-100 Feet from CL	-50 Feet from Outside Conductor	-75 Feet from CL	Maximum on ROW	+75 Feet from CL	+50 Feet from Outside Conductor	+100 Feet from CL
Single Circuit Monopole	57.7/40.7	64.9/47.9	61.9/44.9	78.7/61.7	61.1/44.1	64.3/47.3	57.6/40.6
Single Circuit Lattice	56.8/39.8	63.3/46.3	62.5/45.5	81.7/64.7	62.5/45.5	63.3/46.3	56.8/39.8

CL = Centerline; since the precise ROW width has not yet been determined, the ROI for analysis is 300 feet on either side of a representative centerline.

1 Edges of the ROW have not been established and are assumed to be either 75 feet or 100 feet from centerline.

It is difficult to determine whether the radio noise produced by a transmission line or any other source would cause unacceptable interference without knowing broadcast signal strengths at various locations of interest along the possible line routes. Section 3.4.4 presents a discussion on radio noise interference and Section 3.4.6.6 on radio noise standards.

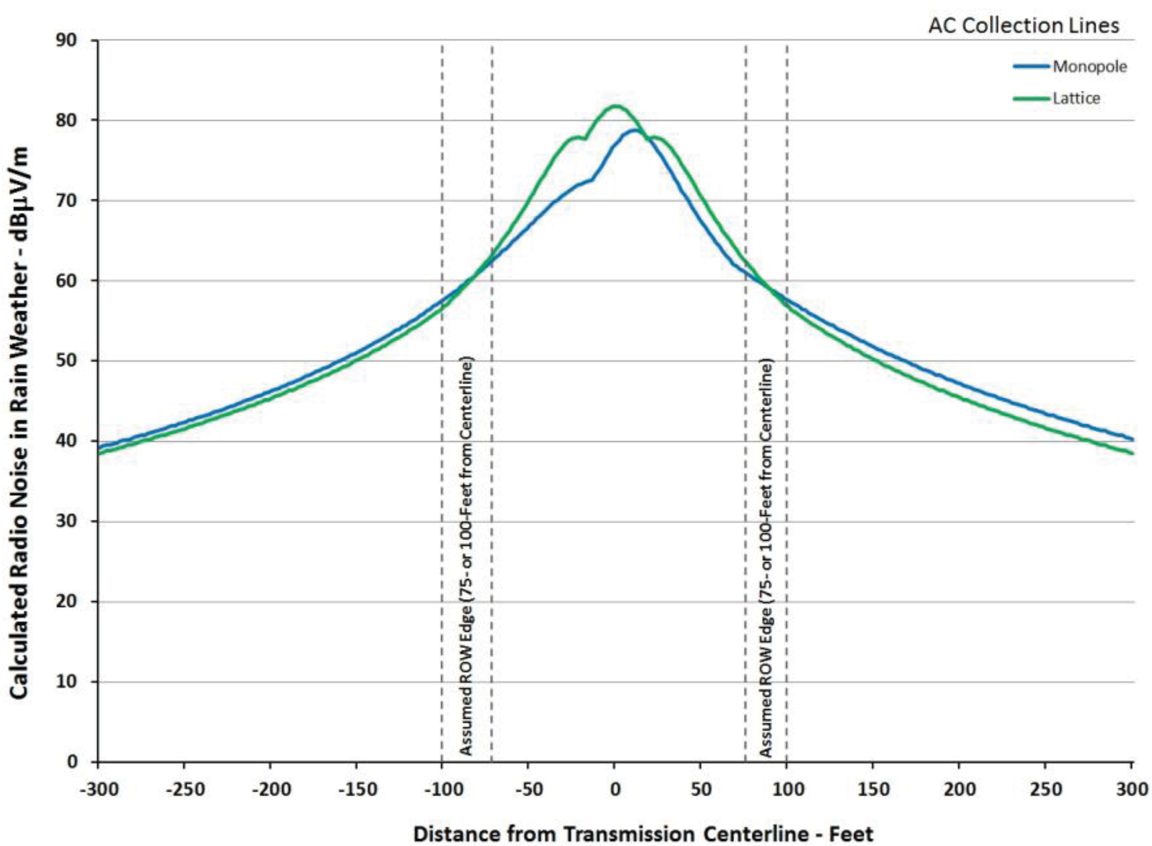

Figure 3.4-30: Calculated Radio Noise for 345kV AC Transmission Lines Associated with the AC Collection System (Rainy Weather)

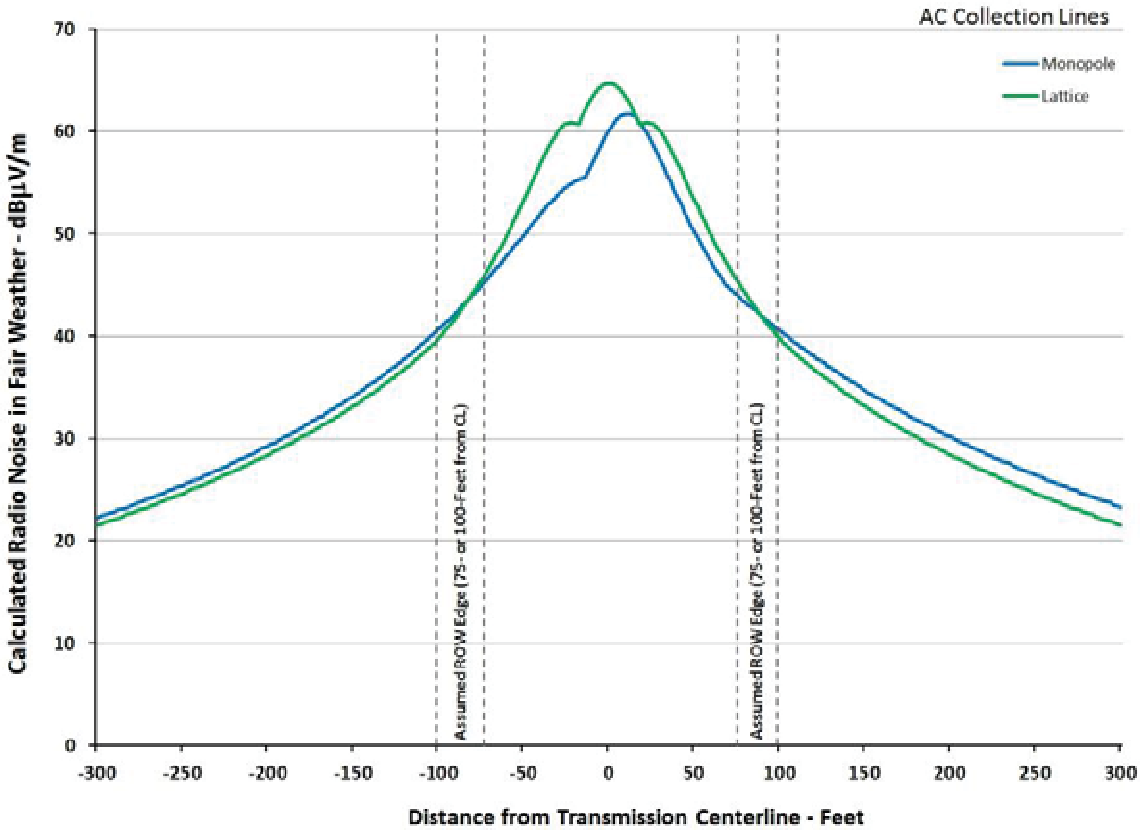

Figure 3.4-31: Calculated Radio Noise for 345kV AC Transmission Lines Associated with the AC Collection System (Fair Weather)

3.4.11.2.2.2.4.1 AC Television Noise Calculation Results

Television noise calculations were performed for both AC transmission line interconnections for rainy weather conditions. Table 3.4-32 presents a summary of the calculated television noise at the ROW edges and for the maximum noise within the ROW for the 75MHz reference level. Calculated television noise levels vary, depending upon the line configuration. Figure 3.4-32 presents a graph of the calculated television noise levels for each AC line configuration in rainy weather.

Table 3.4-32:
Calculated Television Noise for 345kV AC Transmission Line Configurations Associated with the AC Collection System

345kV AC Transmission Line Configuration	Calculated Television Noise (dB:V/m) at 75MHz for Rainy Weather[1]				
	-100 Feet from CL	-75 Feet from CL	Maximum on ROW	+75 Feet from CL	+100 Feet from CL
Single Circuit Monopole	16.8	19.1	31.1	20.7	18.0
Single Circuit Lattice	20.0	22.4	34.1	22.4	20.0

CL = Centerline; since the precise ROW width has not yet been determined, the ROI for analysis is 300 feet on either side of a representative centerline.
1 Edges of the ROW have not been established and are assumed to be either 75 feet or 100 feet from centerline.

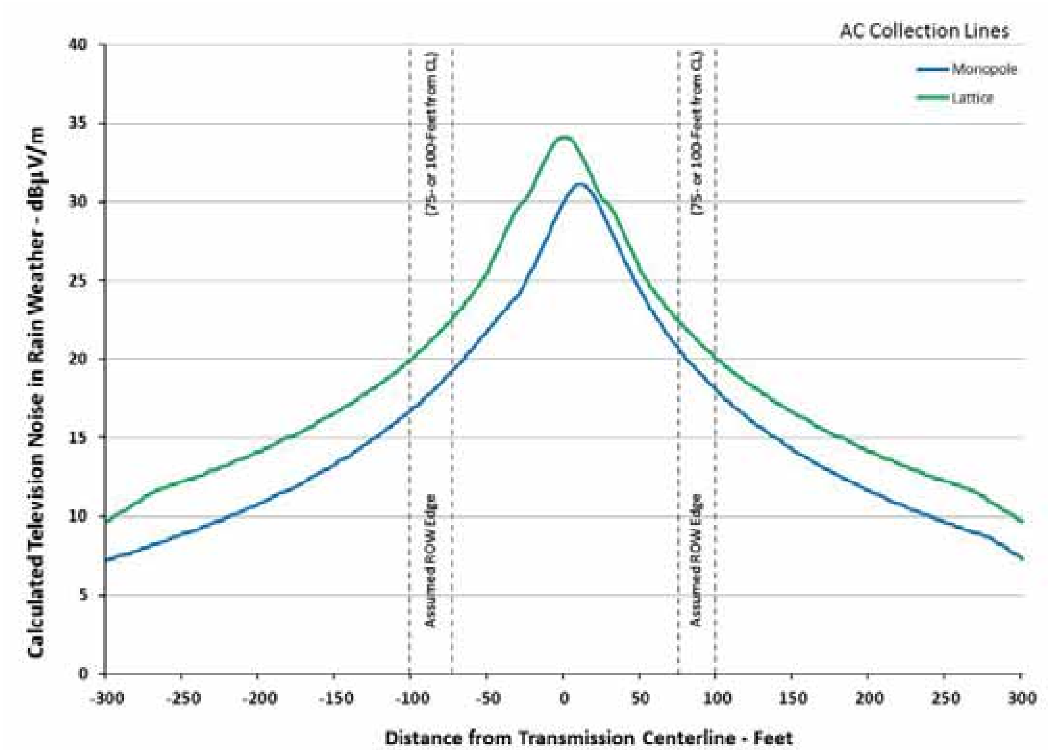

Figure 3.4-32: Calculated Television Noise for 345kV AC Transmission Lines Associated with the AC Collection System (Rainy Weather)

As with radio noise interference, it is difficult to determine whether the television noise level produced by a transmission line would cause unacceptable interference. However, the new digital broadcast system technology for radio and television should provide better coverage and immunity to transmission line noise than analog television signals. No interference resulting from corona-generated noise would be expected for digital signals broadcast at frequencies above 1GHz from satellites (EPRI 2006a).

3.4.11.2.2.2.4.2 Ozone Calculation Results

Ozone levels for both AC transmission line designs were calculated for rainy weather conditions. Table 3.4-33 presents a summary of the calculated maximum ozone concentrations at ground level within 300 feet of the transmission centerline. Maximum ozone levels are far below the EPA standard of 75 ppb for all three line design configurations.

Table 3.4-33:
Calculated Ozone Levels for 345kV AC Transmission Line Configurations Associated with the AC Collection System

AC Transmission Configuration	Calculated Ozone (ppb)
	Maximum within +/-300 Feet of CL
Single Circuit Monopole	0.0
Single Circuit Lattice	0.1

CL = Centerline; since the precise ROW width has not yet been determined, the ROI for analysis is 300 feet on either side of a representative centerline.

3.4.11.2.2.2.5 Summary of Impacts for the AC Collection System

Based on an evaluation of research and guidelines recommended by various agencies, it is unlikely that the AC collection system would pose a known threat to human health (reference Section 3.4.11.2.1.2.2.7). In addition, the likelihood of increased audible noise or interference to AM radio/television reception (due to operation of the line) rising to a level of annoyance is small.

While a variety of electronic devices are known to affect the operation of pacemakers and ICDs, transmission lines have not been reported to produce functional disturbances to these devices. There is a possibility that induced potentials on the leads of these devices by AC electric fields on the ROW could affect the operation of these devices, but the clinical significance of such changes appears small. Persons who are concerned should contact their physician to ascertain the immunity of their device to this potential source of interference.

3.4.11.2.2.3 Decommissioning Impacts

No electrical effects would be associated with the decommissioning of any of the AC collection system. Once decommissioned, no electrical energy would be generated that would create electrical effects such as electric and magnetic fields, audible noise, or radio and television interference.

3.4.11.2.3 HVDC Applicant Proposed Route

Existing electrical facilities (such as overhead transmission lines) are present within each of the proposed transmission routes and regions, some of which already create electrical effects within the environment. Table 3.4-34 presents the number of existing AC transmission lines that parallel the Applicant Proposed Route, as well as nearby communication facilities (which are existing radio-frequency sources) within a 1,000-foot-wide corridor of each Applicant Proposed Route. Table 3.4-34 also presents a summary of the number of existing building structures (residences, agricultural buildings, churches, and schools) within the same 1,000-foot-wide corridor for the Applicant Proposed Route.

Table 3.4-34:
Occurrence of Existing Facilities along the Applicant Proposed Route by Region

Applicant Proposed Route	Parallels Existing AC Transmission Lines (Quantity and Voltage Range)	Existing Building Structures within 1,000-Foot-Wide Corridor (Residential/Agricultural/ Church/School)[1]	Existing Communication Facilities within 1,000-Foot-Wide Corridor (Quantity and Type)[2]
Region 1	4 (69-345kV)	8/24/0/0	0
Region 2	1 (115kV)	26/40/0/0	1 (TV)
Region 3	8 (69-345kV)	114/61/0/0	9 (MT, AS)
Region 4	9 (69-345kV)	151/74/1/0	3 (PM, AS)
Region 5	1 (500kV)	81/41/0/0	0
Region 6	1 (161kV)	26/26/0/0	0

3.4.11.2.3.1 Construction Impacts

No electrical effects would be associated with construction of the Applicant Proposed Route, because the transmission line would not be energized during construction. Electrical facilities need to be energized to create electrical effects such as electric and magnetic fields, audible noise, and radio and television interference.

3.4.11.2.3.2 Operations and Maintenance Impacts

There are two ±600kV HVDC overhead electric transmission line configurations that may be utilized within the seven regions associated with the Applicant Proposed Route: monopole and lattice tower. Figure 3.4-33 presents a diagram of a representative monopole configuration, which is supported on a tubular pole. Figure 3.4-34 presents a diagram of a representative lattice tower configuration. It has not yet been determined which configurations may occur within these regions, so the results of the electrical effects associated with both of these configurations may be applicable to any and/or all of the proposed regions and are therefore assumed to be potentially common impacts to all regions.

Both line designs are bi-polar configurations, located within a 200-foot-wide ROW. Under normal operating conditions, only the main conductor bundles will carry load. However, the HVDC transmission line is designed with two dedicated neutral return (DNR) conductors that could carry load during infrequent situations, such as when a main conductor bundle is de-energized for repair or maintenance. For each of the two transmission line designs (monopole and lattice tower), two different operating conditions were therefore modeled (standard/typical conductor load flow and DNR load flow on both return wires for one polarity).

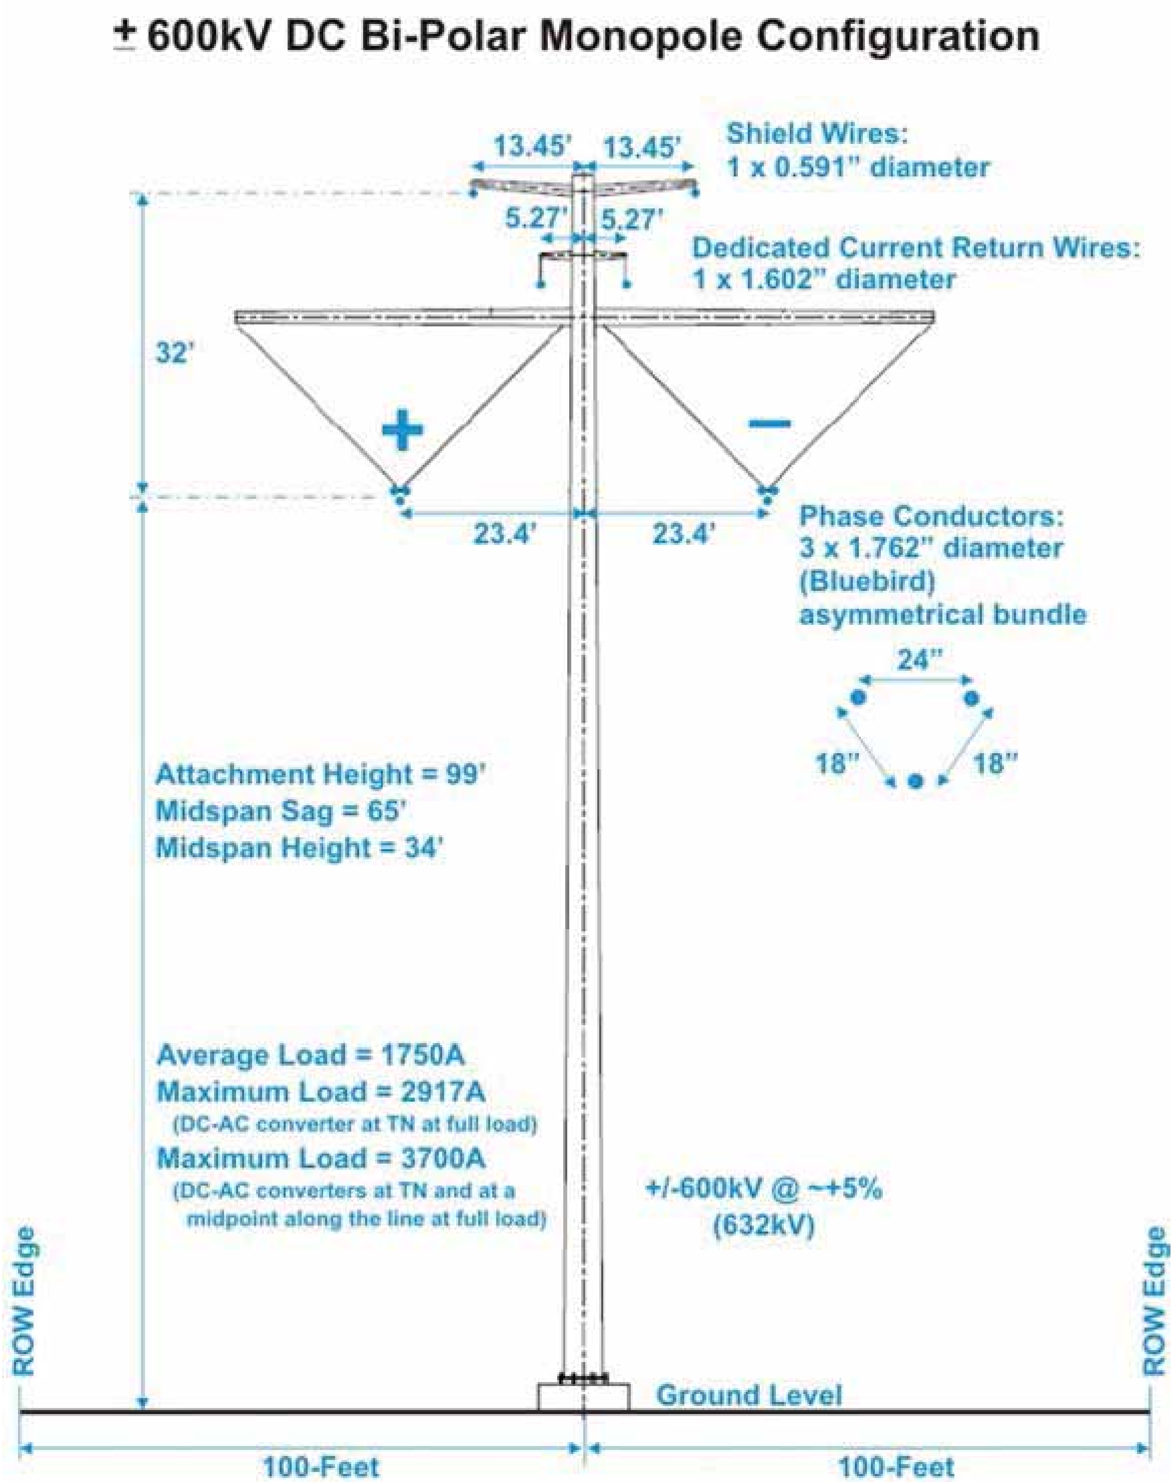

Figure 3.4-33: Proposed ±600kV HVDC Transmission Line Monopole Configuration

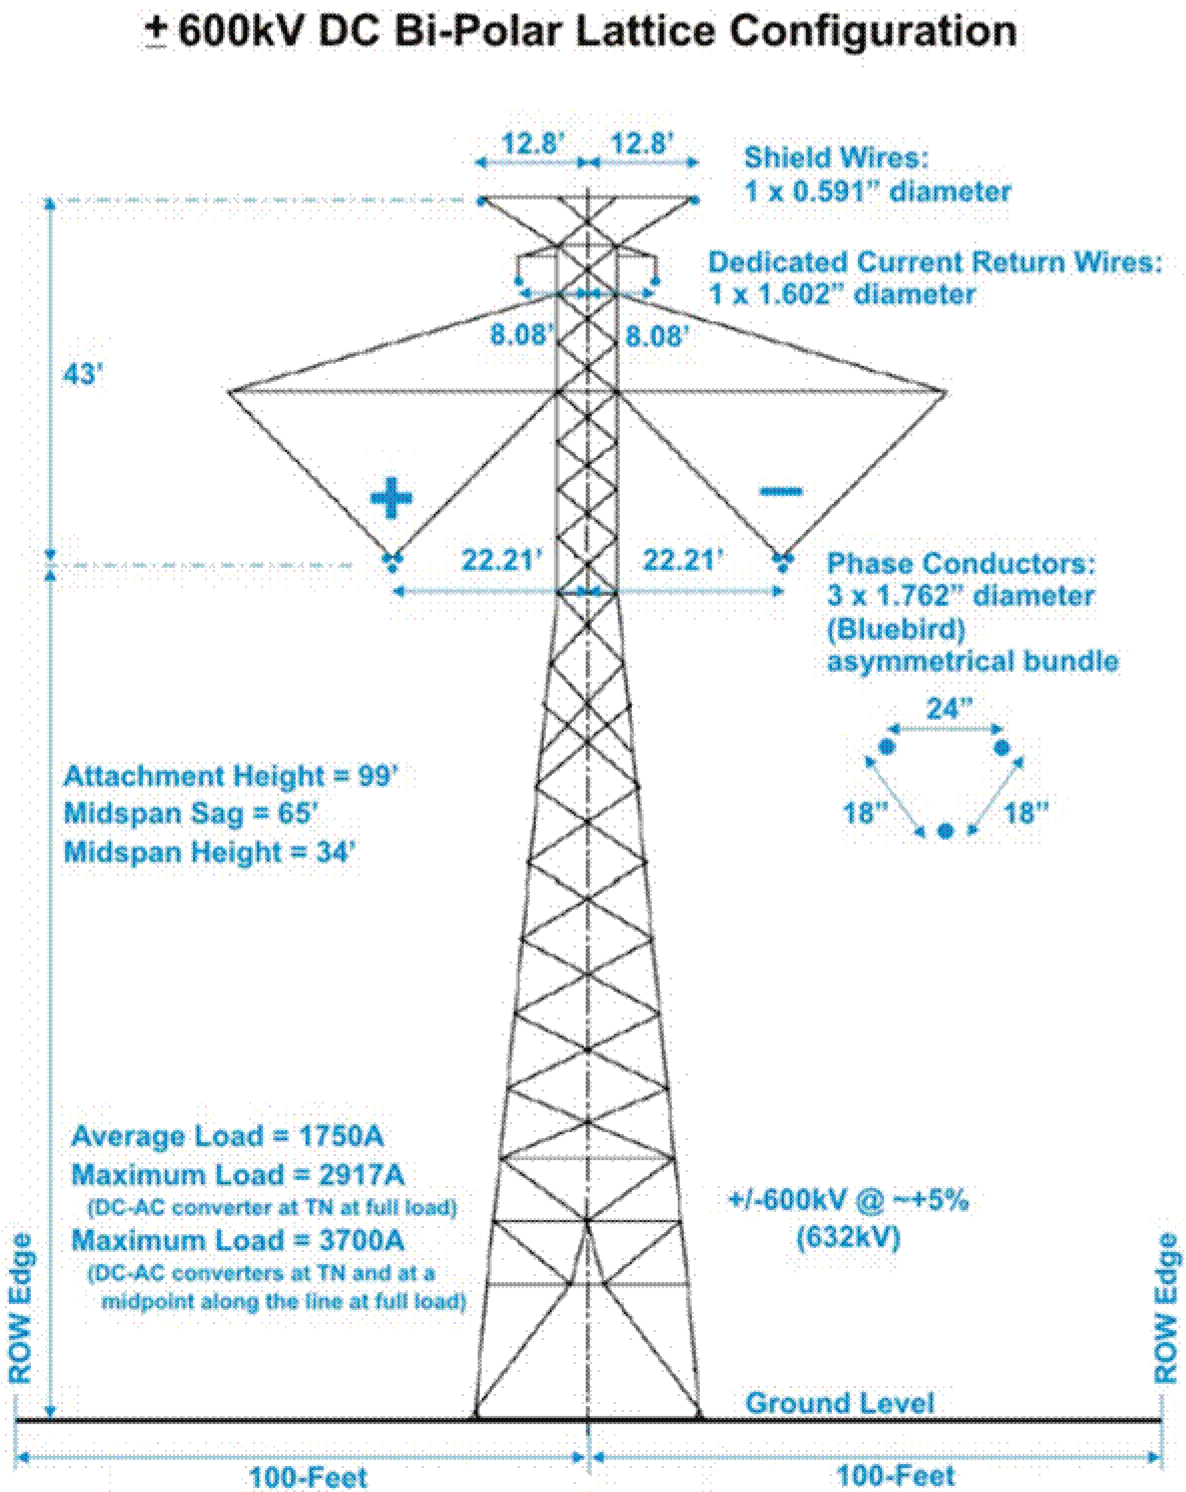

1 Figure 3.4-34: Proposed ±600kV HVDC Transmission Line Lattice Tower Configuration

3.4.11.2.3.2.1 DC Electric Field Calculation Results

DC electric field calculations were performed for the two HVDC transmission line configurations. Table 3.4-35 presents a summary of the calculated DC electric field at the ROW edges and for the maximum field within the ROW. Calculated field levels vary, depending upon the line configuration. Figure 3.4-35 presents a graph of the calculated DC electric field for each line configuration using standard and DNR operating conditions with an approximate overvoltage condition of 10 percent at the highest line elevation (3,000 feet).

Table 3.4-35:
Calculated DC Electric Field Values for DC Transmission Line Configurations (Voltage Only)

DC Transmission Line Configuration	Calculated Electric Field (kV/m)		
	-100 Feet from CL	Maximum on ROW	+100 Feet from CL
Monopole—Standard	2.7	+/- 19.4	-2.7
Monopole—DNR	3.3	23.5	0.6
Lattice—Standard	2.6	+/- 19.6	-2.6
Lattice—DNR	3.2	24.3	0.7

CL = Centerline

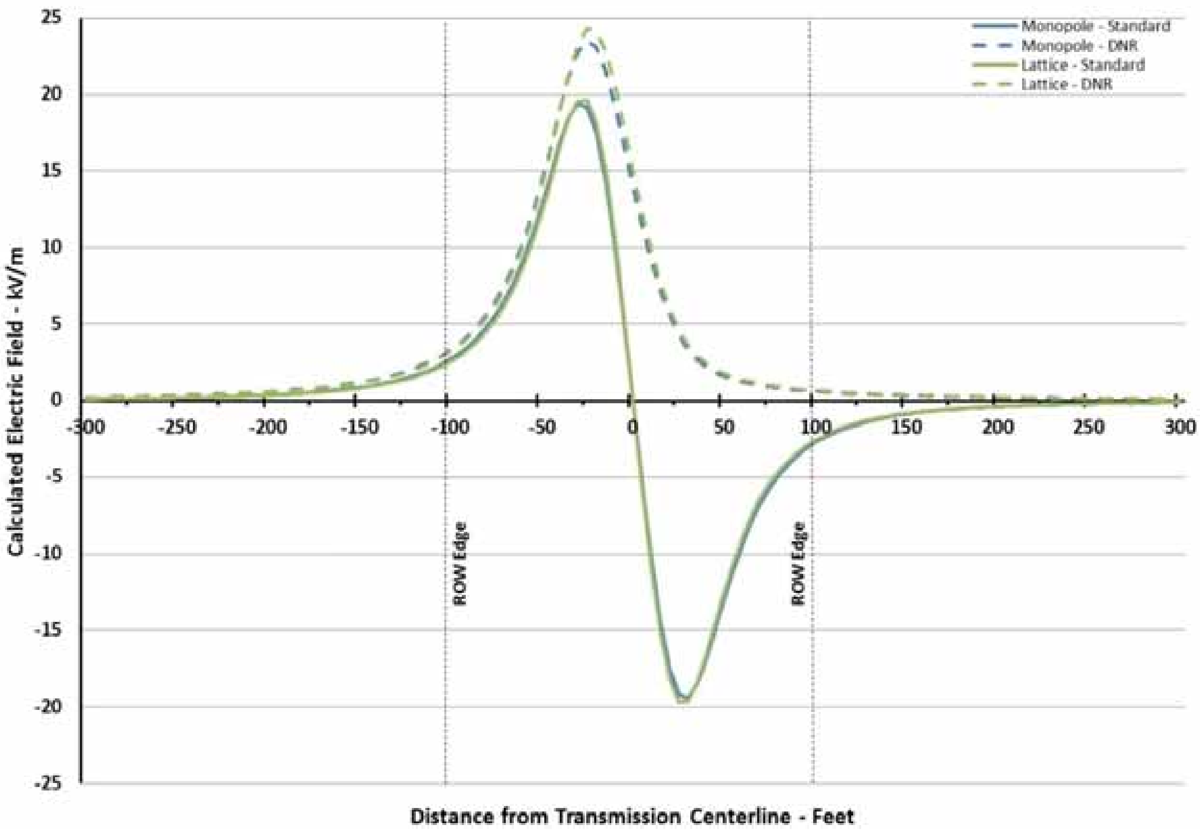

Figure 3.4-35: Calculated DC Electric Fields for ±600kV HVDC Transmission Line

Calculated DC electric field levels at the ROW edges (100 feet from the centerline of the transmission line) for both DC transmission line configurations are below the ICES and ICNIRP public guidelines (5kV/m). However, calculated DC electric field levels exceed the ICES and ICNIRP public guidelines (5kV/m) within the ROW. Calculated DC electric field levels conform to the ACGIH occupational standard (25kV/m) within the ROW for all configurations, but exceed the ICES and ICNIRP occupational standards (20kV/m) for the DNR configurations.

3.4.11.2.3.2.2 DC Magnetic Field Calculation Results

DC magnetic field calculations were performed for both transmission line configurations under three different loading conditions:

- Average loading of 1750 amperes
- Maximum loading of 2917 amperes when only the DC-AC converter at the Tennessee end of the line is supplied full load
- Maximum loading of 3700 amperes when both the DC-AC converter at the Tennessee end of the line and another DC-AC converter at a midpoint along the line are both being supplied full load

Table 3.4-36 presents a summary of the DC calculated magnetic field at the ROW edges and for the maximum field within the ROW. Calculated field levels vary, depending upon the line configuration. Figure 3.4-36 presents a graph of the calculated DC magnetic field for the monopole line configuration using standard and DNR operating conditions and for average and maximum loading conditions. Figure 3.4-37 presents a graph of the calculated DC magnetic field for the lattice tower configuration using standard and DNR operating conditions and for average and maximum loading conditions. In the standard configuration, load flow is balanced in both directions between the positive and negative phases, creating a magnetic field profile which peaks at centerline. In the DNR configuration, return load is split between the two dedicated neutral return conductors, creating a shift in the calculated field to the side more heavily loaded.

Table 3.4-36:
Calculated DC Magnetic Field Levels for DC Transmission Line Configurations

DC Transmission Line Configuration	Calculated Magnetic Field (mG) for Average/Maximum (1750A/2917A/3700A) Load		
	-100 Feet from CL	Maximum on ROW	+100 Feet from CL
Monopole—Standard	51.1/85.2/108.0	354.9/591.5/750.3	51.1/85.2/108.0
Monopole—DNR	46.1/76.8/97.4	219.2/365.4/463.5	30.1/50.2/63.7
Lattice—Standard	48.5/80.9/102.6	360.7/601.2/762.6	48.5/80.9/102.6
Lattice—DNR	51.9/86.6/109.8	237.5/395.9/502.2	34.8/57.9/73.5

CL = Centerline

Calculated DC magnetic field levels at the ROW edges (100 feet from centerline of the transmission line) for both DC transmission line configurations are below guidelines for public exposure (1,180,000mG for ICES and 4,000,000mG for ICNIRP). Calculated DC magnetic field levels are also below the guidelines for implanted medical devices (5,000mG for ACGIH, ICNIRP, and the FDA).

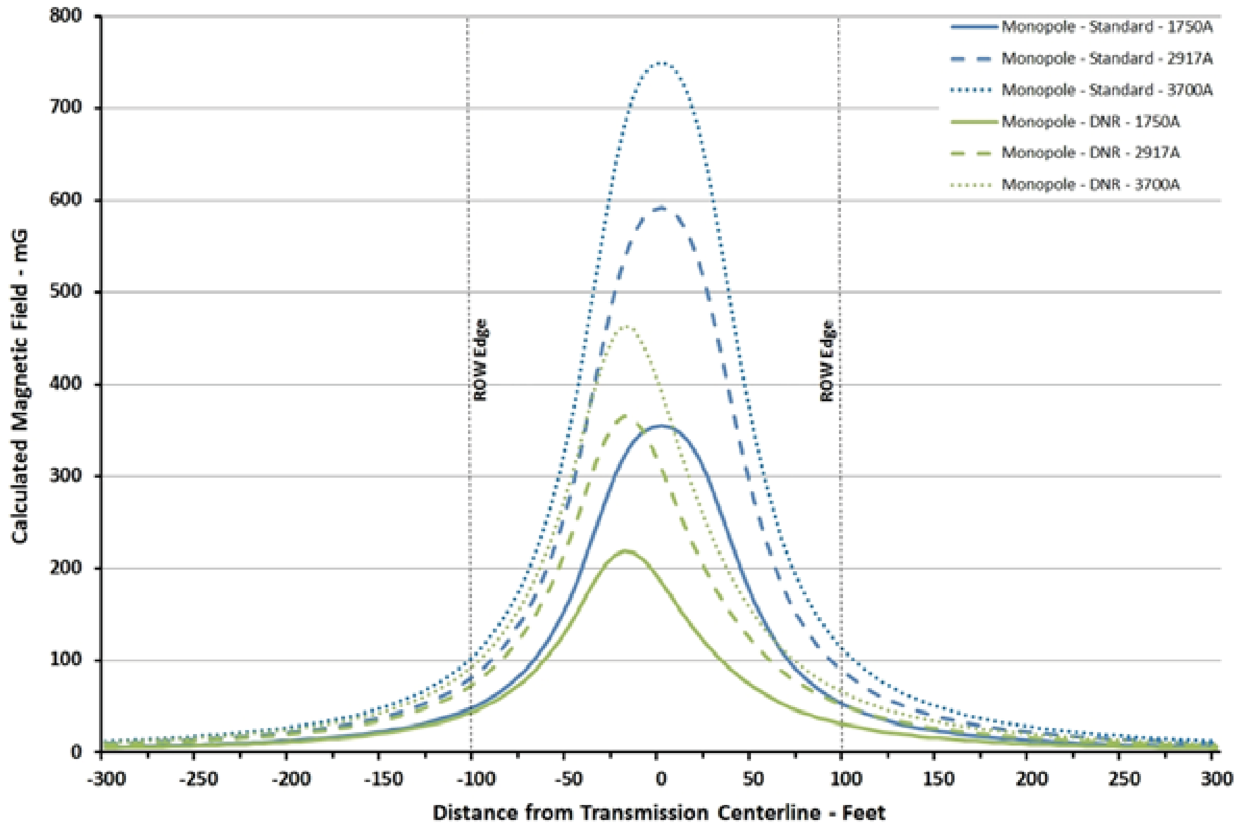

Figure 3.4-36: Calculated DC Magnetic Fields for ±600kV HVDC Transmission Line (Monopole Configuration)

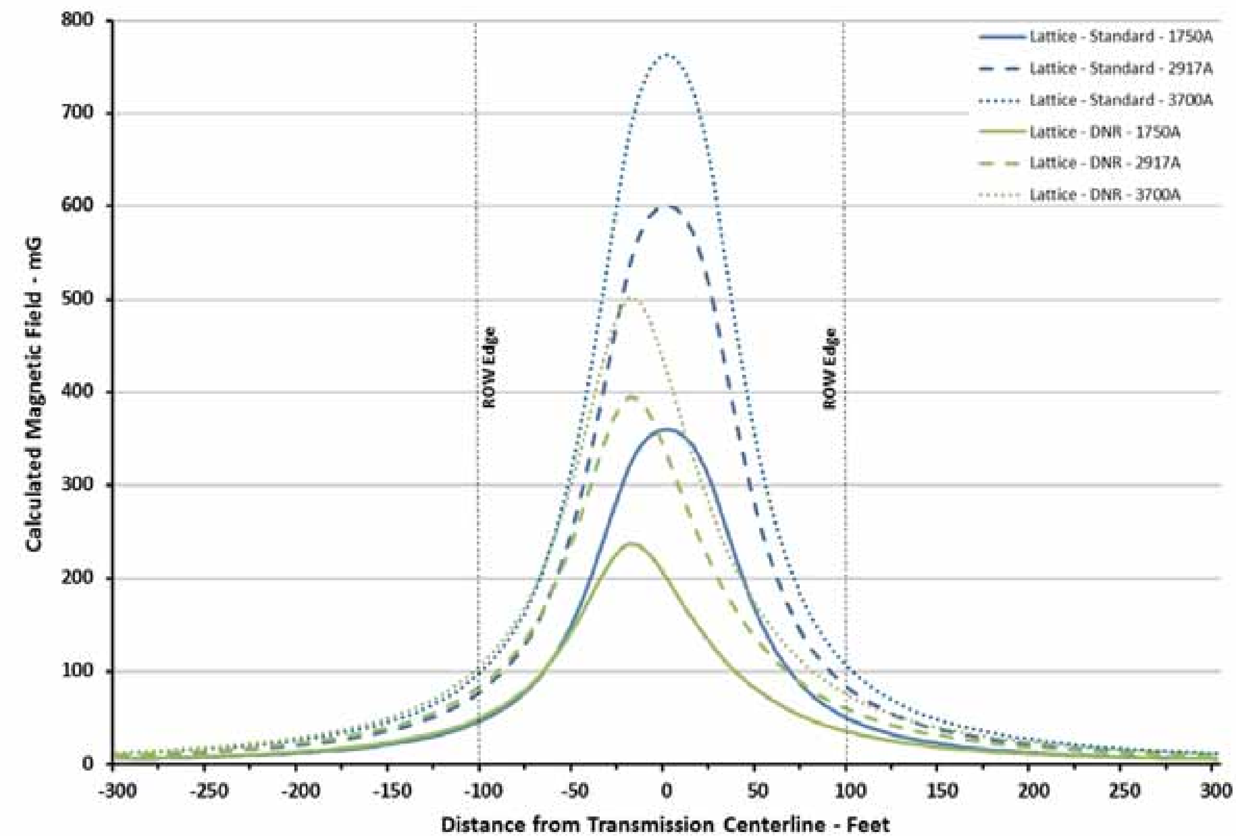

Figure 3.4-37: Calculated DC Magnetic Fields for ±600kV HVDC Transmission Line (Lattice Configuration)

3.4.11.2.3.2.3 DC Audible Noise Calculation Results

Audible noise calculations were performed for both DC transmission line configurations. Table 3.4-37 presents a summary of the calculated day-night (L_{dn}) audible noise at the ROW edges and for the maximum noise level within the ROW. Calculated levels vary, depending upon the line configuration. Figure 3.4-38 presents a graph of the calculated audible noise for each DC transmission line configuration.

Table 3.4-37:
Calculated Audible Noise for DC Transmission Line Configurations

DC Transmission Line Configuration	Calculated Audible Noise (dBA)—L_{dn}		
	-100 Feet from CL	Maximum on ROW	+100 Feet from CL
Monopole—Standard	54.7	57.5	52.8
Monopole—DNR	48.7	51.5	46.8
Lattice—Standard	55.2	58.1	53.4
Lattice—DNR	48.3	51.2	46.5

CL = Centerline

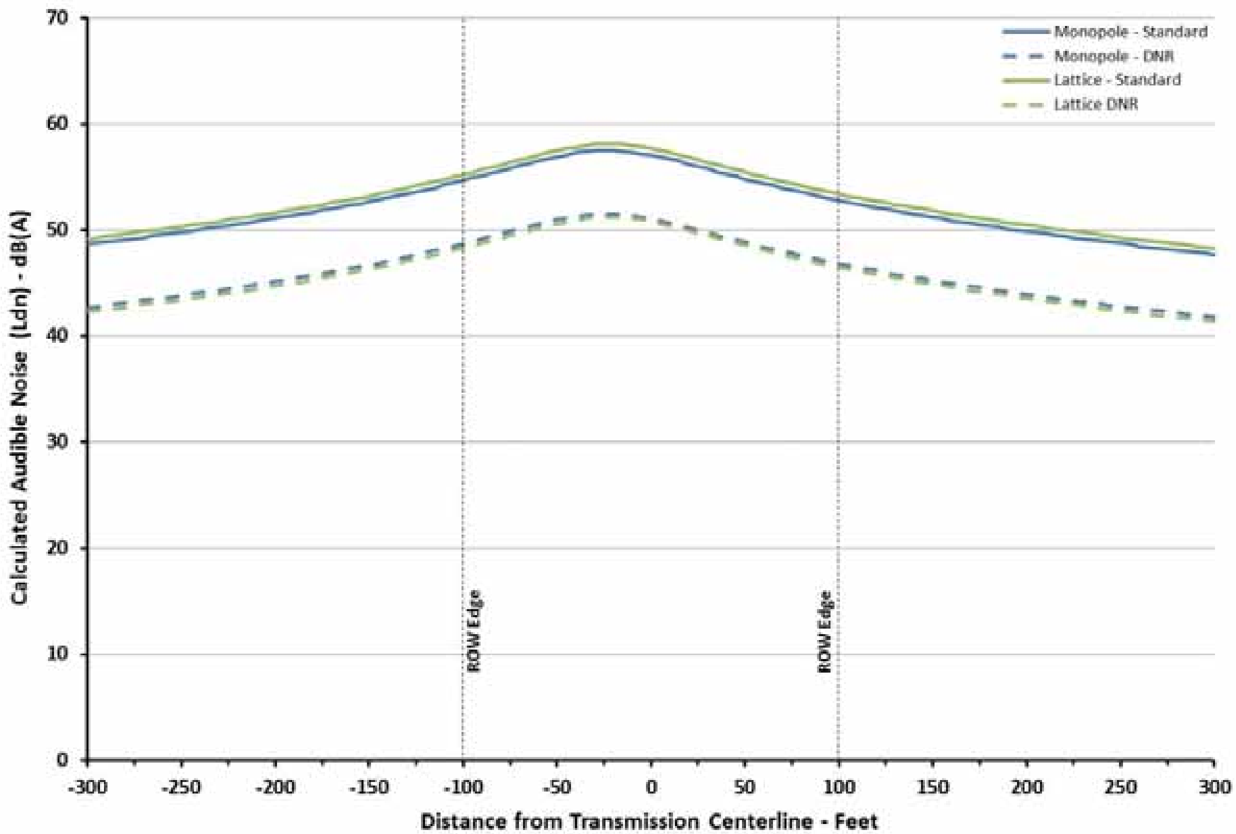

Figure 3.4-38: Calculated Audible Noise Levels (L_{dn}) for ±600kV HVDC Transmission Line

Calculated audible noise levels at the ROW edges (100 feet from centerline of the transmission line) for the standard monopole and lattice line configurations are at or below the EPA guideline for L_{dn} (day-night) noise of 55 dBA (the lattice configuration is slightly higher than the EPA guideline at 55.2 dBA), but calculated audible noise levels assume a 5 percent overvoltage condition at the highest line elevation (3,000 feet). For all configurations utilizing the DNR configuration, calculated audible noise levels are below the EPA standard at either ROW edge (either 75 feet or 100 feet from the transmission line).

Table 3.4-38 presents calculated day-night (L_{dn}) audible noise levels beyond the ROW edges, out to 2,000 feet away from the HVDC transmission line for the four different configurations. Since the elevation of the HVDC transmission line can change from as low an elevation as 200 feet to as high as 3,000 feet above sea level (Regions 1 through 7), audible noise calculations were performed for both the lowest and highest elevations as shown in this table. There is a difference of about a 3 dB in calculated audible noise levels between the lowest and highest elevations. The positive pole results appear on the top rows of this table (with negative distances from centerline), thus resulting in higher calculated audible noise levels nearest this pole.

Table 3.4-38:
Extended Audible Noise Calculation Values for DC Transmission Line Configurations

Distance from Centerline (Feet)	Calculated Audible Noise (dBA)—L_{dn}							
	Monopole—Standard		Monopole—DNR		Lattice—Standard		Lattice—DNR	
	3,000-Foot Elevation	200-Foot Elevation	3,000-Foot Elevation	200-Foot Elevation	3,000-Foot Elevation	200-Foot Elevation	3,000-Foot Elevation	200-Foot Elevation

3.4.11.2.3.2.4 DC Radio Noise Calculation Results

Radio noise calculations were performed for both DC transmission line designs for rainy weather conditions. Table 3.4-39 presents a summary of the calculated radio noise at the ROW edges and for the maximum noise within the ROW at 500kHz. Calculated radio noise levels vary, depending upon the line configuration. As shown in Table 3.4-39, calculated radio noise levels at 50 feet from the outside conductor are below the IEEE 61 dB:V/m threshold in fair or rainy weather for all configurations. Figure 3.4-39 presents a graph of the calculated radio noise levels for each DC line configuration in rainy weather at the 500kHz reference level.

Table 3.4-39:
Calculated Radio Noise Values for DC Transmission Line Configurations in Rainy Weather

DC Transmission Line Configuration	Calculated Radio Noise (dB:V/m) at 500kHz (Rainy Weather)				
	-100 Feet from CL	-50 Feet from Outside Conductor	Maximum on ROW	+50 Feet from Outside Conductor	+100 Feet from CL
Monopole—Standard	52.3	57.7	68.6	56.4	52.9
Monopole—DNR	47.9	53.5	65.3	54.6	51.3
Lattice—Standard	52.0	57.3	69.0	56.7	52.9
Lattice—DNR	48.6	52.8	65.0	54.5	51.6

CL = Centerline

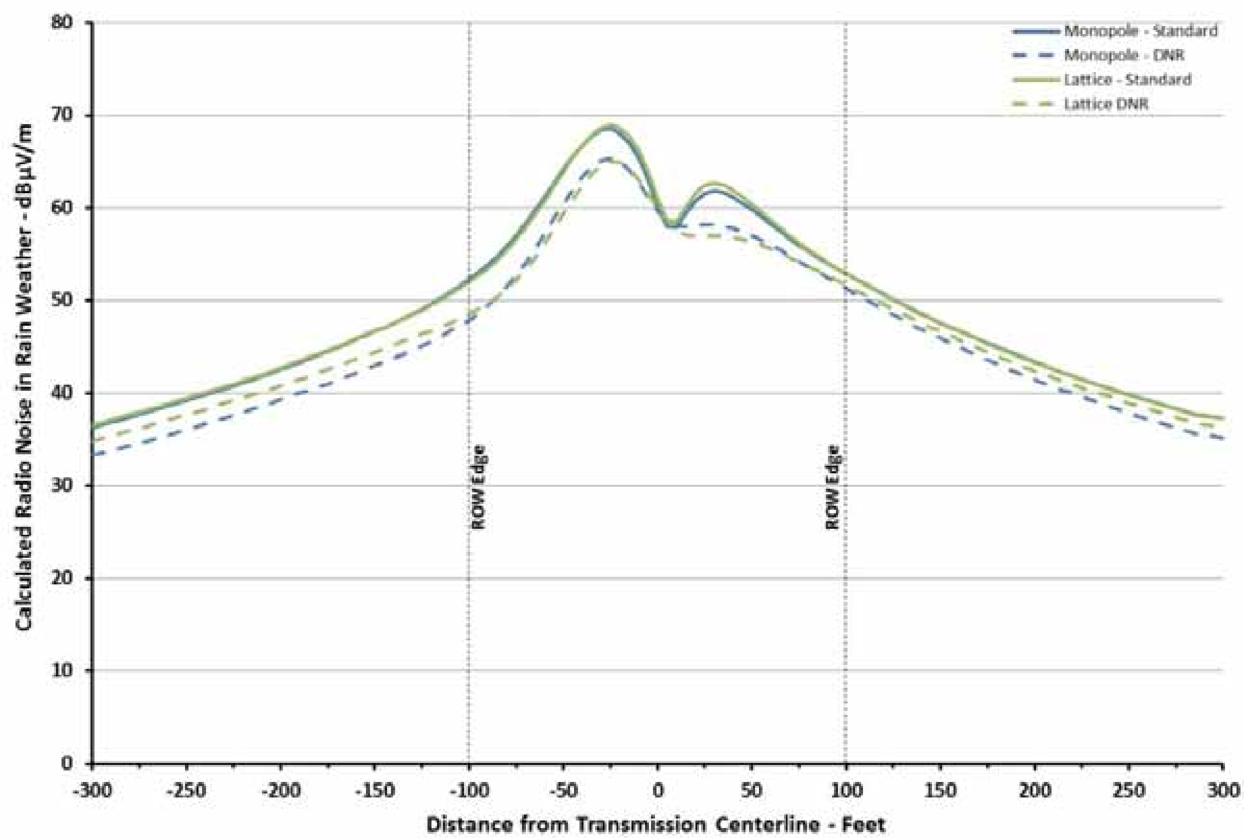

Figure 3.4-39: Calculated Radio Noise for ±600kV HVDC Transmission Line (Rainy Weather)

3.4.11.2.3.2.5 Air Ion Calculation Results

Air ion concentration levels for both DC transmission line configurations and operating conditions were calculated. Table 3.4-40 presents a summary of the calculated air ion concentration levels at the ROW edges and for the maximum field within the ROW.

Table 3.4-40:
Calculated Ion Density Levels for DC Transmission Line Configurations

DC Transmission Line Configuration	Calculated Ion Density Level (ions/cm^3)		
	-100 Feet from CL	Maximum on ROW	+100 Feet from CL
Monopole—Standard	31,300	+/- 284,400	-31,300
Monopole—DNR	41,500	390,700	11,200
Lattice—Standard	29,800	+/-295,700	-29,800
Lattice—DNR	40,100	408,600	12,500

CL = Centerline

Air ion exposures have been extensively studied with no clear evidence of effects. Studies of exposures ranging from ambient levels to levels much higher than those found in proximity of HVDC lines have been made, but findings have often been inconsistent and many studies have reported no effect (Hauth et al. 1997).

3.4.11.2.3.2.6 Overview of DC Electrical Effects Research on Human Health

Research has been conducted in the United States and around the world to determine whether exposure to static DC electric and magnetic fields has human health effects. For DC electric and magnetic fields, studies have shown no consistent evidence of adverse human health effects for exposure to levels comparable to those encountered underneath DC transmission lines. Some DC electric field effects, such as hair sensation (the perception experienced by electrical stimulation of the hair on the arm or head) and spark discharges or micro-shocks (a person touches a grounded object and discharges built-up voltage) may be annoying or uncomfortable to experience (EPRI 2012). The maximum calculated DC electric field within the ROW is about 24.3kV/m. In this level of DC electric field, typically observed perception can include a very slight tingling sensation on the scalp, hair stimulation, and slight feeling on ears and hair (EPRI 1978).

The following discussions report on various organizations and study results concerning DC electrical effects and their conclusions:

- An EPRI State of the Science Report on HVDC transmission lines stated that numerous studies of the effects of DC fields and space charges (air ions) have been made with the general conclusion that there are no significant effects on either humans or animals. In addition, public health surveys and field studies conducted at new HVDC overhead transmission lines indicate that the environment surrounding these lines is not harmful to humans, animals, or crops (EPRI 2010).
- An Oak Ridge National Laboratory review paper summarized that there is no mechanism to explain how exposure to external static fields could produce adverse biological responses. Although the database of studies is small, the experiments overall do not indicate a clear pattern of effect, and provide no basis to conclude that exposure to electric fields, such as those associated with the electric field of a HVDC transmission line, pose health risks (Hauth et al. 1997).
- The WHO published the Environmental Health Criteria 232 (EHC 232) to address the possible health effects of exposure to static electric and magnetic fields. For DC electric fields, this report found that none of the studies conducted to date suggests any untoward health effects, except for possible stress resulting from prolonged exposure to micro-shocks. The WHO did not recommend further research concerning biological effects from exposure to static electric fields. For DC magnetic fields, the WHO officially recognizes the ICNIRP exposure guidelines advice (based upon the health risk assessments published by the WHO and cancer reviews and classifications carried out by the IARC) (WHO 2006).

The HVDC transmission line will produce DC electric and magnetic fields that are similar to those encountered in the natural environment, with magnetic field levels similar to the earth's static geomagnetic field on the ROW (depending upon the line loading—maximum calculated DC magnetic field from the transmission line of about 763mG versus earth's magnetic field of about 510mG in Oklahoma, Arkansas, and Tennessee) and electric field levels outside ROW similar to those produced by atmospheric phenomena. Within the ROW, the maximum calculated DC electric field from the Project transmission line is about 19.4 to 24.3kV/m, which is above some public and occupational thresholds. In this level of electric field, induced currents may create shocks if ungrounded metallic objects are touched. (However, metal buildings and fences on or adjacent to high voltage transmission line easements are typically grounded during transmission line construction.) Outside the ROW, field levels would be even lower. Based upon the reviews of scientific research, it is unlikely that the DC fields from the Project would have adverse effects on human health. Utilities often may supply information on living and working safely around high voltage power lines (BPA 2010, 2007).

Several studies of the effects of DC fields and air ions have been conducted and they all generally conclude that there are no significant effects on either humans or animals from exposure (EPRI 2012, 2010; Charry 1987). Air ion exposures have been extensively studied and the results show no clear evidence of effects. Air ions can be inhaled, and studies have evaluated air ion exposure for respiratory issues. Some reports indicated that exposure (to either positive or negative ions) improved lung function in people with bronchial asthma; other reports suggest that only negative ions improve function and the positive ions aggravate these conditions. While some effects from air ion exposure have been reported, the evidence indicates that such exposures produce no significant or permanent effects on either humans or animals. Many observed effects may be attributed to insufficient control of experimental conditions and other factors. Among studies that reported some effects, there was no indication that the effects were harmful to humans or animals, even at exposure levels much greater than would be found within DC transmission line ROWs (EPRI 2010).

Studies to date have not associated proximity to DC transmission lines or their electric or magnetic fields with an increased risk in autism. Hypersensitivity to noise can be one of the concerns for some children with autism. Engineers take steps in the design of transmission lines to keep noise levels low by using larger or multiple conductors for each phase and hardware with smooth and curved surfaces. In fair weather, the audible noise from a transmission line at a few thousand feet and beyond would not be possible to measure in comparison to background levels. At that distance under rainy conditions, it would be very low as well, much less than the noise of falling rain or wind.

This section is not a comprehensive review of the entire body of evidence, and it excludes consideration of many other relevant published scientific studies. Scientific research utilizes epidemiology studies, animal models, and laboratory studies of basic mechanisms to scientifically evaluate a disease risk. At present there are no U.S. state government or federal government health-based limits established for electric and magnetic fields, and where the proposed Project is to be located, no states have any state-mandated electric and magnetic field limits.

3.4.11.2.3.2.7 Overview of DC Electrical Effects Research on Pacemakers and Implanted Medical Devices

Public concern has been expressed related to the electric and magnetic fields of HVDC transmission lines with the possibility of interference with cardiac pacemakers. Persons with implanted medical devices are constantly exposed to DC electric and magnetic fields from the earth's natural environment. The human body shields implanted medical devices from DC electric fields, protecting the device from naturally occurring electric field interference (EPRI 2012). Medical devices are also designed to withstand electrostatic discharge from DC electric fields. There is also constant exposure from the earth's static magnetic field, which is about 0.51G in the states encompassing Regions 1 through 7. Guidelines for occupational exposure suggest that DC electric field exposure should not exceed 5G for DC magnetic fields for workers with cardiac pacemakers (ACGIH 2010; ICNIRP 2009). The FDA also recommends a limit of 5G for MRI patients with pacemakers (FDA 1998). The potential for pacemaker interference from transmission line fields depends on the manufacturer, model, and implantation method, among other factors.

Other implanted medical devices can include a magnetic valve used in a cranial shunt. Typically, implanted medical devices such as this are set by the doctor within their office or medical facility using a static (DC) magnetic field tool to remotely adjust the valve settings on those implanted devices with adjustable magnetic valves. The presence of strong static (DC) magnetic fields, such as those associated with permanent magnets (such as refrigerator magnets or magnets used in toys), can potentially interact with the programmed settings of a cranial shunt. Patients exposed to stronger static magnetic fields from MRI machines can have even greater chances of interference with cranial shunts. According to some manufacturer's specifications (e.g., Medtronic 2012; Aesculap 2012; Codman 2006; and Sophyusa 2009, 2014), patients with cranial shunts should be able to undergo an MRI up to 3 Tesla (30,000,000mG or 30,000 Gauss) of static magnetic field without experiencing interference with their device. Studies have also been performed about static magnetic fields effects on programmable shunts that are produced by permanent magnets (Liu et al. 2005) and MRI machines (Shellock et al. 2007), as well as numerous other studies (e.g., Miwa et al. 2001; Utsuki et al. 2006; Zuzak et al. 2009; Anderson et al. 2004; Inoue et al. 2005).

Manufacturer's testing of magnetic valves focuses on static magnetic fields rather than on low level AC magnetic fields such as those produced by AC transmission lines. Because adjustable cranial shunts utilize a static magnetic field tool to remotely adjust the settings on the device, AC magnetic fields are not routinely considered for interference evaluation or testing (and testing is not required by the FDA). If low AC magnetic field levels did influence these types of devices, then common appliances (such as hair dryers, shavers, and other household devices) would also be of concern. Medical manufacturers have reported that AC magnetic fields have not caused interference with magnetic shunts (Medtronic 2012). As with any implanted medical device, the user should always consult with their doctor and the device manufacturer to determine safe operational parameters for use of their medical device.

Patients with implanted medical devices should observe certain precautions and need to discuss their treatment with their doctor or physician. In addition, there are a variety of different medical devices that are constantly evolving and changing. It is also impossible to quantify all of the various types of magnetic field sources encountered in people's day-to-day lives. The potential for interference to implanted devices may depend upon a variety of different parameters, including the device manufacturer, model and setting, and implantation method, among other factors. Typically implanted medical devices are set specifically for an individual by their doctor or physician within the doctor's office or medical facility. As with any implanted medical device, the user should always consult with their doctor and the device manufacturer to determine safe operational parameters for use of their specific medical device and associated medical condition.

Medical equipment certified by the U.S. Food and Drug Administration must pass rigorous electromagnetic compatibility testing to gain approval. These assessments allow manufacturers to evaluate the compatibility performance of a medical device and demonstrate that the product achieves an appropriate level of electromagnetic immunity in environments that patients may encounter. These EMF levels are much higher than the Project would produce. For example, for DC magnetic fields, international protocols for implantable cardiac pacemakers, implantable defibrillators and other devices calls for evaluation of static DC magnetic fields up to 1 mT (10,000 mG) (ISO 2012). Three of the major manufacturers of implantable medical devices recommend similar limits for static magnetic field (Medtronic 2013; Boston Scientific 2015; St. Jude Medical 2014).

By comparison, the calculated EMF levels from the proposed transmission lines would be well below these manufacturer's device levels outside the ROW. Within the ROW, calculated DC magnetic fields are also below these levels (> 770 mG). These manufacturers do not cite recommended levels for DC electric field because DC electric fields do not induce internal current on the leads of medical devices. In addition, electric fields are very easily shielded. Electric fields would generally be shielded levels (i.e., lower levels) except directly underneath the line in open areas. For example, the metallic body of the vehicle would provide electric field shielding for occupants inside the vehicle.

Over the past decade or so, major manufacturers of pacemakers and other implantable medical devices have designed these devices to provide shielding and improved filtering from the different types of EMF that arise from many sources in our daily environments. Modern pacemakers are designed to filter out peripheral electrical signals and these electrical filters increase the pacemaker's ability to distinguish extraneous signals from legitimate cardiac signals. In addition, most of the pacemaker circuitry is enclosed within a metallic case that shields the device from external EMF. Based on all of these factors, no interference with medical devices would be expected due to EMF from the Project.

Some types of implanted medical devices (such as metallic stents, joint/metal replacements, etc.) do not incorporate electronic or electrical circuits and do not require power to operate. To date, no adverse interactions related to EMF exposure and metallic implants have been reliably reported or documented.

Hearing aids are another type of medical device used by people. Older hearing aids are analog and amplify all sounds in the same way. Digital hearing aids convert sound waves into digital signals using computer chips with complex amplification processing, and are the most popular form of hearing aid today (FDA 2015a). Digital hearing aids operate within a frequency range of 250Hz–8kHz. For the Project HVDC transmission line, DC magnetic field levels would be comparable to the earth's natural static magnetic field and should not create an interference issue.

In summary, implanted medical devices are shielded by the body from DC electric fields, but even so, the DC magnetic field, even under the line, is too weak to potentially affect the operation of pacemakers and other implanted medical devices.

3.4.11.2.3.2.8 Overview of DC Electrical Effects Research on Plant and Animal Health

Research has been conducted to determine whether exposure to static DC has environmental effects on plant or animal life. Studies have examined the effect of static electric and magnetic field exposure on plant species and found no adverse effects due to DC electric and magnetic field exposure. Studies on some groups of animals also did not find any effect due to DC electric or magnetic fields. The following discussions report on various study results concerning DC electrical effects and their conclusions:

- A 1988 agricultural study performed by Oregon State University monitored beef cattle and crops near the 500kV DC Pacific Intertie transmission line in central Oregon. Researchers established simulated farming and ranching conditions directly under the transmission line and at an identical site 2,000 feet away. For the study, cattle were bred for three seasons, wheat and alfalfa was raised for 2 years, and data from the two sites were then compared. The cattle showed no differences in any health-related measures, including food and water consumption, growth, reproduction, disease, and death rate. Similarly, the wheat and alfalfa grown at the two sites showed no significant differences in growth, yield, or quality (Raleigh 1988).
- The University of Minnesota used records from the Dairy Herd Improvement Association to study the health and productivity of approximately 500 dairy herds—about 24,000 cows—located near a 400kV DC transmission Line

in Minnesota. Researchers examined records from three years before to three years after energization of the transmission line. Herd health and productivity were unchanged over this time, regardless of proximity to the line (Martin et al. 1983).

- Domestic animals grazing near transmission lines are subject to potentially higher levels of DC electric and magnetic field exposure than large game species. Successive offspring of cattle exposed to a 500kV DC transmission line also showed no adverse effects (Angell et al. 1990). No effect was observed in the reproduction of cows and sheep exposed under relatively controlled conditions (Lee et al. 1996).
- A study on cattle and deer herds reported that the animals preferentially aligned themselves along the geomagnetic axis (Begall et al. 2008). Satellite images were used to obtain alignment data for herds over various regions of the earth. A second study (Burda et al. 2009) reported this alignment was disrupted for herds near AC transmission lines. However, a third research group (Hert et al. 2011) was unable to confirm the results using the same satellite-based images. Two different statistical evaluation methods (one evaluation method tried to replicate the original study and the second tried an improved method) did not replicate the same findings.
- A variety of animals can perceive and use the earth's DC magnetic field including birds. The results of decades of homing and migration studies indicate that this is a very complex topic and the mechanisms involved are not yet completely understood (Beason 2005). Different species of birds have different migration patterns (e.g., nocturnally, diurnally, or both) and it appears that there are numerous factors that are used during migration (e.g., landmarks, wind direction, sun, stars, geomagnetism, polarized light). It is now widely accepted that birds have numerous navigational-type problem solving mechanisms available and are capable of using a multiplicity of environmental information for orientation purposes (Southern 1988). One study has shown that higher frequency magnetic fields (50kHz–20MHz) can disrupt the internal magnetic compasses and disorient migratory birds, and birds shielded from these frequencies (but not the earth's field) regained their orientation (Morrison 2014). Since the HVDC transmission line's magnetic field at 1 meter above ground level is comparable to the earth's natural magnetic field (a maximum calculated DC magnetic field from the Project transmission line of about 763mG at 1 meter above ground level versus 510mG for the earth's field), and because distance both farther above and also away from the transmission line would also reduce the DC magnetic field, effects on migratory patterns of birds is not anticipated. Even if the transmission line DC magnetic field were to cause some localized disorientation directly near the line, birds have numerous other environmental factors to use for orientation.

This section provides a review of many of the relevant scientific studies that have been published and is not meant to be a comprehensive review of the entire body of evidence (many other scientific studies have been performed). Based upon a comprehensive review of the scientific literature, the association between DC magnetic fields and adverse effects to plant life and animal health is weak. Overall, studies of DC transmission line environments and DC electric and magnetic fields indicate that the field levels associated with the Project would be unlikely to pose a threat to animals and plants.

3.4.11.2.3.2.9 Grounding and Stray Voltage for DC Fields

For HVDC transmission lines, electric and magnetic fields are static (unchanging). Therefore, electric currents are not induced in conductive objects as they would be near AC transmission lines with alternating fields. For electric fields, an electrical charge can build up on the surface of ungrounded or poorly grounded objects. For example, it is a common occurrence that someone receives a small shock (a discharge of built-up static body voltage) when touching a doorknob after walking across a carpet. Therefore, ungrounded objects within the transmission line ROW may build up a static charge, which is discharged when a path to ground is introduced (such as a person touching an ungrounded object with static charge). The perceived shock (discharge) may range from no sensation to barely perceptible to minor "carpet type" shock, depending upon the quality of grounding (i.e., ground resistance) and the amount of built-up charge on the object (i.e., size of the object) (EPRI 1978). Metal buildings and fences on or adjacent to high voltage transmission line easements are routinely grounded during construction to prevent this occurrence. Also, automobiles, trucks, and farming equipment do not typically accumulate a significant electrical charge since the "carbon black" component in tires is electrically conductive and allows charges to flow to ground, thereby preventing the accumulation of electrical charges on vehicles.

For magnetic fields, the current in the transmission line conductors will create a static magnetic field comparable to the earth's natural magnetic field. Therefore, DC magnetic fields will not create grounding, induced current, or stray voltage issues.

Electric transmission lines can often share utility corridors with pipelines. In these situations, transmission line electrical effects are generally analyzed so that measures can be taken to control the induced voltage on a pipeline to meet the National Association of Corrosion Engineers guideline (NACE 2007). If an electric transmission line route parallels a pipeline, engineers for the Applicant would conduct field investigations to determine any potential safety issues or other design requirements that may result from the presence of the pipeline. The Project would then address those requirements as a part of the detailed transmission line design, including consultation with the pipeline company to determine design requirements specifically related to the presence and location of the pipeline.

Ground return currents are more prevalent on pipelines near HVDC transmission lines whenever the line is operated in a unipolar configuration (using the earth as a path for return current) than in a bi-polar configuration (using dedicated conductors as a path for return current). The Project is designed to operate in a bipolar configuration and also includes a dedicated metallic conductor return configuration in lieu of a ground electrode or earth return system. An HVDC system requires a complete return path for the current. In bi-polar operation, this is accomplished by the current flowing down one pole and returning via the opposite pole in balanced normal operation. However, when one set of pole conductors is not available due to the electrical failure of that pole or maintenance, the current must have a return path for the line to remain in service, which is accomplished through a smaller set of conductors identified as the dedicated metallic return conductors. These conductors would be of sufficient size to carry full load current during any outage of one set of pole conductors and would also accommodate any imbalance in current during normal operation. The dedicated metallic return conductors are located on the transmission structure. During bipolar operation, ground return currents are negligible (Maruvada 2000).

Engineering constraints and obstructions, including oil and gas infrastructure, are also commonly encountered and routinely dealt with during the routing and engineering design processes for electric transmission lines. Oil and gas wells have been identified within the 1,000-foot-wide ROI. In addition, the Applicant has confirmed that, based on current information, there are no existing oil and gas wells or well pads within the 200-foot-wide HVDC ROW, and that future development of wells will not be adversely affected. Although HVDC transmission lines may cause pipeline and well casing corrosion due to stray electric current (by utilizing the earth for transmission/return currents), the Project's dedicated metallic-return design eliminates the risk of stray voltage during operations. The Applicant also stated that there is minimal risk of interference with electronic equipment (since this type of equipment operates at greater frequencies than 60Hz and there are no well pads within the ROW that would utilize this equipment). The transmission line would be designed using adequate minimum clearances so as to not restrict the movement of oilfield equipment, such as drilling rigs, workover rigs, vacuum tracks, tank trucks, and other equipment necessary to operate the oil field facilities. EPM GE-29 states that "Clean Line will work with landowners and operators of oil and gas wells, utilities, and other infrastructure to identify and verify the location of facilities and to minimize adverse impacts. Identification may include use of the One Call system and surveying of existing facilities."

3.4.11.2.3.2.10 Summary of Impacts for the HVDC Transmission Line

Based on an evaluation of research and guidelines recommended by various agencies, it is unlikely that the proposed HVDC transmission line would pose a known threat to human health (see Section 3.4.11.2.3.2.6) along the Applicant Proposed Route. Calculated DC electric fields are above non-regulatory standards for some configurations and operating conditions within the ROW (depending upon ROW width). However, DC electric fields do not induce internal currents on the leads of medical devices. DC magnetic fields on the ROW would be below the levels the manufacturers' cite as capable of affecting the operation of these devices. Persons who are concerned should contact their physician to ascertain the immunity of their medical device to this potential source of interference.

3.4.11.2.3.3 Decommissioning Impacts

No electrical effects would be associated with the decommissioning of the ±600kV HVDC transmission line. Once decommissioned, no electrical energy would be generated that would create electrical effects such as electric and magnetic fields, audible noise, or radio and television interference.

3.4.11.3 Impacts Associated with the DOE Alternatives

This section describes the electrical effects associated with the DOE Alternatives, which includes the Arkansas converter station, the AC transmission line interconnection associated with it, a new substation, and the HVDC alternative routes. Electrical effects would only be present during operation and maintenance of these facilities. Electrical facilities need to be energized to create electrical effects such as electric and magnetic fields, audible noise, and radio and television interference. Electrical effects would not be present during the construction and decommissioning phases of the Project.

Table 3.4-41 presents a summary of the number of existing building structures (residences, agricultural buildings, churches, and schools) within a 1,000-foot-wide corridor for the interconnection route. Currently, no AC transmission lines or communication facilities exist within the siting area.

Table 3.4-41:
Occurrence of Existing Facilities along DOE Alternative Converter Station and AC Interconnection Siting Area

DC Transmission Interconnection Route	Parallels Existing AC Transmission Lines (Quantity and Voltage Range)	Existing Building Structures within 1,000-Foot-Wide Corridor (Residential/Agricultural/Church/ School)[1]	Existing Communication Facilities Within 1,000-Foot-Wide Corridor (Quantity and Type)[2]
Arkansas	0	38/28/1/0	0

2 GIS Data Source: FCC (2012)

3.4.11.3.1 Arkansas Converter Station Alternative Siting Area and AC Interconnection Siting Area

3.4.11.3.1.1 Construction Impacts

No electrical effects would be associated with construction of the Arkansas converter station, because the converter station would not be energized during construction. Electrical facilities need to be energized to create electrical effects such as electric and magnetic fields, audible noise, or radio and television interference.

A new substation will also be constructed where the 500kV AC interconnection line taps the existing Arkansas Nuclear One-Pleasant Hill 500kV line. No electrical effects would be associated with construction of this new substation because the substation would not be energized during construction. Electrical facilities need to be energized to create electrical effects such as electric and magnetic fields, audible noise, or radio and television interference.

3.4.11.3.1.2 Operations and Maintenance Impacts

For the Arkansas converter station and the new substation (where the 500kV AC interconnection line taps the existing Arkansas Nuclear One-Pleasant Hill 500kV line), the dominant sources of electrical effects are the overhead transmission lines entering and exiting the stations. Some types of substation and switching station equipment can potentially be a source of electrical effects (e.g., power transformers can produce audible noise; converter equipment can produce radio noise, etc.). These effects can be reduced or eliminated by the use of filtering equipment, sound walls, and other methods. Because the dominant sources of electrical effects are associated with the overhead transmission lines, an evaluation of electrical effects for the proposed Arkansas converter station and new substation was therefore not performed, except for audible noise as described in Section 3.11.6.

There are two different 500kV AC transmission line configurations associated with the interconnection into the Arkansas converter station. Both line designs are single circuit configurations (i.e., one circuit supported on a single structure). The monopole design is supported on a tubular pole, while the other design is a single circuit supported on a lattice structure. Each transmission line configuration is located within a 150-foot-wide to 200-foot-wide ROW (actual ROW width has not yet been determined). Proposed loading for these lines is 300MW (346 amperes) for average loading and 500MW (577 amperes) for maximum loading. Figures 3.4-40 and 3.4-41 present dimensioned drawings of the two representative 500kV AC transmission line configurations.

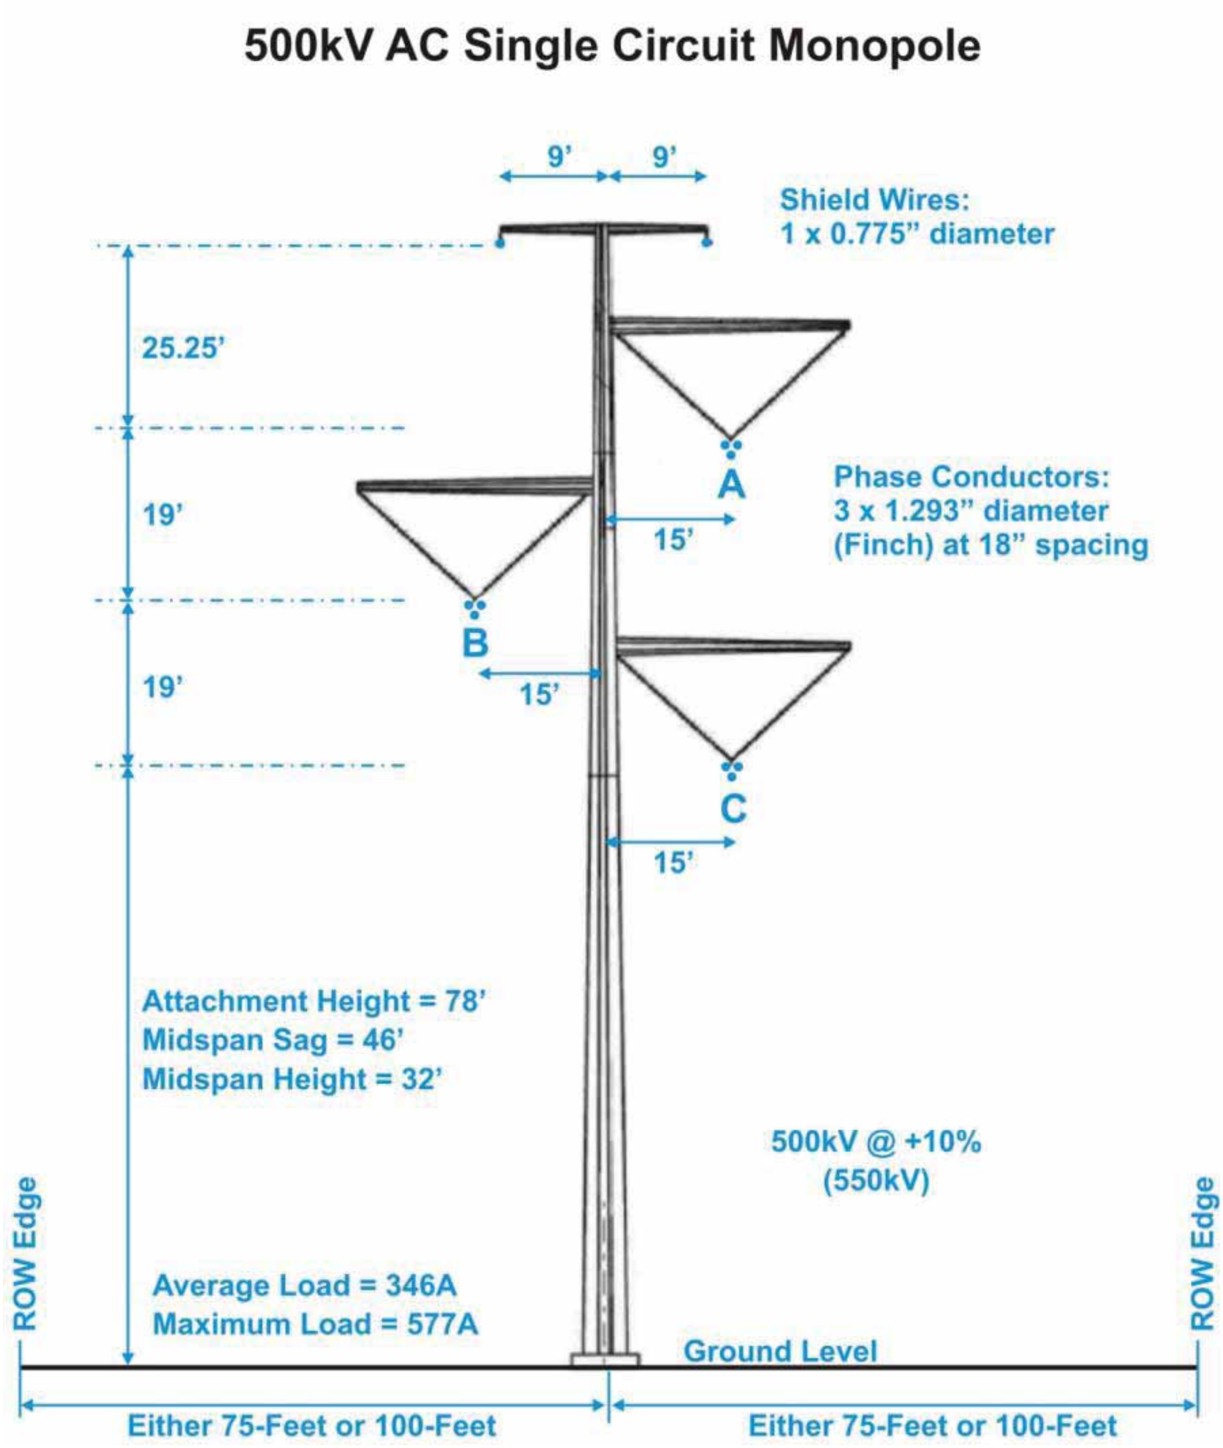

Figure 3.4-40: 500kV AC Transmission Line Single Circuit Monopole Configuration for Interconnection to Arkansas Converter Station

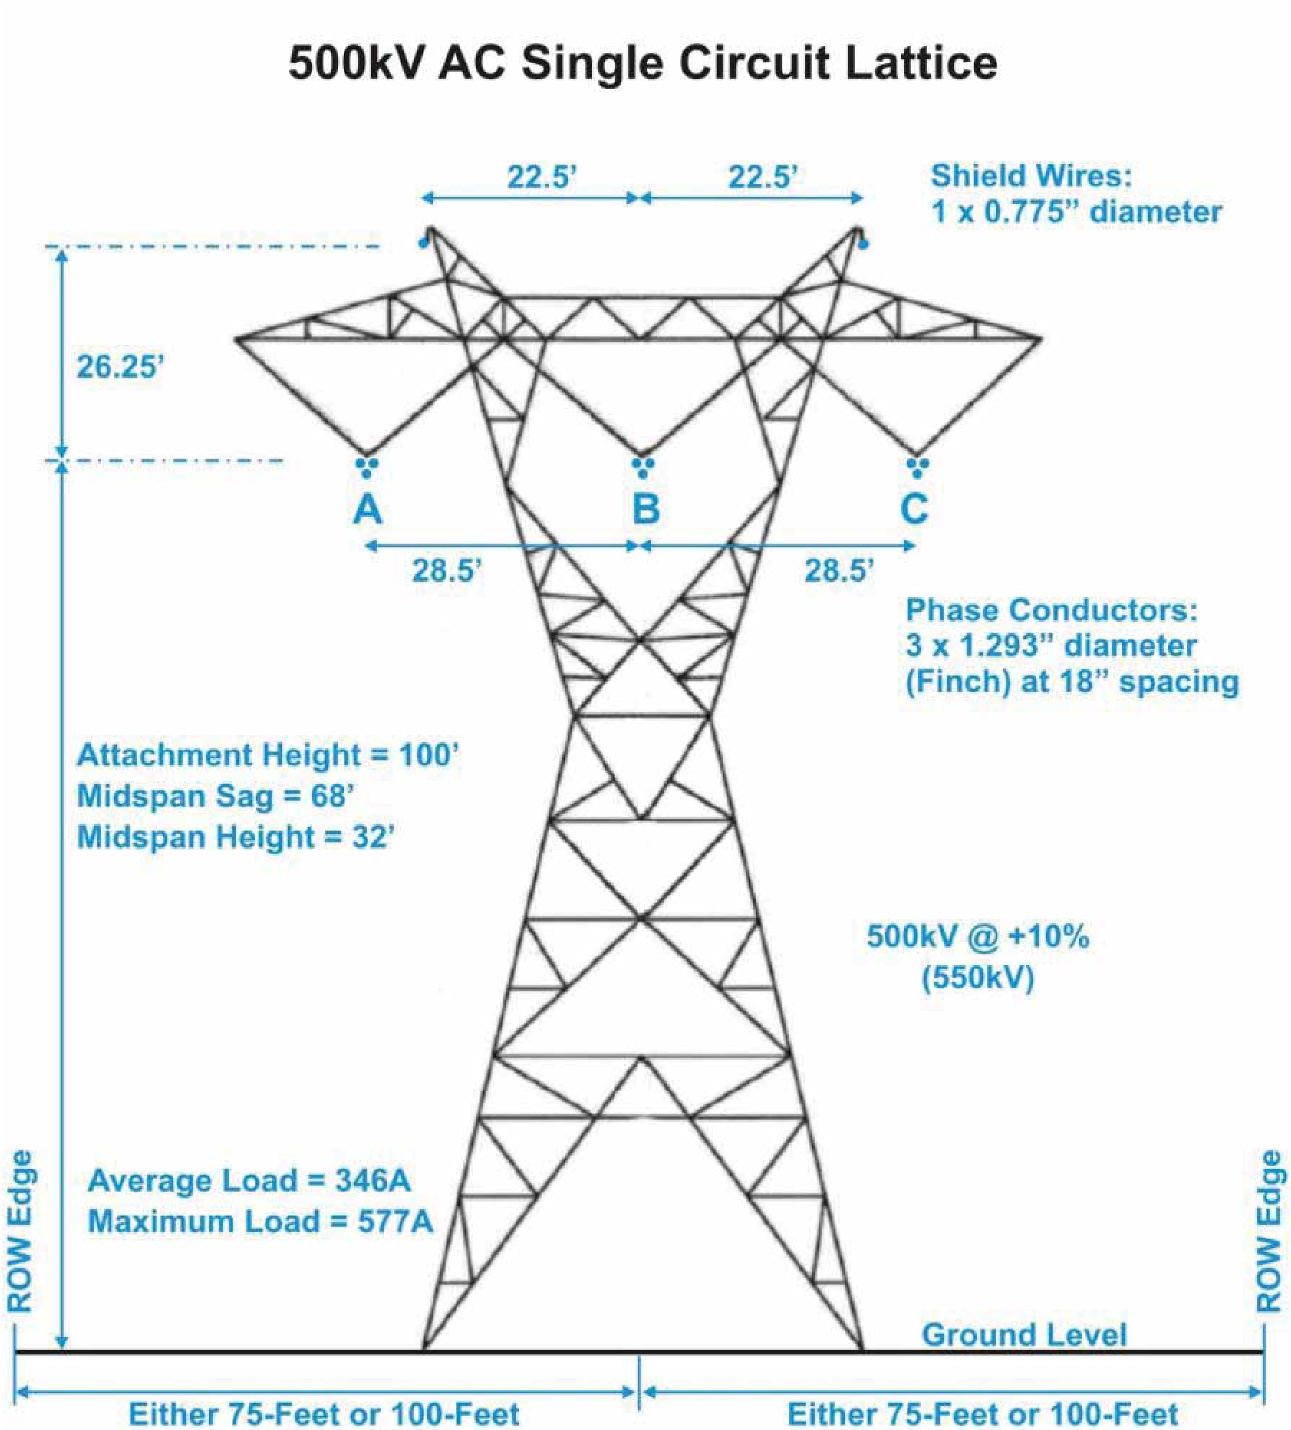

Figure 3.4-41: 500kV AC Transmission Line Double Single Lattice Tower Configuration for Interconnection to Arkansas Converter Station

3.4.11.3.1.2.1 AC Electric Field Calculation Results

AC electric field calculations were performed for the two transmission line configurations. Table 3.4-42 presents a summary of the calculated electric field at the ROW edges and for the maximum field within the ROW. Because the ROW width has not yet been determined, ROW edge values are provided for both possible edge locations (either 75 feet or 100 feet from the transmission centerline). Calculated field levels vary, depending upon the line configuration. Figure 3.4-42 presents a graph of the calculated AC electric field for each line configuration.

Table 3.4-42:
Calculated AC Electric Field Values for AC Transmission Line Interconnections to Arkansas Converter Station

500kV AC Transmission Line Configuration	Calculated AC Electric Field (kV/m)[1]				
	-100 Feet from CL	-75 Feet from CL	Maximum on ROW	+75 Feet from CL	+100 Feet from CL
Single Circuit Monopole	1.1	1.9	10.0	1.5	0.9
Single Circuit Lattice	1.4	3.1	10.2	3.1	1.4

CL = Centerline; since the precise ROW width has not yet been determined, the ROI for analysis is 300-feet on either side of a representative centerline.

1 Edges of the ROW have not been established and are assumed to be either 75 feet or 100 feet from centerline.

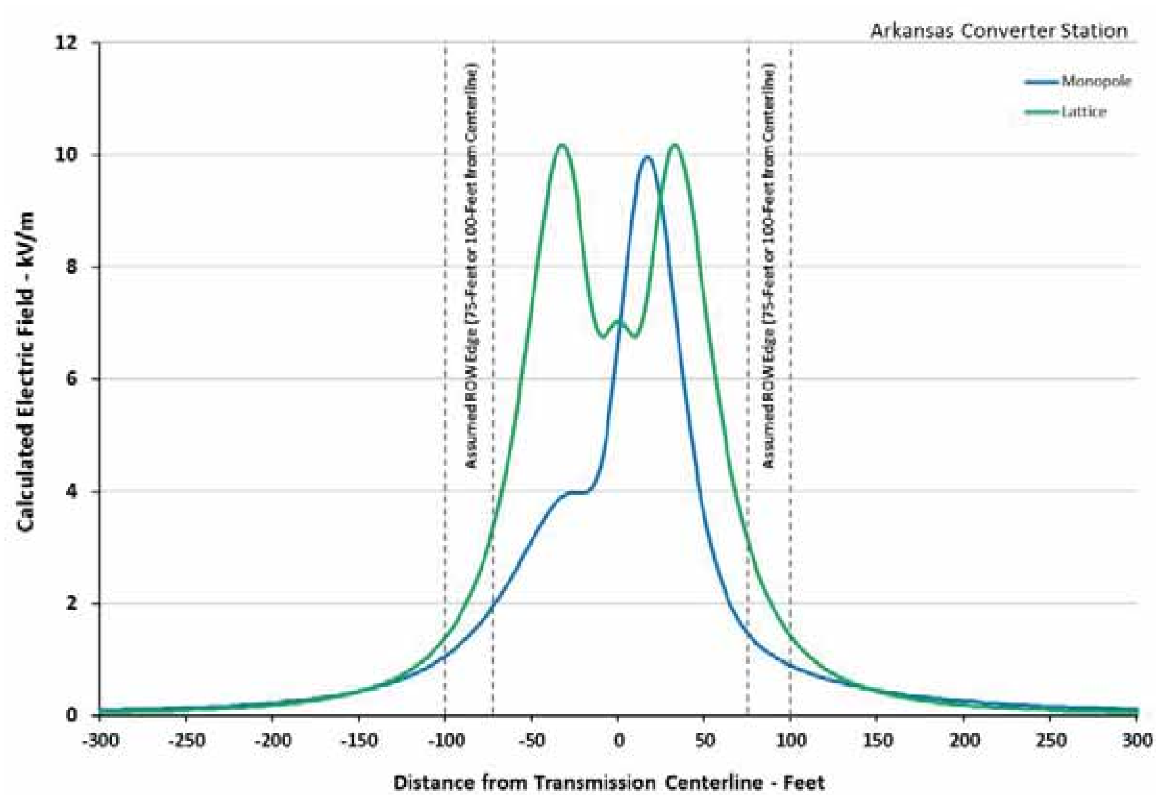

Figure 3.4-42: Calculated AC Electric Fields for 500kV AC Transmission Line Interconnections to Arkansas Converter Station

Calculated electric field levels at the ROW edges (either 75 feet or 100 feet from centerline of the transmission line) for all of the AC transmission line interconnections are below the ICES and ICNIRP guidelines for public exposure (5kV/m and 4.2kV/m respectively). Within the ROW, calculated electric field levels are slightly higher than the ICES guideline of 10kV/m for the single circuit lattice tower configuration. For both configurations, calculated electric field levels exceed the ACGIH guideline of 1kV/m for workers with implanted medical devices within the ROW and at most ROW edges.

3.4.11.3.1.2.2 AC Magnetic Field Calculation Results

AC magnetic field calculations were performed for the two transmission line configurations under two different loading conditions (average and maximum loading of 300MW [346 amperes] and 500MW [577 amperes] respectively). Table 3.4-43 presents a summary of the calculated magnetic field at the ROW edges and for the maximum field within the ROW. Calculated field levels vary, depending upon the line configuration and loading conditions. Figure 3.4-43 presents a graph of the calculated AC magnetic field for each line configuration under average and maximum loading conditions.

Table 3.4-43:
Calculated AC Magnetic Field Values for 500kV AC Transmission Line Interconnections to Arkansas Converter Station

500kV AC Transmission Line Configuration	Calculated AC Magnetic Field (mG) for Average/Maximum Load[1]				
	-100 Feet from CL	-75 Feet from CL	Maximum on ROW	+75 Feet from CL	+100 Feet from CL
Single Circuit Monopole	7.9/13.2	12.1/20.1	50.5/84.2	14.5/24.2	9.0/15.0
Single Circuit Lattice	11.1/18.5	19.4/32.4	78.9/131.6	19.6/32.7	11.3/18.8

CL = Centerline; since the precise ROW width has not yet been determined, the ROI for analysis is 300 feet on either side of a representative centerline.
1 Edges of the ROW have not been established and are assumed to be either 75 feet or 100 feet from centerline.

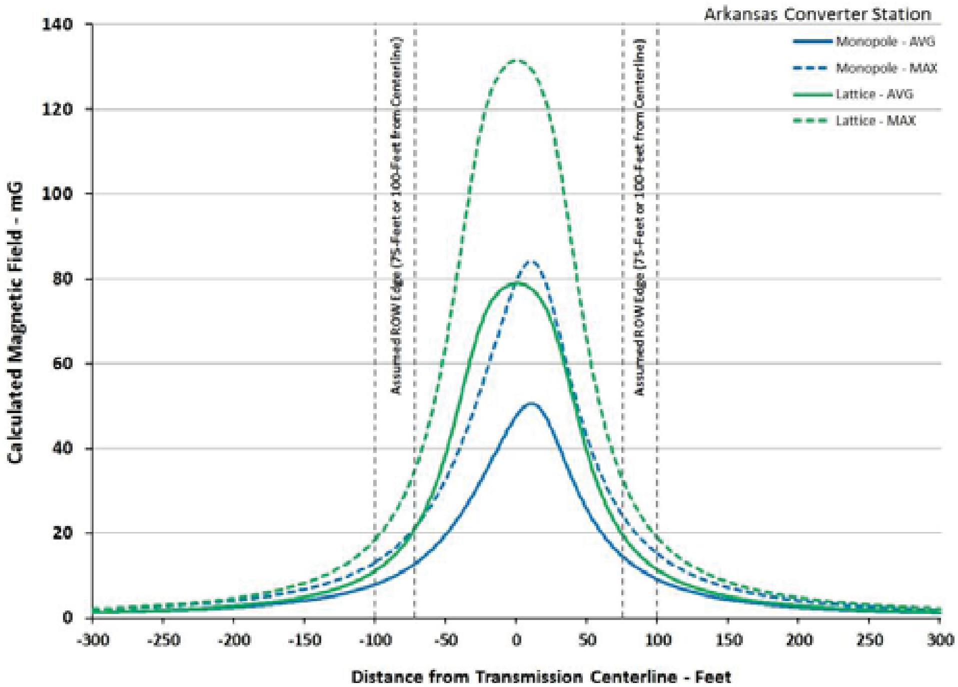

Figure 3.4-43: Calculated AC Magnetic Fields for 500kV AC Transmission Line Interconnections to Arkansas Converter Station (Average and Maximum Loading)

Calculated magnetic field levels at the ROW edges for both AC transmission line interconnection designs are below the ICES and ICNIRP guidelines for public exposure (9,040mG and 2,000mG, respectively). Calculated magnetic field levels within the ROW are also below the ACGIH guideline of 1,000mG for workers with implanted medical devices for both configurations.

3.4.11.3.1.2.3 AC Audible Noise Calculation Results

Audible noise calculations were performed for both AC transmission line interconnection designs. Table 3.4-44 presents a summary of the calculated day-night (L_{dn}) audible noise at the ROW edges and for the maximum noise level within the ROW. Calculated levels vary, depending upon the line configuration. Figure 3.4-44 presents a graph of the calculated audible noise for each AC transmission line configuration.

Table 3.4-44:
Calculated Audible Noise for 500kV AC Transmission Line Interconnections to Arkansas Converter Station

500kV AC Transmission Line Configuration	Calculated Audible Noise (dBA)—L_{dn}[1]				
	-100 Feet from CL	-75 Feet from CL	Maximum on ROW	+75 Feet from CL	+100 Feet from CL
Single Circuit Monopole	54.8	55.8	58.4	56.3	55.3
Single Circuit Lattice	56.7	57.8	60.2	57.8	56.7

CL = Centerline; since the precise ROW width has not yet been determined, the ROI for analysis is 300 feet on either side of a representative centerline.

1 Edges of the ROW have not been established and are assumed to be either 75 feet or 100 feet from centerline.

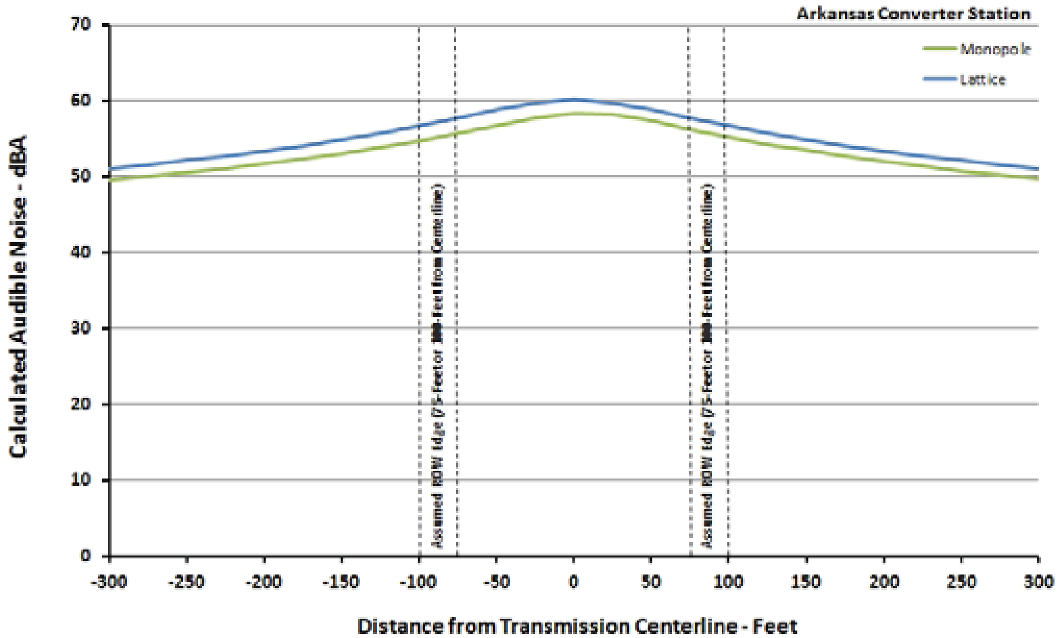

Figure 3.4-44: Calculated Audible Noise Levels (L_{dn}) for 500kV AC Transmission Line Interconnections to Arkansas Converter Station

Calculated audible noise levels at the ROW edges (either 75 feet or 100 feet from centerline of the transmission line) for both AC transmission line interconnections are at or above the EPA guideline for L_{dn} (day-night) noise of 55 dBA (the monopole configuration is just under the EPA guideline at 54.8 dBA for one ROW edge at 100 feet from centerline). Calculated audible noise levels assume an overvoltage condition of 10 percent at the highest line elevation (3,000 feet).

3.4.11.3.1.2.4 AC Radio Noise Calculation Results

Radio noise calculations were performed for both AC transmission line interconnection designs for rainy and fair weather conditions. Table 3.4-45 presents a summary of the calculated radio noise at the ROW edges and for the maximum noise within the ROW at 500kHz for both weather conditions. Table 3.4-45 also presents calculated 500kHz radio noise at 50 feet from the outside conductor for comparison with the IEEE Standard. Calculated radio noise levels vary, depending upon the line configuration and weather conditions. As shown in Table 3.4-45, calculated radio noise levels at 50 feet from the outside conductor comply with the IEEE 61 dB:V/m threshold in fair weather conditions. Figure 3.4-45 presents a graph of the calculated radio noise levels for each AC line configuration in rainy weather, adjusted to the 500kHz reference level. Figure 3.4-46 presents a corresponding graph of the calculated radio noise levels for fair weather (adjusted to the 500kHz reference level).

Table 3.4-45:
Calculated Radio Noise for 500kV AC Transmission Line Interconnections to Arkansas Converter Station

500kV AC Transmission Line Configuration	Calculated Radio Noise (dB:V/m) at 500kHz (Rainy/Fair Weather)[1]						
	-100 Feet from CL	-50 Feet from Outside Conductor	-75 Feet from CL	Maximum on ROW	+75 Feet from CL	+50 Feet from Outside Conductor	+100 Feet from CL
Single Circuit Monopole	65.3/48.3	71.3/54.3	69.5/52.5	85.9/68.9	69.9/52.9	72.5/55.5	65.8/48.8
Single Circuit Lattice	65.8/48.8	71.0/54.0	71.9/54.9	88.1/71.1	71.9/54.9	71.0/54.0	65.8/48.8

CL = Centerline; since the precise ROW width has not yet been determined, the ROI for analysis is 300 feet on either side of a representative centerline.

1 Edges of the ROW have not been established and are assumed to be either 75 feet or 100 feet from centerline

It is difficult to determine whether the radio noise produced by a transmission line or any other source would cause unacceptable interference without knowing broadcast signal strengths at various locations of interest along the possible line routes.

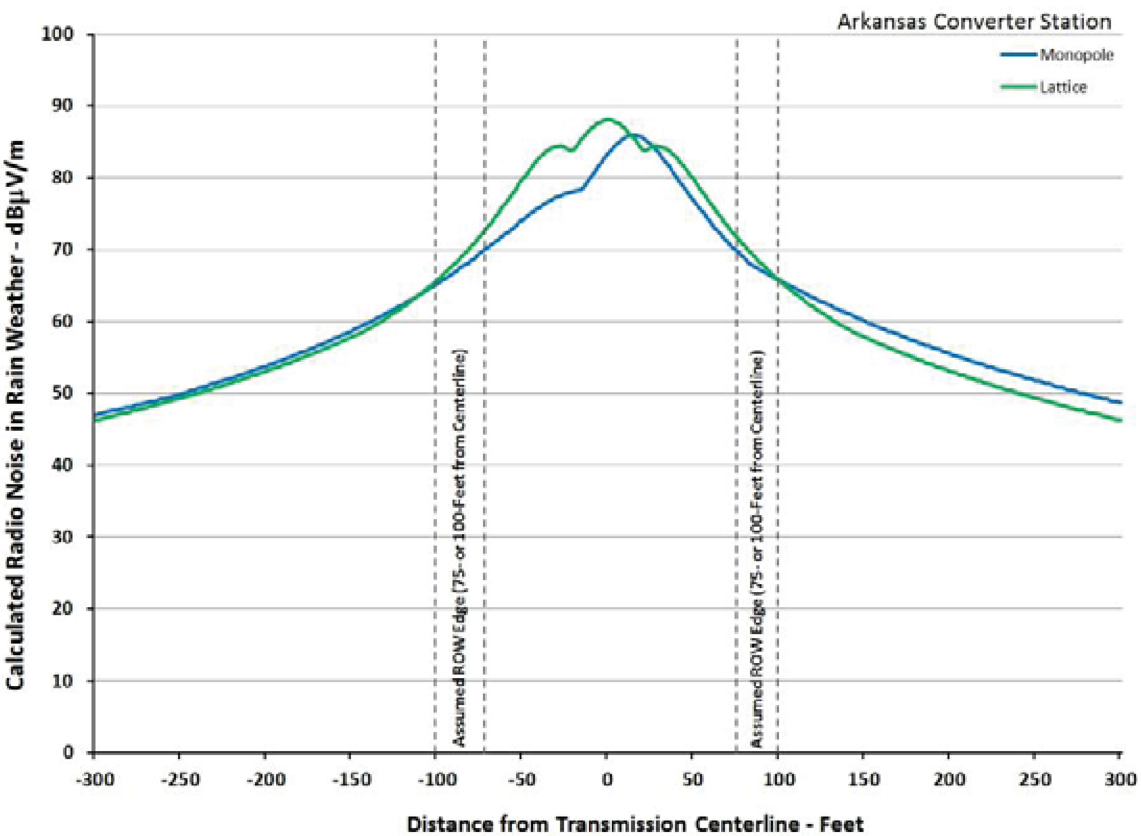

Figure 3.4-45: Calculated Radio Noise for 500kV AC Transmission Line Interconnections to Arkansas Converter Station (Rainy Weather)

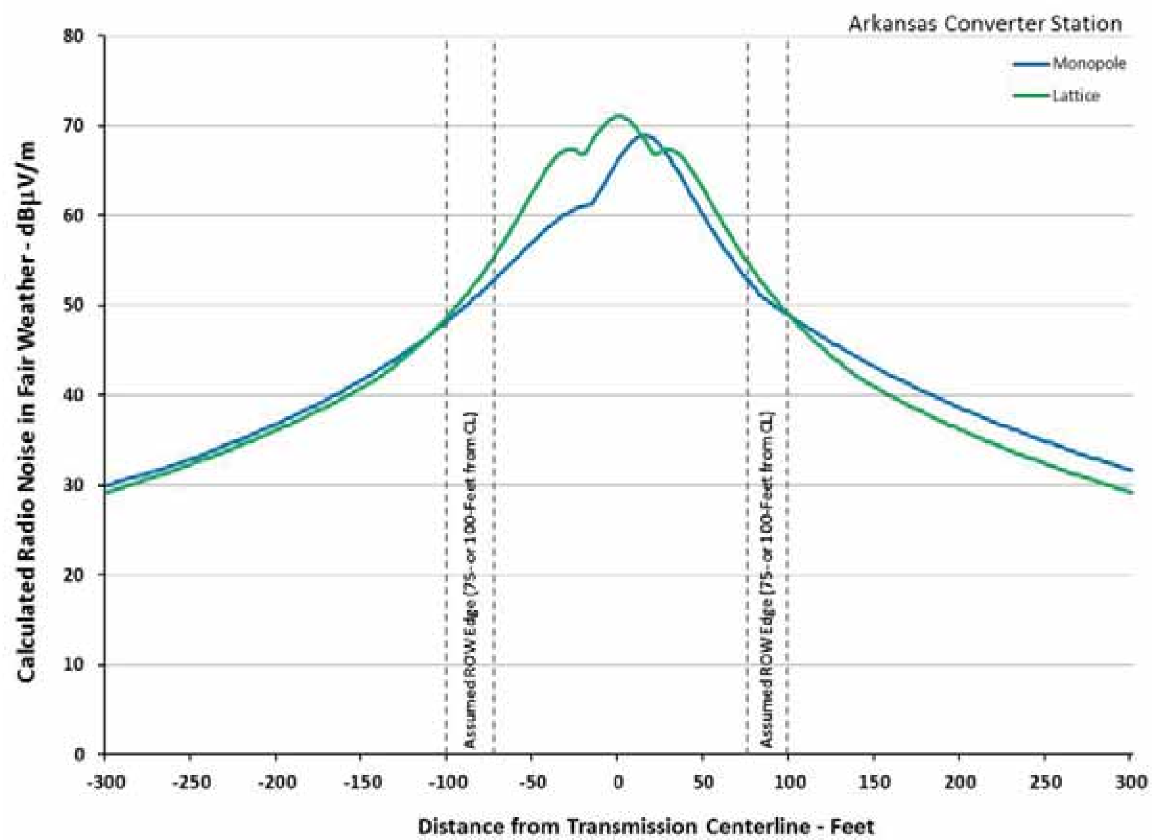

Figure 3.4-46: Calculated Radio Noise for 500kV AC Transmission Line Interconnections to Arkansas Converter Station (Fair Weather)

3.4.11.3.1.2.5 AC Television Noise Calculation Results

Television noise calculations were performed for both AC transmission line interconnections for rainy weather conditions. Table 3.4-46 presents a summary of the calculated television noise at the ROW edges and for the maximum noise within the ROW for the 75MHz reference level. Calculated television noise levels vary, depending upon the line configuration. Figure 3.4-47 presents a graph of the calculated television noise levels for each AC line configuration in rainy weather.

Table 3.4-46:
Calculated Television Noise for 500kV AC Transmission Line Interconnections to Arkansas Converter Station

500kV AC Transmission Line Configuration	Calculated Television Noise (dB:V/m) at 75MHz for Rainy Weather[1]				
	-100 Feet from CL	-75 Feet from CL	Maximum on ROW	+75 Feet from CL	+100 Feet from CL
Single Circuit Monopole	23.9	25.9	38.3	29.1	26.4
Single Circuit Lattice	27.2	29.5	40.5	29.5	27.2

CL = Centerline; since the precise ROW width has not yet been determined, the ROI for analysis is 300 feet on either side of a representative centerline.

1 Edges of the ROW have not been established and are assumed to be either 75 feet or 100 feet from centerline.

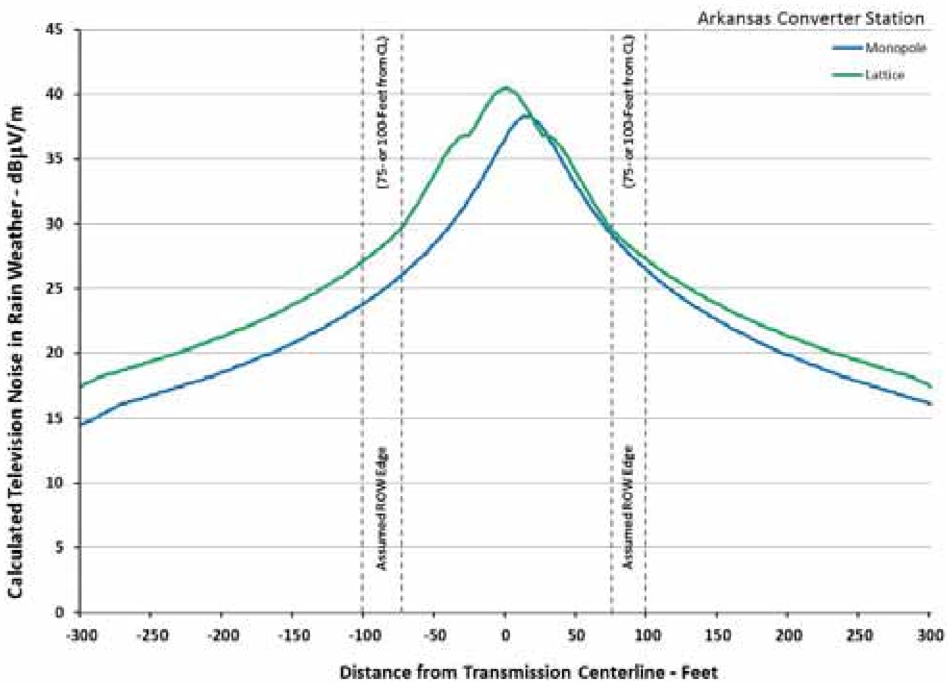

Figure 3.4-47: Calculated Television Noise for 500kV AC Transmission Line Interconnections to Arkansas Converter Station (Rainy Weather)

As with radio noise interference, it is difficult to determine whether the television noise level produced by a transmission line would cause unacceptable interference. However, the new digital broadcast system technology for radio and television should provide better coverage and immunity to transmission line noise than analog television signals. No interference resulting from corona-generated noise would be expected for digital signals broadcast at frequencies above 1GHz from satellites (EPRI 2006a).

3.4.11.3.1.2.6 Ozone Calculation Results

Ozone levels for both AC transmission line interconnections were calculated for rainy weather conditions. Table 3.4-47 presents a summary of the calculated maximum ozone concentrations at ground level within 300 feet of the transmission centerline. Maximum ozone levels are far below the EPA standard of 75 ppb for all three line design configurations.

Table 3.4-47:
Calculated Ozone Levels for 500kV AC Transmission Line Interconnections to Arkansas Converter Station

500kV AC Transmission Line Configuration	Calculated Ozone (ppb)
	Maximum within +/-300 Feet of CL
Single Circuit Monopole	0.1
Single Circuit Lattice	0.2

CL = Centerline; since the precise ROW width has not yet been determined, the ROI for analysis is 300 feet on either side of a representative centerline.

3.4.11.3.1.3 Decommissioning Impacts

There are no electrical effects associated with the decommissioning of the Arkansas converter station, the 500kV AC transmission line interconnections, or the new substation. Once decommissioned, there would be no electrical energy to create electrical effects such as electric and magnetic fields, audible noise, and radio and television interference.

3.4.11.3.2 HVDC Alternative Routes

This section describes the electrical effects associated with the HVDC alternative routes. Electrical effects would only be present during operation and maintenance of the transmission line. Electrical facilities need to be energized to create electrical effects such as electric and magnetic fields, audible noise, and radio and television interference. Electrical effects would not be present during the construction and decommissioning phases of the Project.

Existing facilities are present within these alternative transmission line routes, some of which already create electrical effects within the environment. Table 3.4-48 presents the number of existing AC transmission lines that parallel alternative HVDC transmission line routes as well as nearby communication facilities (which are existing radio-frequency sources) within a 1,000-foot-wide corridor for each proposed route alternative. Table 3.4-48 also presents a summary of the number of existing building structures (residences, agricultural buildings, churches, and schools) within the same 1,000-foot-wide corridor for each HVDC transmission line alternative route.

Table 3.4-48:
Occurrence of Existing Facilities along HVDC Alternative Routes

HVDC Alternative Route	Parallels Existing AC Transmission Lines (Quantity and Voltage Range)	Existing Building Structures within 1,000-Foot-Wide Corridor (Residential/ Agricultural/Church/School)[1]	Existing Communication Facilities Within 1,000-Foot-Wide Corridor (Quantity and Type)[2]

2 GIS Data Source: FCC (2012)

3.4.11.3.2.1 Construction Impacts

No electrical effects would be associated with construction of the ±600kV HVDC overhead electric transmission line along any of the HVDC alternative routes, because these facilities would not be energized during construction.

3.4.11.3.2.2 Operations and Maintenance Impacts

Section 3.4.11.2.3 describes the results of the modeling calculations for electrical effects for the two proposed DC transmission line configurations.

3.4.11.3.2.2.1 Summary of Impacts for the DOE Alternative Transmission Lines

Based on an evaluation of research and guidelines recommended by various agencies, it is unlikely that the DOE alternative transmission lines would pose a known threat to human health (reference Section 3.4.11.2.1.2.2.7). In addition, the likelihood of annoyance to landowners by audible noise from the line or interference to AM radio or television reception is small.

While a variety of electronic devices are known to affect the operation of pacemakers and ICDs, transmission lines have not been reported to produce functional disturbances to these devices. There is a possibility that induced potentials on the leads of these devices by AC electric fields on the ROW could affect the operation of these devices, but the clinical significance of such changes appears small. Persons who are concerned should contact their physician to ascertain the immunity of their device to this potential source of interference.

3.4.11.3.2.3 Decommissioning Impacts

No electrical effects would be associated with the decommissioning of the ±600kV HVDC overhead electric transmission line. Once decommissioned, no electrical energy would be generated that would create electrical effects such as electric and magnetic fields, audible noise, and radio and television interference.

3.4.11.4 Best Management Practices

Based upon the EPMs already proposed by the Applicant, no BMPs are suggested.

Concerns were raised in public comments on the Draft EIS that EMP hardening of the transmission lines should be considered to protect them from solar flares or a nuclear weapon. While this issue is not directly related to electrical effects, environmental or man-made pulses of this type could possibly have an effect on the converter station electrical equipment rather than the transmission line itself. Natural events or intentional destructive acts could potentially impact the system. DOE has identified a BMP to develop and implement a Health and Safety Plan that includes overall natural disaster and emergency responder contact procedures (Section 3.8.5.2).

3.4.11.5 Unavoidable and Adverse Impacts

Impacts concerning electrical effects are discussed in Section 3.4.6. Unavoidable and potentially adverse impacts are the electrical effects (electric and magnetic fields, radio and television noise, audible noise, ozone, and air ions) associated with the operation of overhead HVDC and/or AC transmission lines. These effects are present within, and to a more limited extent outside of, the transmission line ROW. Outside of the ROW, calculated electrical effects for the Project are generally limited to levels that comply with associated standards and guidelines.

3.4.11.6 Irreversible and Irretrievable Commitment of Resources

No irreversible or irretrievable commitment of resources associated with electrical effects and the Project.

3.4.11.7 Relationship between Local Short-term Uses and Long-term Productivity

No short-term uses or resource removal exist that would affect long-term productivity associated with electrical effects from the Project.

3.4.11.8 Impacts from Connected Actions

3.4.11.8.1 Wind Energy Generation

Electricity for numerous wind energy generation facilities may be transported across the ±600kV HVDC overhead electric transmission line. Electrical equipment associated with wind farms includes wind turbine generators (rotor blades connected to a turbine generator/drive train and supported on a steel tower approximately 200 to 330 feet above ground level), underground collection cables to carry lower-voltage electricity from individual wind turbine generators to an electric transformer (usually located within a substation), electric transformers (to convert lower-voltage electricity to higher-voltage), and AC transmission lines to connect the wind power generation to the electrical grid. Often substations will also contain circuit breakers, capacitor banks, relaying equipment, high voltage bus work, metal clad switchgear, and related electrical equipment.

An evaluation of the electrical effects associated with wind energy generation facilities only includes AC magnetic fields. No DC electric or magnetic fields from Project sources are present, since the wind farm electrical system is strictly an AC system. Because the wind turbine generator is housed within a steel structure, and the collection cables are located either within the steel tower structure or underground (i.e., shielded); there are no AC corona effects (audible noise, radio and television noise, and ozone generation) associated with this equipment. Likewise, there are no AC electric field effects. While audible noise and interference may be present from the generator itself and/or the turning rotor blades, this does not result from the flow of electricity and is therefore not an electrical effect. The only remaining electrical effect under consideration then is the AC magnetic field.

A wind turbine generator is located at the top of the steel support tower, typically 200 to 300 feet (or more) above ground level, and housed within the structural steel tower. This arrangement results in very low (if any) magnetic field at ground level due to the generator (McCallum et al. 2014). The collection cables are located either within the steel support tower or collocated together within an underground duct. Placing the cables in close proximity to each other increases the magnetic field cancellation between cables (because the magnetic field produced by a set of conductors is proportional to the average spacing between conductors) (EPRI 1999), so a magnetic field may be present directly above an underground cable (depending upon a number of parameters, including the loading, phase configuration, grounding configuration, and depth of the cables). Nevertheless, the magnetic field will typically decrease very quickly with distance away from cable (Naikun 2014), much more so than from overhead transmission lines. Magnetic fields from these cables will usually be located within the wind farm facility (connecting the wind farm turbines to the substation), so it is not anticipated that significant magnetic fields will be associated with the wind farm generation system itself outside the ROI (SCC 2011; Rideout et al. 2010; Fortin et al. 2013).

For substations, the dominant sources of electrical effects are the overhead transmission lines entering and exiting the substations (which are addressed within the AC collection system). Some types of substation equipment can potentially be a source of electrical effects (for example, power transformers can produce audible noise). These effects can be reduced or eliminated by the use of filtering equipment, sound walls, and other methods. Because the dominant sources of electrical effects are associated with the overhead transmission lines, not substation equipment, an evaluation of electrical effects for substations associated with wind generation facilities was not performed.

3.4.11.8.2 Optima Substation

For substations, the dominant sources of electrical effects are the overhead transmission lines entering and exiting the stations. Some types of substation equipment can potentially be a source of electrical effects (for example, power transformers can produce audible noise, and converter equipment can produce radio noise, etc.).

3.4.11.8.3 TVA Upgrades

Upgrades required to interconnect into the TVA transmission grid could contribute to AC electric fields, AC magnetic fields, audible noise caused by corona discharge from the transmission line conductors, radio and television noise interference, and ozone. These effects are associated with energized AC transmission lines so electrical effects of concern would not occur during construction of the required TVA upgrades.

Electrical impacts from the new TVA 500kV transmission line would be expected to be similar to those described for the 500kV AC transmission lines associated with the Tennessee and Arkansas converter stations (Sections 3.4.11.2.1.2.2 and 3.4.11.3.1). Lower impacts would be expected from the TVA upgrades to transmissions lines because the 161kV transmission lines that would be affected already exist. Impacts at or near ground level can vary substantially based on the height of the transmission structure and on the structure/line configuration as well as the electrical energy transmitted. The loading would also impact magnetic field levels.

Upgrades to substation equipment would also be made for the TVA interconnection, which would include modifications to existing substations on the terminal ends of the new line and upgrading terminal equipment at three existing 500kV and three existing 161kV substations (reference Section 2.5.2 for a complete description of these upgrades). For substations, the dominant sources of electrical effects are typically the overhead transmission lines entering and exiting the substations (rather than substation equipment). However, some types of substation equipment can potentially be a source of electrical effects (for example, power transformers can produce long-term audible noise). These long-term effects can be reduced or eliminated by the use of filtering equipment, sound walls, and other methods. Because the dominant sources of electrical effects are typically associated with the overhead transmission lines, not substation equipment, an evaluation of electrical effects for substation upgrades associated with the TVA interconnection was not performed.

3.4.11.9 Impacts Associated with the No Action Alternative

Under the No Action Alternative, DOE assumes for analytical purposes that the Project would not move forward. The existing electrical environment would remain in its present condition. DC electric and magnetic fields would always be present because of other existing facilities and natural sources. If the ±600kV HVDC overhead electric transmission line is not constructed, then no additional DC electric or magnetic fields would be introduced along any of the Project routes. Because AC electric fields, audible noise, and radio and television interference attributable to corona activity from overhead AC power lines already exist along portions of the Project routes, and voltage on a power line is held relatively constant, these existing electrical effects would remain unchanged. AC magnetic fields attributable to existing overhead AC power lines vary with loading on each of the lines and would continue to do so.

Tables

Figures Presented in Appendix A

3.5 Environmental Justice

This section presents the affected environment and provides an assessment of the potential for disproportionately high and adverse environmental or human health effects on minority and/or low-income populations from the Plains & Eastern Project, in accordance with Executive Order (EO) 12898.

Minority populations include individuals who are Black or African American, American Indian and Alaska Native, Asian, Native Hawaiian and other Pacific Islander, other non-white race, or persons of two or more races and Hispanic or Latino. Low-income populations include individuals living below the poverty line, as defined by the U.S. Census Bureau.

3.5.1 Regulatory Background

Environmental justice laws and regulations relevant to the resources in the ROI are summarized in Table 3.5-1.

Table 3.5-1:
Legal Authorities Addressing Environmental Justice

Statute/Regulation	Applicability to the Project
Federal	
EO 12898 (59 FR 7629): Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations as amended by EO 12948	Requires each federal agency to make the achievement of environmental justice part of its mission by identifying and addressing disproportionately high and adverse human health or environmental effects of its programs, policies, and activities on minority and low-income populations. The EO further directs agencies to conduct their programs and activities in a manner that does not have the effect of excluding persons from participation in them, denying persons the benefits of them, or subjecting persons to discrimination because of their race, color, or national origin.

3.5.2 Data Sources

This environmental justice analysis uses the U.S. Census Bureau 2010 Census of Population and Housing and the 2011 American Community Survey Demographic and Housing Estimates for population and income data for Census Block and Block Groups that are wholly or partially within the ROI. The data used were the most current data available during the preparation of the EIS. Subsequently, 2013 Census data were released during the preparation of the Final EIS. An analysis of the 2013 data shows while small changes in minority and low-income populations occurred, no substantial changes occurred between the 2011 and 2013 data that would change the conclusion regarding environmental justice impacts.

The U.S. Census Bureau has defined levels of statistical geographic entities to present data from the decennial census and American Community Survey. Counties are divided into Census Tracts, Census Tracts into Census Block Groups, and Census Block Groups into Census Blocks, the smallest statistical area the Census uses to report sample data. Figure 3.5-1 in Appendix A shows the Census Block Groups with low income populations in the ROI.

3.5.3 Region of Influence

The ROI for environmental justice considers the area where potential impacts could occur. The ROI for identifying low-income and minority populations consists of Census Block Groups or Census Blocks, respectively, within the counties intersected by the Project as described in Section 3.1. Census Blocks within the ROI are used to identify potential minority populations while Census Block Groups are used to identify potential low-income populations.

Census Block Groups are used in the analysis of low-income populations because income data are not collected/not available at the Census Block level. Poverty thresholds are based on the Office of Management and Budget's Statistical Policy Directive 14.

Census Blocks are statistical areas bounded by visible features, such as streets, roads, streams, and railroad tracks, and by nonvisible boundaries, such as property lines and city, township, school district, and county limits and short line-of-sight extensions of streets and roads.

Census Block Groups are generally defined to contain between 600 and 3,000 people and usually cover a contiguous area. Census Block Groups do not cross state, county, or census tract boundaries, but may cross boundaries of any other geographic entity. Census data on income are reported only for a sample of the population and therefore are reported only at the Census Block Group level.

3.5.3.1 Region of Influence for the Applicant Proposed Project

The environmental justice ROI for the Applicant Proposed Project consists of Census Blocks and Census Block Groups in the counties where the proposed facilities would be located. The ROI is divided into seven regions for the purposes of this analysis. Table 3.5-2 presents the counties within the environmental justice ROI.

Table 3.5-2:
Counties Potentially Affected by the Applicant Proposed Project by Region

Region	State	County[1]
1	Oklahoma	Cimarron, Texas, Beaver, Harper
	Texas	Hansford, Ochiltree, Sherman
2	Oklahoma	Woodward, Major, Garfield
3	Oklahoma	Garfield[2], Kingfisher, Logan, Payne, Lincoln, Creek, Okmulgee, Muskogee[2]
4	Oklahoma	Muskogee[2], Sequoyah
	Arkansas	Crawford, Franklin, Johnson, Pope[1]
5	Arkansas	Pope[2], Conway, Faulkner, Van Buren, Cleburne, White, Jackson
6	Arkansas	Jackson[2], Poinsett[2], Cross
7	Arkansas	Poinsett, Mississippi
	Tennessee	Tipton, Shelby

1 Counties are generally listed from west to east by region.
2 Counties located in more than one region.

Several route variations to the Applicant Proposed Route in Regions 2–7 were developed in response to public comments on the Draft EIS and are described in Appendix M and summarized in Sections 2.4.2.1–2.4.2.7. Assessments of the impacts related to the route variations by Project region, including accompanying HVDC alternative route adjustments, are provided below. The variations are presented graphically in Exhibit 1 of Appendix M.

3.5.3.2 Region of Influence for the DOE Alternatives

The ROI for the DOE Alternatives consist of the same counties as those listed for the Applicant Proposed Project.

3.5.3.3 Region of Influence for Connected Actions

3.5.3.3.1 Wind Energy Generation

Census Block Groups are used for the wind energy generation analysis because the exact location of wind farms and turbines has not been identified; therefore, larger geographic units for the environmental justice analysis were used. The ROI for wind energy generation includes Census Block Groups within the counties that contain WDZs. These counties include Beaver, Cimarron, and Texas counties in Oklahoma and Hansford, Ochiltree, and Sherman counties in Texas.

3.5.3.3.2 Optima Substation

The ROI for the future Optima Substation includes Census Blocks and Census Block Groups in Texas County, Oklahoma.

3.5.3.3.3 TVA Upgrades

The ROI for evaluation of impacts on environmental justice from the TVA upgrades is the same as that identified in Section 3.1.1.

3.5.4 Affected Environment

The affected environment for environmental justice analysis includes Census Blocks and Census Block Groups (described in Section 3.5.3) in Texas, Oklahoma, Arkansas, and Tennessee. The sections below identify low-income and minority populations within the affected environment.

For the analysis in this EIS, a population is defined as minority population in terms of race and ethnicity if 50 percent or more of the population within the Census Block is minority or if the Census Block population has a “meaningfully greater” percentage of minorities compared to the entire county. For this analysis “meaningfully greater” is defined as 10 percentage points higher than the minority population of the whole county.

Low-income populations are identified as low-income populations if 20 percent or more of the households within the Census Block Group live below the poverty level. Poverty thresholds vary based on the size of the family and age of its members, but do not vary based on geographic region. The weighted average threshold ranges from $11,484 for a one-person household to $46,572 for a household with nine or more family members (GIS Data Source: USCB 2011).

3.5.4.1 Texas

The 2-mile-wide corridor for the AC collection system routes in Texas includes 246 Census Blocks and 5 Census Block Groups in three counties in Texas. A majority of the Census Blocks and Census Block Groups have demographics similar to their respective counties.

Table 3.5-3 presents data on Census Blocks with identified minority populations, and Table 3.5-4 presents data on Census Block Groups with identified low-income populations.

No route variations were proposed in Texas.

Table 3.5-3:
Race and Ethnicity Comparison for Census Blocks in the AC Collection System Routes in Texas

Census Block by County[1]	Total Population	Minority	AC Collection System Route
Ochiltree	10,147	49.80%	
Census Tract 950100, Block 2036	11	54.50%	NE-2, SE-3
Sherman	3,019	40.60%	
Census Tract 650200, Block 1179	12	100.00%	SW-2

1 Blocks presented represent identified minority populations as defined in Section 3.5.4.
Source: USCB (2011)

Table 3.5-4:
Poverty Status for Census Block Groups in the AC Collection System Routes in Texas

Census Block Group[1]	Total Households	Percentage of People Below Poverty	Household Median Income	AC Collection System Route
Hansford	1,895	13.3	$52,610	
Census Tract 9503, Block Group 1	417	28.5	$40,179	SE-1

1 Block Groups presented represent identified low-income and minority populations as defined in Section 3.5.4.
GIS Data Source: USCB (2011)

Two Census Blocks in the AC collection system routes were identified as having minority populations that are 50 percent or more of the population within the Census Block (Table 3.5-3). One Census Block Group was identified as having populations (Table 3.5-4) of low income and poverty.

3.5.4.2 Oklahoma

The 1,000-foot-wide corridor for the Applicant Proposed Route includes 891 Census Blocks and 51 Census Block Groups in 15 counties in Oklahoma. A majority of the Census Blocks and Census Block Groups have demographics similar to their respective counties and are predominantly white.

Nine route variations to the Applicant Proposed Route were developed in Oklahoma in response to public comments on the Draft EIS. Only three Census Blocks in Region 4, Link 3, Variation 2, were identified as having minority populations. The route variations are described in Appendix M and summarized in Sections 2.4.2.1–2.4.2.7. The variations are illustrated in Exhibit 1 of Appendix M.

- Region 2, Link 1, Variation 1—The location is in Woodward County. The variation is located in five of the same Census Blocks as the Applicant Proposed Route and two additional Census Blocks not included in the Applicant Proposed Route. The variation is located in the same Census Block Groups as the Applicant Proposed Route.
- Region 2, Link 2, Variation 2—The location is in Major County. The variation is located in the same Census Blocks as the Applicant Proposed Route and five additional Census Blocks not included in the Applicant Proposed Route. The variation is located in the same Census Block Group as the Applicant Proposed Route.
- Region 3, Link 1, Variation 2—The location is in Payne County. The variation is located in the same Census Blocks and Census Block Groups as the Applicant Proposed Route.
- Region 3, Link 1 and 2, Variation 1—The location is in Payne County. The variation is located in the same Census Blocks and Census Block Groups as the Applicant Proposed Route.
- Region 3, Link 4, Variation 1—The location is in Lincoln County. The variation is located in the same Census Blocks and Census Block Groups as the Applicant Proposed Route.

- Region 3, Link 4, Variation 2—The location is in Creek County. The variation is located in the same Census Blocks and Census Block Groups as the Applicant Proposed Route.
- Region 3, Link 5, Variation 2—The location is in Muskogee County. The variation is located in the same Census Blocks and Census Block Groups as the Applicant Proposed Route and one additional Census Block not included in the Applicant Proposed Route.
- Region 4, Link 3, Variation 1—The location is in Sequoyah County. The variation is located in the same Census Blocks and Census Block Groups as the Applicant Proposed Route.
- Region 4, Link 3, Variation 2—The location is in Sequoyah County. The variation is located in six of the same Census Blocks as the Applicant Proposed Route and eight additional Census Blocks not included in the Applicant Proposed Route. Three of the eight additional Census Blocks contained minority populations. The variation is located in the same Census Block Group as the Applicant Proposed Route.

The 2-mile-wide corridor for the AC Collection System Route includes 1,075 Census Blocks and eight Census Block Groups in Beaver, Cimarron, and Texas counties in Oklahoma. The population in all three counties is predominantly white. Of the three counties, Texas County has the highest minority population with more than 40 percent of the county's population identifying as Hispanic.

Nineteen Census Blocks and one Census Block Group were identified in the Oklahoma Converter Station Siting Area.

Table 3.5-5 presents data on Census Blocks with identified minority populations and Table 3.5-6 presents data on Census Block Groups with identified low-income populations.

Table 3.5-5:
Race and Ethnicity Comparison for Census Blocks in the ROI in Oklahoma

Census Block by County[1]	Total Population	Minority	Project Feature
Creek	69,450	21.60%	
Census Tract 0211.02, Block 2087	11	54.60%	Applicant Proposed Route (Region 3)

1 Block Groups presented represent identified low-income populations as defined in Section 3.5.4. Project features not listed indicate that no low-income and minority populations were identified within that project feature. For example, the Oklahoma Converter Station is not listed because no low-income and minority populations were identified within the Oklahoma Converter Station Siting Area.
Source: USCB (2011)

Eighteen Census Blocks in the Applicant Proposed Route and one Census Block in the HVDC alternative routes were identified as having greater minority populations (Table 3.5-5). Seven Census Block Groups in the Applicant Proposed Route and three Census Block Groups in the HVDC alternative routes were identified as having low-income populations in terms of income and poverty (Table 3.5-6). Ten Census Blocks were identified in the AC collection system routes as having a greater minority population (Table 3.5-5). One Census Block Group was identified in the AC collection system routes as having low-income populations in terms of income and poverty (Table 3.5-6).

Only one of the 19 Census Blocks in the Oklahoma Converter Station Siting Area in Texas County, Oklahoma, was populated. There are no minority or low-income populations in the Oklahoma Converter Station Siting Area.

3.5.4.3 Arkansas

The 1,000-foot-wide corridor for the Applicant Proposed Route and HVDC Alternative Routes includes 597 Census Blocks and 51 Census Block Groups in 13 counties in Arkansas. A majority of the Census Blocks have demographics similar to their respective counties and is predominantly white.

Thirteen route variations to the Applicant Proposed Route were developed in Arkansas in response to public comments on the Draft EIS. No new Census Blocks or Census Block Groups in the route variations were identified as having minority or low-income populations. The route variations are described in Appendix M and summarized in Sections 2.4.2.1–2.4.2.7. The variations are illustrated in Exhibit 1 of Appendix M.

- Region 4, Link 3—The location is in Crawford County. The variation is located in four of the same Census Blocks as the original Applicant Proposed Route and six additional Census Blocks not included in the original Applicant Proposed Route. The variation is located in the same Census Block Groups as the original Applicant Proposed Route.
- Region 4, Link 6, Variation 1—The location is in Crawford County. The variation is located in the same Census Blocks and Census Block Groups as the original Applicant Proposed Route.
- Region 4, Link 6, Variation 2—The location is in Crawford County. The variation is located in the same Census Blocks and Census Block Groups as the original Applicant Proposed Route.

- Region 4, Link 6, Variation 3—The location is in Crawford County. The variation is located in the same Census Blocks and Census Block Groups as the original Applicant Proposed Route.
- Region 4, Link 9, Variation 1—The location is in Pope County. The variation is located in the same Census Blocks and Census Block Groups as the original Applicant Proposed Route.
- Region 5, Link 1, Variation 2—The location is in Pope County. The variation is located in the same Census Blocks as the original Applicant Proposed Route and one additional Census Block not included in the original Applicant Proposed Route. The variation is located in the same Census Block Groups as the original Applicant Proposed Route.
- Region 5, Link 2, Variation 2—The location is in Pope County. The variation is located in the same Census Blocks and Census Block Groups as the original Applicant Proposed Route.
- Region 5, Link 2 and 3, Variation 1—The location is in Pope County. The variation is located in the same Census Blocks and Census Block Groups as the original Applicant Proposed Route.
- Region 5, Link 3 and 4, Variation 2—The location is in Van Buren County. The variation is located in the same Census Blocks and Census Block Groups as the original Applicant Proposed Route.
- Region 5, Link 7, Variation 1—The location is in White County. The variation is located in the same Census Blocks and Census Block Groups as the original Applicant Proposed Route.
- Region 6, Link 2, Variation 1—The location is in Jackson County. The variation is located in the same Census Blocks and Census Block Groups as the original Applicant Proposed Route.
- Region 7, Link 1, Variation 1—The location is in Mississippi County. The variation is located in the same Census Blocks and Census Block Groups as the original Applicant Proposed Route.
- Region 7, Link 1, Variation 2—The location is in Mississippi County. The variation is located in one of the same Census Blocks as the original Applicant Proposed Route and four additional Census Blocks not included in the original Applicant Proposed Route. The variation is located in the same Census Block Groups as the original Applicant Proposed Route.

One hundred thirty Census Blocks and two Census Block Groups occur in the Arkansas Converter Station Alternative Siting Area and AC Interconnection Siting Area.

Table 3.5-7 presents data on Census Blocks with identified minority populations and Table 3.5-8 presents data on Census Block Groups with identified low-income populations.

1 Block Groups presented represent identified low-income populations as defined in Section 3.5.4. Project features not listed indicate that no low-income and minority populations were identified within that project feature. Poverty statuses for Cleburne, Cross, and Johnson counties in Arkansas are not included because there were no Census Block Groups identified within the ROI with 20 percent or more of households below the poverty level.

GIS Data Source: USCB (2011)

Ten Census Blocks in the Applicant Proposed Route and one Census Block in the HVDC alternative routes were identified as having a greater minority population (Table 3.5-7) and 19 Census Block Groups in the Applicant Proposed Route and 12 Census Block Groups in the HVDC alternative routes were identified as having low-income populations (Table 3.5-8).

One Census Block in the Arkansas Converter Station Alternative Siting Area and new substation in Pope County was identified as having minority populations (Table 3.5-7), and three Census Block Groups were identified as having low-income populations (Table 3.5-8).

3.5.4.4 Tennessee

The 1,000-foot-wide corridor for the Applicant Proposed Route includes 33 Census Blocks and 8 Census Block Groups in two counties in Tennessee. A majority of the 33 Census Blocks have demographics similar to their respective counties.

One route variation to the Applicant Proposed Route was developed in Tennessee in response to public comments on the Draft EIS. No new Census Blocks or Census Block Groups in the route variations were identified as having minority or low-income populations. The route variation is described in Appendix M and summarized in Section 2.4.2.7. The variation is illustrated in Exhibit 1 of Appendix M:

- Region 7, Link 5 and 4, Variation 1—The location is in Shelby County. The variation is located in the same Census Blocks and Census Block Groups as the Applicant Proposed Route.

Table 3.5-9 presents data on Census Blocks with identified minority populations and Table 3.5-10 presents data on Census Block Groups with identified low-income populations.

Table 3.5-9:
Race and Ethnicity Comparison for Census Blocks in the ROI in Tennessee

Census Block by County[1]	Total Population	Minority	Project Features
Tipton	60,462	23.60%	
Census Tract 0401.00, Block 2001	307	54.00%	Applicant Proposed Route (Region 7), Alternative Route 7-A, AR 7-B, AR 7-C
Census Tract 0401.00, Block 3014	190	34.20%	Applicant Proposed Route (Region 7), Alternative Route 7-C
Census Tract 0403.03, Block 3006	63	65.10%	Applicant Proposed Route (Region 7), Alternative Route 7-C

1 Blocks presented represent identified minority populations as defined in Section 3.5.4. Project features not listed indicate that no minority populations were identified within that project feature.

Poverty Status for Census Block Groups in the ROI in Tennessee

Census Block Group[1]	Total Households	Percentage of People Below Poverty	Household Median Income	Project Features
Shelby	340,394	20.1	$46,102	
Census Tract 202.10, Block Group 3	848	20.2	$32,933	Applicant Proposed Route (Region 7), Alternative Route 7-B, AR 7-C, Tennessee Converter Station
Tipton	21,578	15.3	$50,869	
Census Tract 401,Block Group 2	394	31.5	$46,722	Applicant Proposed Route (Region 7), Alternative Route 7-A, AR 7-B, AR 7-C

1 Block Groups presented represent identified low-income populations as defined in Section 3.5.4. Project features not listed indicate that no low-income populations were identified within that project feature.
GIS Data Source: USCB (2011)

Three Census Blocks in the Applicant Proposed Route and HVDC Alternative Routes were identified as having a greater minority population (Table 3.5-9), and two Census Block Groups were identified as having low-income populations (Table 3.5-10).

No Census Blocks were identified as having minority populations within the Tennessee Converter Station Siting Area in Shelby County, Tennessee, and one Census Block Group was identified as having low-income populations (Table 3.5-10).

3.5.5 Regional Description

The following includes demographic and economic profiles of the counties within the Project. Table 3.5-11 presents demographic and economic profile of the counties and regions.

3.5.5.1 Region 1

Region 1, located in the Oklahoma Panhandle in Hansford, Ochiltree, and Sherman counties in Texas and Cimarron, Texas, Beaver, and Harper counties in Oklahoma, includes the Applicant Proposed Route and HVDC Alternative Routes I-A through I-D. Figure 3.5-1a in Appendix A shows Census Block Groups containing low-income populations within Region 1.

3.5.5.2 Region 2

Region 2, located in the Oklahoma Central Great Plains in Woodward, Major, and Garfield counties in Oklahoma, includes Applicant Proposed Route and HVDC Alternative Routes 2-A through 2-B. Figure 3.5-1b in Appendix A shows Census Block Groups containing low-income populations within Region 2.

3.5.5.3 Region 3

Region 3, located in the Oklahoma Cross Timbers in Kingfisher, Logan, Payne, Lincoln, Creek, Okmulgee, and Muskogee counties in Oklahoma, includes Applicant Proposed Route and HVDC Alternative Routes 3-A through 3-E. Figure 3.5-1c in Appendix A shows Census Block Groups containing low-income populations within Region 3.

3.5.5.4 Region 4

Region 4, located in the Arkansas River Valley in Sequoyah County in Oklahoma and Crawford, Franklin, and Johnson counties in Arkansas, includes Applicant Proposed Route and HVDC Alternative Routes 4-A through 4-E as well as the Lee Creek Variation. Figure 3.5-1d in Appendix A shows Census Block Groups containing low-income populations within Region 4.

3.5.5.5 Region 5

Region 5, located in Central Arkansas in Pope, Conway, Van Buren, Cleburne, Faulkner, White, and Jackson counties in Arkansas, includes Applicant Proposed Route and HVDC Alternative Routes 5-A through 5-F. Figure 3.5-1e in Appendix A shows Census Block Groups containing low-income populations within Region 5.

3.5.5.6 Region 6

Region 6, located in the Cache River, Crowley's Ridge Area, and St. Francis Channel in Poinsett and Cross counties in Arkansas, includes Applicant Proposed Route and HVDC Alternative Routes 6-A through 6-D. Figure 3.5-1f in Appendix A shows Census Block Groups containing low-income populations within Region 6.

1 Counties located in more than one region. These counties are assigned to one region for the purposes of analysis. Garfield and Muskogee counties, Oklahoma, and Pope County, Arkansas, are assigned to the region that includes the majority of the HVDC transmission line located in that county. The length of transmission line in Jackson and Poinsett counties, Arkansas, is fairly evenly divided between two regions. These counties are included in the first region from east to west. This distribution of counties by region is used throughout the following analysis.

Source: USCB (2011); GIS Data Source: USCB (2011).

3.5.5.7 Region 7

Region 7, located in the Arkansas Mississippi River Delta and Tennessee in Mississippi County in Arkansas, and Shelby and Tipton counties in Tennessee, includes Applicant Proposed Route and HVDC Alternative Routes 7-A through 7-D. Figure 3.5-1f in Appendix A shows Census Block Groups containing low-income populations within Region 7.

3.5.5.8 Connected Actions

3.5.5.8.1 Wind Energy Generation

Table 3.5-12 presents data on Census Block Groups with identified minority populations within the WDZs. Table 3.5-13 presents data on Census Block Groups with identified low-income populations within the WDZs.

Table 3.5-12:
Race and Ethnicity Comparison for Census Block Groups within the WDZs

Census Block Group by County[1]	Total Population	Minority	WDZ
Beaver County	5,586	27.87%	J, K
Census Tract 9516, Block Group 3	680	49.26%	J
Texas County	33,964	41.86%	A, B, C, D, E, F, G, H, I, J
Census Tract 9507, Block Group 2	1,593	79.66%	D, E, F, J
Census Tract 9509, Block Group 1	1,566	88.51%	E
Census Tract 9509, Block Group 5	1,797	103.06%	E
Census Tract 9510, Block Group 2	845	92.19%	F
Hansford County	5,524	57.86%	A, B, C, L
Census Tract 9503, Block Group 1	1,063	69.33%	A, L
Census Tract 9503, Block Group 3	1,728	73.03%	L
Ochiltree County	10,147	71.38%	A, K, L
Census Tract 9503, Block Group 2	2,031	98.97%	A

Census Tract 9504, Block Group 3	2,430	81.69%	A

1 Block Groups presented represent identified minority populations. For Wind Energy Generation, a population is defined as minority population if 50 percent or more of the population within the Block Group is minority or if the Block Group population has a “meaningfully greater” minority population compared to the whole county. Source: USCB (2011)

Table 3.5-13:
Poverty Status for Census Block Groups in the WDZs

Census Block Group by County1	Total Households	Percentage of People Below Poverty	WDZ
Texas County	7,122	14.4%	A, B, C, D, E, F, G, H, I, J
Census Tract 9506, Block Group 4	342	20.5%	I
Census Tract 9509, Block Group 1	630	22.2%	E
Census Tract 9509, Block Group 5	552	23.4%	E
Hansford County	1,895	13.2%	A, B, C, L
Census Tract 9503, Block Group 1	417	28.5%	A, L

Table 3.5-13:
Poverty Status for Census Block Groups in the WDZs

Census Block Group by County1	Total Households	Percentage of People Below Poverty	WDZ
Ochiltree County	3,735	16.9%	A, K, L
Census Tract 9503, Block Group 1	314	21.7%	A
Census Tract 9503, Block Group 2	679	29.9%	A

1 Block Groups presented represent identified low-income populations. Low-income populations are identified as low-income if 20 percent or more of the households within the Block Group live below the poverty level.
GIS Data Source: USCB (2011)

3.5.5.8.1.1 WDZ-A

WDZ-A contains a portion of 10 Census Block Groups in Hansford and Ochiltree counties, Texas. Of the 10 Census Block Groups in WDZ-A, two Census Block Groups were identified as having both minority and low-income populations (i.e., Census Block Group populations were greater than 50 percent minority and people living in poverty exceeded 20 percent), two Census Block Groups were identified as having only minority populations, and one Census Block Group was identified as having only low-income populations (Tables 3.5-12 and 3.5-13).

3.5.5.8.1.2 WDZ-B

WDZ-B contains one Census Block Group in Hansford County, Texas. No potential minority or low-income populations were identified in the WDZ-B (Tables 3.5-12 and 3.5-13).

3.5.5.8.1.3 WDZ-C

WDZ-C contains a portion of two Census Block Groups in Hansford and Sherman counties, Texas. No potential minority or low-income populations were identified in the WDZ-C (Tables 3.5-12 and 3.5-13).

3.5.5.8.1.4 WDZ-D

WDZ-D contains one Census Block Group in Texas County, Oklahoma. One Census Block Group was identified as a minority population within the Census Block Group exceeding 50 percent (Table 3.5-12). No low-income populations were identified in WDZ-D (Table 3.5-13).

3.5.5.8.1.5 WDZ-E

WDZ-E contains a portion of three Census Block Groups in Texas County, Oklahoma. Of the three Census Block Groups in the WDZ-E, two Census Block Groups were identified as having both minority and low-income populations (i.e., Census Block Group populations were greater than 50 percent minority and people living in poverty exceeded 20 percent), and one Census Block Group was identified as having only minority populations (Tables 3.5-12 and 3.5-13).

3.5.5.8.1.6 WDZ-F

WDZ-F contains all or a portion of eight Census Block Groups in Hansford and Sherman counties, Texas. Of the eight Census Block Groups in WDZ-F, two Census Block Groups were identified as having minority populations (Table 3.5-12). No low-income populations were identified in WDZ-F (Table 3.5-13).

3.5.5.8.1.7 WDZ-G

The WDZ-G contains a portion of two Census Block Groups in Cimarron and Texas counties, Oklahoma. No minority or low-income populations were identified in the WDZ-G (Tables 3.5-12 and 3.5-13).

3.5.5.8.1.8 WDZ-H

The WDZ-H contains one Census Block Group in Texas County, Oklahoma. No minority or low-income populations were identified in WDZ-H.

3.5.5.8.1.9 WDZ-I

The WDZ-I contains all or a portion of five Census Block Groups in Texas County, Oklahoma. Of the five Census Block Groups in WDZ-I no minority populations were identified (Table 3.5-12). One Census Block Group was identified as a low-income population in WDZ-I (Table 3.5-13).

3.5.5.8.1.10 WDZ-J

WDZ-J contains all or a portion of three Census Block Groups in Beaver and Texas counties, Oklahoma. Of the three Census Block Groups in WDZ-J, two Census Block Groups were identified as having only minority populations (Table 3.5-12). No low-income populations were identified in WDZ-J (Table 3.5-13).

3.5.5.8.1.11 WDZ-K

WDZ-K contains a portion of three Census Block Groups in Beaver and Ochiltree counties, Texas. No minority or low-income populations were identified in WDZ-K.

3.5.5.8.1.12 WDZ-L

WDZ-L contains a portion of four Census Block Groups in Hansford and Ochiltree counties, Texas. Of the four Census Block Groups in the WDZ-L, one Census Block Group was identified as having both minority and low-income populations (i.e., Census Block Group populations were greater than 50 percent minority and people living in poverty exceeded 20 percent) and one Census Block Group was identified as having only minority populations (Tables 3.5-12 and 3.5-13).

3.5.5.8.2 Optima Substation

The ROI for the future Optima Substation includes Census Blocks and Census Block Groups in Texas County, Oklahoma. The affected environment for the future Optima Substation would be similar to the affected environment discussed in Section 3.5.4.2.

3.5.5.8.3 TVA Upgrades

The ROI for the direct assignment facilities (which are included in the Applicant Proposed Project) would occur within the Tennessee Converter Station Siting Area and more specifically within the Shelby Substation. The ROI for the network upgrades, and in particular TVA's future 500kV transmission line, cannot be fully determined at this time. The new 500kV transmission line would be constructed in western Tennessee. The upgrades to existing facilities would mostly be in western and central Tennessee. Upgrades to existing infrastructure would include upgrading terminal equipment at three existing 500kV substations and six existing 161kV substations, making appropriate upgrades to increase heights on 16 existing 161kV transmission lines to increase line ratings, and replacing the conductors on eight existing 161kV transmission lines. Identification of potential low-income and minority populations by Census Blocks or Block Groups is not possible without more detailed information about the locations of the TVA upgrades. Where possible, general impacts associated with the required TVA upgrades are discussed in the impact sections that follow.

3.5.6 Environmental Justice Impacts

This section discusses potential impacts to minority or low-income populations from the construction and operation of the Project.

3.5.6.1 Methodology

Identifying whether disproportionately high and adverse human health or environmental effects on minority and/or low-income populations would occur typically involves identifying whether minority and/or low-income communities are present and whether the effects identified are predominantly borne by such populations. Minority populations and low-income populations are defined in Section 3.5.4.

The approach used to assess environmental justice concerns is consistent with guidance provided by the White House Council on Environmental Quality (CEQ) (1997): "Environmental Justice: Guidance Under the National Environmental Policy Act" and the 1998 EPA guidance: "Final Guidance for Incorporating Environmental Justice Concerns in EPA's NEPA Compliance Analyses" (EPA 1998).

Impacts can result if the proposed activities cause disproportionately high and adverse human health or environmental effects to minority and/or low-income populations. The environmental impacts from most projects tend to be highly concentrated at the actual project site and tend to decrease with distance from the project site. The environmental justice analysis for the Project examines Census Blocks and Census Block Groups in areas crossed by and in the immediate vicinity of the Project as described in Section 3.5.3. All resource areas analyzed in this EIS have been included in the environmental justice analysis. While impacts from the majority of the resource areas can be measured by proximity to the Project, special attention is given to the effects on human health in local communities. Disproportionately high and adverse human health effects are identified by assessing the following factors:

- Whether the health effects, which may be measured in risks or rates, are adverse and significant (as defined by NEPA) or above generally accepted norms. Adverse health effects may include bodily impairment, infirmity, illness, or death.
- Whether the risk or rate of exposure to a minority or low-income population to an environmental hazard exceeds the risk or rate to the general population.
- Whether adverse health effects occur in a minority or low-income population because of multiple exposures to environmental hazards.

The Applicant would implement the EPMs listed in Appendix F as part of the Project to avoid or minimize potential impacts to environmental resources from construction, operations and maintenance, and/or decommissioning.

3.5.6.2 Impacts Associated with the Applicant Proposed Project

Impacts associated with the Applicant Proposed Project include those from construction, operations and maintenance, and decommissioning of the converter stations, AC transmission lines, and HVDC transmission lines and do not differ significantly. Based on the analysis of impacts for resource areas, few long-term significant impacts from construction, operation and maintenance, and decommissioning activities are expected.

Construction-related impacts could include removal of residential landscaping, power outages or damage to existing utility structures, potential groundwater contamination from excavation and handling of hazardous materials, increases in local traffic at some highway crossings and noise, and fugitive dusts. These impacts would be temporary and localized.

Unavoidable adverse impacts could occur during construction, operations and maintenance, and decommissioning of the Project. These impacts would be expected after implementation of the EPMs and those BMPs that DOE includes in a ROD or participation agreement; however, in all cases, the impacts would have been minimized through implementation of these measures. Unavoidable adverse impacts that could occur for each environmental resource are provided in Chapter 3.

Long-term impacts could include the decrease in the long-term productivity of soils if they are not reclaimed to their existing quality condition; decrease in long-term productivity of recreational areas; increase in economic productivity; and impairment of long-term visual resources where trees or areas of thick vegetation are removed and will take years to grow back. Soil impacts are discussed in Section 3.6, Recreation resources are discussed in Section 3.12, Socioeconomics are discussed in Section 3.13, and Visual resources are discussed in Section 3.18.

Decommissioning-related impacts could include removal of residential landscaping, power outages or damage to existing utility structures, potential groundwater contamination from excavation and handling of hazardous materials, increases in local traffic at some highway crossings and noise, and fugitive dusts. These impacts would be temporary and localized, and are not expected to be high. Decommissioning would remove the long-term visual impacts related to the presence of transmission structures.

Impacts may occur in areas where minority and/or low-income populations were identified; however, it is expected that any impacts would affect all populations in the ROI equally. Therefore, no unavoidable adverse impacts would be disproportionately borne by minority and/or low-income populations as a result of the Project. No long-term significant impacts were discernable to agricultural resources; air quality and climate change; electrical environment; geology, paleontology, soils, and minerals; groundwater; health, safety, and intentional destructive acts; historic and cultural resources; land use; and noise. As shown in Section 3.8, there are no long-term health and safety impacts to any population.

3.5.6.2.1 Converter Stations and AC Interconnection Siting Areas

Section 3.5.4 presents the affected environmental justice characteristics for the Oklahoma Converter Station Siting Area and Tennessee Converter Station Siting Area and AC Interconnection Tie. No minority or low-income populations were identified in the Oklahoma Converter Station Siting Area. No minority populations were identified in the Tennessee Converter Station Siting Area. One Census Block Group in Shelby County contained low-income populations. Impacts from construction, operations and maintenance, and decommissioning activities would be the same as those discussed in Section 3.5.6.2.

3.5.6.2.2 AC Collection System

Section 3.5.4 presents the affected environmental justice characteristics for the AC collection system. Table 3.5-14 lists the AC collection system routes, counties crossed, and counties where minority or low-income populations were identified. Impacts from construction, operation and maintenance, and decommissioning activities would be the same as those discussed in Section 3.5.6.2.

Table 3.5-14:
AC Collection System Route Corridors and Counties where Minority or Low-Income Populations were Identified

AC Collection System Route	Counties Crossed	Counties where Minority or Low-income Populations were Identified
E-1	Oklahoma—Texas and Beaver	Oklahoma—Texas
E-2	Oklahoma—Texas and Beaver	Oklahoma—Texas
E-3	Oklahoma—Texas and Beaver	Oklahoma—Texas
NE-1	Oklahoma—Texas	Oklahoma—Texas
NE-2	Oklahoma—Texas	Oklahoma—Texas

3.5.6.2.3 Applicant Proposed Route

Section 3.5.4 presents the affected environmental justice characteristics for the Applicant Proposed Route in Regions 1-7. Table 3.5-15 lists the HVDC applicant proposed route by region, counties crossed, and counties where minority or low-income populations were identified. Impacts from construction, operation and maintenance, and decommissioning activities would be the same as those discussed in Section 3.5.6.2.

Table 3.5-15:
Applicant Proposed Route and Counties where Minority or Low-Income Populations were Identified

Region	Counties Crossed	Counties where Minority or Low-income Populations were Identified
Region 1	Oklahoma—Texas, Beaver, and Harper	Oklahoma—Texas County
Region 2	Oklahoma—Woodward, Major, and Garfield	Oklahoma—Woodward and Major
Region 3	Oklahoma—Garfield, Kingfisher, Logan, Payne, Lincoln, Creek, Okmulgee, and Muskogee	Oklahoma—Okmulgee and Muskogee

Table 3.5-15:
Applicant Proposed Route and Counties where Minority or Low-Income Populations were Identified

	Tennessee—Tipton and Shelby	Tennessee—Tipton and Shelby

3.5.6.3 Impacts Associated with the DOE Alternatives

Impacts associated with the DOE Alternatives would be the same as those discussed in Section 3.5.6.2 for the Applicant Proposed Project.

3.5.6.3.1 Arkansas Converter Station Alternative Siting Area and AC Interconnection Siting Area

Section 3.5.4 presents the affected environmental justice characteristics for the Arkansas Converter Station and AC Interconnection Siting Areas. Only one Census Block in Pope County had minority and low-income populations. Impacts from construction, operations and maintenance, and decommissioning activities would be the same as those discussed in Section 3.5.6.2.

3.5.6.3.2 HVDC Alternative Routes

Section 3.5.4 presents the affected environmental justice characteristics for the HVDC Alternative routes. Table 3.5-16 lists the counties crossed and the counties where minority or low-income populations were identified for the HVDC alternative routes. Impacts from construction, operation and maintenance, and decommissioning activities under all alternatives would be the same as those discussed in Section 3.5.6.2.

Table 3.5-16:
HVDC Alternative Routes and Counties where Minority or Low-Income Populations were Identified

HVDC Alternative Route	Counties Crossed	Counties where Minority or Low-income Populations were Identified
Region I		
1-A	Oklahoma—Texas, Beaver, Harper, and Woodward	Oklahoma—Texas and Woodward

7-C	Tennessee—Tipton and Shelby	Tennessee—Tipton and Shelby
7-D	Tennessee—Tipton and Shelby	Tennessee—Tipton and Shelby

3.5.6.4 Communities of Shared Interest

The term ‘community of shared interest’ is used to refer to geographically dispersed individuals who could experience common conditions of environmental impacts. The National Agricultural Workers Survey for fiscal years 2001 and 2002 found that 83 percent of crop workers in the United States identified themselves as members of a Hispanic group and that 78 percent of crop workers were born outside the United States, primarily in Mexico (75 percent of all crop workers) (DOL 2005). This survey also found that 30 percent of all farm workers had total family incomes below federal poverty guidelines.

The potential effects of construction on agriculture production are addressed in Section 3.2, and the potential effects to the agricultural sector and employment are discussed in Section 3.13. Operation of the Project has the potential to disproportionately affect minority and low-income farm workers. Viewed in terms of agricultural operations in the potentially affected counties, however, total estimated construction disturbance represents a very small percentage and is not likely to noticeably impact agricultural production or employment or cause adverse impacts to human health or the environment.

3.5.6.5 Best Management Practices

No BMPs have been identified. The Applicant would implement the EPMs listed in Appendix F to avoid or minimize potential impacts to environmental resources from construction, operations and maintenance, and/or decommissioning of the Project.

3.5.6.6 Unavoidable Adverse Impacts

No unavoidable adverse impacts would be disproportionately borne by minority and/or low-income populations as a result of the Project.

3.5.6.7 Irreversible and Irretrievable Commitment of Resources

No irreversible or irretrievable commitment of resources was identified.

3.5.6.8 Relationship between Local Short-term Uses and Long-term Productivity

Because the EIS did not identify any disproportionately high and adverse impacts to low-income or minority populations, there would be no short-term or long-term impact to these populations.

3.5.6.9 Impacts from Connected Actions

3.5.6.9.1 Wind Energy Generation

Section 3.5.3.3.1 presents the affected environmental justice characteristics for wind energy generation. Environmental justice areas were identified in 7 of the 12 WDZs. Tables 3.5-12 and 3.5-13 lists Census Block Groups where minority or low-income populations were identified within WDZs.

Based on the analysis of impacts for resource areas, few long term impacts from construction and operations and maintenance activities are expected.

Impacts related to the construction of wind farms would be short term and could include noise impacts from machinery and blasting, increased levels of fugitive dust and increases in local traffic. Impacts related to operations and maintenance could include visual, noise, or shadow flicker.

In areas where minority and/or low-income populations were identified, it is expected that any impacts would affect all populations in the ROI equally. No high or adverse impacts were discernible to agricultural resources; air quality and climate change; electrical environment; geology, paleontology, soils, and minerals; groundwater; health, safety, and intentional destructive acts; historic and cultural resources; land use; and noise. As shown in Section 3.8, there are no long term impacts to any population.

3.5.6.9.2 Optima Substation

Section 3.5.5.8.2 presents the affected environmental justice characteristics for the future Optima Substation. The future Optima Substation is anticipated to be located within the Oklahoma AC Interconnection Siting Area in Texas County, Oklahoma. Impacts associated with the future Optima Substation would be the same as those discussed in Section 3.5.6.2 for the Applicant Proposed Project.

3.5.6.9.3 TVA Upgrades

Identification of potential low-income and minority populations by county would require more detailed information about the potential locations of the TVA upgrades. Some of the affected counties may have qualifying minority and low-income populations that could raise environmental justice concerns. Depending on location, construction of the new electric transmission line that would be required may have greater potential to affect qualifying minority and low-income populations than required upgrades to existing facilities.

3.5.6.10 Impacts Associated with the No Action Alternative

Under the No Action Alternative, DOE assumes for analytical purposes that the Project would not move forward, so no disproportionately high and adverse effects to low-income and minority populations would result from activities related to construction, operations and maintenance, or decommissioning.

Tables

Figures Presented in Appendix A

3.6 Geology, Paleontology, Minerals, and Soils

This section is divided under two major headings: geology, paleontology, and mineral resources (section 3.6.1) and soils (section 3.6.2). The reason for the separation is that the affected environment and impacts associated with soils—such as farmland, erosion, and compaction—are generally much different than those for geology (e.g. geologic hazards such as earthquakes and karst).

3.6.1 Geology, Paleontology, and Minerals

3.6.1.1 Regulatory Background

One federal law related to geology, paleontology, minerals, or soils that could affect the proposed Project or the manner in which it would be implemented is listed in (Table 3.6.1-1). No applicable state or local quantitative geological or soil regulations exist for the states of Oklahoma, Arkansas, Tennessee, or Texas. Seismic activity prone areas, such as Shelby County, Tennessee, are in the process of evaluating the adoption of the 2009 National Earthquake Hazards Reduction Program Recommended Provisions for Seismic Regulations for New Buildings and Other Structures (FEMA 2009) or other applicable regulations.

Table 3.6.1-1:
Federal Law Associated with Geological Resources

Statute/Regulation	Key Elements
National Earthquake Hazards Reduction Program Reauthorization Act of 2004 (42 USC 7701 *et seq.*)	The purpose of the National Earthquake Hazards Reduction Program Reauthorization Act of 2004 (42 USC 7701 et seq.) is to reduce the risks to life and property from future earthquakes in the United States through the establishment and maintenance of an effective earthquake hazards reduction program. The Act supports the development of standards and technology for buildings and structures to withstand damage from earthquakes.

3.6.1.2 Data Sources

Data sources include published maps and reports and internet websites of the U.S. Geological Survey (USGS), Oklahoma Geological Survey, Arkansas Geological Survey, and Federal Emergency Management Agency (FEMA). Digital information on faults, earthquakes, landslides, karst features, soil liquefaction, and seismicity was obtained from USGS datasets and maps (GIS Data Sources: EIA 2011a, 2011b; Tobin and Weary 2004, USGS 2005a, 2005b, 2008a, 2008b, 2014, 2010; CUSEC 2008; NRCS 2006, 2013; EPA 2014b; Garrity and Soller 2009). Other data sources included academic and professional journals and publications. Reference citations are provided within the text and a complete listing of each reference is provided in Chapter 6. A summary description of the reference sources follows:

- The probabilistic seismic hazard analyses incorporate estimates of the magnitude and location of all likely earthquakes, how often these earthquakes would occur, and the strength of ground shaking they would cause (USGS 2010a, 2010b; USGS and TBEG 2006).
- Karst areas were identified based on information from USGS.
- FEMA Hazus Program Liquefaction Susceptibility Maps (GIS Data Source: CUSEC 2008) were used to determine liquefaction susceptibility.
- USGS-prepared Landslide Inventory Maps (GIS Data Source: USGS 2001) were used to evaluate geologic formations or groups of formations as having high, moderate, or low landslide susceptibility.

- The potential for impacts to mineral resource accessibility and fossil resources was determined as follows. Mineral resources were mapped to determine whether the Project might impact accessibility to existing and potential extraction operations. The primary mineral resources produced in the region are fossil fuels including oil, natural gas, and coal. Additional minerals mined in the region include limestone, building stone, sand and gravel, gypsum, clay and shale, granite, volcanic ash, Tripoli, salt, bentonite, iron ore, and chat.
- The BLM and local natural history museums (Clean Line 2014) were contacted regarding potential significant fossil finds/beds.

3.6.1.3 Region of Influence

3.6.1.3.1 Region of Influence for the Project

The ROI for paleontology resources is the same as the description provided in Section 3.1.1.

Specific to geologic and mineral resources, the ROI was increased, and the following areas for Project components were evaluated to provide an indication of surrounding mineral resource operations to evaluate potential impacts related to the potential future expansion of mineral mines and oil and gas drilling operations that might encroach on the Project:

- Oil and gas wells and mines: a 4,000-foot-wide corridor along the HVDC transmission lines
- Oil and gas wells and mines: a 1,500-foot-wide buffer surrounding the converter station siting areas

3.6.1.3.2 Region of Influence for Connected Actions

The geology, minerals, and paleontology ROI for wind energy generation, the future Optima substation, and the TVA upgrades is described in Section 3.1.1.

3.6.1.4 Affected Environment

Several route variations to the Applicant Proposed Route in Regions 2–7 were developed in response to public comments on the Draft EIS, and are described in Appendix M and summarized in Sections 2.4.2.1–2.4.2.7. Assessments of the impacts related to the route variations by Project region, including accompanying HVDC alternative route adjustments, are provided below. The variations are presented graphically in Exhibit 1 of Appendix M.

3.6.1.4.1 Physiography and Surface Geology

The Project traverses three physiographic divisions: the Interior Plains, Ouachita-Ozark Highlands, and the Atlantic Plain (GIS Data Source: NRCS 2006). The Interior Plains Division encompasses the Oklahoma converter station and AC interconnection in Region 1; the HVDC transmission line in Regions 1, 2, and part of 3; and the AC collection system in Region 1.

The Interior Plains Division is characterized by thick layers of sediments that accumulated in shallow seas that once covered large areas of North America. These sediments were buried and lithified (transformed into stone) into marine shales, limestones, and sandstones. They were subsequently uplifted, and rocks and sediments that were deposited earlier were exposed and eroded. Uplift processes include the gentle arching of broad areas, and mountain building, whereby rocks were intensely folded, faulted, and thrust upward. The majority of the region has low relief, reflecting more than 500 million years of relative tectonic stability, and is drained by tributaries of either the Mississippi or Missouri River system (Fenneman 1928).

The Arkansas converter station and AC interconnection, and the HVDC transmission line in the remainder of Region 3, Region 4, and the majority of Region 5, are within the Ouachita-Ozark Highlands Division, which includes the Osage Cuestas Lower Boston Mountains, Lower Boston Mountains, and Arkansas Valley Hills. The Oucahita-Ozark Highlands Division contains ancient eroded mountains surrounded by nearly flat-lying sedimentary rocks and deposits of the Interior and Atlantic Plains divisions. Unlike the relatively young rocks that characterize neighboring physiographic provinces, the rocky outcrops that make up the core of the Ouachita-Ozark Highlands consist of Paleozoic-age carbonate and other marine sedimentary rocks (Foti and Bukenhofer 1998).

The Tennessee Converter Station Siting Area and AC Interconnection Tie and the HVDC transmission line in Regions 5, 6, and the western portion of Region 7 are within the Atlantic Plain Division. The Atlantic Plain Division consists of an intra-continental rift zone, centered under the New Madrid Fault, covered by thick layers of sedimentary and volcanic debris thousands of feet thick (Foti and Bukenhofer 1998). The Atlantic Plain Division slopes gently seaward from the Inland Highlands in a series of terraces, continuing far into the Atlantic and Gulf of Mexico, where it forms the continental shelf. The Atlantic Plain Division is the flattest physiographic region traversed by the Project.

3.6.1.4.2 Bedrock Geology and Paleontological Resources

This section discusses the bedrock geology and paleontological resources throughout the ROI and focuses primarily on the upper strata of bedrock and fossils formed during the Quaternary Period, the most recent geological period in Earth's history, which is divided into the Pleistocene and Holocene epochs.

Oklahoma and Texas

The Oklahoma converter station and AC interconnection; the AC collection system routes; and the HVDC transmission line in Regions 1, 2, 3, and the western part of Region 4 are located in Oklahoma and Texas and have similar geology (GIS Data Source: Garrity and Soller 2009).

Clay, silt, sand, and gravel from Pleistocene and Holocene deposits are typically unconsolidated and range in depth from 25 to 100 feet thick. Modern floodplains consist mainly of alluvium deposited during the Holocene Epoch. Quaternary river-borne sediments decrease in grain size from west to east across Oklahoma; gravel, commonly mixed with river sands in the west, is abraded so much during transport that it is almost absent in the east. Eolian (wind carried) sediments characterize Quaternary deposits in sand dunes in western Oklahoma and occur primarily on the northern sides of major rivers (Johnson 2008).

The Anadarko Shelf and northern portion of the Anadarko Basin underlie the AC collection system routes and HVDC transmission line in Regions 1 and 2. The Cherokee Platform underlies the HVDC transmission line that traverses Region 3. The western portion of the Anadarko Basin consists of Tertiary river and windblown deposits of sand, clay, gravel, and caliche deposited from ancient rivers draining the Rocky Mountains, generally 200 to 600 feet thick. The eastern portion of the Anadarko Basin and the western Cherokee Platform consists of Permian, shallow-marine, deltaic, and alluvial deposits of predominately red sandstone and shale, with conspicuous outcrops of white gypsum and thick salt deposits in the subsurface of the Anadarko, generally 1,000 to 6,500 feet thick (Johnson 2008).

The upper portion of the eastern Anadarko Basin and the lower portion of the western Cherokee Platform consist of marine red sandstone and shale with some thin beds of limestone. The eastern Cherokee Platform consists of Pennsylvanian marine shale, with interbedded sandstone, limestone, and coal, commonly 2,000 to 5,000 feet thick. The Ozark Uplift underlies western portion of the HVDC transmission line traverse in Region 4. The Uplift is typified by mostly marine Mississippian shale and sandstone commonly 1,000 to 6,000 feet thick, but up to 10,000 feet thick in the Ouachita Mountains, as well as Silurian-Devonian marine chert, shale, and sandstone in 500- to 1,500-foot-thick units (Johnson 2008). Shale plays (defined geographic areas containing an organic-rich, fine-grained sedimentary rock with unique characteristics) in the ROI are shown on Figure 3.6-1 (located in Appendix A).

Arkansas and Tennessee

The state of Arkansas is broken into different geological regions, two of which are traversed by the ROI: the Ozark Plateaus and the Mississippi Embayment and Gulf Coastal Plain (GIS Data Source: EPA 2010). The eastern portion of the HVDC transmission line in Region 4, the western section of Region 5, and the Arkansas converter station occur within the Ozark Plateau. This area is generally flat-lying Paleozoic-age strata divided into three plateau surfaces. The plateau that the ROI traverses is the Boston Mountains, the southernmost and highest plateau in the Ozark Region. Pennsylvanian age shales, siltstones, and sandstones dominate the bedrock (McFarland 1998).

The Tennessee Converter Station Siting Area and AC Interconnection Tie, and the HVDC transmission line in eastern part of Region 5 and in Regions 6 and 7 are in the Mississippi Embayment and Gulf Coastal Plain. The Mississippi River Alluvial Plain (within the Mississippi Embayment) consists of recent sedimentary deposits with small areas of igneous intrusions. Cretaceous sedimentary deposits are exposed in southwestern Arkansas and represent shallow, marginal, and often restricted marine environments. This region's upper strata are dominated by Quaternary terrace and alluvial deposits (McFarland 1998).

3.6.1.4.3 Geologic Hazards

3.6.1.4.3.1 Seismic Hazards

Seismicity refers to the intensity and the geographic and historical distribution of earthquakes (USGS 2013; GIS Data Source: USGS 2008a). This analysis includes earthquakes of magnitude (M) 3.5 or greater that have occurred within 50 miles of the ROI over the last 150 years (USGS 2013; GIS Data Source: USGS 2008a). Earthquake damage is a function of magnitude and proximity to vulnerable structures/features. While earthquakes of M3.5 to M4.0 may not be noticed by most people, they can cause minor damage (e.g., cracks in mortar or stone cladding) to structures within a few miles. Earthquakes of M4.0 to M4.9 are typically felt and can cause slight damage, overturn unstable objects, and trigger landslides on extremely unstable slopes. Earthquakes of M5.0 to M5.9 will cause slight to moderate damage in well-built ordinary structures and considerable damage in poorly built or badly designed structures (USGS 2013).

Recently, an increase in seismic events within 50 miles of the ROI has occurred (more than 250 since 2005, with approximately 100 greater than M3.5, compared to 67 between 1980 and 2005 and 33 between 1863 and 1980). Most are low intensity (less than M4.0) and located around the Woodford shale in Oklahoma and Fayetteville shale in Arkansas. Recent USGS research (USGS 2014) has confirmed that the increased frequency of these seismic events may be at least partially caused by hydraulic fracturing (the fracturing of rock by a pressurized liquid) and enhanced recovery operations in some areas.

The probabilistic seismic hazard analyses data used to assess the ROI incorporate estimates of the magnitude and location of all likely earthquakes, how often these earthquakes occur, and the strength of ground shaking that they cause. The data are time independent, represent a long-term average hazard, and are not affected by when the last earthquake rupture occurred (USGS 2010a, 2010b, USGS and TBEG 2010). The USGS Seismic Hazard Mapping Program (GIS Data Source: USGS 2008a) expresses the probabilistic seismic hazard analyses for the peak ground acceleration (PGA) as a factor of gravity (g), with a 10 percent probability of exceedance within a 50-year period. PGA is defined as a measure of earthquake acceleration on the ground. It is not a measure of the total energy (magnitude or size) of the earthquake, but rather of how hard the earth shakes in a given geographic area (the intensity). In this analysis, PGA is expressed in g (the acceleration due to Earth's gravity, equivalent to g-force).

3.6.1.4.3.2 Landslides

The primary cause of landslides is gravity acting on an over-steepened slope. Other contributing factors include intense or prolonged rainfall, earthquakes, rapidly melting snow, volcanic activity, and various human actions. USGS prepared Landslide Inventory Maps (GIS Data Source: USGS 2001) that DOE used to evaluate the ROI by evaluating geologic formations or groups of formations as having high, medium, or low landslide susceptibility.

Landslide incidence is defined as the number of landslides that have occurred in a given geographic area. Landslide susceptibility is defined as the probable degree of slope failure. The landslide susceptibility/incidence map for the ROI is shown in Figure 3.6-3 in Appendix A. The map units are divided into three incidence categories according to the percentage of the area affected by landslides:

- Low (less than 1.5 percent of area has experienced landslides)
- Moderate (1.5 percent to 15 percent area has experienced landslides)
- High (greater than 15 percent of area has experienced landslides)

Low, moderate, and high susceptibility are delimited by the same percentages as those used to define the incidence categories. Susceptibility is not indicated where it is the same as or lower than incidence. The map units are divided into three additional incidence/susceptibility categories:

- Moderate susceptibility/low incidence
- High susceptibility/low incidence
- High susceptibility/moderate incidence

3.6.1.4.3.3 Subsidence

Subsidence hazards involve either the sudden collapse of the ground to form a depression or the slow movement downward or compaction of the sediments near the earth’s surface. The most common types of subsidence are subsidence due to erosion of soil or rock and collapses involving the dissolution of carbonate rocks (limestones) beneath the surface. Subsidence in the ROI can occur in areas of karst geologic formations, or elsewhere, as result of drainage of wet soils.

The presence of karst formations can contribute to land subsidence. Karst is distinctive topography in which the landscape is largely shaped by the dissolving action of water on carbonate and evaporative rock (usually limestone, dolomite, or marble). Karst terrain is characterized by disappearing streams, springs, caves, and sinkholes (Epstein et al 2005). Karst areas were identified for the ROI based on information from USGS (GIS Data Source: Tobin and Weary 2004). Karst areas for the ROI are shown on Figure 3.6-4 in Appendix A.

3.6.1.4.3.4 Soil Liquefaction

Liquefaction may occur when loose, cohesionless, and water-saturated soils lose strength and stiffness in response to stress, such as the ground shaking from an earthquake, causing the soil to behave like a liquid (NRCS 2014). Liquefaction potential in a soil layer increases with decreasing fines content and plasticity of the soil. Liquefaction is more likely to occur in soil/sediment layers with at least 80 to 85 percent saturation and located within 50 feet of the ground surface.

State geologists for Arkansas, Tennessee, and the six other states surrounding the New Madrid Seismic Zone developed Liquefaction Susceptibility Maps for the FEMA Hazus program (GIS Data Source: CUSEC 2008). The maps include six categories for Liquefaction Susceptibility: None, Very Low, Low, Moderate, High, and Very High. Data are not available for portions of the ROI located in Oklahoma and Texas. However, soil liquefaction is less likely in these states because of lower probable PGA. Liquefaction susceptibility for the ROI is shown in Figure 3.6-5 (located in Appendix A).

3.6.1.4.3.5 Paleontological Resources

Fossils would be more likely encountered in areas of shallow bedrock. Quaternary rocks may contain fossils of wood, clams, snails, horses, camels, bison, and mammoths. Tertiary rocks may contain abundant fossils of mammals, including the remains of horses, camels, mastodons, and rhinoceroses. Petrified wood can also be found in these rocks. Lake sediments can contain fossil snails, clams, and algae. Cretaceous, Jurassic, and Triassic rocks may contain abundant fossils, including large oysters, echinoids (sea biscuits), clams, and snails, as well as shark teeth and the occasional remains of large reptiles, such as crocodiles, mosasaurs, and plesiosaurs. Permian rocks may contain fossils of amphibians and reptiles as well as vertebrate footprints.

3.6.1.4.3.6 Mineral Resources

In the ROI, the primary mineral resource production is from fossil fuels, oil, natural gas, and coal. Additional minerals mined include limestone, building stone, sand and gravel, gypsum, clay and shale, granite, volcanic ash, Tripoli, salt, bentonite, iron ore, and chat. Portions of the Project traverse significant oil and natural gas fields, particularly the Anadarko Basin and Arkoma Basin (GIS Data Source: USGS 2005b).

The western portion of the ROI (particularly in Regions 4 and 5) is located within a part of the United States that is experiencing a boom in natural gas production because of the use of hydraulic fracturing and horizontal drilling technologies. This new technology has made the recovery of shale gas economically viable. Mineral resources within the ROI are shown on Figure 3.6-6 (located in Appendix A).

3.6.1.5 Regional Description

3.6.1.5.1 Region 1

Geologic hazards and mineral resources within the ROI in Region 1 for the HVDC alternative routes and AC collection system route alternatives are summarized in Table 3.6.1-2. Tables throughout the regional description sections that follow show only the information that is relevant for each. For example, because landslide potential is low, and no seismic fault lines, mines, or shale gas plays are located in Region 1, these are not shown in the table. Soil liquefaction is unlikely in the ROI because of the low probable PGA.

Table 3.6.1-2:
Geologic Hazards and Mineral Resources—Region 1

Hazard/Mineral Resource	HVDC Alternative Routes				APR Total	Oklahoma Converter Station
	AR 1-A	AR 1-B	AR 1-C	AR 1-D		
Geologic Hazard						
3.5–3.9 Earthquakes (number)[1]	1	1	1	1	1	0
4.0+ Earthquakes (number)[1]	2	1	1	1	2	1
Karst Formation (acres and percentage of entire ROI)[2]	1,215 (8%)	2,202 (35%)	1,203 (19%)	0 (0%)	3,474 (25%)	626 (100%)
Shallow Bedrock (acres and percentage of entire ROI)[3]	2,852 (19%)	515 (8%)	341 (5%)	225 (5%)	1,681 (12%)	264 (42%)

Hazard/Mineral	AC Collection System Routes												
Resource	E-1	E-2	E-3	NE-1	NE-2	NW-1	NW-2	SE-1	SE-2	SE-3	SW-1	SW-2	W-1
Karst Formation (acres and percentage of entire ROI)[2]	11,404 (29%)	37,409 (71%)	30,576 (57%)	25,271 (63%)	17,079 (49%)	28,979 (43%)	61,241 (83%)	33,789 (64%)	18,926 (100%)	48,940 (76%)	19,142 (100%)	13,176 (27%)	7,686 (27%)
Shallow Bedrock (acres and percentage of entire ROI)[3]	7,015 (18%)	3,713 (7%)	6,176 (12%)	3,517 (9%)	5,326 (15%)	4,240 (6%)	3,950 (5%)	4,270 (8%)	1,927 (10%)	3,825 (6%)	1,986 (10%)	5,787 (12%)	2,522 (9%)
Mineral Resources													
Oil and Gas Wells[4]	12	19	15	0	0	4	0	0	0	43	0	0	0
Mineral Resources[5]	4	8	8	8	7	9	7	5	1	7	1	3	6

GIS Data Sources:
1 USGS (2008a)
2 Tobin and Weary (2004)
3 NRCS (2013)
4 OCC (2013)
5 USGS (2005b)

No known fossil bed sites were identified in the ROI in Region 1. Fossils would be more likely encountered in areas of shallow bedrock, which underlies 12 percent of the Applicant Proposed Route and 5 to 19 percent of the HVDC alternative routes. Shallow bedrock underlies 5 to 18 percent of the AC collection system routes.

No route variations were proposed in Region 1.

3.6.1.5.2 Region 2

Geologic hazards and mineral resources within the ROI in Region 2 are summarized in Table 3.6.1-3. Soil liquefaction is unlikely in the ROI because of the low probable PGA.

Table 3.6.1-3:
Geologic Hazards and Mineral Resources within the ROI—Region 2

Hazard/Mineral Resource[1a]	HVDC Alternative Route		APR Total
	AR 2-A	AR 2-B	
Geologic Hazards			
3.5–3.9 Earthquakes(number)[1]	6	27	28
4.0+ Earthquakes (number)[1]	1	4	5
Karst Formation (acres and percentage of entire ROI)[2]	1,531 (22%)	0 (0%)	941 (7%)
Shallow Bedrock (acres and percentage of entire ROI)[3]	2,703 (39%)	1,504 (41%)	2,336 (18%)
Mineral Resources			
Oil and Gas Wells[4]	0	3	5
Mineral Resources[5]	0	0	1
Shale Gas Plays (acres and percentage of entire ROI)[6]	0 (0%)	0 (0%)	2,609 (20%)

1a The values in the table do not reflect the minor changes that would result from application of the minor route variations and adjustments.
GIS Data Sources:
1 USGS (2008a)
2 Tobin and Weary (2004)
3 NRCS 2013
4 OCC 2013
5 USGS 2005b
6 EIA (2011a)

No known fossil bed sites were identified in the ROI in Region 2. Fossils would be more likely encountered in areas of shallow bedrock, which occur in isolated areas in 18 percent of the Applicant Proposed Route and in all segments of the HVDC alternative route ROIs (39 to 41 percent).

Two route variations to the Applicant Proposed Route were developed in Region 2 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.2. The variations are illustrated in Exhibit 1 of Appendix M. These variations represent minor adjustments to the Applicant Proposed Route, and the geologic hazards and mineral resources would remain consistent within the ROI.

3.6.1.5.3 Region 3

Geologic hazards and mineral resources within Region 3 are summarized in Table 3.6.1-4. The ROI in Region 3 has a higher number of recorded seismic events than other regions, particularly where it crosses the Nemaha uplift and energy productions areas of the Woodford shale. Soil liquefaction is unlikely in the ROI because of the low probable PGA. Three percent of the ROI for the Applicant Proposed Route is within an area of high susceptibility to landslides. HVDC Alternative Routes AR 3-C and AR 3-D also include areas of high susceptibility to landslides.

Table 3.6.1-4:
Geologic Hazards and Mineral Resources within the ROI—Region 3

Hazard/Mineral Resource[1a]	HVDC Alternative Route					APR Total
	AR 3-A	AR 3-B	AR 3-C	AR 3-D	AR 3-E	
Geologic Hazards						
3.5–3.9 Earthquakes (number)[1]	44	45	43	3	0	47
4.0+ Earthquakes (number)[1]	9	9	9	0	0	9
Seismic Fault Lines (number)[2]	0	0	0	0	0	1
High Susceptibility to Landslides and Low Incidence (acres and percentage of ROI)[3]	0 (0%)	0 (0%)	605 (41%)	605 (13%)	0 (0%)	611 (3%)
Shallow Bedrock (acres and percentage of ROI)[4]	3,426 (74%)	4,264 (73%)	7,435 (50%)	1,615 (34%)	580 (54%)	11,092 (56%)
Mineral Resources						
Oil and Gas Wells[5]	7	7	15	0	0	120
Mineral Resources[6]	0	0	2	0	0	10

1a The values in the table do not reflect the minor changes that would result from application of the minor route variations and adjustments.
GIS Data Sources:
1 USGS (2008a)
2 USGS (2005a)
3 USGS (2001)
4 NRCS 2013
5 OCC 2013
6 USGS 2005b

No known fossil bed sites were identified in ROI in Region 3. Occurrences of shallow bedrock occur in all segments of the Applicant Proposed Route and HVDC alternative routes.

The Ripley Quarry, a crushed stone quarry, is located within the Region 3 ROI. Based on aerial reconnaissance (Clean Line 2013), the quarry does not currently appear to be active. The Applicant Proposed Route and HVDC alternative routes intersect up to 10 mineral resource locations.

Five route variations to the Applicant Proposed Route were developed in Region 3 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.3. The variations are illustrated in Exhibit 1 of Appendix M. These variations represent minor adjustments to the Applicant Proposed Route, and the geologic hazards and mineral resources would remain consistent within the ROI.

3.6.1.5.4 Region 4

Geologic hazards and mineral resources within the ROI in Region 4 are summarized in Table 3.6.1-5. Although the ROI in Region 4 is an area of low earthquake activity, four active surface faults are located within the ROI. Approximately 20 percent of the soils within the ROI in Arkansas have high liquefaction susceptibility, but none have very high liquefaction susceptibility. As previously discussed, soil liquefaction data are not available for Oklahoma.

Table 3.6.1-5:
Geologic Hazards and Mineral Resources within the ROI—Region 4

Hazard/Mineral Resource[1a]	HVDC Alternative Routes					APR Total
	AR 4-A	AR 4-B	AR 4-C	AR 4-D	AR 4-E	
Geologic Hazards						
3.5–3.9 Earthquakes (number)[1]	0	1	0	0	16	16
4.0+ Earthquakes (number)[1]	0	0	0	0	3	3
Seismic Fault Lines (number)[2]	2	2	0	1	0	4
Karst Formation (acres and percentage of ROI)[3]	4,251 (59%)	5,233 (54%)	425 (100%)	2,753 (89%)	0 (0%)	3,356 (22%)
High-Very High Soil Liquefaction Potential (acres and percentage of ROI)[4]	0 (0%)	0 (0%)	160 (38%)	28 (1%)	475 (11%)	2,151 (14%)
Shallow Bedrock (acres and percentage of ROI)[5]	6,080 (85%)	7,706 (80%)	425 (100%)	2,711 (87%)	2,646 (59%)	9,679 (63%)
Mineral Resources						
Oil and Gas Wells[6]	18	48	4	12	76	181
Mineral Resources[7]	1	1	0	0	2	3
Shale Gas Plays (acres and percentage of ROI)[8]	2,870 (40%)	4,743 (49%)	425 (100%)	3,106 (100%)	4,491 (100%)	9,618 (62%)

1a The values in the table do not reflect the minor changes that would result from application of the minor route variations and adjustments.
GIS Data Sources:
1 USGS (2008a)
2 USGS (2005a)
3 Tobin and Weary (2004), USFWS (2010)
4 CUSEC (2008)
5 NRCS 2013
6 OCC 2013 and AOGC 2014
7 USGS 2005b
8 EIA (2011a)

No known fossil bed sites were identified in the ROI in Region 4, but fossils would be more likely encountered in areas of shallow bedrock. Intersected shale gas plays and oil and gas wells are primarily located in the eastern part of Region 4.

Seven route variations to the Applicant Proposed Route were developed in Region 4 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.4. The variations are illustrated in Exhibit 1 of Appendix M. These variations represent minor adjustments to the Applicant Proposed Route, and the geologic hazards and mineral resources would remain consistent with the corresponding ROI.

3.6.1.5.5 Region 5

Geologic hazards and mineral resources within Region 5 are summarized in Table 3.6.1-6. The ROI in Region 5 is an area of low to moderate earthquake activity with seven active surface faults. An unclassified fault crosses the south quarter of the Arkansas converter station alternative (GIS Data Source: Garrity and Soller 2009). Earthquake hazard transitions from low to moderate with eastward progression within the Region 5 ROI. Soils with high liquefaction susceptibility are mostly located in the easternmost portion of the ROI. Approximately 9 percent of the soils within the siting area for the Arkansas Converter Station Alternative have high liquefaction potential, but there are no soils with a very high liquefaction potential.

Table 3.6.1-6:
Geologic Hazards and Mineral within the ROI—Region 5

Hazard/Mineral Resource[1a]	HVDC Alternative Route						APR Total	Arkansas Converter Station
	AR 5-A	AR 5-B	AR 5-C	AR 5-D	AR 5-E	AR 5-F		
Geologic Hazards								
3.5–3.9 Earthquakes (number)[1]	23	23	21	27	22	22	29	23
4.0+ Earthquakes (number)[1]	9	9	9	11	9	9	11	9
Seismic Fault Lines (number)[2]	0	1	0	1	1	0	2	1
High Susceptibility to Landslides and Low Incidence (acres and percentage of ROI)[3]	0 (0%)	0 (0%)	0 (0%)	761 (29%)	0 (0%)	0 (0%)	559 (49%)	0 (0%)
Karst Formation (acres and percentage of ROI)[4]	0 (0%)	0 (0%)	0 (0%)	1,930 (73%)	0 (0%)	0 (0%)	1,535 (11%)	0 (0%)
High-Very High Soil Liquefaction Potential (acres and percentage of ROI)[5]	0 (0%)	305 (4%)	0 (0%)	862 (32%)	0 (0%)	0 (0%)	1,316 (10%)	31 (9%)
Shallow Bedrock (acres and percentage of ROI)[6]	1,289 (83%)	7,985 (92%)	1,032 (91%)	2,085 (78%)	4,197 (94%)	2,516 (92%)	11,962 (87%)	282 (79%)
Mineral Resources								
Oil and Gas Wells[7]	14	212	65	5	103	57	282	3
Mineral Resources[8]	0	4	0	0	2	2	0	0
Shale Gas Plays (acres and percentage of ROI)[9]	1,553 (100%)	8,686 (100%)	1,137 (100%)	2,547 (96%)	4,449 (100%)	2,748 (100%)	13,128 (95%)	360 (100%)

1a The values in the table do not reflect the minor changes that would result from application of the minor route variations and adjustments.
GIS Data Sources:
1 USGS (2008a)
2 USGS (2005a)
3 USGS (2001)
4 Tobin and Weary (2004), USFWS (2010)
5 CUSEC (2008)
6 NRCS (2013)
7 AOGC (2014)
8 USGS (2005b)
9 EIA (2011a)

Forty-nine percent of the Applicant Proposed Route ROI is within an area of high susceptibility to landslides. The Arkansas Converter Station Siting Area is characterized by moderate susceptibility to landsliding and low incidence.

Eleven percent of Applicant Proposed Route ROI and 73 percent of HVDC Alternative Route 5-D ROI is located within karst formations. No karst formations have been identified for the remainder of the HVDC Alternative Route ROIs in Region 5 or in the Arkansas Converter Station Alternative Siting Area, so the susceptibility for land subsidence as a result of karst formations is low.

No known fossil bed sites were identified in the ROI in Region 5. Fossils would be more likely encountered in areas of shallow bedrock.

Five route variations to the Applicant Proposed Route were developed in Region 5 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.5. The variations are illustrated in Exhibit 1 of Appendix M. These variations represent minor adjustments to the Applicant Proposed Route, and the geologic hazards and mineral resources would remain consistent within the ROI. Applicant Proposed Route Link 2, Variation 2, would cross fewer oil and gas wells (one versus three) than the original Applicant Proposed Route Link 2.

3.6.1.5.6 Region 6

Geologic hazards and mineral resources within Region 6 are summarized in Table 3.6.1-7. The earthquake hazard transitions from low to moderate to moderate to high with eastward progression along the ROI in Region 6. The easternmost portion of the Applicant Proposed Route ROI and HVDC Alternative Routes 6-C and 6-D are located within moderate to high seismic hazard areas and are closer to the New Madrid Seismic Zone. Ninety-four percent of the soils have high to very high liquefaction susceptibility in the Region 6 ROI.

Table 3.6.1-7:
Geologic Hazards and Mineral Resources within the ROI—Region 6

Hazard/Mineral Resource[1a]	HVDC Alternative Routes				APR Total
	AR 6-A	AR 6-B	AR 6-C	AR 6-D	
Geologic Hazards					
3.5–3.9 Earthquakes (number)[1]	6	6	10	9	11
4.0+ Earthquakes (number)[1]	3	3	6	6	6
High-Very High Soil Liquefaction Potential (acres and percentage of ROI)[2]	1,982 (100%)	1,724 (100%)	2,550 (89%)	1,134 (100%)	6,233 (94%)
Shallow Bedrock (acres and percentage of ROI)[3]	1,180 (60%)	983 (57%)	1,329 (47%)	15 (1%)	3,095 (47%)

1a The values in the table do not reflect the minor changes that would result from application of the minor route variations and adjustments.
GIS Data Sources:
1 USGS (2008a)
2 CUSEC (2008)
3 NRCS (2013)

No known fossil bed sites were identified in the Cretaceous-age rocks of the Region 6 ROI. Shallow bedrock is present in 47 percent of the Region 6 ROI. The ROI in Region 6 does not contain mineral resources.

One route variation was developed in Region 6 in response to public comments on the Draft EIS to parallel more parcel boundaries in order to minimize impacts to agricultural operations. The variation is illustrated in Exhibit 1 of Appendix M. The variation represents a minor adjustment to the Applicant Proposed Route, and the geologic hazards and mineral resources would remain consistent with those described for Region 6.

3.6.1.5.7 Region 7

Geologic hazards and mineral resources within Region 7 are summarized in Table 3.6.1-8. The ROI in Region 7 is an area of moderate to high seismic hazard, although there are no active surface faults located within the ROI. The PGA for HVDC Alternative Route 7-A is higher at 20 to 30 percent because it is closer to the New Madrid Seismic Zone. Approximately 99 percent of the soils in the ROI in Region 7 have high to very high liquefaction. Soils within the Tennessee Converter Station Siting Area and AC Interconnection Tie have high liquefaction susceptibility.

In the ROI in Region 7, high susceptibility to landslides is present in most areas with incidence ranging from low to moderate. Moderate incidence occurs along HVDC Alternative Route 7-D. The Tennessee Converter Station Siting Area and AC Interconnection Tie has a moderate incidence rate and a high susceptibility to landsliding because of the underlying lower Paleozoic interbedded shale and limestone and the localized significant slopes.

Table 3.6.1-8:
Geologic Hazards and Mineral Resources within the ROI—Region 7

Hazard/Mineral Resource[1a]	HVDC Alternative Route				APR Total	Tennessee Converter Station Siting Area
	AR 7-A	AR 7-B	AR 7-C	AR 7-D		
Geologic Hazards						
3.5–3.9 Earthquakes (number)[1]	17	11	11	11	11	11
4. + Earthquakes (number)[1]	7	7	7	7	7	7
High Susceptibility to Landslides and Low Incidence (acres and percentage of ROI)[2]	2,947 (56%)	203 (19%)	203 (7%)	0 (0%)	2,328 (45%)	0 (0%)
High Susceptibility to Landslides and Moderate Incidence (acres and percentage of ROI)[2]	0 (0%)	0 (0%)	1,240 (43%)	551 (69%)	504 (10%)	218 (100%)
High Susceptibility to Landslides and High Incidence (acres and percentage of ROI)[2]	0 (0%)	0 (0%)	0 (0%)	0 (0%)	0 (0%)	0 (0%)
High-Very High Soil Liquefaction Potential (acres and percentage of ROI)[3]	5,181 (99%)	1,056 (100%)	2,887 (100%)	803 (100%)	5,165 (99%)	218 (100%)
Shallow Bedrock (acres and percentage of ROI)[4]	0 (0%)	91 (9%)	664 (23%)	83 (10%)	205 (4%)	48 (22%)
Mineral Resources						
Mineral Resources[5]	1	0	0	0	1	0

1a The values in the table do not reflect the minor changes that would result from application of the minor route variations and adjustments.
GIS Data Sources:
1 USGS (2008a)
2 USGS (2001)
3 CUSEC (2008)
4 NRCS 2013
5 USGS (2005b)

No known fossil bed sites were identified in Region 7. Shallow bedrock is limited to isolated areas of the Applicant Proposed Route and HVDC Alternative Routes 7-B, 7-C, and 7-D. About 22 percent of the Tennessee Converter Station Siting Area and AC Interconnection Tie is underlain by shallow bedrock.

Three route variations to the Applicant Proposed Route were developed in Region 7 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.7. The variations are illustrated in Exhibit 1 of Appendix M. The geologic hazards and mineral resources would remain consistent with those described for Region 7.

3.6.1.5.8 Connected Actions

3.6.1.5.8.1 Wind Energy Generation

3.6.1.5.8.1.1 Physiography, and Surface and Bedrock Geology

The WDZs are located in the Interior Plains Division in the vicinity of the AC collection system and the western part of Region 1. Elevations range from 950 feet above mean sea level (AMSL) to 4,800 feet AMSL. Three ecoregions with varying physiographic characteristics and surface geology are associated with the WDZs as described below:

- Canadian Cimarron Breaks—Nearly level, rolling, or hummocky plains. Elevation ranges from 2,400 to 4,800 feet AMSL. Local relief ranges from 10 to 120 feet. Surface geology consists of widely mantled Quaternary alluvium underlain by sand, gravel, silt, clay, and caliche (all WDZs except WDZ-L).
- Canadian Cimarron High Plains—Dissected canyons, hills, escarpments, buttes, terraces, and along rivers, dunes. Elevation ranges from 1,900 to 3,450 feet AMSL. Local relief ranges from 100 to 400 feet. Surface geology consists of Quaternary alluvium, colluvium, terrace deposits, and loess. Widely underlain by sand, gravel, silt, and clay (all WDZs except WDZ-L).
- Rolling Sand Plains—Gently undulating to hummocky, sandy plains with sand hills, depressions, and stabilized, partially stabilized, or active sand dunes. Locally, blow-outs occur. Small wetlands are found between dunes where the water table is high. Drainage networks are not well established. Elevation ranges from 2,400 to 4,800 feet AMSL. Local relief ranges from 10 to 120 feet. Surface geology consists of Quaternary sand and silt deposits that were laid down by rivers, and subsequently reworked by wind (WDZ-G and WDZ-I).
- The Anadarko Shelf and northern portion of the Anadarko Basin underlie the WDZs. Surface bedrock and geologic formations include undifferentiated Pleistocene and Pliocene deposits, undifferentiated Permian shale, sandstone and siltstone; Quaternary alluvial and playa deposits, Quaternary Blackwater Draw Formation Sand, Tertiary interbedded sand, siltstone, clay, gravel lenses, caliche, and thin limestone of the Ogallala formation; and undifferentiated Mesozoic shale and sandstone.

3.6.1.5.8.2 Geologic Hazards, and Paleontological and Mineral Resources

Geologic hazards and mineral resources within the WDZs are summarized in Table 3.6.1-9. The WDZs are all located in an area of low earthquake activity and do not contain active surface faults. In the WDZs, incidence and susceptibility to landslides are both low because of the area's primarily flat topography. The WDZs are located in an area with numerous karst formations. Soil liquefaction is unlikely because of the low probable PGA.

Table 3.6.1-9:
Geologic Hazards and Mineral Resources within the ROI—Wind Development Zones

Hazard/Mineral Resource	WDZ											
	A	B	C	D	E	F	G	H	I	J	K	L
Area (acres)	109,747	125,479	161,048	69,189	47,092	112,461	187,315	116,226	105,203	92,567	92,894	165,848
Geologic Hazards												
3.5–3.9 Earthquakes[1] (number)	1	2	2	0	0	1	1	0	0	0	1	3
4. + Earthquakes (number)[1]	1	1	1	1	1	1	0	0	1	1	1	1
Karst Formation (acres)[2]	93,920 (86%)	53,123 (42%)	140,395 (87%)	35,765 (52%)	184 (<1%)	0 (0%)	119,576 (64%)	66,643	39,207 (57%)	17,560 (19%)	28,947 (31%)	118,751 (72%)
Shallow Bedrock (acres)[3]	4,762 (4%)	2,306 (2%)	6,565 (4%)	8,037 (12%)	4,318 (9%)	6,631 (6%)	1,117 (1%)	7,892 (7%)	202 (<1%)	9,772 (11%)	0 (0%)	11,911 (7%)

Table 3.6.1-9:
Geologic Hazards and Mineral Resources within the ROI—Wind Development Zones

	A	B	C	D	E	F	G	H	I	J	K	L
Mineral Resources												
Oil and Gas Wells[4]	0	0	0	0	0	0	32	0	1	75	62	0
Mineral Resources[5]	0	0	0	8	8	15	2	18	4	14	11	0

GIS Data Sources:
1 USGS (2008a)
2 Tobin and Weary (2004)
3 NRCS (2013)
4 AOGC (2014)
5 USGS (2005b)

No known fossil bed sites were identified in the WDZs. The approximate percentages of shallow bedrock contained within the WDZs range from 0 to 12 percent.

3.6.1.5.8.3 Optima Substation

The general geologic and related features in the area of the future Optima substation are the same as described for the western area of Region 1. Seismicity characteristics are low. The entire Optima substation is within karst, and shallow bedrock is present in 15 acres (9 percent of the 160-acre site). Mineral resources are not present in the siting area.

3.6.1.5.8.4 TVA Upgrades

The ROI for the direct assignment facilities (which are included in the Applicant Proposed Project) would occur within the Tennessee Converter Station Siting Area and more specifically within the Shelby Substation. The ROI for the network upgrades, and in particular TVA's future 500kV transmission line, cannot be fully determined at this time. The 500kV transmission line would be constructed in western Tennessee in the Gulf Coastal Plain region. The upgrades to existing facilities would mostly be in western and central Tennessee. Mineral resources in this area, as in the eastern portion of Region 7 described above, are limited, and karst formations are not present. Upgrades to existing infrastructure would include upgrading terminal equipment at three existing 500kV substations and six existing 161kV substations, making appropriate upgrades to increase heights on 16 existing 161kV transmission lines to increase line ratings, and replacing the conductors on eight existing 161kV transmission lines. Where possible, general impacts associated with the required TVA upgrades are discussed in the impact sections that follow.

3.6.1.6 Impacts to Geology, Paleontology, and Minerals

3.6.1.6.1 Methodology

The impact analysis area for geologic, mineral, and paleontological resources includes the Project components. Analysis was based on review of publicly available government documents and published literature as well as comments from scoping as described in Table 3.6.1-10.

Table 3.6.1-10:
Impacts Analysis Considerations and Relevant Assumptions

Resource Topic	Analysis Considerations and Relevant Assumptions
Geologic Hazards	Evaluate potential impact to the Project from geologic hazards that include seismicity, landslides, subsidence related to karst, and liquefaction. Evaluate risk to nearby populations from any increases in geologic hazards caused by the Project. Major assumptions in the analysis of the risk to the Project because of geological hazards include the following: • The location of active faults is based on information available from GIS Data Source: USGS (2008). Ground motion estimates are based on recent updates of the USGS seismic hazard mapping by the USGS. Quaternary faults are numerous in the impact analysis area, and may rupture at any time. Only those faults that have moved in the last 15,000 years, however, are considered to be active as determined by the GIS Data Source: USGS (2008). • Landslide risk information is based on landslide maps, landslide incident and susceptibility areas, and USGS-prepared Landslide Inventory Maps (GIS Data Source: USGS 2001).
Mineral Resources	Analyze the Applicant Proposed Route and HVDC Alternative Routes with regard to potential interference with existing mineral extraction operations, reduced access to underlying minerals, and interference with future mineral extraction operations.
Paleontological Resources	Evaluate the potential for loss of important fossils because of the following activities or conditions: • Ground-disturbing activities such as clearing, grading, and foundation excavation • Operations and maintenance activities that would require disturbance of previously undisturbed areas within the established ROW

The following impacts could occur as result of the construction, operations and maintenance, and decommissioning of the Project components:

- Damage or interruption of services from seismicity, landslides, subsidence, or liquefaction generated during ground-disturbing activities; or damage from these hazards that interferes with construction of the Project
- Loss or inaccessibility of mineral resources of economic value for future use
- Loss or damage to scientifically important paleontological resources

The Applicant would adopt the EPMs listed in Appendix F. EPMs that would specifically avoid or minimize the potential for impacts on geology, paleontology, and minerals are listed below:

- GE-1: Clean Line will train personnel on health, safety, and environmental matters. Training will include practices, techniques, and protocols required by federal and state regulations and applicable permits.
- GE-9: Clean Line will avoid and/or minimize damage to drainage features and other improvements such as ditches, culverts, levees, tiles, and terraces; however, if these features or improvements are inadvertently damaged, they will be repaired and or restored.
- GE-27: Clean Line will minimize compaction of soils and rutting through appropriate use of construction equipment (e.g., low ground pressure equipment and temporary equipment mats).
- GE-29: Clean Line will work with landowners and operators of active oil and gas wells, utilities, and other infrastructure to identify and verify the location of facilities and to minimize adverse impacts. Identification may include use of the One Call system and surveying of existing facilities.
- GEO-1: Clean Line will stabilize slopes exposed by its activities to minimize erosion.
- LU-1: Clean Line will work with landowners and operators to ensure that access is maintained as needed to existing operations (e.g., to oil/gas wells, private lands, agricultural areas, pastures, hunting leases).

- LU-4: Clean Line will coordinate with landowners to site access roads and temporary work areas to avoid and/or minimize impacts to existing operations and structures.

In addition, Clean Line will develop the following plans to avoid or minimize effects to geology, paleontology, and minerals from construction, operations and maintenance, or decommissioning as appropriate:

- Blasting Plan: This plan will describe measures designed to minimize adverse effects due to blasting.
- Storm Water Pollution Prevention Plan (SWPPP): This plan, consistent with federal and state regulations, will described the practices, measures, and monitoring programs to control sedimentation, erosion, and runoff from disturbed areas. The SWPPP will be required to minimize adverse effects from erosion during ground disturbing activity.
- Restoration Plan: This plan will describe post-construction activities to reclaim disturbed areas. This plan will be required to minimize adverse effects associated with areas (particularly slopes) exposed during construction.

3.6.1.6.1.1 Impacts Common to All Alternatives

3.6.1.6.1.1.1 Construction Phase

The following impacts could occur as result of the construction of the Project:

- Damage or interruption of services resulting from seismicity, landslides, subsidence, or liquefaction generated during ground-disturbing activities
- Loss or damage to scientifically important paleontological resources
- Loss or inaccessibility of mineral resources of economic value for future use

In addition, geologic hazards could affect construction and use of access roads, but to a small extent given the simplicity of road construction. Construction and use of access roads is not likely to affect access to mineral resources, though pre-planning for the road routes would need to occur to avoid crossing locations of existing mineral resources (i.e., oil or gas well locations, or other actively mined sites).

Seismic Hazards

While it is not likely that services would be damaged or interrupted by seismic activity, the Applicant would construct Project components to withstand probable seismic events within the seismic risk zones crossed and comply with all applicable federal and state regulations and requirements to prevent accidents and ensure adequate protection for the public and the Project.

Landslides

While it is not likely that services would be damaged or interrupted by landslides, the Applicant would design Project components to avoid loading of slopes. Where unstable slopes cannot be avoided, construction activities, including vegetation clearing and alteration of surface drainage patterns, may increase landslide risk. Erosion control measures and monitoring programs to control sedimentation, erosion, and runoff from disturbed areas would be implemented per the Project SWPPP. In addition, areas subjected to clearing and grading would be stabilized and/or revegetated consistent with the Applicant's Restoration Plan and landowner or land manager requirements. Implementation of EPMs GE-9, GE-27, and GEO-1 would serve to maintain slope stability. If transmission structures or new roads are sited on steep slopes, an excavated bench would be created to increase foundation stability.

Blasting

During construction, blasting may be necessary in areas of shallow bedrock. Softer sedimentary rocks can generally be removed without blasting, but if blasting is required as determined by a geotechnical study (to be completed as part of the engineering design), a Blasting Plan would be developed. Blasting and removal of shallow bedrock has the potential to impact paleontological resources and would be avoided or minimized during engineering design.

Subsidence

The Applicant would complete geologic/geotechnical investigations during engineering design to reduce the potential for impacts related to karst. The presence of karst can cause subsidence that could damage Project infrastructure and result in the temporary failure of the electric transmission system. The placement of Project components would be governed in part by site conditions and construction requirements, which would minimize the risks associated with constructing the Project across karst. In general, placement of Project infrastructure would avoid areas of identified karst if feasible. If it is not feasible to avoid karst in some areas, measures such as specialized foundation design, filling of subsidence areas, and/or more frequent monitoring protocols would be implemented as appropriate.

Liquefaction

The Applicant would complete geologic/geotechnical investigations during the engineering design in the areas identified as containing high susceptibility to soil liquefaction to reduce potential impacts to the Project components. Areas of high liquefaction potential might increase the risk of damage to Project infrastructure from earthquakes and subsequent destabilization of underlying soils. The placement of Project components would be governed in part by site conditions and construction requirements, which would minimize risks related to soil liquefaction. If it is not feasible to avoid areas of high liquefaction, measures such as specialized foundation design, specialized fill materials, and additional monitoring protocols following seismic events would be implemented as appropriate.

Paleontological Resources

A direct impact to fossil resources would be loss during ground-disturbing activities such as clearing, grading, and excavation. These impacts could occur where fossils are at or near the ground surface in rock outcrops and/or areas of shallow bedrock. Indirect impacts during construction would include erosion of fossil beds due to slope re-grading and vegetation clearing or the unauthorized collection of scientifically important fossils by construction workers or the public due to increased access to fossils along the ROW. These impacts could occur where fossils are at or near the ground surface in rock outcrops and/or areas of shallow bedrock. Grading activities would be limited to the minimum amount needed to create safe working surfaces, and foundation excavations would typically be made using a power drill or auger, which would reduce the potential for impact to paleontological resources.

Mineral Resources

A direct impact to mineral resources would occur if construction activities were to interfere with ongoing mineral extraction operations, reduce access to underlying resources, or interfere with future access to mineral extraction operations. Impacts to mineral resources would be avoided or minimized during the design phase of the Project by avoiding mineral resource features and maintaining access to identified mineral resources. EPMs LU-1, GE-29, and LU-4 would be implemented to avoid or minimize potential impacts to mineral resources from construction. These EPMs would also be implemented for subsurface collection systems and any other infrastructure for oil and gas wells that may be within and near the ROW. Therefore, these collection systems would not be impacted during grading activities associated with the Project. Micrositing of the lines and structures would be employed when necessary to allow adequate access to existing infrastructure. New oil and gas wells would be prohibited within the ROW;

however, drilling rigs could drill at an adjacent location. The Applicant would allow access roads to oil and gas wells or other mineral resources to cross the ROW.

3.6.1.6.1.1.2 Operations and Maintenance Phase

Overall impacts during the operations and maintenance phase of the Project would be similar, but would have a much smaller degree of impact as the construction phase. Seismic activity could impact Project infrastructure and cause service interruptions. Design standards for specific seismic concerns would avoid and minimize such impacts. The engineering design would avoid or minimize potential effects from karst. No blasting would take place during operation and maintenance of the Project. Project infrastructure would avoid impacts to active mineral resources features and would not preclude development of underground mineral resources in most cases.

3.6.1.6.1.1.3 Decommissioning Phase

During the removal of Project components, some ground disturbance would occur from the use of machinery such as bulldozers to demolish facility buildings or cranes used to deconstruct the transmission structures. However, ground disturbance would be limited to near surface depths in areas previously disturbed during the construction and operation phases. EPMs used during construction would be applied during decommissioning, and the amount of ground disturbance associated with decommissioning would be less than during construction. Overall impacts during the decommissioning phase of the Project would be similar as the construction phase. Because the Project infrastructure would be removed, there would be complete access to mineral resources.

3.6.1.6.2 Impacts Associated with the Applicant Proposed Project

In general, the Applicant Proposed Project would not affect geologic features or resources of the area. Construction activities would require the removal or surface disturbance of small amounts of near-surface materials. This would have no measurable impact on geologic resources or features for any of the components of the Applicant Proposed Project. Similarly, the Project would have minimal impact on paleontology or mineral resources. However, geologic hazards could cause potential impacts to the Project depending on the final location of the specific facilities in relationship to these hazards. The implementation of EPMs and appropriate engineering design would reduce or eliminate impacts from such hazards.

3.6.1.6.2.1 Converter Stations and AC Interconnection Siting Areas

3.6.1.6.2.1.1 Construction Impacts

3.6.1.6.2.1.1.1 Oklahoma Converter Station Siting Area and AC Interconnection Siting Area

Subsidence from karst is a possible geologic hazard of concern within the Oklahoma Converter Station Siting Area. Implementation of EPMs and appropriate engineering design, including geotechnical investigations, would avoid or minimize the potential for impacts from karst. No known fossil bed sites were identified in the Oklahoma Converter Station Siting Area. About 40 percent of the siting area is located in the shallow bedrock, however, so grading and excavation activities could cause direct impacts to paleontological resources if fossils are at or near the ground surface in rock outcrops and/or areas of shallow bedrock.

3.6.1.6.2.1.1.2 Tennessee Converter Station Siting Area and AC Interconnection Tie

The Tennessee Converter Station Siting Area is located adjacent to the existing TVA Shelby Substation, and the 500 kV AC interconnection ties are expected to be contained entirely within the converter station and substation footprints. The Tennessee converter station and AC interconnection would be constructed to withstand probable seismic events in the moderate to high seismic hazard zones. They would be constructed in accordance with applicable federal and state regulations and requirements to prevent accidents and to ensure adequate protection for the public and the Project components. All of the soils within the Tennessee Converter Station Siting Area have high liquefaction potential, which could contribute to unstable conditions and potential structural damage during seismic events. Appropriate placement of Project components following completion of geologic/geotechnical investigations during engineering design would minimize risks related to soil liquefaction.

The Applicant would implement EPMs GE-9, GE-27, and GEO-1 to minimize the direct effects of landslides in this area of moderate susceptibility and low incidence. About 22 percent of the siting area is located in shallow bedrock, and blasting may be required. Impacts would be minimized by appropriate engineering design and through implementation of the Blasting Plan.

3.6.1.6.2.1.2 Operations and Maintenance Impacts

3.6.1.6.2.1.2.1 Oklahoma Converter Station Siting Area and AC Interconnection Siting Area

Impacts from geological hazards or to mineral resources are not anticipated during operations and maintenance because the area is located in an area of low seismic risk, soil liquefaction risk is expected to be low, and no mineral resources are located within the siting area.

3.6.1.6.2.1.2.2 Tennessee Converter Station Siting Area and AC Interconnection Tie

The Project components would be operated and maintained in an area of moderate to high seismic hazard, and expected ground motions from an earthquake would be moderate to high given the proximity of the New Madrid Seismic Zone. Damage from earthquakes would be negligible to minimal in structures designed in accordance with seismic protection standards. The Project components would be constructed to withstand probable seismic events and constructed in accordance applicable federal and state regulations to prevent accidents and to ensure adequate protection for the public and the Project.

Soils within the siting area have high liquefaction potential. Geotechnical investigations would be completed in these areas during engineering design. The placement of Project components would be governed in part by site conditions, construction requirements, and EPMs, which would minimize risks related to soil liquefaction.

3.6.1.6.2.1.3 Decommissioning Impacts

Impacts from decommissioning are described in Section 3.6.1.6.1.

3.6.1.6.2.2 AC Collection System

3.6.1.6.2.2.1 Construction Impacts

In the area of the AC collection system, the excavation and drilling required for the foundations of the transmission structures would permanently impact the geologic formation underneath the structure footprint to depths ranging from 30 to 45 feet. Specific foundation depths would depend on the specific geotechnical conditions and the engineering design. The area of potential impact to a geologic formation represents a very small portion of the total area of the geologic formation. The total areal extent of transmission structure footprints for the AC collection system routes are estimated to range from 1.7 acres (AC Collection System Route SE-2) to 7.1 acres (AC Collection System Route NW-2), which is a conservative estimate of the areal extent of affected geologic formations.

Table 3.6.1-11 summarizes the geologic hazards and mineral resources that could potentially impact or be impacted by the AC collection system routes.

Table 3.6.1-11:
Geological Hazards and Mineral Resources Impacts—AC Collection System Routes

Route	Analysis Area (acres)	Geologic Hazard (within 200 feet of representative centerline)		Mineral Resources (based on representative centerline)[3]
		Karst Formation[1]	Shallow Bedrock[2]	
E-1	708	198 acres	138 acres	Intersects 1 mineral resource. 12 oil and gas wells and 4 mineral resources within 2 miles.
E-2	974	682 acres	81 acres	19 oil and gas wells and 8 mineral resources are located within 2 miles of the representative centerline.
E-3	977	577 acres	117 acres	15 oil and gas wells and 8 mineral resources are located within 2 miles of the representative centerline.
NE-1	730	463 acres	63 acres	8 mineral resources are located within 2 miles of the representative centerline.
NE-2	637	300 acres	119 acres	7 mineral resources are located within 2 miles of the representative centerline.
NW-1	1,265	510 acres	64 acres	4 oil and gas wells and 9 mineral resources are located within 2 miles of the representative centerline.
NW-2	1,365	1,125 acres	71 acres	7 mineral resources are located within 2 miles of the representative centerline.
SE-1	979	611 acres	69 acres	5 oil and gas wells are located within 2 miles of the representative centerline.
SE-2	325	325 acres	66 acres	1 mineral resource is located within 2 miles of the representative centerline.
SE-3	1,194	901 acres	81 acres	144 acres of shale gas play are traversed by the alternative representative centerline; 43 oil and gas wells and 7 mineral resources located within 2 miles of the representative centerline.
SW-1	326	326 acres	66 acres	3 mineral resources are located within 2 miles of the representative centerline.
SW-2	901	213 acres	86 acres	3 mineral resources are within 2 miles of the representative centerline.
W-1	508	128 acres	43 acres	6 mineral resources are within 2 miles of the representative centerline.

GIS Data Sources:
1 Tobin and Weary (2004)
2 NRCS (2013)
3 USGS (2005b) (metallic and non-metallic mineral resources); EIA (2011a); OCC (2013)

The AC collection system is located in Region 1, which, west to east, is an area of low earthquake activity and does not contain active surface faults. The USGS seismic hazard mapping indicates that in areas crossed by the Project in Region 1, the likelihood of ground movement that could be triggered by a maximum credible earthquake is expected to be low. Incidence and susceptibility to landslides are low for the AC collection system. Soil liquefaction is generally not a concern in this portion of the Project due to the low seismic activity and low PGA. Based on the existing conditions, earthquakes, landslides, and liquefaction are not anticipated to impact the AC collection system routes.

Karst covers about 60 percent of the AC collection system route representative ROWs. The final location of a ROW would be designed to avoid or minimize impacts to karst areas. Shallow bedrock underlies 5 to 20 percent of each AC collection system route ROW, and blasting may be necessary in this area.

Only the AC Collection System Routes E-1 and SE-3 representative centerlines traverse mineral resources (mineral deposit and shale gas play). EPMs LU-1, GE-29, and LU-4 would be implemented to avoid or minimize potential impacts to mineral resources.

3.6.1.6.2.2.2 Operations and Maintenance Impacts

Impacts to geology, paleontology, and mineral resources resulting from the operation and maintenance of the AC Collection System Routes would be minor during construction because ground disturbing activities would be comparatively negligible. The implementation of EPMs and appropriate engineering design would minimize or prevent impacts from geologic hazards during operation and maintenance. With implementation of EPMs (LU-1, GE-29, and LU-4) potential impacts to mineral resources would be avoided or minimized.

3.6.1.6.2.2.3 Decommissioning Impacts

Impacts from decommissioning are described in Section 3.6.1.6.1.

3.6.1.6.2.3 HVDC Applicant Proposed Route

Assessments of the impacts related to the route variations in Regions 2–7, including accompanying HVDC alternative route adjustments, are described at the end of applicable sections.

3.6.1.6.2.3.1 Construction Impacts

Table 3.6.1-12 summarizes geologic hazards and mineral resources that could be potentially impacted by or impact the Applicant Proposed Route. The excavation and drilling required for the foundations of the transmission structures would permanently impact the geologic formation underneath the transmission structure footprint to depths ranging from 15 to 30 feet in most areas of the Applicant Proposed Route. In the area of the Mississippi River crossing, foundation depths could reach 17 to 158 feet deep for lattice structures and 26 to 115 feet for pole structures. The area of potential impact to a geologic formation represents a very small portion of the total area of the geologic formation. In areas of karst formations, excavation and drilling could potentially create new preferential flow pathways, which could increase the risk of introducing constituents into the karst system that could eventually impact groundwater quality. The total estimated transmission structure footprints by region range from 5.4 to 20.4 acres, which is a conservative estimate of the areal extent of affected geologic formation. In total, the tower footprints would affect about 90.6 acres of geologic formation for the entire Applicant Proposed Route.

Table 3.6.1-12:
Geologic and Mineral Resources Impacts—200-Foot-Wide Representative ROW of the Applicant Proposed Route

Parameter[1a]	Region 1	Region 2	Region 3	Region 4	Region 5	Region 6	Region 7
Impact Area (acres)	2,826	2,589	3,950	3,088	2,760	1,331	1,048
Seismicity[1]	No active faults; low ground motion potential (PGA of 1% of gravity)	No active faults; low ground motion potential (PGA of 1–2% of gravity)	1 active fault; low ground motion potential (PGA of 2–3% of gravity)	3 active faults; low ground motion potential (PGA of 2–4% of gravity)	2 active faults; low to moderate ground motion potential (PGA of 4–10% of gravity)	0 active faults; low to high ground motion potential (PGA of 10–30% of gravity)	0 active faults; moderate to high ground motion potential (PGA of 15–30% of gravity)
Landslides[2]	Incidence and susceptibility to landslides are both low	Incidence and susceptibility to landslides are both low	High susceptibility, Low incidence (122 acres or 3%) Moderate susceptibility, Low incidence (204 acres or 5%)	Moderate susceptibility, Low incidence (2,650 acres or 86%)	High susceptibility, Low incidence (112 acres or 4%) Moderate susceptibility, Low incidence (2,513 acres or 91%)	Incidence and susceptibility to landslides are both low	High susceptibility, Moderate incidence (100 acres or 10%) High susceptibility, Low incidence (468 acres or 45%) Low incidence (480 acres or 46%)
Subsidence (karst)[3]	690 acres (24%)	189 acres (7%)	No Karst	678 acres (22%)	308 (11%)	No Karst	No Karst
Liquefaction[4]	Low	Low	Low	High (431 acres or 14%) Moderate (163 acres or 5%) Very Low (1,430 acres or 46%)	High (262 acres or 9%) Very Low (2,498 acres or 91%)	Very High (358 acres or 27%) High (889 acres or 67%) Moderate (84 acres or 6%)	Very High (737 acres or 70%) High (296 acres or 28%)
Mineral Resources (shale gas plays acres, oil/gas wells)[5]	No Resources	521 acres (20%)	12 oil/gas wells	1,929 acres (62%), 6 oil/gas wells	2,778 acres (95%), 10 oil/gas wells	No mineral resources	No mineral resources
Shallow Bedrock[6]	328 acres (12%)	775 acres (30%)	2,227 acres (56%)	1,974 acres (64%)	2,398 acres (87%)	622 acres (46%)	54 acres (5%)

1a The values in the table do not reflect the minor changes that would result from application of the minor route variations and adjustments.
GIS Data Sources:
1 Garrity and Soller (2009) and USGS (2008b)
2 USGS (2001)
3 Tobin and Weary (2004)
4 CUSEC (2008)
5 OCC (2013), AOGC (2014), USGS (2005b), EIA (2011a). Oil and gas wells and mineral resources are present in the larger ROI (EIA 2011a).
6 NRCS (2013). Shallow bedrock is present in 18% of the larger ROI.

This page intentionally left blank.

3.6.1.6.2.3.1.1 Seismicity

No active faults are present in Regions 1 and 2, and expected ground motions from an earthquake would be low, so seismicity impacts are expected to be minimal in the representative ROW for the Applicant Proposed Route. Although one active fault is present in Region 3 and three active surface faults are present in Region 4, the expected ground motions from an earthquake would be low. Two active surface faults transect the Applicant Proposed Route in Region 5 and expected ground motions from an earthquake would be low to moderate. Earthquake hazard transitions from low to moderate with eastward progression along Region 5. No active surface faults are present in Region 6, and expected ground motions from an earthquake would be low to high. From west to east within Region 6, the earthquake hazard transitions from low to moderate and from moderate to high. The Applicant Proposed Route in the easternmost portion of Region 6 is located within moderate to high seismic hazard that is closer to the New Madrid Seismic Zone. No active surface faults are present in Region 7, but expected ground motions from an earthquake would be moderate to high given the proximity of the New Madrid Seismic Zone.

The route variations have the same characteristic seismicity as the original Applicant Proposed Route.

With proper engineering design, impacts from seismicity are anticipated to be minimal for the Applicant Proposed Route. The Project would be constructed to withstand probable seismic events within the seismic risk zones crossed and constructed in accordance with all applicable federal and state regulations to prevent accidents and to ensure adequate protection for the public and the Project.

3.6.1.6.2.3.1.2 Soil Liquefaction

Soil liquefaction is unlikely in Regions 1 and 2 because of the low probable PGA. Approximately 15 percent of the soils within the Applicant Proposed Route representative ROW in Region 4 have high liquefaction susceptibility and approximately 4 percent of the soils within the easternmost portion of the Applicant Proposed Route in Region 5 have high liquefaction susceptibility. Approximately 90 percent of the soils within the Region 6 Applicant Proposed Route representative ROW have high liquefaction susceptibility; and approximately 98 percent of the soils within the Region 7 Applicant Proposed Route have high or very high liquefaction susceptibility. The proper placement of Project components following completion of geologic/geotechnical investigations performed during engineering design would minimize risks related to soil liquefaction.

The route variations have the same soil liquefaction susceptibility as the original Applicant Proposed Route.

3.6.1.6.2.3.1.3 Landslides

Regions 1 and 2 have a generally low incidence and low susceptibility to landslides, so impacts to the Project from landslides are not anticipated. The Applicant Proposed Route in Region 3 has low incidence for landslides, but susceptibility ranges from low to high. Region 4 is characterized by moderate susceptibility to landsliding and low incidence. Region 5 is characterized by moderate susceptibility to landsliding and low incidence with the exception of the very easternmost area of the region, where landslides are low incidence and high susceptibility. In Region 6, incidence and susceptibility to landslides are both low. High susceptibility areas are located in most areas of the Applicant Proposed Route in Region 7. Implementation of EPMs and appropriate engineering design would minimize impacts from areas susceptible to landslides.

The route variations generally have the same landslide incidence and susceptibility as the original Applicant Proposed Route. The Region 7 variation, Applicant Proposed Route Link 1, Variation 1, contains a greater acreage of land classified as having high susceptibility to landslides.

3.6.1.6.2.3.1.4 Karst Formations

Karst is present over about 25 percent of the Applicant Proposed Route representative ROW in Region 1. Isolated areas of karst occur in the western area of Region 2 of the Applicant Proposed Route. The remainder of the Applicant Proposed Route in Region 2 does not contain identified karst formations and therefore has a low susceptibility related land subsidence. Region 3 does not contain any identified karst formations. Region 4 contains karst formations in the western area of the Applicant Proposed Route (12 percent of the representative ROW). The Applicant Proposed Route contains isolated pockets of karst in Region 5 in the easternmost area. Regions 6 and 7 do not contain karst formations. Karst is present in a larger percentage of the ROI than the impact areas in Regions 2 and 4; and that karst is present in the ROI in Region 5 but is not present in the impact area for Region 5. Depending on the final location of the Applicant Proposed Route in these regions, impacts to karst might be expected to vary from what is presented in the table. EPMs and appropriate engineering design would focus on avoiding karst and maintaining ground disturbance over as small an area as possible to reduce impacts.

The route variations have similar amounts of karst as the original Applicant Proposed Route. The original Applicant Proposed route contains slightly less acreage of karst compared to the Region 2 variation, Link 2, Variation 2, as well as the Region 4 variation, Link 3, Variation 2.

3.6.1.6.2.3.1.5 Shallow Bedrock

Shallow bedrock underlies 12 percent of the Applicant Proposed Route representative ROW in Region 1 and 30 percent in Region 2. Shallow bedrock is present within 56 percent of the Applicant Proposed Route representative ROW in Region 3; within 63 percent of the Applicant Proposed Route representative ROW in Region 4; within 87 percent in Region 5; within 46 percent in Region 6; and within 4 percent in Region 7. Blasting may be required in these areas and impacts would be minimized by following provisions of the Blasting Plan. Depending on the final location of the Applicant Proposed Route, impacts in areas of shallow bedrock might be expected to vary from what is presented in the table.

The route variations generally have similar amounts of shallow bedrock as the original Applicant Proposed Route. The Applicant Proposed Route contains slightly greater acreage of shallow bedrock compared to the Applicant Proposed Route variations in Region 3 (Link 1 and Link 2, Variation 1), and less acreage of shallow bedrock compared to Region 3 (Link 1, Variation 2), Region 4 (Link 3, Variation 3), Region 5 (Link1, Variation 2, and Link 2, Variation 2), and Region 6 (Link 2, Variation 1).

3.6.1.6.2.3.1.6 Paleontological Resources

Although no known fossil bed sites were identified in the representative ROW in any of the Applicant Proposed Route Regions, shallow bedrock is present throughout the Project and there is the potential for fossil resources to be impacted. Areas of the Project that have a high percentage of shallow bedrock would have a greater potential for impacting paleontological resources. The Applicant would avoid or minimize impacts on paleontological resources by training personnel in the practices, techniques, and protocols required by federal and state regulations and applicable permits (GE-1).

Given the similar amounts and type of shallow bedrock, the route variations would be expected to contain similar paleontological resources as the original Applicant Proposed Route.

3.6.1.6.2.3.1.7 Mineral Resources

The Applicant Proposed Route in Region 1 traverses no shale gas plays within the representative ROW. Shale gas plays (1,428 acres) are traversed in Region 2. The route does not traverse any oil and gas wells in Regions 1 and 2. The Applicant Proposed Route representative ROW in Region 3 traverses 12 oil and gas wells. The potential for impact to oil and gas operations is greatest in Regions 4 and 5. Given the ongoing development of the Fayetteville shale, the presence of oil and gas wells and other related infrastructure could be frequent. For example, as described in Section 3.6.1.5., within the 4,000-foot-wide corridor along the Applicant Proposed Route there are 181 and 282 oil and gas wells in Region 4 and Region 5, respectively. The Applicant Proposed Route representative ROW in Region 4 would traverse just six oil and gas wells and 1,929 acres of shale gas play, and in Region 5, would traverse only 10 oil and gas wells and 2,778 acres of shale gas play (Table 3.6.1-12). However, in some areas, the prevalence of oil and gas wells, combined with other gas development infrastructure (well pads, access roads, compressor stations, and gathering and transmission pipelines), would make implementation of EPMs LU-1, GE-29, and LU-4 of critical importance during routing and engineering surveys to determine the least disruptive route within the 1,000-foot-wide corridor. The Applicant used LiDar, field survey, and infrastructure and mineral rights data sets to further refine and microsite the route to avoid mineral resources. As currently understood from the most current and comprehensive data available, through the use of micrositing the representative ROW would avoid all existing oil and gas wells or well pads. Should additional information be discovered, the Applicant would microsite as needed to minimize impacts to existing mineral resources and operations. No mineral resources are traversed by the Applicant Proposed Route representative ROWs for Regions 6 and 7, so no impacts to mineral resources are indicated. EPMs LU-1, GE-29, and LU-4 would be implemented to minimize impacts to mineral resources.

The route variations have similar amounts of mineral resources and oil and gas wells as the original Applicant Proposed Route and do not traverse mines.

3.6.1.6.2.3.2 Operations and Maintenance Impacts

Impacts from the Applicant Proposed Route during operations and maintenance would be less than impacts described during construction. Once construction has been completed, blasting would not occur and other soil-disturbing activities would be negligible; thus, impacts to fossils and karst are not anticipated. Operations and maintenance activities would not increase the risk of landslides.

Given the implementation of the appropriate EPMs and engineering design, the Applicant Proposed Route is not anticipated to be impacted by seismicity, subsidence, liquefaction, or landslides that results in damage to Project infrastructure or interruption of service; the Applicant Proposed Route would not adversely impact access to mineral resources; and impacts to paleontological resources would be minimized. Regions 6 and 7 are located in an area of low to high seismic risk and high potential for liquefaction; therefore, there is still potential that seismicity and liquefaction could impact Project infrastructure; however, EPMs and appropriate engineering design would reduce the risk.

3.6.1.6.2.3.3 Decommissioning Impacts

Impacts from decommissioning are described in Section 3.6.1.6.1. Because minor ground disturbance associated with construction and operations and maintenance would no longer be necessary and because structure foundations would only be removed below ground level, the potential to affect paleontological resources would be reduced.

3.6.1.6.3 Impacts Associated with the DOE Alternatives

3.6.1.6.3.1 Arkansas Converter Station Alternative Siting Area and AC Interconnection Siting Area

3.6.1.6.3.1.1 Construction Impacts

The Arkansas converter station and AC interconnection would be located near the New Madrid Seismic Zone in an area of low to moderate seismic hazard. Nine percent of the soils within the siting area for the Arkansas converter station have high liquefaction potential, and about 47 percent of the soils within the AC interconnection have high liquefaction potential. To reduce impacts from seismic hazard and liquefaction, the Applicant would implement the same measures as described for the Tennessee Converter Station Siting Area and AC Interconnection Siting Area.

The Arkansas Converter Station and AC Interconnection Siting Areas do not contain karst, so no impacts from karst are anticipated during construction. The areas have moderate susceptibility and low incidence with respect to landslides. Potential landslide impacts would be reduced or mitigated using the same techniques as described for the Tennessee Converter Station Siting Area and AC Interconnection Tie.

Approximately 79 percent of the Arkansas Converter Station Siting Area is underlain by shallow bedrock (Table 3.6.1-6). Impacts from blasting would be minimized by following provisions of the Blasting Plan.

A new substation would also be required at the point where the 500kV AC interconnection line taps the existing Arkansas Nuclear One-Pleasant Hill 500kV line. The footprint of this substation is estimated to be between 25 and 35 acres, with an additional 5 acres for temporary materials staging and equipment storage. The substation is within the AC Interconnection Siting Area and thus high liquefaction potential, low to moderate seismicity, and moderate susceptibility to landslides have the potential to impact the new substation. The same measures as described for the Tennessee Converter Station Siting area and AC Interconnection Tie would be implemented. The placement of Project components would be governed in part by site conditions, construction requirements, and EPMs, which would minimize risks related to soil liquefaction, seismicity, and landslides.

Shale gas play is located within the Arkansas Converter Station and AC Interconnection Siting areas; three oil and gas wells were identified within the Arkansas Converter Station Siting Area. EPMs LU-1, GE-29, and LU-4 would be implemented to avoid or minimize potential impacts to mineral resources from construction.

3.6.1.6.3.1.2 Operations and Maintenance Impacts

The Arkansas Converter Station Siting Area and AC Interconnection Siting Area have moderate susceptibility and low incidence with respect to landslides. If operations and maintenance activity is conducted on unstable slopes, including vegetation clearing and alteration of surface-drainage patterns, landslide risk would be increased. Effects would be minimized utilizing the same measures as described for the Tennessee Converter Station Siting Area and AC Interconnection Tie. The Project components would be operated and maintained in an area of low to moderate seismic hazard. The soils within the siting areas have high liquefaction potential. Impacts from seismic hazards and liquefaction would be minimized utilizing the same measures as described for the Tennessee Converter Station Siting Area and AC Interconnection Tie.

Once construction has been completed, blasting and other soil-disturbing activities would be negligible, so impacts to fossils are not anticipated. The siting areas do contain oil and gas wells or other mineral resources; however, impacts to mineral resources are not expected during operations.

3.6.1.6.3.1.3 Decommissioning Impacts

Impacts from decommissioning are described in Section 3.6.1.6.1.

3.6.1.6.3.2 HVDC Alternative Routes

3.6.1.6.3.2.1 Construction Impacts

3.6.1.6.3.2.1.1 Region 1

Table 3.6.1-13 summarizes relevant analysis considerations for geologic and mineral resources that could potentially impact or be impacted by all the Region 1 HVDC alternative routes compared to the corresponding Applicant Proposed Route links. HVDC alternative route impacts in Region 1 related to active faults, ground motion potential, landslides, and mineral resources are comparatively the same as the Applicant Proposed Route, and these geologic hazards are not presented in Table 3.6.1-13.

Table 3.6.1-13:
Geological and Mineral Resources within the 200-Foot-Wide Representative ROW—Region 1

Parameter	Impact Area (acres)	Subsidence (acres of karst)[1]	Shallow Bedrock[2]	Impacts Comparison with Applicant Proposed Route Corresponding Links
AR 1-A[3]	3,004	244 (8%)	582 (19%)	Greater impact to karst formations and shallow bedrock.
Corresponding APR Links 2, 3,4, 5	2,778	No karst	299 (10%)	NA
AR 1-B[3]	1,268	437 (34%)	100 (8%)	Lesser impact to karst formation and more impact to shallow bedrock.
Corresponding APR Links 2, 3	1,316	643 (49%)	40 (3%)	NA
AR 1-C[3]	1,272	242 (19%)	63 (5%)	Lesser impact to karst formations and more impact to shallow bedrock.
Corresponding APR Links 2, 3	1,316	643 (48%)	40 (3%)	NA
AR 1-D[3]	819	No karst	46 (6%)	More impact to shallow bedrock.
Corresponding APR Links 3, 4	823	No karst	25 (3%)	NA

GIS Data Sources:
1 Tobin and Weary (2004)
2 NRCS (2013)
3 Oil and gas wells and mineral resources are present in the larger ROI area (GIS Data Sources: USGS [2005a] and OCC [2013]).

Representative ROWs in Region 1, except for Alternative Route 1-D and Applicant Proposed Route Links 1 and 2, have isolated areas of karst formations. The presence of karst and potential need for blasting in areas of shallow bedrock would require the use of EPMs and appropriate engineering design to reduce the potential for impacts. No known fossil bed sites were identified in Region 1. No mineral resources are traversed in Region 1. However, oil and gas wells and mineral resources are present in the larger ROI areas for all of the HVDC alternative routes and corresponding Applicant

Proposed Route links. Depending on the final route locations, mineral resources have the potential to be affected in these areas.

3.6.1.6.3.2.1.2 Region 2

Table 3.6.1-14 summarizes relevant analysis considerations for geologic and mineral resources that could potentially impact or be impacted by the HVDC alternative routes compared to the corresponding Applicant Proposed Route links. HVDC alternative route impacts in Region 2 related to active faults, ground motion potential, landslides, and soil liquefaction are comparatively the same as the Applicant Proposed Route, and these geologic hazards are not presented in Table 3.6.1-14.

Table 3.6.1-14:
Geological and Mineral Resources within the 200-Foot-Wide Representative ROW—Region 2

Parameter	Impact Area (acres)	Subsidence[1] (acres of karst)	Mineral Resources (acres of shale gas play)[2]	Shallow Bedrock (acres)[3]	Impact Comparison with Applicant Proposed Route Corresponding Links
AR 2-A	1,396	310 (22%)	0 (0%)	0 (0%)	More impact to karst formation less impact to shallow bedrock, and less impact to shale gas deposits.
Corresponding APR Link 2	1,331	189 (14%)	521 (39%)	296 (22%)	NA
AR 2-B	728	0 (0%)	0 (0%)	550 (76%)	More impact to soils with shallow bedrock and less impact to karst formations.
Corresponding APR Link 3	764	0 (0%)	0 (0%)	180 (24%)	NA

GIS Data Sources:
1 Tobin and Weary (2004)
2 EIA (2011a)
3 NRCS (2013). In HVDC Alternative Route 2-A, shallow bedrock is present in 22% of the larger ROI in HVDC Alternative Route 2-A, and in HVDC Alternative Route 2-B, shallow bedrock is present in 41% of the larger ROI.

Isolated areas of karst formations (22 percent of the total area of the representative ROW) occur in HVDC Alternative Route 2-A and Applicant Proposed Route Link 2 (14 percent). The remainder of Region 2 does not contain identified karst formations and therefore has a low susceptibility for land subsidence as a result of karst formations. There is potential for direct impacts to paleontological resources in areas of shallow bedrock (76 percent for HVDC Alternative Route 2-B). Shale gas plays are traversed along the Applicant Proposed Route Link 2, but are not traversed along the corresponding HDVC Alternative Route 2-A. There are no other mineral resources traversed in the Region 2 representative ROWs.

3.6.1.6.3.2.1.3 Region 3

Table 3.6.1-15 summarizes relevant analysis considerations for geologic and mineral resources that could potentially impact or be impacted by the Region 3 HVDC alternative routes compared to the corresponding Applicant Proposed Route links. There are no karst formations present in any of the routes of Region 3, and soil liquefaction is unlikely because of the low probable PGA. All HVDC alternative route impacts in Region 3 related to these geologic hazards are therefore comparatively the same as the Applicant Proposed Route, and these geologic hazards are not presented in Table 3.6.1-15.

Table 3.6.1-15:
Geological and Mineral Resources within the 200-Foot-Wide Representative ROW—Region 3

Parameter[1a]	Representative ROW Impact Area (acres)	Seismicity[1]	Landslides[2, 2a]	Mineral Resources (acres of shale gas play)[3]	Shallow Bedrock (acres)[4]	Impact Comparison with Applicant Proposed Route Corresponding Links
AR 3-A	919	No active faults; low ground motion potential (PGA of 2–3% of gravity)	Incidence and susceptibility to landslides are both low	0 (0%)	681 (74%)	Crosses nearly the same amount of shallow bedrock.
Corresponding APR Link 1	977	Same as AR 3-A	Same as AR 3-A	0 (0%)	696 (71%) —greater impact	NA
AR 3-B	1,167	Same as AR 3-A	Same as AR 3-A	0 (0%)	852 (73%)	Crosses nearly the same amount of shallow bedrock.
Corresponding APR Links 1,2, 3	1,221	Same as AR 3-A	Same as AR 3-A	0 (0%)	838 (21%) —less impact	NA
AR 3-C	2,968	Same as AR 3-A	Low incidence mod-high susceptibility (318 acres and 11%)	0 (0%)	1,481 (50%)	Crosses nearly the same amounts of shallow bedrock and landslide susceptibility is nearly the same.
Corresponding APR Links 3, 4, 5, 6	2,896	Same as AR 3-A	Low incidence and mod-high susceptibility (326 acres and 11%)	12 oil/gas wells - greater impact	1,490 (51%) —greater impact	NA
AR 3-D	959	Same as AR 3-A	Low incidence, mod-high susceptibility (318 acres and 33%)	0 (0%)	320 (33%)	Crosses more amounts of shallow bedrock; landslide susceptibility is nearly the same.
Corresponding APR Links 5,6	857	1 active fault; low ground motion potential—greater impact	Low incidence, mod-high susceptibility (326 acres and 38%)	0 (0%)	268 (31%) —less impact	NA
AR 3-E	208	Same as AR 3-A	100% of route is low incidence and moderate susceptibility (208 acres and 100%)	0 (0%)	112 (54%)	Crosses nearly the same amounts of shallow bedrock; landslide susceptibility is nearly the same.
Corresponding APR Links 6	190	Same as AR 3-A	Same as AR 3-E	0 (0%)	98 (52%) —less impact	

1a The values in the table do not reflect the minor changes that would result from application of the minor route variations and adjustments.
2a High susceptibility and low incidence is 41% in the larger ROI for HVDC Alternative Route 3-C.
GIS Data Sources:
1 Garrity and Soller (2009), USGS (2008b)
2 USGS (2001)
3 OCC (2013), EIA (2011a)
4 NRCS (2013)

This page intentionally left blank.

Although one active fault is present in Region 3, the earthquake and seismic activity are low within Region 3 and potential related impacts are expected to be minimal. HVDC Alternative Routes 3-C, 3-D, and 3-E, are located in areas with low incidence for landslides, but where susceptibility ranges from low to high. There are no appreciable differences (Table 3.6.1-15) between the Region 3 HVDC alternative routes and corresponding Applicant Proposed Route links in terms of the low potential seismic ground motion and landslide risks.

Shallow bedrock is present along all routes, and blasting may be required in these areas. There is potential for direct impacts to paleontological resources in areas of shallow bedrock (33 to 74 percent for the HVDC Alternative Routes). All of the alternative routes in Region 3 traverse shale gas plays, but no other mineral resources are traversed.

As described in Appendix M and summarized in Section 2.4.2.3, a route adjustment was developed for HVDC Alternative Route 3-A to maintain an end-to-end route with Applicant Proposed Route Link 1, Variation 2, and Links 1 and 2, Variation 1. The geologic hazards and mineral resources for this route adjustment would be the same as for the original HVDC Alternative Route 3-A.

3.6.1.6.3.2.1.4 Region 4

Table 3.6.1-16 summarizes relevant analysis considerations for geologic and mineral resources that could potentially impact or be impacted by the Region 4 HVDC alternative routes compared to the corresponding Applicant Proposed Route links. Four active surface faults are present in Region 4, but expected ground motions from an earthquake would be low and any related impacts would be minimal. HVDC Alternative Routes 4C, 4-D, and 4-E and the corresponding Applicant Proposed Route links contain areas of high liquefaction susceptibility. The appropriate placement of project components during engineering design would minimize risks related to soil liquefaction.

Region 4 is characterized by moderate susceptibility to landsliding and low incidence. HVDC Alternative Routes 4-A through 4-D representative ROWs contain greater amount of landslide hazard than the corresponding Applicant Proposed Route links. HVDC Alternative Routes 4-A and 4-B have isolated areas of karst formations covering about 59 and 54 percent of the respective representative ROWs. The corresponding links of the Applicant Proposed Route have slightly lower amounts of karst formations within the representative ROWs.

Shallow bedrock is present along all alternative routes, and blasting may be required in these areas. There is potential for direct impacts to paleontological resources in areas of shallow bedrock (57 to 100 percent for the HVDC Alternative Routes in Region 3). Oil and gas wells and shale gas plays are traversed in Region 4.

3.6.1.6.3.2.1.5 Region 5

Table 3.6.1-17 summarizes relevant analysis considerations for geologic and mineral resources that could potentially impact or be impacted by the Region 5 HVDC alternative routes compared to the corresponding Applicant Proposed Route links. There are no karst formations present in all route areas of Region 5, so karst is not presented in Table 3.6.1-17. However, karst is present in the larger ROIs for HVDC Alternative Route 5-D (73 percent of ROI) and the Applicant Proposed Route (11 percent of ROI).

This page intentionally left blank.

Table 3.6.1-16:
Geological and Mineral Resources within the 200-Foot-Wide Representative ROW—Region 4

Parameter	Representative ROW Impact Area (acres)	Seismicity[1]	Landslides[2]	Subsidence (acres of karst)[3]	Liquefaction susceptibility (acres)[4]	Mineral Resources (shale gas plays acres, oil/gas wells)[5]	Shallow Bedrock[6] (acres)	Impact Comparison with Applicant Proposed Route Corresponding Links
AR 4-A	1,426	2 active faults; low ground motion potential (PGA of 2–3% of gravity)	Low incidence and moderate susceptibility (1,426 acres and 100%)	847 (59%)	69 (5%) (moderate)	572 acres (40%)	1,228 (86%)	Crosses more shallow bedrock and more karst formations; fewer potential shale gas deposits; and lower number of oil and gas wells.
Corresponding APR Links 3, 4, 5, 6	1,475	2 active faults; low ground motion potential	Low incidence and moderate susceptibility (1,202 acres and 81%)—less impact	415 (13%) —less impact	431(29%) (high); 139 (9%) (moderate)–greater impact due to high susceptibility areas	622 acres (42%), 4 oil/gas wells—greater impact	946 (64%) —less impact	NA
AR 4-B	1,920	2 active faults; low ground motion potential I (PGA of 2–3% of gravity)	Low incidence and moderate susceptibility (1,920 acres and 100%)	1,043 (54%)	No moderate or high susceptibility areas	948 acres (49%), 6 oil/gas wells	1,542 (80%)	Crosses more shallow bedrock and more karst formations and fewer potential shale gas deposits and is less susceptible to liquefaction.
Corresponding APR Links 2, 3, 4, 5, 6, 7, 8	1,988	2 active faults; low ground motion potential	Low incidence and moderate susceptibility (1,550 acres and 78%);—less impact	518 (17%) —less impact	405 (20%) (high); 163 (8%) (mod)—greater impact	1,032 acres (52%), 6 oil/gas wells—greater impact	1,334 (67%) —less impact	NA
AR 4-C	83	0 active faults; low ground motion potential I (PGA of 3% of gravity)	Low incidence and moderate susceptibility (83 acres and 100%)	83 (100%)	32 (39%) (high)	83 acres (100%)	83 (100%)	Crosses more shallow bedrock, more potential shale gas deposits, and more karst formations and is more susceptible to liquefaction.
Corresponding APR Link 5	53	0 active faults; low ground motion potential	Low incidence and moderate susceptibility (53 acres and 100%)	53 (100%) – less impact	2 (4%) (high)—less impact	53 acres (100%) —less impact	53 (100%) —less impact	NA

Parameter[1a]	Representative ROW Impact Area (acres)	Seismicity[1]	Landslides[2]	Subsidence[3] (acres of karst)	Liquefaction[4]	Mineral Resources (shale gas plays acres, oil/gas wells)[5]	Shallow Bedrock (acres)[6]	Impact Comparison with Applicant Proposed Route Corresponding Links
Corr. APR Link 9	500	Same as corresponding AR	High susceptibility, Low incidence (112 acres and 22%), Moderate susceptibility, Low incidence (253 acres and 51%)	308 (62%)	Very low	375 acres (75%)	332 (66%)	NA
AR 5-E	885	1 active faults; low to moderate ground motion potential (PGA of 7–9% of gravity)	Low incidence and moderate susceptibility	No Karst	Very low	885 acres (100%), 4 oil/gas wells	837 (95%)	Crosses more potential shale gas deposits, less oil and gas wells, and more shallow bedrock.
Corr. APR Links 4, 5, 6	811	Same as corresponding AR	Same as corresponding AR	No Karst	Very low	811 acres (100%), 8 oil/gas wells	766 (94%)	NA
AR 5-F	544	0 active faults; low to moderate ground motion potential (PGA of 8–9% of gravity)	Low incidence and moderate susceptibility	No Karst	Very low	544 acres (100%), 2 oil/gas wells	501 (92%)	Crosses more potential shale gas deposits, more oil and gas wells, and more shallow bedrock.
Corr. APR Links 5, 6	459	Same as corresponding AR	Same as corresponding AR	No Karst	Very low	459 acres (100%)	416 (91%)	NA

1a The values in the table do not reflect the minor changes that would result from application of the minor route variations and adjustments.
GIS Data Sources:
1 Garrity and Soller (2009), USGS (2008b)
2 USGS (2001)
3 Tobin and Weary (2004)
4 CUSEC (2008)
5 AOGC (2014), USGS (2005b) (metallic and non-metallic mineral resources), EIA (2011a)
6 NRCS (2013)

Active surface faults are present in Region 5 along HVDC Alternative Routes 5-B, 5-D, and 5-E, and expected ground motions from an earthquake would be low to moderate. Earthquake hazard transitions from low to moderate with eastward progression along the region, and seismicity impacts are expected to be minimal for all Region 5 alternatives. High liquefaction susceptibility is present in HVDC Alternative Route 5-D. The corresponding Applicant Proposed Route representative ROW is located in areas that have no high liquefaction susceptibility.

Region 5 is characterized by moderate susceptibility to landsliding and low incidence with the exception of the representative ROW for HVDC Alternative Route 5-D, for which landslides are low incidence and high susceptibility. Shallow bedrock is present along all routes (78 to 95 percent), and blasting may be required in these areas. There is also potential for direct impacts to paleontological resources in areas of shallow bedrock. Mineral resources and shale gas plays are traversed by both HVDC alternative routes and corresponding Applicant Proposed Project links.

As described in Appendix M and summarized in Section 2.4.2.5, a route adjustment was developed for HVDC Alternative Route 5-B to maintain an end-to-end route with Applicant Proposed Route Links 2 and 3, Variation 1. The geologic hazards and mineral resources for this route adjustment would be similar to the original HVDC Alternative Route 5-B.

As described in Appendix M and summarized in Section 2.4.2.5, a route variation was developed for HVDC Alternative Route 5-E in response to public comments on the Draft EIS to maintain continuity with Applicant Proposed Route Links 3 and 4, Variation 2. The geologic hazards and mineral resources for this route adjustment would be similar to the original HVDC Alternative Route 5-E.

3.6.1.6.3.2.1.6 Region 6

Table 3.6.1-18 summarizes relevant analysis considerations for geologic and mineral resources that could potentially impact or be impacted by the Region 6 HVDC alternative routes compared with the corresponding Applicant Proposed Route links. Because no active faults or karst formations occur, and landslides risks are low, these geologic hazards are not presented in Table 3.6.1-18.

From west to east within Region 6, the earthquake hazard transitions from low-moderate to moderate-high. HVDC Alternative Routes 6-C and 6-D, as well as the Applicant Proposed Route corresponding links, on the easternmost portion of Region 6 are located within moderate to high seismic hazard and are closer to the New Madrid Seismic Zone. Seismicity impacts are expected to be minimal for the four HVDC alternative routes and corresponding Applicant Proposed Route Links 2, 3, 4, 6, and 7. Most of the soils in both the HVDC alternative routes and Applicant Proposed Route representative ROWs have high liquefaction susceptibility.

Shallow bedrock is present along all routes in Region 6 (2 to 61 percent), and blasting may be required in these areas. There are only slight differences between the Region 6 alternative routes in terms of geologic hazards; and the HVDC alternative routes, compared to Applicant Proposed Route Links 2, 3, 4, 6, and 7, would have nearly the same impacts. There is also potential for direct impacts to paleontological resources in areas of shallow bedrock. HVDC Alternative Route 6-A traverses only one oil and gas well (listed as inactive).

As described in Appendix M and summarized in Section 2.4.2.6, a route adjustment was developed for HVDC Alternative Route 6-A to maintain an end-to-end route with Applicant Proposed Route Link 2, Variation 1. The geologic hazards and mineral resources for this route adjustment would be similar to the original HVDC Alternative Route 6-A.

This page intentionally left blank.

Table 3.6.1-18:
Geological and Mineral Resources within the 200-Foot-Wide Representative ROW—Region 6

Parameter[1a]	Representative ROW Impact Area (acres)	Seismicity[1]	Liquefaction[2]	Mineral Resources[3]	Shallow Bedrock[4] (acres)	Impact Comparison with Applicant Proposed Route Corresponding Links
AR 6-A	396	0 active faults; low to moderate ground motion potential (PGA of 10 to 20% of gravity)	High (396 acres and 100%)	1 oil/gas well (inactive)	238 (60%)	Nearly the same impacts with less impact to shallow bedrock.
Corresponding APR Links 2,3,4	433	Same as AR 6-A	High (433 acres and 100%)	None—less impact	278 (64%)—greater impact	NA
AR 6-B	344	0 active faults; low to moderate ground motion potential (PGA of 10 to 15% of gravity)	High (344 acres and 100%)	None	209 (61%)	Nearly the same impacts with somewhat greater impact to shallow bedrock.
Corresponding APR Link 3	236	Same as AR 6-B	High (236 acres and 100%)	Same as AR 6-B	173 (73%)—less impact	NA
AR 6-C	566	0 active faults; moderate to high ground motion potential (PGA of 20 to 30% of gravity)	High (264 acres and 47%), Moderate (61 acres and 11%) Very High (241 acres and 43%)	None	262 (46%)	Nearly the same impacts with slightly less impact to soil liquefaction and shallow bedrock.
Corresponding APR Links 6,7	606	Same as AR 6-C	High (260 acres and 43%), Moderate (84 acres and 14%), Very High (262 acres and 43%)—greater impact	Same as AR 6-C	291 (48%)—greater impact	NA
AR 6-D	209	0 active faults; high ground motion potential (PGA of 30% of gravity)	Very high (209 acres and 100%)	None	4 (2%)	Nearly the same impacts.
Corresponding APR Link 7	224	Same as AR 6-D.	Very high (224 acres and 100%)	Same as AR 6-D	0 (0%)—less impact	

1a The values in the table do not reflect the minor changes that would result from application of the minor route variations and adjustments.
GIS Data Sources:
1 Garrity and Soller (2009), USGS (2008b)
2 CUSEC (2008)

3.6.1.6.3.2.1.7 Region 7

Table 3.6.1-19 summarizes relevant analysis considerations for geologic and mineral resources that could potentially impact or be impacted by construction of the HVDC transmission line within the alternative routes in Region 7. Because no karst formations or mineral resources occur in Region 7, they are not presented in Table 3.6.1-19.

No active surface faults are present in Region 7, and expected ground motions from an earthquake would be moderate to high. Expected ground motion for HVDC Alternative Route-7A and the corresponding Applicant Proposed Route links is the highest of the HVDC alternative routes because it is closest to the New Madrid Seismic Zone. Susceptibility to liquefaction is high to very high for all HVDC alternative routes and the corresponding Applicant Proposed Route links.

High susceptibility areas for landslides are located in all of the HVDC alternative routes. Landslide incidence varies from low to moderate. Moderate incidence occurs along HVDC Alternative Routes 7-C and 7-D. The Applicant Proposed Route in Region 7 has somewhat less impact to high susceptibility areas for landslides than the HVDC alternative routes. Landslide hazards would be minimized in the same manner described for the Applicant Proposed Route. Shallow bedrock is present along routes HVDC Alternative Route 7-B, 7-C, and 7-D, with slightly more shallow bedrock present in the corresponding Applicant Proposed Route links for 7-B and 7-D. Blasting may be required in these areas. The HVDC alternative routes and corresponding Applicant Proposed Route Links 1, 3, 4, and 5 would have nearly the same overall impacts in terms of geologic hazards.

There is also potential for direct impacts to paleontological resources in areas of shallow bedrock during grading and excavation activities. Mineral resources were not identified within the representative ROWs in Region 7.

3.6.1.6.3.2.2 Operations and Maintenance Impacts

Impacts to and from geologic hazards during operations and maintenance would be the same as described in 3.6.1.6.2 for the Applicant Proposed Route.

3.6.1.6.3.2.3 Decommissioning Impacts

Impacts to and from geologic hazards during decommissioning would be the same as described in 3.6.1.6.2 for the Applicant Proposed Route.

3.6.1.6.4 Best Management Practices

No BMPs are recommended because implementation of the EPMs and appropriate engineering design methods is anticipated to avoid and minimize impacts related to geologic hazards, paleontological resources, and mineral resources.

3.6.1.6.5 Unavoidable Adverse Impacts

Appropriate engineering design and adherence to applicable design standards would reduce the risk from geological hazards, but damage to Project components could occur if a rare, major geologic event such as a large magnitude earthquake or landslide occurred.

Despite EPMs and appropriate engineering design, scientifically valuable fossils may be disturbed and lost during construction activities. If this occurred, the small loss of fossil material would be offset to a degree by material that is recovered and preserved for scientific study purposes.

This page intentionally left blank.

Table 3.6.1-19:
Geological and Mineral Resources within the 200-Foot-Wide Representative ROW—Region 7

Parameter	Impact Area (acres)	Seismicity[1]	Landslides[2]	Liquefaction[3]	Shallow Bedrock (acres)[4]	Impact Comparison with Applicant Proposed Route Corresponding Links
AR 7-A	1,052	0 active faults; moderate to high ground motion potential (PGA of 20 to 30% of gravity)	High susceptibility, low incidence (594 acres and 56%)	Very high (1,052 acres and 100%)	0 (0%)	Nearly the same impacts with somewhat more impact to potential landslide areas.
Corresponding APR Link 1	698	Same as AR 7-A.	High susceptibility, low incidence (414 acres and 59%)—less impact	Very high (698 acres and 100%)	0 (0%)	NA
AR 7-B	210	0 active faults; moderate to high ground motion potential (PGA of 20% of gravity)	High susceptibility, low incidence (39 acres and 19%)	High (165 acres and 79%); very high (45 acres and 21%)	13 (6%)	Nearly the same impacts with somewhat more impact to landslide and soil liquefaction areas; and less impact to shallow bedrock.
Corresponding APR Links 3,4	205	Same as AR 7-B	High susceptibility, low incidence (27 acres and 13%)—less impact	High (178 acres and 87%); very high (27 acres and 13%)—less impact	33 (16%)—greater impact	NA
AR 7-C	579	0 active faults; moderate ground motion potential (PGA of 15 to 20% of gravity)	High susceptibility, low incidence (39 acres and 7%)	High (416 acres and 72%), Very High (162 acres and 28%)	134 (23%)	Crosses more shallow bedrock, and is more susceptible to liquefaction and landslides. Slightly lower overall seismicity (PGA).
Corresponding APR Links 3,4,5	323	0 active faults; moderate ground motion potential (PGA of 20% of gravity) – slightly higher seismicity	High susceptibility, low incidence (27 acres and 8%); high susceptibility, moderate incidence (100 acres and 31%); low incidence (196 acres and 61%)—less impact	High (296 acres and 92%), very high (27 acres and 8%)—less impact	54 (17%)—less impact	NA
AR 7-D	160	0 active faults; moderate ground motion potential (PGA of 20% of gravity)	High susceptibility, moderate incidence (110 acres and 69%)	High (160 acres and 100%)	14 (9%)	Crosses less shallow bedrock, and is somewhat more susceptible to landslides.
Corresponding APR Links 4,5	157	Same as AR 7-D	High susceptibility, moderate incidence (100 acres and 64%)—less impact	High (157 acres and 100%)	35 (22%)—greater impact	NA

2 USGS (2001)
3 CUSEC (2008)
4 NRCS (2013)

This page intentionally left blank.

Mineral resources may exist below the surface within the Project ROWs and/or converter station sites, in which case some resources could be less accessible for the life of the Project. The types of mineral resources that would be more affected are near-surface mineral material deposits (e.g., common sand, gravel, and stone). Oil and gas resources would be less affected because recovery of the resources would be possible, even with a minimum stand-off of 250 feet from the edge of the route ROWs and converter station sites using a vertically installed well, without the use of directional drilling. With directional drilling, such areas could be accessed at considerable distance from the Project.

3.6.1.6.6 Irreversible and Irretrievable Commitment of Resources

Because paleontological resources are nonrenewable, any impacts would render the resource disturbance irreversible and the integrity of the resource irretrievable.

3.6.1.6.7 Relationship between Local Short-term Uses and Long-term Productivity

No relationships exist between local short-term uses and long-term productivity for geological hazards. Short-term impacts associated with the exposure of any scientifically important fossils from Project activities would not adversely impact the long-term potential for discovery of potential fossil resources. Any short-term effects to access to mineral resources are not expected to cause long-term impairment to the productivity of mineral resources.

3.6.1.6.8 Impacts from Connected Actions

3.6.1.6.8.1 Wind Energy Generation

3.6.1.6.8.1.1 Construction Impacts

No impacts from seismic hazards, landslides, or soil liquefaction were identified, and no impacts to mineral resources are anticipated from construction activities in the WDZs. Subsidence from karst is a possible geologic hazard of concern within the WDZs. The approximate percentages of karst contained within the WDZs range from 0 to 87 percent. Appropriate engineering design and proper placement of wind farm infrastructure would typically be implemented to minimize the risks associated with constructing wind farms across karst. However, complete avoidance of karst is not possible, and the risk to wind farm components from subsidence would still exist. Additionally, the excavation and drilling required for the foundations of the wind turbines could create new preferential flow pathways, which could increase the risk of introducing constituents into the karst system that could eventually impact groundwater quality.

Although no known fossil bed sites were identified in the wind energy generation ROI, grading and excavation activities have the potential to cause direct impacts to paleontological resources. These impacts could occur if fossils are at or near the ground surface in rock outcrops and/or areas of shallow bedrock. Grading activities would typically be limited to the minimum amount needed to create safe working surfaces. Foundation excavations would typically be made using power drill or augers; blasting would typically only be used where necessary and in accordance with wind developer's Blasting Plan. Typically, project personnel would be trained in the practices, techniques, and protocols required by federal and state regulations and applicable permits. Training of personnel if required would increase the likelihood that any unique fossils exposed during an excavation would be identified and the necessary steps taken to preserve them.

Wind turbines and other infrastructure would be dispersed within the wind farms, such that alternative placement of drilling equipment would be possible, if required, and access to oil, gas, and mineral resources should not be greatly diminished. Additionally, turbines and associated facilities are often microsited to avoid sensitive land uses, or as preferred by the participating landowners in lease provisions. Impacts on mineral resources extraction during construction are anticipated to be minor.

3.6.1.6.8.1.2 Operations and Maintenance Impacts

During operations and maintenance, impacts to wind farm facilities from seismicity are not anticipated, because the area is located in an area of low seismic risk, so soil liquefaction risk is also expected to be low. Wind farm facilities would not likely be affected by karst because the engineering design and placement of facilities to minimize risks from karst would typically be put in-place during construction. However, due to the prevalence of karst in the area the risk for subsidence does exist. Impacts to mineral resource accessibility would not be expected if protective measures described for the construction phase were put in place; and the locations of the facilities would be designed to avoid mineral resources to the extent possible. Blasting would not occur and other soil disturbing activities would be negligible, so no impacts to fossils would be expected.

3.6.1.6.8.1.3 Decommissioning Impacts

Any risks to the wind farm facilities associated with identified geologic hazards would be removed when the facilities were decommissioned. Some ground disturbance would occur from the use of machinery such as bulldozers to demolish facility buildings or cranes used to deconstruct the wind turbines. However, ground disturbance would be limited to the near surface in previously disturbed areas. Decommissioning would not impact karst because protective measures used during construction would also be applied during decommissioning and the amount of ground disturbance associated with decommissioning would be less than during construction. Access to oil and gas or mineral resources would no longer be potentially affected by the presence of the facilities.

3.6.1.6.8.2 Optima Substation

Seismicity characteristics for the future Optima substation are low and similar to those described in Region 1. The area is within karst; and shallow bedrock is present in 15 acres (9 percent of the 160-acre siting area). Mineral resources are not present. Potential effects from karst associated with subsidence could be avoided or minimized through appropriate engineering design. Potential effects to fossil resources would be avoided or minimized through limiting the area of disturbance during construction activities.

3.6.1.6.8.3 TVA Upgrades

Like the Project, the required TVA upgrades would not be expected to increase geologic hazards, except potentially landslide hazards. Depending on the location of the new transmission line, the potential to impact landslide risks could occur during construction. Impacts from upgrades to existing transmission lines and substations are expected to minimal or non-existent.

Grading and excavation activities have the potential to uncover and impact paleontological resources. If paleontological resources are similar to those analyzed for the Project, the potential associated with the TVA upgrades would be expected to be minimal. Some impacts to paleontological resources could occur during construction of the new 500kV transmission line.

The required TVA upgrades would be unlikely to affect mineral resources because they would not affect new areas of potential mineral resources. Effects could occur if construction of the new transmission line impeded access to mineral resources. Recoverable mineral resources in western Tennessee are relatively limited and these effects would likely be minor.

3.6.1.6.9 Impacts Associated with the No Action Alternative

Under the No Action Alternative, the Project would not be constructed and geology, paleontology, and mineral resources would not be impacted. Areas of geologic hazard would not be impacted, nor would these hazards impact Project infrastructure.

3.6.2 Soils

3.6.2.1 Regulatory Background

Soil resources are managed through a broad set of regulations, guidelines, and formal planning processes. These controls and directions are administered through federal, state, or local units of government. Through state and local agency offices, the NRCS administers soil conservation programs on private lands. In addition, the NRCS inventories Prime and Unique Farmlands, as identified in 7 CFR Part 657 and further described in Table 3.6.2-1. Prime Farmland in the ROI is shown on Figure 3.6-7 (located in Appendix A).

Table 3.6.2-1:
Federal and State Laws and Regulations Associated with Soils Resources

Statute/Regulation	Key Elements
Federal	
FPPA (7 CFR Part 657)	The FPPA authorizes the USDA to develop criteria for identifying the effects of federal programs on the direct or indirect conversion of farmland to nonagricultural uses. For the purposes of the law, federal programs include construction projects sponsored or financed in whole or part by the federal government and the management of federal lands. Federal agencies are directed to (1) use the developed criteria, (2) identify and take into account the adverse effects of federal programs on the preservation of farmland, (3) consider appropriate alternative actions that could minimize potential adverse effects to farmland, and (4) ensure that such federal programs, to the extent practicable, are compatible with state and local units of government, as well as private programs and policies, so that farmland is protected (NRCS 2014a). Farmland protected by the FPPA is either (1) prime or unique farmland, which is not already committed to urban development or water storage, or (2) other farmland, which is of statewide or local importance as determined by the appropriate state or local governmental agency with the concurrence of the Secretary of Agriculture. Farmland subject to FPPA is not required to be currently used for cropland. Farmland can be forestland, pastureland, cropland, or other land (NRCS 2014a). The county soil survey provided by the NRCS determines which soils are protected. The DOE has consulted with the Oklahoma, Arkansas, and Tennessee NRCS offices concerning impacts to farmland protected under the Farmland Protection Policy Act (FPPA) and has received a determination from the agencies that the transmission lines do not irreversibly convert farmland (Saronga 2014, Adams 2014, Baker 2014). This determination has been further confirmed with the NRCS National Leader for FPPA. It should be noted, however, that this determination does not apply to the converter stations, which would potentially convert farmland and would require a Form AD-1006 to be submitted for evaluation. Once the exact locations of Project components have been determined, a farmland conversion assessment would be completed by the NRCS for any remaining components for which the NRCS has not yet issued a determination. The assessment would require the NRCS to complete a Farmland Conversion Impact Rating worksheet, Form AD-1006. The purpose of the FPPA is to minimize the impact that federal programs have on the unnecessary and irreversible conversion of farmland to nonagricultural uses. However, the FPPA does not authorize the federal government to regulate the use of private or nonfederal land or in any way affect the property rights of owners. As such, the FPPA does not regulate farmland, but is a mechanism for the reporting and documentation of farmland conversion activities and is used to alert decision makers in cases of farmland conversion concerns.

Table 3.6.2-1:
Federal and State Laws and Regulations Associated with Soils Resources

Statute/Regulation	Key Elements
National Pollutant Discharge Elimination System (NPDES) stormwater program	Soil erosion is governed by regulations contained in EPA's stormwater management regulations, derived as part of the Clean Water Act. Under the Clean Water Act, the National Pollutant Discharge Elimination System (NPDES) stormwater program requires operators of construction sites 1 acre or larger (including smaller sites that are part of a larger common plan of development) to obtain authorization to discharge stormwater under an NPDES construction stormwater permit. The development and implementation of SWPPPs is the focus of NPDES stormwater permits for regulated construction activities. Stormwater permits would be required for the Project from federal, state, and local agencies based on specific jurisdictional authority.

3.6.2.2 Data Sources

Soil information and data from the NRCS Soil Survey Geographic (SSURGO) database (GIS Data Source: NRCS 2013) were obtained to determine soil characteristics and potential soil hazards. General regional soil information was obtained from the NRCS (GIS Data Source: Jin et al. 2013) Land Resource Regions and Major Land Resource Areas of the United States, the Caribbean, and the Pacific Basin (GIS Data Source: NRCS 2006). Soil information for prime farmlands and for farmland soils of state and local importance was obtained from the SSURGO database (GIS Data Source: NRCS 2013). It should be noted that soil information is not available for unique farmland in the SSURGO database and that coordination with state agencies is ongoing to obtain this information as further discussed in Section 3.2. Information and data regarding potential soil contamination are based on available information from regulatory databases including EPA's Facility Registry Service (FRS) Database (GIS Data Source: EPA 2014b).

NRCS soil surveys (typically one per county) are mapped independently, and soil scientists that map the survey areas sometimes apply the available soil categories differently. For example, two soil map units on either side of a county boundary may be mapped with slightly different prime farmland categories. Therefore, slight variations in the consistency of the impacts to designated farmland across counties could occur. Such variations are not expected to be significant in terms of the overall analysis.

The description of each region below was derived from the broad landform characteristic areas that NRCS denotes as major land resource areas (MLRAs). The more detailed discussion of soils in Regions 1 through 7 follow the NRCS soil taxonomy/classification system that includes six ranking categories (in descending rank): order, suborder, great group, subgroup, family, and series. The soils descriptions are presented broadly by soil order to allow for a meaningful characterization of the ROI without describing the more than 3,000 individual soils series that exist in the ROI. Exceptions have been made for specific convertor station site areas where more detailed information is provided.

Throughout this section, characteristics that may indicate potential impacts or differentiate between the Applicant Proposed Project and DOE Alternatives are presented in tables, while other factors are omitted.

3.6.2.3 Region of Influence

3.6.2.3.1 Region of Influence for the Project

The ROI for soils is the same as the description provided in Section 3.1.1.

3.6.2.3.2 Region of Influence for Connected Actions

The ROI for soils for wind energy development, the future Optima substation, and TVA upgrades is described in Section 3.1.1.

3.6.2.4 Affected Environment

Soil characteristics across Regions 1 through 7 are influenced by the semi-arid conditions in the west and humid conditions in the east. Landforms in Oklahoma include rolling hills, plateaus, and ridgetops dissected by drainages and river valleys. Landforms in Arkansas include large areas of the eroded mountainous areas of the Ozarks. Landforms in eastern Arkansas and Tennessee (Region 7) are dominated by loess uplands and floodplain areas of the Mississippi River Valley. Figure 3.6-8 in Appendix A shows the MLRAs traversed by the Project.

Several route variations to the Applicant Proposed Route in Regions 2–7 were developed in response to public comments on the Draft EIS and are described in Appendix M and summarized in Sections 2.4.2.1–2.4.2.7. These variations also required adjustments to four of the HVDC alternative routes so that these routes could connect with the Applicant Proposed Route. These variations represent minor adjustments to the Applicant Proposed Route and the soils resources would remain consistent within the ROI. The variations are presented graphically in Exhibit 1 of Appendix M.

3.6.2.4.1 Designated Farmland

Designated farmland within the ROI includes NRCS categories including the “prime farmland” categories, and the category of “state and local importance.” No designated “unique farmland” is mapped in the Project ROI. Prime farmland is land that has the best combination of physical and chemical characteristics for producing food, feed, forage, fiber, oilseed, and other agricultural crops with minimum inputs of fuel, fertilizer, pesticides, and labor, and without intolerable soil erosion as determined by the USDA. Prime farmland can include land that possesses these characteristics but is being used currently to produce livestock and timber. Urbanized land and open water are excluded from prime farmland. Prime farmland typically contains few or no rocks, is permeable to water and air, is not excessively erodible or saturated with water for long periods, and is not subject to frequent, prolonged flooding during the growing season. Soils that do not meet the above criteria may be considered prime farmland if the limiting factor is mitigated (e.g., using artificial drainage or irrigation). Farmland of state and local Importance is identified by the associated state and local conservation agencies and officials.

3.6.2.4.2 Soil Limitations

The affected environment section provides a general baseline for the soil limitations parameters to set the stage for the more detailed discussion in the impacts section. Soil limitations of concern are described in greater detail in Section 3.6.2.6 of the impacts analysis. Important soil limitation characteristics used to describe the affected environment include the following:

3.6.2.4.2.1.1 Hydric Soils

Hydric soils are defined as “soils that formed under conditions of saturation, flooding, or ponding long enough during the growing season to develop anaerobic conditions in the upper part” (59 FR 16835, July 13, 1994). Soils that are artificially drained or protected from flooding (e.g., by levees) are considered hydric if the soil in its undisturbed state would meet the definition of a hydric soil. Hydric soils are typically associated with jurisdictional wetlands, which must meet three required criteria: hydric soils, wetland hydrology, and hydrophytic vegetation, except in “difficult wetland situations" where not all criteria are evident. These situations are defined in the regional interim supplements to the USACE's Wetland Delineation Manual (Environmental Laboratory 1987).

3.6.2.4.2.1.2 Erosion Potential

Erosion is a continuing natural process that can be accelerated by human disturbances. Factors that influence soil erosion include soil texture, structure, length and percent of slope, vegetative cover, and rainfall or wind intensity. Soils most susceptible to erosion by wind or water are typified by bare or sparse vegetative cover, non-cohesive soil particles with low infiltration rates, and moderate to steep slopes. Wind erosion processes are less affected by slope angles but highly influenced by wind intensity.

Soils with a severe water erosion potential indicate that erosion is very likely and that erosion control measures are advisable. Very severe water erosion potential indicates that significant erosion is expected, loss of soil productivity and off-site damage are likely, and erosion-control measures are costly and generally impractical.

3.6.2.4.2.1.3 Compaction Potential

Soil compaction is the process by which soil pore air space is reduced in size because of physical pressure exerted on the soil surface. Compaction results in soil conditions that reduce infiltration, permeability, and gaseous and nutrient exchange rates of the soil. Physical resistance to root growth can occur with high soil bulk densities. Soil compaction changes the soil structure by reducing the porosity and increasing the bearing strength of the soil. As a result, the ability to receive water is reduced, leading to an overall reduction in the moisture-holding capacity of the soil. The degree of compaction depends on the moisture content at the time of compaction and soil texture. Compaction decreases infiltration and thus increases runoff and the hazard of water erosion. Fine-textured soils with poor internal drainage are the most susceptible to compaction. Sandy loam, loam, and sandy clay loam soils compact more easily than silt, silt loam, silty clay loam, silty clay, or clay soils.

Soil compaction and displacement reduces water infiltration and often diverts lateral movement of the water within the soil. These conditions not only lead to increased erosion and sedimentation potential but could contribute to higher stormwater runoff from normal peak flows. The movement of heavy construction equipment, soil mixing or displacement from grading/excavation activities, or rutting from equipment or vehicle traffic could result in soil compaction and damage to soil structure.

3.6.2.4.2.1.4 Corrosion

Soils that are rated as having a risk of corrosion for "uncoated steel" or concrete are directly related to the susceptibility of uncoated steel or concrete to corrode when in contact with the soil (GIS Data Source: NRCS 2013). Corrosion is generally defined as the soil property that would create conditions for potential damage to these construction materials. Soil properties contributing to risk of corrosion to uncoated steel include high acidity, texture, existence of soluble salts, and a pH of 4.0 or less. Soil properties contributing to risk of corrosion to concrete include high acidity, texture, existence of soluble salts, and the presence of gypsum or other sulfate minerals.

3.6.2.4.2.1.5 Restrictive Layer

A "restrictive layer" is a nearly continuous layer that has one or more physical, chemical, or thermal properties that significantly impede the movement of water and air through the soil or that restrict roots or otherwise provides an unfavorable root environment (GIS Data Source: NRCS 2013). Examples are bedrock, cemented layers, dense layers, and frozen layers. Soils that are rated as having a restrictive layer are shallow soils that have a lithic, paralithic, or other restrictive soil layer within 60 inches of the soil surface. A shallow restrictive layer can affect land development and is also is indicative of potential reclamation concerns. The restrictive layer for the ROI is shown on Figure 3.6-9 (located in Appendix A).

3.6.2.4.2.1.6 Steep Slopes

Slopes were evaluated for slopes from 15 to 30 percent and for slopes greater than 30 percent. These slope ranges were selected because the operation of rubber-tired equipment becomes hazardous when the slope approaches and exceeds 30 percent. In addition, soil erosion concerns are generally greater as slopes become steeper. The two ranges provide a broad indication of locations that might present construction and operational limitations related to ground vehicle maneuverability, development limitations, and potential erosion concerns.

3.6.2.4.2.1.7 Large Stones

Soils with a high percentage of cobbles and stones in the soil profile can present significant problems with surface reclamation because they hold less available water for plant growth and generally require broadcast seeding methods.

3.6.2.4.2.2 Soil Contamination

Areas of potential soil contamination are identified within the ROI based on searches of the EPA FRS Database (GIS Data Source: EPA 2014b). The database integrates information from a variety of sources about facilities that are required to report activity about hazardous waste, toxic and air releases, Superfund sites, and water discharge permits to a state or federal system. Most of the EPA tracked sites are indicative of inventoried sites that have permits or are otherwise under regulatory authority, but do not raise a red flag in terms of existing contamination issues. The affected environment evaluation provides a broad evaluation and identifies sites that might raise such a concern. More detailed evaluation of individual sites that might raise contamination issues for the Project is included in the impacts section. EPA Sites in the ROI are shown on Figure 3.6-10 (located in Appendix A). The FRS database categories identified in the ROI include the following (which are identified by region in Section 3.6.2.5):

- LUST–ARRA—The Leaking Underground Storage Tank (LUST)–American Recovery and Reinvestment Act (ARRA) system collects data on LUST releases that are tracked by ARRA performance measures or for which ARRA funds are being spent. Data are collected for each release, including identification, performance measures, reference information, and location information.
- TCEQ—Texas Commission on Environmental Quality (TCEQ) Alternative Capacity Requirement (ACR)—The TCEQ ACR is a computer application that allows the TCEQ to use a single centralized area to record common information, such as the company names, addresses, and telephone numbers of entities the TCEQ regulates. It also contains additional information about permits, registrations, authorizations, etc. including their status.
- RCRAInfo—Hazardous waste information is contained in the Resource Conservation and Recovery Act Information (RCRAInfo), a national program management and inventory system about hazardous waste handlers. In general, all generators, transporters, treaters, storers, and disposers of hazardous waste are required to provide information about their activities to state environmental agencies. This regulation is governed by the Resource Conservation and Recovery Act (RCRA), as amended by the Hazardous and Solid Waste Amendments of 1984.
- NPDES—The EPA's Office of Wastewater Management leads and manages the NPDES permit program in partnership with EPA Regional Offices, states, tribes, and other stakeholders.

- Permit Data Summary (PDS)—PDS is an Arkansas system maintaining data on air quality, mining, tires, solid waste, tank, water and hazardous waste, as well as inspections, invoicing and complaints.
- BR—The EPA Hazardous Waste Report (Biennial Report or “BR”) collects data on the generation, management, and minimization of hazardous waste.
- eGRID—The Emissions & Generation Resource Integrated Database (eGRID) is a comprehensive source of data on the environmental characteristics of almost all electric power generated in the United States.
- EIA—U.S. Energy Information Administration (EIA)-860—The survey Form EIA-860 collects generator-level specific information about existing and planned generators and associated environmental equipment at electric power plants with 1MW or greater of combined nameplate capacity.
- TRI—The Toxics Release Inventory (TRI) tracks the management of more than 650 toxic chemicals that pose a threat to human health and the environment. U.S. facilities in certain industry sectors that manufacture, process, or otherwise use these chemicals in amounts above established levels must report how each chemical is managed through recycling, energy recovery, treatment, and releases to the environment. A “release” of a chemical means that it is emitted to the air or water, or placed in some type of land disposal.
- ICIS—The Integrated Compliance Information System (ICIS) is a web-based system that provides information for the Federal Enforcement and Compliance and the NPDES programs.
- CERCLA—EPA administers the Superfund program in cooperation with individual states and tribal governments. The Comprehensive Environmental Response, Compensation, and Liability Information System database provides information regarding these Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) or otherwise named Superfund sites.
- NCDB—National Compliance Data Base (NCDB) supports implementation of the Federal Insecticide, Fungicide, and Rodenticide Act and the Toxic Substances Control Act. The system tracks inspections in regions and states with cooperative agreements, enforcement actions, and settlements.
- SSTS—Section Seven Tracking System (SSTS) tracks the registration of all pesticide-producing establishments and tracks annually the types and amounts of pesticides, active ingredients, and related devices that are produced, sold, or distributed.

3.6.2.5 Regional Description

3.6.2.5.1 Region 1

Southern High Plains, Northern Part MLRA

The western portion of the ROI in Region 1, including the Oklahoma Converter Station Siting Area, Oklahoma AC Transmission Interconnection Siting Area, and AC collection system routes, is located in the Southern High Plains, Northern Part MLRA. This area is characterized by open plains on an elevated plateau cut by draws with moderate to very steep slopes (GIS Data Source: NRCS 2006). The narrow floodplains generally trend from southwest to northeast. Interspersed playa basins are also present in the MLRA and can range from 5 acres to more than 100 acres. Topographical relief is generally nearly level to very gently sloping and elevations increase gradually from southeast to northeast. Almost all of the MLRA is agricultural; nearly one-fifth of the area is irrigated.

Soil resource concerns in the MLRA are wind erosion, water erosion, maintenance of the content of soil organic matter and productivity, and management of soil moisture. Conservation practices on cropland generally include systems of crop residue management (especially no-till systems that reduce the need for tillage), cover crops, windbreaks, vegetative wind barriers, wind stripcropping, and nutrient management. The dominant conservation practice on rangeland is prescribed grazing.

Alfisols and mollisols are the predominant soil orders in the MLRA. These soils are characterized by a mesic soil temperature regime, an ustic soil moisture regime, and mixed minerology. The mesic soil temperature regime has mean annual soil temperatures of 8 degrees centigrade (°C) or more, but less than 15°C, and the difference between mean summer and mean winter soil temperatures is greater than 5°C at 50 centimeters (cm) below the surface (Plant and Soil Sciences eLibrary 2014). The ustic soil moisture regime indicates a semiarid climate. The soils are generally very deep, well drained, and loamy. These soils are present as loess and loamy material on plains, sandy eolian material on sandhills, and as loess on ridges and side slopes adjacent to drainage ways. Soils in the area are also present as lacustrine deposits on playa floors.

Southern High Plains, Breaks MLRA

The central portion of ROI in Region 1 is located in the Southern High Plains, Breaks MLRA. The MLRA is characterized by very steep escarpments, very gently sloping to moderately sloping plains, strongly sloping hills and ridges, and integrated drainage networks along the Canadian and Beaver rivers (GIS Data Source: NRCS 2006). The landscape has undulating to hilly topography and well developed, dendritic drainage systems. Elevations increase in the MLRA from the southeast to northwest.

Soil resource concerns in the MLRA are wind erosion, water erosion, maintenance of the content of soil organic matter and productivity of the soils, and management of soil moisture. Soil conservation practices on cropland generally include systems of crop residue management (especially no-till systems that reduce the need for tillage), cover crops, windbreaks, vegetative wind barriers, wind stripcropping, and nutrient management. The most important conservation practice on rangeland is prescribed grazing.

Alfisols, inceptisols, and mollisols are the predominant soil orders in the MLRA. These soils are characterized by a thermic soil temperature regime, an ustic soil moisture regime, and mixed or carbonatic mineralogy (GIS Data Source: NRCS 2006). The soils are shallow to very deep, well drained, and generally loamy or sandy. The thermic soil temperature regime has mean annual soil temperatures of 15°C or more, but less than 22°C; and a difference between mean summer and mean winter soil temperatures of greater than 5°C at 50 cm below the surface (Plant and Soil Sciences eLibrary 2014). The soils are present as loamy sediments, old alluvium, and weathered caliche on plains and loamy material on stream terraces. Soils are also present in alluvium on floodplains, in mixed alluvium and colluvium on backslopes, and along footslopes on escarpments and hillslopes. Area soils also form in sandy and gravelly old alluvium on knobs and hillslopes, in older loamy alluvium on hillslopes, and in coarse-textured sediments on floodplains. Weathered caliche soils are found on hills, ridges, and escarpments, and in wind-reworked sandy alluvium on dunes.

Central Rolling Red Plains, Eastern Part MLRA

The eastern portion of the ROI in Region 1 is located in the Central Rolling Red Plains, Eastern Part MLRA. This area is characterized by smooth to rolling hills and valleys that are moderately dissected. The rolling plains contain prominent ridges and valleys, some local areas of badlands, and numerous stream terraces. Elevations in the area are around 2,000 feet in Oklahoma.

Soil resources concerns include water erosion and conservation of soil moisture on cultivated soils and on overgrazed rangeland. Conservation practices on cropland generally include contour farming and crop residue management. Soil conservation practices on rangeland generally include proper grazing use, fencing, and development of watering facilities (GIS Data Source: NRCS 2006).

Alfisols, inceptisols, and mollisols are the predominant soil orders in the MLRA (GIS Data Source: NRCS 2006). These soils are characterized by a thermic soil temperature regime, an ustic soil moisture regime, and mixed or smectitic mineralogy (i.e., involving the family of clays that swell when immersed in water). The soils are generally moderately deep to very deep, are well drained and moderately well drained, and loamy or clayey. Soils are present as bedrock residuum on hills and ridges, loamy alluvium on stream terraces, and in mixed alluvium and colluvium on hills and stream terraces and in valleys. Soils are also present in sandy eolian deposits on dunes adjacent to the major rivers.

3.6.2.5.1.1 Designated Farmland

The percentage of designated farmland within the ROI of Region 1 is provided in Table 3.6.2-2.

Table 3.6.2-2:
Designated Farmland in Region 1 (Percentage of ROI)

Project Component	Total Acres within ROI	Prime Farmland (%)	Prime Farmland if Protected[1] (%)	Total Designated Farmland[2] (%)
Oklahoma Convertor Station Siting Area	626	0	0	0
Oklahoma AC Interconnection	871	8	0	8
AC Collection System	597,006	42	0	42
E-1	39,340	19	0	19
E-2	52,982	49	0	49
E-3	53,520	43	0	43

AR 1-B	6,363	46	0	46
AR 1-C	6,377	54	0	54
AR 1-D	4,097	40	0	40
APR	14,143	50	0	50

GIS Data Source: NRCS (2013)
1 Prime farmland if protected from flooding or not frequently flooded during the growing season (NRCS 2013).
2 Total designated farmland categories that are present ("prime farmland" and "prime farmland if protected" are the only categories present in the Region 1 ROI).

3.6.2.5.1.2 Soil Limitations

Existing soil hazards within the ROI in Region 1 are summarized in Table 3.6.2-3 by Project component.

Table 3.6.2-3:
Soil Limitations in Region 1 (Percentage of ROI)

Project Component	High Compaction Potential [1]	Moderate to High Wind Erosion Potential[2]	High Water Erosion Potential [3]	Corrosion Potential[4]	Hydric Soils[5]	Restrictive Layer [6]	15 to 30 Percent Slopes	>30 Percent Slopes
Oklahoma Convertor Station Siting Area	100	100	0	0	0	42	0	0
Oklahoma AC Interconnection	100	92	0	0	0	39	0	0
AC Collection System	93	56	0	24	<1	9	<1	<1
E-1	95	80	0	11	<1	18	<1	0
E-2	99	49	0	26	0	7	0	0
E-3	97	53	0	12	0	12	0	0
NE-1	95	47	0	6	1	9	0	0
NE-2	96	63	0	2	<1	15	0	0
NW-1	95	51	0	27	<1	6	0	0
NW-2	88	48	0	30	<1	5	0	0
SE-1	89	48	0	46	0	8	1	0
SE-2	93	39	0	54	0	10	4	0
SE-3	99	43	0	44	0	6	0	0
SW-1	77	73	0	7	<1	10	4	0
SW-2	89	87	0	20	<1	12	6	<1
W-1	92	65	0	7	<1	9	0	0
AR 1-A	90	69	<1	8	0	19	5	0
AR 1-B	98	51	0	12	0	8	0	0
AR 1-C	99	46	0	13	0	5	0	0
AR 1-D	94	74	<1	26	0	6	<1	0
APR	91	51	<1	26	0	12	2	0

GIS Data Source: NRCS (2013)

1 SSURGO severe rutting hazard.
2 SSURGO Wind Erosion Groups: 1–3 and 4L.
3 SSURGO Kf > 0.4.
4 SSURGO High steel or concrete potential.
5 SSURGO Hydric Condition (includes only entirely hydric soils and not partially hydric soils).
6 Bedrock < 60 inches from ground surface.

3.6.2.5.1.3 Soil Contamination

No areas of potential soil contamination were identified within the most Project components based on EPA FRS database information (GIS Data Source: EPA 2014b). Eleven facilities/sites were identified in the AC collection system routes, including two LUST–ARRA sites, two NPDES sites, one RCRAInfo site, and six TCEQ ACR sites. The NPDES and RCRAInfo sites are indicative of permits being granted for the discharge of stormwater and generation, and handling or transport of hazardous substances. The TCEQ ACR sites indicate entities under TCEQ regulation such as for permits, registrations, and other authorizations. The LUST-ARRA sites indicate identified leaking underground storage tank sites that are under regulatory oversight for cleanup and closure activities. The presence of these sites on the database are simply indicative of a records inventory of such regulated sites and do not raise a concern at this time in regards to potential areas of soil contamination.

3.6.2.5.2 Region 2

Central Rolling Red Plains, Eastern Part MLRA

The western portion of the ROI in Region 2 is located in the Central Rolling Red Plains, Eastern Part MLRA, and the predominant soils orders are alfisols, inceptisols, and mollisols. These are described above under Region 1.

Central Rolling Red Prairies MLRA

The eastern portion of the ROI in Region 2 is in the Central Rolling Red Prairies MLRA. The area is characterized by dark red Permian rocks that are exposed dominantly on gently sloping plains dissected by rivers flowing from northwest to southeast. Elevation ranges from about 850 to 1,500 feet.

Agricultural uses dominate the area. Soil resource concerns on cropland include water erosion, surface compaction, conservation of soil moisture, and maintenance of the content of organic matter in the soils. Soil conservation practices on cropland generally include high residue crops in the cropping system; systems of crop residue management, such as no-till and strip-till; conservation crop rotations; and nutrient management. Conservation practices on grassland generally include brush management and proper grazing use.

Mollisols are the predominant soil order in the MLRA. Mollisols have a thermic soil temperature regime, an ustic soil moisture regime, and mixed, siliceous, or smectitic mineralogy. These soils generally are shallow to very deep, are well drained, and generally are loamy or clayey (GIS Data Source: NRCS 2006). The soils are present in clayey and loamy alluvium of Pleistocene age on plains, in Permian sandstone residuum on ridges and hillslopes, in Permian shale residuum on hillslopes, and in Holocene alluvium on floodplains.

3.6.2.5.2.1 Designated Farmland

The percentage of designated farmland within the ROI is provided in Table 3.6.2-4. Two route variations were developed in Region 2 in response to public comments on the Draft EIS. The ROI for Applicant Proposed Route Link 1, Variation 1, has 14 acres of designated farmland. The ROI for Applicant Proposed Route Link 2, Variation 2, has 659 acres of designated farmland. The variations are illustrated in Exhibit 1 of Appendix M.

Table 3.6.2-4:
Designated Farmland in Region 2 (Percentage of ROI)

Project Component[1]	Total Acres in ROI	Prime Farmland (%)	Total Designated Farmland (%)[2]
AR 2-A	6,992	25	25
AR 2-B	3,631	48	48
APR	12,932	22	22

1 The values in the table do not reflect the minor changes that would result from application of the minor route variations and adjustments.
2 Total designated farmland categories that are present ("prime farmland" is the only category contained in the Region 2 ROI).
GIS Data Source: NRCS (2013)

3.6.2.5.2.2 Soil Limitations

Existing soil limitations within Region 2 are summarized in Table 3.6.2-5 by Project component. Two route variations were developed in Region 2 in response to public comments on the Draft EIS. The ROI for Applicant Proposed Route Link 1, Variation 1, has 54 acres of soils with high wind erosion potential. The ROI for Applicant Proposed Route Link 1, Variation 2, would have the following soils acreages: 45 acres with high water erosion potential, 114 acres with high wind erosion potential, and 149 acres with high susceptibility to compaction. The variations are illustrated in Exhibit 1 of Appendix M.

Table 3.6.2-5:
Soil Limitations in Region 2 (Percentage of ROI)

Project Component[1a]	High Compaction Potential[1]	Moderate to High Wind Erosion Potential[2]	High Water Erosion Potential [3]	Corrosion Potential[4]	Restrictive Layer[5]	15 to 30 Percent Slopes
AR 2-A	63	78	15	26	39	9
AR 2-B	81	38	12	29	41	<1
APR	40	74	8	16	18	4

1a The values in the table do not reflect the minor changes that would result from application of the minor route variations and adjustments.

GIS Data Source: NRCS (2013)
1 SSURGO severe rutting hazard.
2 SSURGO Wind Erosion Groups: 1–3 and 4L.
3 SSURGO Kf > 0.4.
4 SSURGO High Concrete or Steel Corrosion Potential.
5 SSURGO restrictive layer < 60 inches from ground surface.

3.6.2.5.2.3 Soil Contamination

No areas of potential soil contamination were identified within the Region 2 ROI based on EPA FRS database information. There are no listed sites in the ROIs of the two route variations.

3.6.2.5.3 Region 3

Central Rolling Red Prairies MLRA

The ROI in western Region 3 crosses two portions of the Central Rolling Red Prairies MLRA, and mollisols is the dominant soil order. These are described above under Region 2.

North Cross Timbers MLRA

The ROI in west-central Region 3 crosses two portions of the North Cross Timbers MLRA. This area is characterized by rolling to hilly uplands with hilltop summits that are nearly level to strongly rolling and divides that are narrow to moderately broad. Stream valleys in the MLRA are narrow and have steep gradients, and bedrock outcrops occur on both hilltops and hillsides (GIS Data Source: NRCS 2006). Elevation ranges from 985 to 1,300 feet. Large valleys can be 165 feet or more below the adjacent uplands.

Soil resource concerns are water erosion, surface compaction, moisture conservation, and conservation of organic matter. Soil conservation practices on cropland generally include terraces, grassed waterways, nutrient management, grade-control structures, and conservation tillage. Conservation practices on rangeland generally include brush management, fencing, nutrient management, proper grazing, and range planting.

Alfisols, entisols, mollisols, and inceptisols are the predominant soil orders in the MLRA. The soils have a thermic soil temperature regime, an ustic or udic soil moisture regime, and mixed, siliceous, or smectitic mineralogy. Udic soil moisture is characteristic of a humid or subhumid climate (Plant and Soil Sciences eLibrary 2014). Soils are generally shallow to very deep, somewhat excessively drained to somewhat poorly drained and loamy or clayey. Area soils are present in alluvium on stream terraces, in bedrock residuum on hills, in colluvium and/or bedrock residuum on footslopes, and in alluvium on floodplains (GIS Data Source: NRCS 2006).

Cherokee Prairies MLRA

The ROI in central Region 3 crosses two portions of the Cherokee Prairies MLRA. The area is characterized by gently sloping to rolling dissected plains with elevations ranging from 330 to 1,310 feet. Even though the area is thoroughly dissected, major valleys generally are less than 8 feet below the adjacent uplands (GIS Data Source: NRCS 2006).

Soil resource concerns on cropland are water erosion, maintenance of the content of organic matter in soils, surface compaction, and low pH in the soils. Soil conservation practices on cropland generally include high residue crops in the cropping system, systems of crop residue management (such as no-till, strip-till, and mulch-till systems), a combination of gradient terraces and grassed waterways, contour farming, conservation crop rotations, and nutrient management. Conservation practices on rangeland generally include prescribed grazing and brush management.

Mollisols and alfisols are the predominant soil orders in the MLRA. The soils have a thermic soil temperature regime, an aquic or udic soil moisture regime, and mixed or smectitic mineralogy. The aquic soil moisture regime indicates soils that are saturated with water long enough to cause oxygen depletion. The soils generally are moderately deep to very deep, well-drained to poorly drained, and loamy or clayey. Soils in the area are present in alluvium on flood plains, in bedrock residuum on uplands, and in colluvium mixed with bedrock residuum. Soils are also present in old alluvium on plains and in alluvium on flood plains and stream terraces.

Arkansas Valley and Ridges, Western Part MLRA

The ROI in east-central Region 3 also crosses the Arkansas Valley and Ridges, Western Part MLRA. The topography of the area is characterized by long, narrow sandstone-capped ridges that trend northeastward. The ridges are dissected by valleys cut by streams at right angles to the ridges; the valleys and scarp areas generally are cut into less resistant shale units (GIS Data Source: NRCS 2006). Elevation ranges from 550 feet to 1,500 feet.

Strip-mining of coal is common throughout the area and has affected soil resources. Stabilizing strip-mine spoil and reclaiming mined areas are major soil management concerns; and efforts to maintain pasture and forest productivity are ongoing (GIS Data Source: NRCS 2006).

Udalfs or udepts soils are predominant in the MLRA. These soils have a thermic soil temperature regime, a udic soil moisture regime, and mixed or siliceous mineralogy. The soils include moderately deep soils and are gently sloping to steep, formed on ridgetops, shoulder slopes, and side slopes. Other soils in the area are very deep, gently sloping to sloping, and are formed on the side slopes of valleys. Deep, gently sloping to steep soils are formed on side slopes and footslopes; and shallow, sloping to steep soils are formed on narrow ridgetops and upper shoulder slopes. Very deep, gently sloping to steep soils formed on terraces along streams. Nearly level to sloping soils formed along floodplains throughout the area (GIS Data Source: NRCS 2006).

Boston Mountains MLRA

The eastern end of the ROI in Region 3 crosses the Boston Mountains MLRA. This MLRA marks the southern extent of the Ozarks and is an old plateau that has been deeply eroded. Ridgetops are narrow and rolling and valley walls are steep. Elevation ranges from 660 feet on the lowest valley floors to 2,625 feet on the highest ridge crests.

Soil resource concerns in this area are gully and streambank erosion and soil contaminants from applications of animal waste. Soil conservation practices on cropland include critical area planting, protection of streambanks and shorelines, riparian forest buffers, forage harvest management, soil nutrient management, waste utilization, brush management, grade-stabilization structures, and prescribed grazing (GIS Data Source: NRCS 2006).

Ultisols and inceptisols are the predominant soil orders in the MLRA. The soils dominantly have a thermic soil temperature regime, a udic soil moisture regime, and mixed or siliceous mineralogy. The soils are shallow to very deep, generally well drained, and loamy. Soils in the area are formed in residuum on hills, plateaus, and mountains, in alluvium or colluvium over residuum, and in alluvium or colluvium on hills and terraces.

3.6.2.5.3.1 Designated Farmland

The percentage of designated farmland within the ROI of Region 3 is provided in Table 3.6.2-6. Five route variations were developed for the Applicant Proposed Route in Region 3 in response to public comments on the Draft EIS. The ROI for Link 1, Variation 2, has 194 acres of designated farmland. The ROI for Links 1 and 2, Variation 1, has 167 acres of designated farmland. It should be noted that a route adjustment was made for HVDC Alternative Route 3-A to maintain continuity with the proposed variation. HVDC Alternate Route 3-A has 38 acres in designated farmland. The ROI for Link 4, Variation 1, has 19 acres, and the ROI for Link 4, Variation 2, has 90 acres of designated farmland. The ROI for Link 5, Variation 2, has 266 acres of designated farmland. The variations are illustrated in Exhibit 1 of Appendix M.

Table 3.6.2-6:
Designated Farmland in Region 3 (Percentage of ROI)

Project Component	Total Acres in ROI	Prime Farmland (%)	Total Designated Farmland (%)[1]
AR 3-A	4,612	38	38
AR 3-B	5,851	40	40
AR 3-C	14,860	53	53
AR 3-D	4,814	70	70
AR 3-E	1,073	52	52
APR	19,760	50	50

GIS Data Source: NRCS (2013)
1 Total designated farmland categories that are present ("prime farmland" is the only category present in the Region 3 ROI).

3.6.2.5.3.2 Soil Limitations

Existing soil limitations within Region 3 are summarized in Table 3.6.2-7 by Project component. Five route variations were developed for the Applicant Proposed Route in Region 3 in response to public comments on the Draft EIS. The ROI for Link 1, Variation 2, has acreage that includes 19 acres with high water erosion potential, 37 acres with high wind erosion potential, and 75 acres of soils with high compaction potential. The ROI for Links 1 and 2, Variation 1, has acreage that includes 23 acres with high water erosion potential, 12 acres with high wind erosion potential, and 53 acres of soils with high compaction potential. It should be noted that a route adjustment was made for HVDC Alternative Route 3-A to maintain continuity with the proposed variation. The ROI for Link 4, Variation 1, has acreage that includes 4 acres with high water erosion potential and 20 acres of soils with high compaction potential. The ROI for Link 4, Variation 2, has acreage that includes 7 acres with high water erosion potential, 10 acres with high wind erosion potential, and 10 acres of soils with high compaction potential. Link 5, Variation 2, has acreage that includes 11 acres with high water erosion potential, 3 acres with high wind erosion potential, and 58 acres of soils with high compaction potential. The variations are illustrated in Exhibit 1 in Appendix M.

3.6.2.5.3.3 Soil Contamination

Three facilities/sites that are required to report activity to a state or federal system were identified within the ROI based on EPA FRS database information. They include an EPA Hazardous Waste Report BR site and two RCRAInfo sites. The BR site is indicative of EPA data reporting of generation, minimization, and management of hazardous waste. There are no listed sites in the ROIs of the five route variations.

Table 3.6.2-7:
Soil Limitations in Region 3 (Percentage of ROI)

Project Component[1a]	High Compaction Potential[1]	Moderate to High Wind Erosion Potential[2]	High Water Erosion Potential[3]	Corrosion Potential[4]	Stony/ Rocky Soil[5]	Hydric Soils[6]	Restrictive Layer[7]	15 to 30 Percent Slopes	>30 Percent Slopes
AR 3-A	86	28	23	43	0	<1	69	5	<1
AR 3-B	87	27	24	46	0	<1	66	4	<1

1a The values in the table do not reflect the minor changes that would result from application of the minor route variations and adjustments.
GIS Data Source: NRCS (2013)
1 SSURGO severe rutting hazard.
2 SSURGO Wind Erosion Groups: 1–3 and 4L.
3 SSURGO Kf > 0.4.
4 SSURGO High concrete or steel corrosion potential.
5 SSURGO soils characterized as stony, cobbly, channery, flaggy, bouldery, and bedrock.
6 SSURGO Hydric Condition (includes only entirely hydric soils and not partially hydric soils).
7 Restrictive layer is < 60 inches from ground surface.

3.6.2.5.4 Region 4

Boston Mountains MLRA

The ROI crosses one MLRA, the Boston Mountains MLRA, and ultisols and inceptisols soil orders are predominant. These are described above under Region 3.

3.6.2.5.4.1 Designated Farmland

The percentage of designated farmland within the ROI of Region 4 is provided in Table 3.6.2-8. Seven route variations were developed for the Applicant Proposed Route in Region 4 in response to public comments on the Draft EIS. The ROI for Link 3, Variation 1, has 137 acres of designated farmland; and the ROI for Link 3, Variation 2, has 273 acres of designated farmland. The ROI for Link 3, Variation 3, has 18 acres in designated farmland. The ROI for Link 6, Variation 1, has 54 acres of designated farmland. The ROI for Link 6, Variation 2, has 200 acres of designated farmland. The ROI for Link 6, Variation 3, has 27 acres of designated farmland. The ROI for Link 9, Variation 1, has 720 acres of designated farmland. The variations are illustrated in Exhibit 1 of Appendix M.

Table 3.6.2-8:
Designated Farmland in Region 4 (Percentage of ROI)

Project Component[1a]	Total Acres in ROI	Prime Farmland (%)	Prime Farmland if Drained[1] (%)	Prime Farmland if Drained[2] (%)	Prime Farmland if Protected[3] (%)	Farmland of State and Local Importance[4] (%)	Total Designated Farmland [5] (%)
AR 4-A	7,160	19	0	4	3	4	23
AR 4-B	9,610	16	0	<1	<1	3	19

APR	15,414	35	<1	<1	1	8	45

1a The values in the table do not reflect the minor changes that would result from application of the minor route variations and adjustments.
GIS Data Source: NRCS (2013)
1 Prime farmland if drained and either protected from flooding or not frequently flooded during the growing season.
2 Prime farmland if protected from flooding or not frequently flooded during the growing season.
3 Prime farmland if drained with no other qualifications.
4 This is land, in addition to prime and unique farmland, that is of statewide importance for the production of food, feed, fiber, forage, and oil seed crops. Criteria for defining and delineating this land are to be determined by the appropriate state agency or agencies.
5 Total of designated farmland categories present in the Region 4 ROI.

3.6.2.5.4.2 Soil Limitations

Existing soil limitations within the ROI are summarized in Table 3.6.2-9 by Project component. Seven route variations were developed for the Applicant Proposed Route in Region 4 in response to public comments on the Draft EIS. The ROI for Link 3, Variation 1, has acreage that includes 21 acres with high water erosion potential, 5 acres with high wind erosion potential, and 42 acres of soils with high compaction potential. The ROI for Link 3, Variation 2, has acreage that includes 48 acres with high water erosion potential, 88 acres of stony soils, 10 acres of soils, 5 acres with slopes greater than 20 percent, and 81 acres with high compaction potential. The ROI for Link 3, Variation 3, has acreage that includes 12 acres with high wind erosion potential, 55 acres of stony soils, 20 acres with slopes greater than 20 percent, and 12 acres of soils with high compaction potential. The ROI for Link 6, Variation 1, has acreage that includes 10 acres with high wind erosion potential, 24 acres of stony soils, and 2 acres with slopes greater than 20 percent. The ROI for Link 6, Variation 2, has acreage that includes 32 acres with high water erosion potential, 23 acres with high wind erosion potential, 39 acres of hydric soils, and 54 acres of soils with high compaction potential. The ROI for Link 6, Variation 3, has acreage that includes 3 acres with high wind erosion potential, 13 acres of stony soils, 9 acres with slopes greater than 20 percent, and 5 acres of soils with high compaction potential. The ROI for Link 9, Variation 1, has acreage that includes 18 acres with high water erosion potential, 48 acres with high wind erosion potential, 5 acres with slopes greater than 20 percent, and 59 acres of soils with high compaction potential. The variations are illustrated in Exhibit 1 of Appendix M.

Table 3.6.2-9:
Soil Limitations in Region 4 (Percentage of ROI)

Project Component[1a]	High Compaction Potential[1]	Moderate to High Wind Erosion Potential[2]	High Water Erosion Potential[3]	Corrosion Potential[4]	Stony/Rocky Soils[5]	Hydric Soils[6]	Restrictive Layer[7]	15 to 30 Percent Slopes	>30 Percent Slopes
AR 4-A	24	22	7	75	54	10	84	52	<1

AR 4-E	21	48	15	33	27	1	59	12	1
APR	42	29	22	63	33	5	58	25	2

1a The values in the table do not reflect the minor changes that would result from application of the minor route variations and adjustments.
GIS Data Source: NRCS (2013)
1 SSURGO severe rutting hazard.
2 SSURGO Wind Erosion Groups: 1–3 and 4L.
3 SSURGO Kf > 0.4.
4 SURGO high concrete or steel corrosion potential.
5 SSURGO soils characterized as stony, cobbly, flaggy, channery, bouldery, and bedrock.
6 SSURGO Hydric Condition (includes only entirely hydric soils and not partially hydric soils).
7 SSURGO restrictive layer <60 inches from ground surface.

3.6.2.5.4.3 Soil Contamination

Nine facilities that are required to report activity to a state or federal system were identified within the Region 4 ROI based on EPA FRS database information. The facilities include an EPA Hazardous Waste Report BR site, a RCRAInfo site, an eGRID site, an EIA-860 site, an NPDES site, and a PDS site. eGRID and EIA-860 sites indicate that data exist for electric power generation sites in the area, with one site generating more than 1MW.

There are no listed sites in the ROIs of the seven route variations.

3.6.2.5.5 Region 5

Boston Mountains MLRA

Region 5 is entirely located within the Boston Mountains MLRA. This MLRA and its associated soils are described in above in Region 4.

A more detailed description of soils in the area of the Arkansas Convertor Station Alternative Siting Area includes three soil associations: Nell-Enders Mountainburg, Mountainburg Linker, and Leadvale–Taft (NRCS 2014b). Nells–Enders Mountainburg soils are well drained, gently sloping to very steep, deep and shallow, loamy soils that are gravelly or stony, and are often found on hills or mountains. The soils formed in loamy and clayey residuum weathered from sandstone and shale. The soils are unsuited for crop cultivation and have a high shrink swell potential; and have a shallow depth to bedrock. Mountainburg Linker soils are well drained, nearly level to moderately deep, loamy soils; some gravelly or stony. These soils are often located on hills or mountains, and are formed in loamy and residuum weathered from level-bedded sandstone. The Leadvale-Taft soils are moderately well-drained and somewhat poorly drained, level to gently sloping, deep, loamy soils with fragipans. These soils are often found on old stream terraces in broad valleys, and are formed in loamy sediment weathered from sandstone and shale washed from local uplands. The primary limitations associated with these soils are slow permeability and erosion hazards.

3.6.2.5.5.1 Designated Farmland

The percentage of designated farmland in the ROI in Region 5 is provided in Table 3.6.2-10. Five route variations were developed for the Applicant Proposed Route in Region 5 in response to public comments on the Draft EIS. The ROI for Link 1, Variation 2, has 157 acres of designated farmland. The ROI for Link 2, Variation 2, does not have any designated farmland. The ROI for Links 2 and 3, Variation 1, has 240 acres in designated farmland. It should be noted that a route adjustment was made for HVDC Alternative Route 5-B to maintain continuity with this variation. The ROI for Links 3 and 4, Variation 2, has 17 acres of designated farmland. It should be noted that a route adjustment was made for HVDC Alternative Route 5-E to maintain continuity with this variation. The ROI for Link 7, Variation 1, has 78 acres of designated farmland. The variations are illustrated in Exhibit 1 of Appendix M.

Table 3.6.2-10:
Designated Farmland in Region 5 (Percentage of ROI)

Project Component[1a]	Total Acres in ROI	Prime Farmland (%)	Prime Farmland if Drained[1] (%)	Prime Farmland if Drained[2] (%)	Prime Farmland if Protected[3] (%)	Farmland of State and Local Importance[4] (%)	Total Designated Farmland[5] (%)

AR 5-C	1,137	69	1	0	0	4	74
AR 5-D	2,660	36	0	4	6	<1	46
AR 5-E	4,449	51	1	0	0	5	57
AR 5-F	2,748	53	1	0	0	8	62
APR	13,777	32	<1	2	1	3	38
Arkansas Converter Station Siting Area	360	32	8	0	0	13	53
Arkansas AC Interconnection	662	48	30	0	0	22	97

1a The values in the table do not reflect the minor changes that would result from application of the minor route variations and adjustments.
GIS Data Source: NRCS (2013)
1 Prime farmland if drained with no other qualifications.
2 Prime farmland if drained and either protected from flooding or not frequently flooded during the growing season.
3 Prime farmland if protected from flooding or not frequently flooded during the growing season.
4 This is land, in addition to prime and unique farmland, that is of statewide importance for the production of food, feed, fiber, forage, and oil seed crops. Criteria for defining and delineating this land are to be determined by the appropriate state agency or agencies.
5 Total designated farmland categories present in the Region 5 ROI.

3.6.2.5.5.2 Soil Limitations

Existing soil limitations within the ROI in Region 5 are summarized in Table 3.6.2-11 by Project component. Five route variations were developed for the Applicant Proposed Route in Region 5 in response to public comments on the Draft EIS. The ROI for Link 1, Variation 2, has acreage that includes 2 acres with high water erosion potential, 32 acres with high wind erosion potential, 12 acres of stony soils, 9 acres with slopes greater than 20 percent, and 6 acres of soils with high compaction potential. The ROI for Link 2, Variation 2, has acreage that includes 26 acres with high wind erosion potential, 37 acres of stony soils, and 50 acres with slopes greater than 20 percent. The ROI for Links 2 and 3, Variation 1, has acreage that includes 25 acres with high wind erosion potential, 15 acres with slopes greater than 20 percent, 21 acres of stony soils, and 11 acres of soils with high compaction potential. It should be noted that a route adjustment was made for HVDC Alternative Route 5-B to maintain continuity with this variation. The ROI for Links 3 and 4, Variation 2, has acreage that includes 52 acres with high wind erosion potential, 8 acres with slopes greater than 20 percent, 46 acres of stony soils, and 3 acres of soils with high compaction potential. It should be noted that a route adjustment was made for HVDC Alternative Route 5-E to maintain continuity with this variation. The ROI for Link 7, Variation 1, has acreage that includes 15 acres with high wind erosion potential, 4 acres with slopes greater than 20 percent, and 4 acres of stony soils. The variations are illustrated in Exhibit 1 of Appendix M.

Table 3.6.2-11:
Soil Limitations in Region 5 (Percentage of ROI)

Project Component Area[1a]	High Compaction Potential[1]	Moderate to High Wind Erosion Potential[2]	High Water Erosion Potential[3]	Corrosion Potential[4]	Stony Soil[5]	Hydric Soils[6]	Restrictive Layer[7]	15 to 30 Percent Slopes	>30 Percent Slopes

Arkansas Interconnect	99	24	50	37	1	0	62	0	0

1a The values in the table do not reflect the minor changes that would result from application of the minor route variations and adjustments.
GIS Data Source: NRCS (2013)
1 SSURGO severe rutting hazard.
2 SSURGO Wind Erosion Groups: 1–3 and 4L.
3 SSURGO Kf > 0.4.
4 SSURGO high concrete or steel corrosion potential.
5 SSURGO soils characterized as stony, cobbly, flaggy, channery, bouldery, and bedrock.
6 SSURGO Hydric Condition (includes only entirely hydric soils and not partially hydric soils).
7 SSURGO restrictive layer < 60 inches from ground surface.

3.6.2.5.5.3 Soil Contamination

Thirteen facilities that are required to report activity to a state or federal system were identified within the ROI based on EPA FRS database information. They include an NPDES site and 12 PDS sites. Two sites, both NPDES sites, were identified in the Arkansas Interconnection Siting Area. Another site is located just outside the siting area boundary and is both a RCRA and NPDES site. The ROIs for the five route variations do not contain any listed sites.

3.6.2.5.6 Region 6

Southern Mississippi River Alluvium MLRA

The ROI crosses two areas of the southern Mississippi River Alluvium MLRA characterized as the alluvial plain along the lower Mississippi River, south of its confluence with the Ohio River. The landforms in the area are level or depressional to very gently undulating alluvial plains, backswamps, oxbows, natural levees, and terraces. Landform shapes range from convex on natural levees and undulating terraces to concave in oxbows (GIS Data Source: NRCS 2006). Average elevations gradually rise from the south/southeast to the northwest.

Most of this area is used for cropland and about 29 percent of this MLRA is not protected from flooding (including most areas of forested wetlands), and flooding occurs occasionally or frequently in these unprotected areas. Levees protect nearly all of the cropland, urban land, and grassland from flooding. Networks of drainage canals and ditches help to remove excess surface water from the cropland. Soil resource concerns are control of surface water, management of soil moisture, and maintenance of the content of organic matter and productivity of the soils. Conservation practices on cropland generally include nutrient management, crop residue management, and alternative tillage systems, especially no-till systems that reduce the cost of tillage. In many areas land leveling or shaping optimizes the control of surface water and the potential for soil erosion (GIS Data Source: NRCS 2006).

Alfisols, vertisols, inceptisols, and entisols are the predominant soil orders in the MLRA. The soils temperature regime is thermic, has an aquic soil moisture regime, has smectitic clay mineralogy, and mixed sand and silt fraction mineralogy. The soils are very deep, dominantly poorly drained and somewhat poorly drained, and dominantly loamy or clayey. Soils are present in areas of alluvial flats and backswamps of Holocene to late Pleistocene age, nearly level to gently sloping soils in natural levees of Holocene age, nearly level to gently undulating, sandy soils in levee splays and point bars of Holocene age, and nearly level to gently undulating in terraces of Pleistocene age.

Southern Mississippi Valley Loess MLRA

This area is characterized by sharply dissected plains that have a loess mantle that is thick at the valley wall but thins rapidly as distance from the valley wall increases (GIS Data Source: NRCS 2006). Valley sides are hilly to steep, especially in the western part of the MLRA. Intervening ridges generally are narrow and rolling, but some of the interfluves between the upper reaches of the valleys are broad and flat. Stream valleys are narrow in the upper reaches but broaden rapidly downstream and have wide flat flood plains and meandering stream channels. Elevation ranges from 80 to 600 feet.

Soil resource concerns are water erosion, maintenance of the content of organic matter and productivity of the soils, and management of soil moisture. Water erosion is a hazard in sloping areas that are bare because of tree harvesting. Soil conservation practices on forestland generally include systems of tree residue management and reforestation. Conservation practices on cropland generally include crop residue management, which increases the content of organic matter in the soils, and applications of lime in areas of low pH. Many of the soils remain wet or have a high water table for some or most of the year.

Alfisols, entisols, inceptisols, and ultisols are the predominant soil orders in the MLRA. The soils in the area are very deep or deep, are medium textured, and have a thermic soil temperature regime, audic soil moisture regime, and mixed mineralogy. Well drained, nearly level to very steep soils are on uplands. Nearly level to steep, well-drained soils and moderately well drained and somewhat poorly drained soils and moderately well drained soils, and well-drained soils formed in thick deposits of loess. Nearly level to gently sloping, somewhat poorly drained soils, moderately well drained soils, well drained to somewhat poorly drained soils, and well drained soils formed in deposits of loess 2 to 4 feet thick. Nearly level and very gently sloping, somewhat poorly drained and poorly drained soils, somewhat poorly drained soils, somewhat poorly drained soils, and somewhat poorly drained soils formed in a thin mantle of loess over loamy alluvium or mixed loess and loamy alluvium. Deep, gently sloping, well drained soils, somewhat poorly drained soils, and somewhat poorly drained soils formed in silty material or in a mantle of loess and the underlying late Pleistocene loamy terrace material. In the eastern part of the area, where the loess mantle thins, well drained soils and moderately well drained soils, all of which are gently sloping to steep, are on ridgetops and side slopes. Well drained soils moderately well drained soils, and somewhat poorly drained soils are on floodplains.

3.6.2.5.6.1 Designated Farmland

Percentages of designated farmland in the affected environment ROI for Region 6 are provided in Table 3.6.2-12. One route variation was developed for the Applicant Proposed Route in Region 6 in response to public comments on the Draft EIS. The ROI for Link 2, Variation 1, has 87 acres of designated farmland. It should be noted that a route adjustment was made for HVDC Alternative Route 6-A to maintain continuity with this variation. The variations are illustrated in Exhibit 1 of Appendix M.

Table 3.6.2-12:
Designated Farmland in Region 6 (Percentage of ROI)

Project Component Area[1a]	Total Acres in ROI	Prime Farmland (%)	Prime Farmland if Drained[1] (%)	Prime Farmland if Drained[2] (%)	Prime Farmland if Protected[3] (%)	Farmland of State and Local Importance[4] (%)	Total Designated Farmland[5] (%)
AR 6-A	1,982	28	22	2	6	6	65
AR 6-B	1,724	37	24	11	9	2	61
AR 6-C	2,857	29	33	10	0	10	81
AR 6-D	1,134	8	24	17	8	21	79
APR	6,652	23	31	4	4	20	82

1a The values in the table do not reflect the minor changes that would result from application of the minor route variations and adjustments.
GIS Data Source: NRCS (2013)
1 Prime farmland if drained with no other qualifications.
2 Prime farmland if drained <u>and</u> either protected from flooding or not frequently flooded during the growing season.
3 Prime farmland if protected from flooding or not frequently flooded during the growing season.
4 This is land, in addition to prime and unique farmland, that is of statewide importance for the production of food, feed, fiber, forage, and oil seed crops. Criteria for defining and delineating this land are to be determined by the appropriate state agency or agencies.
5 Total designated farmland categories present in the Region 5 ROI.

3.6.2.5.6.2 Soil Limitations

Existing soil limitations within the ROI in Region 6 are summarized in Table 3.6.2-13 by Project component. One route variation was developed in Region 6 in response to public comments on the Draft EIS. Applicant Proposed Route Link 2, Variation 1, has acreage that includes 47 acres with high water erosion potential, 10 acres with high wind erosion potential, and 47 acres of soils with high compaction potential. It should be noted that a route adjustment was made for HVDC Alternative Route 6-A to maintain continuity with Applicant Proposed Route Link 2, Variation 1. The variations are illustrated in Exhibit 1 of Appendix M.

Table 3.6.2-13:
Soil Limitations in Region 6 (Percentage of ROI)

Project Component Area	High Compaction Potential[1]	Moderate to High Wind Erosion Potential[2]	High Water Erosion Potential[3]	Corrosion Potential[4]	Stony/Rocky Soil[5]	Hydric Soils[6]	Restrictive Layer[7]	15 to 30 Percent Slopes	>30 Percent Slopes

AR 6-D	78	0	26	51	0	60	1	0	0
APR	92	10	58	70	0	30	47	2	0

1a The values in the table do not reflect the minor changes that would result from application of the minor route variations and adjustments.
GIS Data Source: NRCS (2013)
1 SSURGO severe rutting potential.
2 SSURGO Wind Erosion Groups: 1–3 and 4L.
3 SSURGO Kf > 0.4.
4 SSURGO high concrete or steel corrosion potential.
5 SSURGO soils characterized as cobbly, stony, flaggy, channery, bouldery, and bedrock.
6 SSURGO Hydric Condition (includes only entirely hydric soils and not partially hydric soils).
7 SSURGO restrictive layer < 60 inches from ground surface.

3.6.2.5.6.3 Soil Contamination

No areas of potential soil contamination were identified within the Region 6 ROI based on EPA FRS database information. The ROI for the one route variation does not contain any listed sites.

3.6.2.5.7 Region 7

Southern Mississippi River Alluvium MLRA

The ROI in Region 7 crosses the Southern Mississippi River Alluvium MLRA, and alfisols, vertisols, inceptisols, and entisols are the dominant soil orders. These are described above under Region 6.

Southern Mississippi Valley Loess MLRA

The ROI in Region 7 crosses the Southern Mississippi Valley Loess MLRA, and alfisols, entisols, inceptisols, and utisols are the dominant soil orders. These are described above under Region 6.

The soils located within the Shelby Convertor Station Siting Area are classified in the Memphis-Adler association. These soils consist of very deep moderately to somewhat poorly drained soils that formed in thick loess, silty alluvium, or water reworked loess deposits on broad nearly level to strongly sloping uplands and stream terraces.

3.6.2.5.7.1 Designated Farmland

Percentages of designated farmland in the affected environment ROI for Region 7 are provided in Table 3.6.2-14. Three route variations were developed for the Applicant Proposed Route in Region 7 in response to public comments on the Draft EIS. The ROI for Link 1, Variation 1, does not have any designated farmland. The ROI for Link 1, Variation 2, has 42 acres of designated farmland. The ROI for Link 5, Variation 1, has 42 acres of designated farmland. The variations are illustrated in Exhibit 1 in Appendix M.

Table 3.6.2-14:
Designated Farmland in Region 7 (Percentage of ROI)

Project Component Area[1a]	Total Acres in ROI	Prime Farmland (%)	Prime Farmland if Drained[1] (%)	Prime Farmland if Drained[2] (%)	Prime Farmland if Protected[3] (%)	Farmland of State and Local Importance[4] (%)	Total Designated Farmland[5] (%)
AR 7-A	5,259	10	22	35	29	1	96
AR 7-B	1,055	49	0	0	0	0	49

AR 7-D	803	54	0	0	0	0	54
APR	5,226	25	19	20	14	2	80
Tennessee Converter Station Siting Area[6]	218	68	0	0	0	0	68

1a The values in the table do not reflect the minor changes that would result from application of the minor route variations and adjustments.
GIS Data Source: NRCS (2013).
1 Prime farmland if drained with no other qualifications.
2 Prime farmland if drained and either protected from flooding or not frequently flooded during the growing season.
3 Prime farmland if protected from flooding or not frequently flooded during the growing season.
4 This is land, in addition to prime and unique farmland, that is of statewide importance for the production of food, feed, fiber, forage, and oil seed crops. Criteria for defining and delineating this land are to be determined by the appropriate state agency or agencies.
5 Total designated farmland categories present in the Region 7 ROI.
6 The Tennessee AC Interconnection would be located within the siting area.

3.6.2.5.7.2 Soil Limitations

Existing soil limitations within the ROI for Region 7 are summarized in Table 3.6.2-15 by Project component. Three route variations were developed for the Applicant Proposed Route in Region 7 in response to public comments on the Draft EIS. The ROI for Link 1, Variation 1, has acreage that includes 17 acres of hydric soils and 17 acres of soils with high compaction potential. The ROI for Link 1, Variation 2, has acreage that includes 20 acres with high water erosion potential, 31 acres with high wind erosion potential, 5 acres with slopes greater than 20 percent, 22 acres of hydric soils, and 84 acres of soils with high compaction potential. The ROI for Link 5, Variation 1, has acreage that includes 17 acres with high water erosion potential and 17 acres of soils with high compaction potential. All three variations generally have the same land uses in the ROI as does the original Applicant Proposed Route. The variations are illustrated in Exhibit 1 of Appendix M.

Table 3.6.2-15:
Soil Limitations in Region 7 (Percentage of ROI)

Project Component Area[1a]	High Compaction Potential[1]	Moderate to High Wind Erosion Potential[2]	High Water Erosion Potential[3]	Corrosion Potential[4]	Hydric Soils[5]	Restrictive Layer[6]	15 to 30 Percent Slopes	>30 Percent Slopes

Tennessee Converter Station Siting Area	99	0	95	0	11	22	12	0

1a The values in the table do not reflect the minor changes that would result from application of the minor route variations and adjustments.

GIS Data Source: NRCS (2013)

1 SSURGO severe rutting hazard.

2 SSURGO Wind Erosion Groups: 1–3 and 4L.

3 SSURGO Kf > 0.4.

4 SSURGO high steel or concrete corrosion potential.

5 SSURGO Hydric Condition (includes only entirely hydric soils and not partially hydric soils).

6 SSURGO restrictive layer < 60 inches from ground surface.

3.6.2.5.7.3 Soil Contamination

Two facilities that are required to report activity to a state or federal system were identified within the Region 6 ROI based on EPA FRS database information. The facilities are two PDS sites. Seven facilities are located in the area of the Tennessee Converter Station Siting Area including five PDS sites, one NPDES site, and one TRI site. One listed site is in the ROI for Applicant Proposed Route Link 1, Variation 2. No sites were identified within the Tennessee Converter Station Siting Area.

3.6.2.5.8 Connected Actions

3.6.2.5.8.1 Wind Energy Generation

Southern High Plains, Northern Part MLRA

Wind energy generation in the WDZs would occur in the Southern High Plains and Northern Part MLRA. Alfisols and mollisols are the dominant soil orders. These are described above under Region 1.

3.6.2.5.8.1.1 Designated Farmland

Percentages of designated farmland in the WDZs are provided in Table 3.6.2-16. Farmland of state and local important is not designated or present in the WDZs in Oklahoma and is not included in the table.

Table 3.6.2-16:
Designated Farmland in WDZs (Percentage of ROI)

WDZ	Total Acres in WDZ ROI	Prime Farmland (%)	Prime Farmland if Protected[1] (%)	Total Designated Farmland[2] (%)
A	109,747	68	0	68
B	125,479	59	<1	59
C	161,048	49	<1	49
D	69,189	45	0	45
E	47,092	75	0	75

I	105,203	59	0	59
J	92,567	32	0	32
K	92,894	85	0	85
L	165,848	73	0	73

GIS Data Source: NRCS (2013)
1 Prime farmland if protected from flooding or not frequently flooded during the growing season.
2 Total designated farmland categories present in the WDZ.

3.6.2.5.8.1.2 Soil Limitations

Existing soil limitations within the WDZ ROIs are summarized in Table 3.6.2-17 by Project component.

Table 3.6.2-17:
Soil Limitations in WDZs (Percentage of ROI)

WDZ	High Compaction Potential[1]	Moderate to High Wind Erosion Potential[2]	Corrosion Potential[3]	Hydric Soils[4]	Restrictive Layer[5]	15 to 30 Percent Slopes	>30 Percent Slopes
A	25	25	67	0	4	2	0
B	81	35	70	0	2	3	0
C	37	46	49	<1	4	3	<1
D	18	55	1	<1	12	0	0

J	64	60	17	0	11	<1	0
K	53	15	38	0	0	0	0
L	23	19	66	0	7	3	0

GIS Data Source: NRCS (2013)
1 SSURGO severe rutting hazard.
2 SSURGO Wind Erosion Groups: 1–3 and 4L.
3 SSURGO high steel or concrete corrosion potential.
4 SSURGO Hydric Condition (includes only entirely hydric soils and not partially hydric soils).
5 SSURGO restrictive layer < 60 inches from ground surface.

3.6.2.5.8.1.3 Soil Contamination

Facilities that are required to report activity to a state or federal system for the WDZ boundaries are listed in Table 3.6.2-18. The presence of most of these sites on the databases indicate a records inventory of such regulated sites and do not raise a concern at this time in regards to potential areas of soil contamination. Exceptions include the CERCLA site located in the city of Perryton, Texas (WDZ-A), and the LUST-ARRA sites located in Hardesty, Oklahoma (WDZ-D). These sites are indicated to be in some stage of clean-up under regulatory authority.

Table 3.6.2-18:
FRS Sites in WDZs

WDZ	Total Number of Sites	Sites
A	83 (74 in the vicinity of Perryton, TX)	NPDES (2);ICIS (10); RCRAinfo (34); CERCLIS (City of Perryton Well No. 2); SPCC (1); TCEQ ACR (35)
B	11	NPDES (5); ICIS (1); TCEQ ACR (5)
C	26	NPDES (9); RCRinfo (2); Toxic Substances Control Act (1); TRI (1); TCEQ ACR (13)
D	2	LUST-ARRA (2)
E	3	ICIS (2); NPDES (1)
F	19 (16 within Texhoma, OK)	NPDES (9): ICIS (6); TRI (1); NCDB (3)
G	3	BR (1), RCRAinfo (1); NPDES (1)
H	None	NA
I	16	NPDES (5); ICIS (6); RCRAinfo (1); NCDB (3); SSTS (1)
J	None	NA
K	None	NA
L	11	NPDES (2); TCEQ ACR (9)

GIS Data Source: EPA (2014b)

3.6.2.5.8.2 Optima Substation

General soil characteristics are the same as those described for the western area of Region 1. The future Optima substation is composed of 7.5 acres (5 percent of the 160-acre site) of prime farmland. Fifteen acres (9 percent of the site) is within areas susceptible to high compaction; and 153 acres (95 percent of the site) is within areas of moderate to high wind erosion potential.

3.6.2.5.8.3 TVA Upgrades

The ROI for the direct assignment facilities (which are included in the Applicant Proposed Project) would occur within the Tennessee Converter Station Siting Area and more specifically within the Shelby Substation. The region of influence for the network upgrades, and in particular TVA's future 500kV transmission line, cannot be fully determined at this time. The new 500kV transmission line would be constructed in West Tennessee where designated farmland is extensive. Upgrades to existing infrastructure would include upgrading terminal equipment at three existing 500kV substations and six existing 161kV substations, making appropriate upgrades to increase heights on 16 existing 161kV transmission lines to increase line ratings, and replacing the conductors on eight existing 161kV transmission lines.

3.6.2.6 Impacts to Soils

3.6.2.6.1 Methodology

Impacts to soils from HVDC transmission lines were analyzed based on a 200-foot-wide representative ROW (see Section 3.1). Other Project components were analyzed based on the ROI, recognizing that the actual construction footprints would be smaller than the ROI. Areas of potential disturbance (which would affect soils) are provided in Appendix F for transmission tower footprints, tensioning and pulling sites, access roads, multi-use construction staging yards, and fiber optic regeneration sites. Because specific locations have not been identified for these Project features, an evaluation of designated farmland, soil limitation parameters, and potential contaminated sites is not possible at this time.

3.6.2.6.1.1 Impacts Common to All Project Components

Temporary and short-term impacts to soils would occur during construction, long-term impacts during operations and maintenance, and temporary and short-term impacts during decommissioning. The implementation of EPMs and associated management plans would minimize or avoid impacts to soils and reduce long-term and permanent effects to the extent practicable. Potential impacts from Project activities are discussed below.

Vegetation Removal

Vegetation would be cut and/or removed during construction for equipment access, safe construction purposes and to ensure long-term electrical safety clearances, maintenance, and reliability of the transmission lines. Vegetation would also be removed as necessary for construction and operation of the converter stations. Vegetation removal could indirectly affect soils by increasing potential for wind and water erosion, reducing water and nutrient holding capacity, impacting porosity, and reducing a soil's ability to filter sediments. Removal of trees could alter soil moisture by decreasing evapotranspiration rates and may increase soil temperature because of a lack of shade. Erosion may result in loss of valuable topsoil from its original location through wind and/or water erosion. Reestablishing soil-protective vegetation cover would be performed to minimize and avoid soil erosion. Vegetation removal and vegetation maintenance would be ongoing during the operation phase of the Project for the safe operation of the transmission lines. Specific impacts to vegetation are discussed in Section 3.17.

Maintenance activities for operation and maintenance of facilities would be similar to activities during construction but generally smaller in scale and more localized and infrequent. The ROW would be maintained during operations and maintenance in accordance with a TVMP developed for the Project, consistent with NERC standards. The TVMP may require additional analysis under NEPA depending on whether and under what conditions DOE decides to participate in the Project. The wire zone typically consists of low-growing grasses, legumes, herbs, crops, ferns, and shrubs where the conductor is 50 feet or less from the ground, to prevent accidental grounding contact with conductors. The border zone (i.e., to the edge of the ROW) is managed to consist of tall shrubs or short trees (up to 25 feet in height at maturity), grasses, and forbs. In most areas, standard utility practices consistent with the TVMP, such as tree-trimming and/or brush removal, would be used to maintain vegetation on the ROW.

Grading and Excavation

Grading can directly affect surface soils, resulting in soil mixing and increased wind and water erosion potential. The Project has the potential to cause soil mixing where grading or excavation is required. The mixing of topsoil with subsoil during these activities could result in the loss of soil fertility, loss of seedbank present in the topsoil, and introduction of rock into the topsoil. Construction activities in areas of stony/rocky soils may result in a concentration of large clasts near the surface. Erosion may result in loss of valuable topsoil from its original location through wind and/or water erosion. Reestablishing soil-protective vegetation cover would be performed to minimize and avoid soil erosion.

Impacts to soil resources from construction activities are associated with clearing, grading, excavation, and other activities necessary for construction of the converter station, access roads and the transmission line structures and lines. Impacts during construction could expose erosion-prone soils to conditions of increased erosion potential; soils with high compaction potential would be susceptible to compaction from construction vehicles and equipment.

Construction disturbance to areas of steep slopes could cause increased erosion hazards in these areas and reclamation of these areas might be more difficult and less successful.

Blasting

Blasting of bedrock might be required in the some areas of the Project. Blasting activities have the potential to cause soil mixing and the introduction of rock into the topsoil. Erosion may result in loss of valuable topsoil from its original location through wind and/or water erosion and could lead to poor revegetation following construction.

Access Road Construction and Use

Construction and use of access roads during Project construction could result in direct impacts to soil from rutting and compaction. Construction and use of access roads would range from overland travel in areas with low vegetation, to grading in steep areas. Driving construction equipment through soils can crush vegetation and compact soils, particularly where soils are prone to compaction. The degree of compaction depends on the moisture content and texture of the soil at the time of construction.

Fuel and Lubricant Handling

Inadvertent spills of fluids used during construction, such as fuel, lubricants, antifreeze, detergents, paints, solvents, and herbicides could directly affect soils through contamination.

Previously Contaminated Soils

Excavation activities during construction might uncover previously unknown areas of contaminated soils. Contaminated soils might cause hazardous conditions for workers and cause construction delays and, if disturbed, might allow contaminants to migrate to surrounding soil and water resources.

Herbicide Use

The Applicant may selectively apply herbicides during clearing and grading for construction to minimize regrowth of certain trees and woody species. Herbicides may be toxic to soil organisms and could have a temporary direct impact on the revegetation potential of the area depending on the type used and the concentration.

Dewatering

Open excavations and trenches may occasionally accumulate water as groundwater seeps in or from precipitation. When that occurs, the excavations and trenches may require periodic dewatering to allow for proper and safe construction, which may lead to soil erosion if the water is discharged directly to the ground and soil is washed away.

Conversion of Designated Farmland

The DOE has consulted with the Oklahoma, Arkansas, and Tennessee NRCS offices concerning impacts to farmland protected under the FPPA and has received a determination from the agencies that the transmission lines do not irreversibly convert farmland (Sagona 2014 and Adams 2014). This determination has been further confirmed with the NRCS National Leader for FPPA. It should be noted, however, that this determination does not apply to the converter stations, which would potentially convert farmland and would require a Form AD-1006 to be submitted for evaluation. The locations of access roads needed for the Project has not yet been determined; however, the Applicant would avoid placement of permanent access roads through farmland. Once the exact locations of Project components have been determined, a farmland conversion assessment would be completed by the NRCS and DOE for any remaining components for which NRCS has not yet issued a determination.

Operations and Maintenance

Operations and maintenance impacts to soils generally depend on the area of ground affected by operations and maintenance activities within ROWs, along access roads, and at facility sites such as converter stations. Soil resources may be temporarily affected by periodic vegetation maintenance during the operations and maintenance phase of the Project. Impacts from the construction and use of access roads might expose soils to erosion and compaction. Impacts to soils include permanent removal of soils from other potential uses and ongoing minimal impacts from maintenance activities along Project ROWs. Maintenance activities such as the use of trucks and heavy equipment to maintain low vegetation could result in damage to drainage and ground vegetation along ROWs that might expose soils to erosion and compaction hazards. The application of EPMs would help minimize or avoid impacts to soils during operations and maintenance.

Decommissioning

Decommissioning of the Project could result in impacts to soil resources, similar to those for construction (e.g., increased sedimentation, erosion, soil compaction, limited direct removal of vegetation, and accidental spills of chemicals). Decommissioning would result in an overall decrease in impacts to soil resources because the acreage associated with the structures and ROWs would be available for long-term reclamation.

3.6.2.6.1.2 Environmental Protection Measures

Clean Line would develop and implement the following plans as part of the Project:

- Blasting Plan: This plan will describe measure designed to minimize adverse effects due to blasting.
- Restoration Plan: This plan will describe post-construction activities to reclaim disturbed areas.
- Spill Prevention, Control and Countermeasures (SPCC) Plan: This plan will describe the measures designed to prevent, control, and cleanup spills of hazardous materials.
- Storm Water Pollution Prevention Plan (SWPPP): This plan, consistent with federal and state regulations, would describe the practices, measures, and monitoring programs to control sedimentation, erosion, and runoff from disturbed areas.
- Decommissioning Plan: This plan would describe all measures necessary to ensure the prevention of erosion, compaction, and other adverse impacts to soils during decommissioning. The plan would also include post-decommissioning activities to reclaim disturbed areas.

A complete list of EPMs for the Project is provided in Appendix F; those EPMs that would reduce impacts to soils or minimize the potential for release or mismanagement of hazardous constituents that could eventually result in an impact on soils are listed below:

- GE-1: Clean Line will train personnel on health, safety, and environmental matters. Training will include practices, techniques, and protocols required by federal and state regulations and applicable permits.
- GE-3: Clean Line will minimize clearing vegetation within the ROW, consistent with a Transmission Vegetation Management Plan filed with NERC, and applicable federal, state, and local regulations. The TVMP may require additional analysis under NEPA depending on whether and under what conditions DOE decides to participate in the Project.
- GE-4: Vegetation removed during clearing will be disposed of according to federal, state, and local regulations.
- GE-5: Any herbicides used during construction and operations and maintenance will be applied according to label instructions and any federal, state, and local regulations.
- GE-6: Clean Line will restrict vehicular travel to the ROW and other established areas within the construction, access, or maintenance easement (s).
- GE-7: Roads not otherwise needed for maintenance and operations will be restored to preconstruction conditions to the extent practicable. Roads needed for maintenance and operations will be retained.
- GE-8: Access controls (e.g., cattle guards, fences, gates) will be installed, maintained, repaired, replaced, or restored as required by regulation, road authority, or as agreed to by landowner.
- GE-9: Clean Line will avoid damage to drainage features and other improvements such as ditches, culverts, levees, tiles, and terraces to the extent practicable. If these features or improvements are inadvertently damage, they will be repaired and or restored to the extent practicable.
- GE-11: Clean Line will conduct construction, operation, and maintenance activities to minimize the creation of dust. This may include measures such as limitations on equipment, speed, and/or travel routes utilized. Water, dust palliative, gravel, combinations of these, or similar control measures may be used. Clean Line will implement measures to minimize the transfer of mud onto public roads.
- GE-12: Clean Line will avoid remedial structures (e.g., capped areas, monitoring equipment, or treatment wells) on contaminated sites, Superfund sites, CERCLA remediation sites, and other similar sites. Workers will use appropriate protective equipment and appropriate safe working techniques when working at or near contaminated sites.
- GE-13: Emergency and spill response equipment will be kept on hand during construction.
- GE-14: Clean Line will restrict the refueling and maintenance of vehicles and the storage of fuels and hazardous chemicals within at least 100 feet from wetlands, surface waterbodies, and groundwater wells, or as otherwise required by federal, state, or local regulations.
- GE-15: Waste generated during construction or maintenance, including solid waste, petroleum waste, and any potentially hazardous materials will be removed and taken to an authorized disposal facility.
- GE-22: Clean Line will impose speed limits during construction for access roads (e.g., to reduce dust emissions, for safety reasons, and for protection of wildlife).
- LU-1: Clean Line will work with landowners and operators to ensure that access is maintained as needed to existing operations (e.g., to oil/gas wells, private lands, agricultural areas, pastures, hunting leases).
- GE-27: Clean Line will minimize compaction of soils and rutting through appropriate use of construction equipment (e.g., low ground pressure equipment and temporary equipment mats).

- GE-28: Hazardous materials and chemicals will be transported, stored, and disposed of according to federal, state, or local regulations or permit requirements.
- GE-29: Clean Line will work with landowners and operators of active oil and gas wells, utilities, and other infrastructure to identify and verify the location of facilities and to minimize adverse impacts. Identification may include use of the One Call system and surveying of existing facilities.
- GE-30: Clean Line will minimize the amount of time that any excavations remain open.
- AG-1: Clean Line will avoid or minimize adverse effects to surface and subsurface irrigation and drainage systems (e.g., tiles). Clean Line will work with landowners to minimize the placement of structures in locations that would interfere with the operation of irrigation systems.
- AG-2:–Agricultural soils directly impacted by construction, operation, or maintenance activities will be restored to pre-activity conditions to the extent practicable. Appropriate soil remediation efforts may include decompaction, liming, tillage, fertilization, or use of other soil amendments.
- AG-3: Clean Line will consult with landowners and/or tenants to identify the location and boundaries of agriculture or conservation reserve lands and to understand the criteria for maintaining the integrity of these committed lands.
- AG-4: Clean Line will work with landowners and/or tenants to identify specialty agricultural crops or lands (e.g., certified organic crops or products that require special practices, techniques, or standards) that may require protection during construction, operation, or maintenance. Clean Line will avoid and/or minimize impacts that could jeopardize standards or certifications that support specialty croplands or farms.
- GEO-1: As appropriate, Clean Line will stabilize exposed slopes to minimize erosion.
- W-5: Clean Line will construct access roads to minimize disruption of natural drainage patterns including perennial, intermittent, and ephemeral streams.
- W-8: Dewatering will be conducted in a manner designed to prevent soil erosion (e.g., through discharge of water to vegetated areas and/or the use of flow control devices).

3.6.2.6.2 Impacts Associated with the Applicant Proposed Project

3.6.2.6.2.1 Converter Stations and AC Interconnection Siting Areas

3.6.2.6.2.1.1 Oklahoma and Tennessee Converter Station and AC Interconnection Tie

3.6.2.6.2.1.1.1 Construction Impacts

No areas of designated farmland are present in the Oklahoma Converter Station Siting Area and 8 percent (73 acres) of the Oklahoma AC Interconnection Siting Area contains designated farmland. The Tennessee Converter Station Siting Area and AC Interconnection Tie consists of 68 percent (149 acres) designated farmland. Depending on the specific siting of the converter stations and the Oklahoma Interconnection line, impacts from construction activities could include exposing prime farmland to conditions of increased erosion potential, and soils with high compaction potential would be susceptible to compaction from construction vehicles and equipment. Either impact could result in a decrease in the productivity of such soils and a loss of fertile topsoil. Depending on the specific siting of the converter stations, areas susceptible to erosion and hydric soils could be avoided or impacted during construction activities.

Two facilities (one NPDES site and one TRI site) that are required to report activity to a state or federal system were identified in the Tennessee Converter Station Siting Area. The NPDES site, located within the northeastern portion of the siting area, indicates a stone and gravel operation where a permit was granted in 2008 for the discharge of stormwater. The TRI site is the existing Shelby 500kV substation. These sites indicate a records inventory and do not raise a concern at this time in regards to areas of soil contamination.

3.6.2.6.2.1.1.2 Operations and Maintenance Impacts

Impacts from operations and maintenance are described in Section 3.6.2.6.1.

3.6.2.6.2.1.1.3 Decommissioning Impacts

Impacts from decommissioning are described in Section 3.6.2.6.1.

3.6.2.6.2.2 AC Collection System

3.6.2.6.2.2.1 Construction Impacts

The amounts of designated farmland for the AC collection system routes are summarized in Table 3.6.2-19. The AC collection system routes representative ROWs only traverse areas of prime farmland and do not traverse other categories of designated farmland and therefore the other categories are not presented in the table.

Table 3.6.2-19:
Designated Farmland—AC Collection System Routes 200-Foot-Wide Representative ROW (Percentage and Acreage)

AC Collection System Route	Total Representative ROW (acres)	Total Designated Farmland Impacted[1] (acres and percentage of representative ROW)
E-1	708	142 (20%)
E-2	974	502 (51%)
E-3	977	432 (44%)
NE-1	730	367(50%)
NE-2	637	209 (33%)
NW-1	1,265	646 (51%)
NW-2	1,365	670 (49%)
SE-1	979	517 (53%)
SE-2	325	167 (49%)
SE-3	1,194	671 (56%)
SW-1	326	9 (3%)
SW-2	901	108 (12%)
W-1	508	193 (38%)

GIS Data Source: NRCS 2013: In Route E-1 designated farmland is present in 42% of the larger ROI; and in Route E-2 designated farmland is present in 19% of the larger ROI.

1 Includes all designated farmland categories (prime farmland is the only category present in the AC collection system impact areas).

Impacts to soil limitation parameters for the 200-foot-wide representative ROW of the AC collection system routes are summarized in Table 3.6.2-20.

One facility, the Lasley Cattle Feedlot (latitude/longitude: 36.2994/-101.82411), is a NPDES stormwater discharge permit site identified within the AC Collection System Route SW-2. Discharge from the feedlot is indicated to be permitted and does not pose a soil contamination concern at this time. Ten other facilities/sites that are required to report activity to a state or federal system were identified in the surrounding AC collection system ROI. Based on available information, these sites do not pose a soil contamination concern.

Table 3.6.2-20:
Soil Limitations—AC Collection System Routes 200-Foot-Wide Representative ROW (Percentage and Acreage)

Project Component Area	High Compaction Potential[1]	Moderate to High Wind Erosion Potential[2]	High Water Erosion Potential[3]	Corrosion Potential[4]	Stony Soils[5]	Hydric Soils[6]	Restrictive Layer[7]	15 to 30% Slopes	>30% Slopes	Summary of Impact Comparison to All AC Collection System Routes (unless otherwise specified)

GIS Data Source: NRCS (2013). In AC Collection System Route E-2, moderate to high wind erosion potential is present in 49% of the larger ROI. In AC Collection System Route NW-2, high compaction potential is present in 88% of the larger ROI. In AC Collection System Route SE-1, high compaction potential is present in 89% of the larger ROI.

1 SSURGO severe rutting hazard.
2 SSURGO WEG wind erosion groups: 1-4L.
3 SSURGO Kf >0.4.
4 SSURGO high steel or concrete potential.
5 SSURGO soils characterized as stony, cobbly, channery, flaggy, bouldery, or bedrock.
6 SSURGO Hydric Condition (includes only entirely hydric soils and not partially hydric soils).
7 Bedrock < 60 inches from ground surface.

3.6.2.6.2.2.2 Operations and Maintenance Impacts

Impacts from operations and maintenance are described in Section 3.6.2.6.1.

3.6.2.6.2.2.3 Decommissioning Impacts

Impacts from decommissioning are described in Section 3.6.2.6.1.

3.6.2.6.2.3 HVDC Applicant Proposed Route

3.6.2.6.2.3.1 Construction Impacts

Designated Farmland

Acreages and percentages of designated farmland for the Applicant Proposed Route 200-foot-wide representative ROW are provided in Table 3.6.2-21 by Project region. The total impact to designated farmland from the Applicant Proposed Route encompasses 48 percent (or 8,321 acres). The greatest impacts to designated farmland are in Regions 1 and 3. The greatest impact to the "farmland–if–drained" category is in Region 6; the greatest impact to "farmland if drained and either protected from flooding or not frequently flooded during the growing season" is in Region 7. The greatest impact to farmland of statewide and local importance is in Region 6. Temporary impacts in the tensioning areas would impact 1,682 acres within the Applicant Proposed Route.

Table 3.6.2-21:
Designated Farmland in Applicant Proposed Route 200-Foot-Wide Representative ROW—All Regions (Percentage and Acreage)

Applicant Proposed Route by Region[1]	Total Acres of Representative ROW	Total Designated Farmland (acres and percentage of Impact Area)[2]
Region 1	2,825	1,405 (50%)
Region 2	2,588	593 (23%)
Region 3	3,949	1,961 (50%)
Region 4	3,088	1,382 (42%)
Region 5	2,760	1,052 (38%)
Region 6	1,332	1,097 (78%)
Region 7	1,048	836 (81%)
Total APR (all Regions)	17,590	8,321 (48%)

1 The values in the table (Regions 2–7) do not reflect the minor changes that would result from application of the minor route variations and adjustments.
2 Includes total for all designated farmland categories.
GIS Data Source: NRCS (2013)

Soil Limitations

Impacts to soil limitation parameters for the Applicant Proposed Route impact areas are summarized in Table 3.6.2-22 by Project region. Impacts to soils with high compaction potential are greater than 1,000 acres in Regions 1, 2, 3, and 4. Total impacts to soils with high compaction potential could occur for 56 percent (9,996 acres) of the Applicant Proposed Route. Wind erosion potential is greatest in Regions 1, 2, and 5, with total impact to 6,648 acres potentially occurring in all Regions for this parameter. Water erosion potential is greatest in Regions 3, 4, and 6. Steep slopes are most prevalent in Regions 3, 4, and 5. Impacts associated with soil limitations are further discussed by Region below. Temporary impacts in the tensioning areas would impact 949 acres of soils with high compaction potential with the Applicant Proposed Route.

This page intentionally left blank.

Table 3.6.2-22:
Soil Limitations in Applicant Proposed Route 200-Foot-Wide Representative ROW—All Regions (Percentage and Acreage)

Project Component Area[1a]	High Compaction Potential[2]		Moderate to High Wind Erosion Potential[3]		High Water Erosion Potential[4]		Corrosion Potential[5]		Stony Soils[6]		Hydric Soils[7]		Restrictive Layer[8]		15 to 30% Slopes		>30% Slopes

1a The values in the table (Regions 2–7) do not reflect the minor changes that would result from application of the minor route variations and adjustments.

GIS Data Source: NRCS (2013)

1 SSURGO severe rutting potential.
2 SSURGO WEG wind erosion groups: 1-4L.
3 SSURGO Kf >0.4.
4 SSURGO high concrete or steel corrosion potential.
5 SSURGO soils characterized as cobbly, stony, flaggy, channery, bouldery, and bedrock.
6 SSURGO Hydric Condition (includes only entirely hydric soils and not partially hydric soils).
7 SSURGO restrictive layer < 60 inches from ground surface.

This page intentionally left blank.

Soil Contamination

No areas of potential soil contamination were identified within the Applicant Proposed Route Regions 1, 2, 3, 4, and 6 representative ROWs or larger ROI. The representative ROW in Region 5 includes the DeSoto Gathering/Phillips Mountain gas facility, located along Applicant Proposed Link 3. The representative ROW in Region 7 includes a PDS site, Mitchell Station. The PDS site could be indicative of any number of potential reported issues. Additional information would be obtained for the site during final design to ascertain if avoidance of the area is necessary. In comments on the Draft EIS, the Tennessee Division of Solid Waste Management identified a potential concern in relation to the Chickasaw Bluffs (crossed by Applicant Proposed Route 7 Link 3), where large gullies might have been used for illicit disposal of waste. The Applicant would implement EPMs to address previously undiscovered waste disposal sites and any necessary handling of waste materials in Project construction areas.

Route Variations

No route variations were proposed in Region 1. Two route variations were developed for the Applicant Proposed Route in Region 2 in response to public comments on the Draft EIS. Link 1, Variation 1, would affect 4 more acres of designated farmland, a greater acreage (5 acres) of soils with high wind erosion potential, and less acreage (3 acres) of soils with high compaction potential. The variation was developed to reduce impacts to cultivated fields and structures. Link 2, Variation 2, was developed to reduce impacts to agricultural operations on several parcels, but would affect a slightly greater acreage (3 acres) of designated farmland. Effects to soil limitations parameters would vary slightly higher and lower (within 8 acres).

Five route variations were developed for the Applicant Proposed in Region 3 in response to public comments on the Draft EIS. Link 1, Variation 2, would reduce impacts to cultivated cropland, but would have approximately 8 acres of greater impacts to designated farmland. Effects to soils with high water erosion potential and shallow bedrock would be less, but effects to soils with high wind erosion potential would be greater. Effects to soil limitation parameters would generally be less (<8 acres) except for soils susceptible to high compaction (2 acres more). Link 4, Variation 1, would have less impact to designated farmland (1 acre) and erosive soils (2 acres), and slightly more impacts (<1 acre) to soils susceptible to compaction. Link 4, Variation 2, would impact slightly less (<1 acre) designated farmland and would have less acreage impacts to soils with limitations (<5 acres); however, the variation would impact approximately 4 acres more of soils with high wind erosion potential. Link 5, Variation 2, would have about the same acreage (within 0.5 acre) impact to designated farmland and slightly greater impact to soils with high water erosion potential (3 acres), but would have less impacts to all other soils with soil limitations (<5 acres).

Seven route variations were developed for the Applicant Proposed in Region 4 in response to public comments on the Draft EIS. Link 3, Variation 1, would have 6 acres greater impact to designated farmland; and greater impact to soils with high water erosion potential (7 acres) and less impact to soils with high susceptibility for compaction (2 acres). Link 3, Variation 2, would have 6 acres more of impacts to designated farmland, 2 acres less of impacts to soils with high water erosion potential, and 50 acres less of impacts to soils with a high susceptibility to compaction. Link 3, Variation 3, would have 1 acre more impact to designated farmland, 9 more acres impact to soils with high wind potential, 38 acres less impact to stony soils, and 12 acres greater impact to soils with high susceptibility to compaction. Link 6, Variation 1, would impact about the same amount of designated farmland, and have 4 acres greater impact to both soils with high water erosion potential and soils with high wind erosion potential. Link 6, Variation 2, would have 3 acres less impact to designated farmland and avoid a WRP easement, but it otherwise generally has the same land use. Link 6, Variation 3, would have slightly less impact to designated farmland (<1 acre), 3 acres less impact to slopes of greater than 20 percent, about 3 acres greater impact to soils with high water erosion potential, 1 acre less impact to soils with high wind erosion potential, and about 6 acres greater impact to soils with high susceptibility to compaction. Link 9, Variation 1, would have 3 acres less impact to designated farmland, 2 acres less impact to soils with high water erosion potential, and 2 acres greater impact to soils with high wind erosion potential.

Five route variations were developed for the Applicant Proposed Route in Region 5 in response to public comments on the Draft EIS. Link 1, Variation 2, would have 30 acres less impact to designated farmland, 2 acres greater impact to soils with high water erosion potential, 3 acres less impact to soils with high wind erosion potential, and 3 acres greater impact to soils with high susceptibility to compaction. Link 2, Variation 2, would reduce impacts to designated farmland by 1 acre, have 1 greater acre of impact to soils with high wind erosion potential, and 13 acres more impact to stony soils. Links 2 and 3, Variation 1, would have 7 acres more impact to designated farmland, 2 acres more impact to soils with high wind erosion potential, and 3 acres more impact to soils with high susceptibility to compaction. It should be noted that a route adjustment was made for HVDC Alternative Route 5-B to maintain continuity with the proposed variation. Links 3 and 4, Variation 2, would have almost 3 acres more impact to designated farmland, 24 acres more impact to soils with high wind erosion potential, and 8 acres less impact to soils with high susceptibility to compaction. It should be noted that a route adjustment was made for HVDC Alternative Route 5-E to maintain continuity with the proposed variation. Link 7, Variation 1, would have almost 4 acres more of impacts to designated farmland and soils with high wind erosion potential.

One route variation was developed for the Applicant Proposed Route in Region 6 in response to public comments on the Draft EIS. Link 2, Variation 1, would have 0.7 acre less impact to designated farmland, 17 acres more impact to soils with high water erosion potential, 1 acre less impact to soils with high wind erosion potential, and 17 acres more impact to soils with high susceptibility to compaction. It should be noted that a route adjustment was made for HVDC Alternative Route 6-A to maintain continuity with the proposed variation. The variation is illustrated in Exhibit 1 of Appendix M.

Three route variations were developed for the Applicant Proposed Route in Region 7 in response to public comments on the Draft EIS. Link 1, Variation 1, would have almost 5 acres more impact to hydric soils and to soils with high susceptibility to compaction. Link 1, Variation 2, would have 11 acres less impact to soils with high water erosion potential, 3 acres less impact to soils with high wind erosion potential, and almost 13 more acres impact to soils with high susceptibility to compaction. Link 5, Variation 1, would have almost the same impacts to designated farmland and to soils with evaluated limitations.

3.6.2.6.2.3.2 Operations and Maintenance Impacts

Impacts from operations and maintenance are described in Section 3.6.2.6.1.

3.6.2.6.2.3.3 Decommissioning Impacts

Impacts from decommissioning are described in Section 3.6.2.6.1.

3.6.2.6.3 Impacts Associated with the DOE Alternatives

3.6.2.6.3.1 Arkansas Converter Station Alternative Siting Area and AC Interconnection Siting Area

3.6.2.6.3.1.1 Construction Impacts

The Arkansas Converter Station Alternative Siting Area is located within 192 acres of designated farmland. The converter station would require 20 to 35 acres of land. The AC interconnection representative ROW includes 662 acres (or 100 percent) within designated farmland. Depending on the specific siting of the converter station and AC interconnect line within these areas, impacts from construction activities could include exposing designated farmland to conditions of increased erosion potential, and soils with high compaction potential would be susceptible to compaction from construction vehicles and equipment. Either impact could result in a decrease in the productivity of such soils and a loss of fertile topsoil.

Five sites were identified in the Arkansas converter station ROI. All are private farmstead or ranch locations. Implementation of EPMs would minimize potential contamination of soils.

A new substation would be required at the point where the 500kV AC interconnection line taps the existing Arkansas Nuclear One-Pleasant Hill 500kV line. The footprint of this substation is estimated to be between 25 and 35 acres, with an additional 5 acres for temporary materials staging and equipment storage. Impacts to designated farmland could increase by up to 35 acres. Impacts to soils with soil limitations are expected to potentially increase to a lesser degree based on the presence or lack thereof of these specific limitation parameters listed for the ROI in Region 5. Soils within the substation site would be permanently impacted.

3.6.2.6.3.1.2 Operations and Maintenance Impacts

Impacts from operations and maintenance are described in Section 3.6.2.6.1.

3.6.2.6.3.1.3 Decommissioning Impacts

Impacts from decommissioning are described in Section 3.6.2.6.1.

3.6.2.6.3.2 HVDC Alternative Routes

3.6.2.6.3.2.1 Construction Impacts

Construction impacts to soil resources would be similar to those of the Application Proposed, but acres of designated farmland and soil limitations would vary by route alternatives. The amounts of designated farmland and soil limitations for HVDC alternative routes representative ROWs and the Applicant Proposed Route are compared for each region in Tables 3.6.2-23 and 3.6.2-24, respectively. Impacts for the individual alternatives are summarized and compared with the Applicant Proposed Route in the far right column of the tables.

1a The values in the table do not reflect the minor changes that would result from application of the minor route variations and adjustments.
GIS Data Source: NRCS (2013)
1 SSURGO severe rutting potential.
2 SSURGO WEG wind erosion groups: 1-4L.
3 SSURGO Kf >0.4.
4 SSURGO high concrete or steel corrosion potential.
5 SSURGO soils characterized as cobbly, stony, flaggy, channery, bouldery, and bedrock.
6 SSURGO Hydric Condition (includes only entirely hydric soils and not partially hydric soils).
7 SSURGO restrictive layer < 60 inches from ground surface.

No areas of potential soil contamination were identified within the HVDC alternative routes representative ROW or ROI for Regions 1, 2, 3, or 6. An eGRID site and an EIA-860 site occur in the 200-foot-wide representative ROW for HVDC Alternative Route 4-B. These are electric power generation facilities and are not indicative of a potential contamination concern at this time. Another two facilities/sites were identified in the Region 4 HVDC alternatives ROI, but also do not raise a concern at this time in regards to areas of soil contamination. No sites/facilities were identified in the representative ROW for the HVDC alternative routes in Regions 5 or 7. Thirteen facilities/sites were identified in the Region 5 ROI and two in the Region 7 ROI, but they do not raise concerns at this time in regards to areas of soil contamination. In a public comment on the Draft EIS, the Tennessee Division of Solid Waste Management identified a potential concern in relation to the Chickasaw Bluffs (crossed by HVDC Alternate Route 7-C), where large gullies might have been used for illicit disposal of waste. The Applicant would implement EPMs to address previously undiscovered waste disposal sites and any necessary handling of waste materials in Project construction areas.

A route adjustment was developed for HVDC Alternative Route 3-A to maintain continuity with Applicant Proposed Route Link 1, Variation 1, and Links 1 and 2, Variation 1, which were developed in response to public comments on the Draft EIS. The route adjustment would have 1 acre less impact to designated farmland, over 3 acres less impact to soils with high water erosion potential, and almost 4 acres less impact to soils with high susceptibility to compaction.

A route adjustment was developed for HVDC Alternative Route 5-B to maintain continuity with Applicant Proposed Route Links 2 and 3, Variation 1, which was developed in response to public comments on the Draft EIS. The adjustment would have over 8 acres more impact to stony soils, but is otherwise similar in terms of soil resources impacts. A route variation was developed for HVDC Alternative Route 5-E in response to public comments on the Draft EIS to maintain continuity with Applicant Proposed Route Links 3 and 4, Variation 2. The variation would cross 0.3 acre more designated farmland and 0.8 acre more soil with high wind erosion potential.

A route adjustment was developed for HVDC Alternative Route 6-A to maintain continuity with Applicant Proposed Route Link 1, Variation 1, and Link 2, Variation 1, which were developed in response to public comments on the Draft EIS. The route adjustment would impact about 10 acres less designated farmland, 4 acres less soil with high water erosion potential, 10 acres less soil with high wind erosion potential, and 4 acres less soil with high susceptibility to compaction.

3.6.2.6.3.2.2 Operations and Maintenance Impacts

Impacts from operations and maintenance are described in Section 3.6.2.6.1.

3.6.2.6.3.2.3 Decommissioning Impacts

Impacts from decommissioning are described in Section 3.6.2.6.1.

3.6.2.6.4 Best Management Practices

One BMP has been identified that could avoid and minimize impacts to soils:

- If signs of contaminated soils are uncovered during construction activities, work would be stopped in the area of potentially contaminated soils until appropriate Project representatives could be consulted.

3.6.2.6.5 Unavoidable Adverse Impacts

The Project would result in unavoidable impacts to soil resources during construction and operations and maintenance phases. Removal of vegetation during construction grading and excavation activities associated with the Project could result in the exposure of soils to erosion and compaction of soils susceptible to compaction. Transmission line structures and converter station sites would permanently impact agricultural soils and remove them from productivity during construction and operations and maintenance. Access roads used during construction would temporarily remove agricultural soils from productivity, and the use of unpaved access roads during all Project phases could result in the exposure of soils to erosion and compaction. All Project phases could result in the loss of fertile topsoil from activities that would either remove topsoil or expose topsoil to erosion. Adverse impacts therefore include the potential depletion of soil productivity, including erosion and loss of fertile topsoil and potential erosion of exposed areas and compaction of areas traversed by equipment and vehicles. Reclamation activities and Applicant EPMs would be implemented to avoid and minimize adverse impacts to soil resources. However, the loss of soil resources used for agricultural activities within the Project footprint during construction and operations and maintenance of the Project is unavoidable.

3.6.2.6.6 Irreversible and Irretrievable Commitment of Resources

There would be no irreversible and irretrievable commitments of soil resources provided that all transmission line concrete foundations, converter station facilities, and access roads were removed and successful reclamation was achieved as part of decommissioning the Project.

3.6.2.6.7 Relationship between Local Short-term Uses and Long-Term Productivity

Overall site productivity is primarily a matter of revegetation/reclamation success and availability for agricultural or other uses. Impacts to short-term uses of soil resources would result from construction and operations and maintenance of the Project, while impacts to long-term productivity would depend on the success of the reclamation activities. Short-term impacts are associated with land areas directly affected by construction and operations and maintenance of the Project. Short-term impacts include the construction and use of access roads during the construction phase of the Project and the use of access roads for operations and maintenance. Other short-term impacts to soil resources could occur at the footprint areas of construction work areas, converter station sites, transmission line structures, fiber optic sites, and construction tensioning and pulling areas. These areas could all be returned to other productive uses following decommissioning. A decrease in the long-term productivity of soils would result if soils were not reclaimed to their existing quality condition including such characteristics as aeration, permeability, texture, salinity and alkalinity, microbial populations, fertility, and other physical and chemical characteristics that are accepted as beneficial to overall plant growth and establishment.

3.6.2.6.8 Impacts from Connected Actions

3.6.2.6.8.1 Wind Energy Generation

3.6.2.6.8.1.1 Construction Impacts

The potential impacts to soils common to all Project components (Section 3.6.2.6.1.1) apply to similar activities during wind energy generation. Specific locations of wind generation facilities are not known at this time and therefore specific impacts to designated farmland, soil limitation parameters, or contaminated soil cannot be determined. Based on the general characteristics of the WDZs, some affected soils may be susceptible to compaction or have moderate to high wind erosion potential. The remaining soil limitation characteristics are not prominent in the WDZs.

Most of the EPA FRS sites located in WDZs are indicative of a records inventory of such regulated sites and do not raise a concern at this time in regards to areas of soil contamination. If wind development is considered in feedlot discharge areas, areas of potential leaking storage tanks, or other potential contaminant release areas, the developers may collect additional information to avoid potential soil contamination.

3.6.2.6.8.1.2 Operations and Maintenance

Permanent wind farm facilities that would impact soils include turbine footprint areas, collector lines, substations, meteorological towers, operation and maintenance buildings, and access roads for the maintenance and operation of these facilities. A conservative estimate is that this infrastructure would impact 1 percent of each WDZ-where wind energy generation occurs. Permanent facilities would typically be maintained for proper drainage and vegetation specifications and would not contribute to soil erosion hazards. Placement of these facilities in areas of steep slopes would typically be avoided or minimized to prevent erosion or other hazards.

Permanent impacts to designated farmland during operations and maintenance would include conversion of the operations and maintenance facility, wind turbine, substation, and access roads to these facilities. Temporary construction areas would be reclaimed for potential farmland use. Designated farmland could continue to be used in areas above underground lines and surrounding these facilities and structures. Agricultural activities such as cultivating crops and livestock grazing are generally permitted up to the wind turbine pads, so only a very minimal area of existing agricultural land would be removed from production for the life of the Project, although long-term access roads and the configuration of wind turbines may change the configuration of fields for crops and grazing.

Operation and maintenance activities have the potential to result in the release of fuels, oil, hydraulic fluid, and other potential contaminants to area soils. Such releases would be most likely to occur at wind turbines, substations, and the operations and maintenance facilities. Operations practices generally include measures to avoid releases of contaminant materials. However, in the event of such releases, immediate actions would be generally implemented to contain and clean up such materials. Adsorbent and containment materials would be generally stored in appropriate areas and workers would likely be trained for such events.

3.6.2.6.8.1.3 Decommissioning Impacts

Wind farm decommissioning could occur at the end of the useful life of the facilities and if the facilities were no longer required. Decommissioning of the WDZs could result in temporary impacts to soil resources, similar to those for construction (e.g., increased sedimentation, erosion, soil compaction, limited direct removal of vegetation, and accidental spills of chemicals). Impacts related to soil disturbance during decommissioning are anticipated to be similar to construction but would be temporary. Impacts to soils would be associated with the removal of wind farm infrastructure, temporary storage of waste and demolition debris, temporary access roads for such removal, and any related clearing and grading that might be necessary. Similar EPMs and BMPs that would be implemented during decommissioning activities for the Project would typically be implemented for the wind generation facilities to avoid and minimize impacts to soil resources.

3.6.2.6.8.2 Optima Substation

Potential impacts to designated farmland may occur, including potential conversion to utility uses. Construction activities may result in soil compaction and erosion given the susceptibility of existing soils. Implementation of a SWPPP would reduce the likelihood for soil erosion.

3.6.2.6.8.3 TVA Upgrades

General impacts from the construction of the new 500kV transmission line would be similar to those described for the Project. Depending on the locations of the required TVA upgrades, ground-disturbing activities could result in decreased productivity and quality of designated farmland and in places of permanent structures some farmland could be taken out of production. Site-specific soil characteristics would determine the potential for erosion impacts to erosion-prone or steep soils or potential compaction impacts from construction vehicles and equipment to soils with high compaction potential. The upgrades to existing transmission lines and the new transmission line, like the Project, are linear (long, narrow) projects with relatively small amounts of ground disturbance considering the amount of area crossed.

3.6.2.6.9 Impacts Associated with the No Action Alternative

Under the No Action Alternative, DOE assumes for analytical purposes that the Project would not be constructed and soils would not be impacted. The land would continue to be used for existing agricultural and other uses.

Figures Presented in Appendix A

3.7 Groundwater

3.7.1 Regulatory Background

Laws and regulations associated with the management and protection of groundwater could affect the Project or the manner in which it would be implemented. Key elements of select federal and state laws and regulations associated with groundwater management are summarized in Table 3.7-1.

Table 3.7-1:
Federal and State Laws and Regulations Associated with Groundwater Management

Statute/Regulation	Key Elements
Safe Drinking Water Act (42 USC § 300f *et seq.*)	Establishes measures to protect the quality of public water supplies and sources of drinking water Requires states to develop Wellhead Protection Programs to protect public water supply wells
Oklahoma	
Oklahoma Administrative Code 785:30, "Taking and Use of Groundwater"	Requires a permit for use of groundwater for any purpose other than domestic use
Oklahoma Administrative Code 785:45, "Oklahoma's Water Quality Standards"	Establishes groundwater protection measures through groundwater classification, beneficial use designations, and vulnerability level designations Specifies that no groundwater degradation will be allowed that will interfere with attainment or maintenance of an existing or designated beneficial use
Oklahoma Administrative Code 785:46, "Implementation of Oklahoma's Water Quality Standards"	Ensures compliance with the anti-degradation standard by limiting permitted groundwater withdrawals to the maximum annual yield and avoiding withdrawals that would cause contaminated groundwater or surface water to move into groundwater not already contaminated
Arkansas	
Arkansas Act 1051 of 1985	Requires non-domestic users of groundwater or a natural spring involving potential flow rates of more than 50,000 gallons per day to report withdrawals to the Arkansas Natural Resources Commission (ANRC) (pre-use notification is not required)
Arkansas Act 154 of 1991	Requires the ARNC to define critical groundwater areas, sustainable yield, and groundwater level trends and gives ANRC authority to regulate groundwater use in designated critical groundwater areas (such regulations have not yet been proposed)
Arkansas Act 472 of 1949	Establishes authority for development and implementation of groundwater quality standards, which are currently being drafted by the ANRC
Tennessee	
Chapter 0400-40-03, General Water Quality Criteria	Establishes groundwater classifications and quality criteria Describes TDEC authority to require remediation when a release or other event causes groundwater to not meet applicable quality criteria Requires landowner or prospective purchaser of property to notify TDEC if groundwater testing shows contamination in excess of applicable groundwater quality criteria
Chapter 0400-45-08, Water Registration Requirements	Requires users withdrawing water from either a surface or groundwater source at an average rate of 10,000 gallons or more per day to be pre-registered with the TDEC (agricultural, emergency and certain non-recurring withdrawals are exempt) Purchase of water from a utility is not considered withdrawal
Texas	
Texas Administrative Code 30-293.19 and 30-294.41–294.44	Sets procedures for the designation of Priority Groundwater Management Areas and issues related to creation of Groundwater Conservation Districts in designated management areas

3.7.2 Data Sources

Data were obtained from multiple publicly available sources. Because of the length of the area being evaluated as part of the Project, the analysis relies strongly on GIS datasets (GIS Data Sources: EPA 2011; ODEQ 2012; OWRB 2014, 2011a; AWWCC 2014; TWDB 2013; Clean Line 2013b, 2013c; USGS 2014a, 2004a) to develop a picture of resources within the ROI. GIS datasets were obtained primarily from federal and state programs. For example, the USGS National Hydrography Dataset was used as part of the effort to characterize the affected environment. Databases kept by state agencies were also used to search for specific groundwater-related information such as locations of leaking underground storage tanks. Representatives of state agencies were contacted in some cases and information was obtained via conversations or electronic correspondence. Much of the information presented in this section was obtained from state webpages.

Water use information presented in this section is from the USGS and is for the year of 2010. The USGS compiles water use data every 5 years and since the Draft EIS, the USGS data for 2010 were published and are presented in this Final EIS.

3.7.3 Region of Influence

3.7.3.1 Region of Influence for the Project

The ROI considered in the groundwater affected environment and subsequent evaluation of potential impacts varied by Project component and by specific environmental evaluations. The baseline ROIs for the Project are as presented in Section 3.1.1. When considering wells and well systems for the groundwater evaluation, the 1,000-foot-wide corridor ROI for transmission lines was increased by 150 feet on both sides to account for possible adverse effects of blasting, should it be required, within the main portions of the ROI. The ROI for the AC collection system, already at 2 miles wide, was not expanded for evaluating wells and well systems. The ROIs for groundwater evaluations other than wells and well systems are as described in Section 3.1.1.

3.7.3.2 Region of Influence for Connected Actions

The ROI for the wind energy generation, the future Optima Substation, and TVA upgrades is described in Section 3.1.1 for those actions.

3.7.4 Affected Environment

The affected environment for groundwater, as described separately for each region below, addresses the following elements:

- Principal Aquifers and Their Characteristics: The principal, or important, aquifers over which Project elements would be located are described for each region of the proposed HVDC transmission line route. The discussion of aquifer characteristics includes information, where available, on depths to the water table, groundwater quality, as well as areal extent. No EPA-designated sole-source aquifers occur within the Project ROI (GIS Data Source: EPA 2011).
- Groundwater of Special Interest: The ROI intersects areas where the applicable state has designated the underlying groundwater to be of particular value or concern. The discussion of each region below identifies the specific groundwater designations and the amount of area in which the various Project components overlie designated groundwater.

- Wells and Wellhead Protection Areas: The discussion of each region below identifies the number of public, domestic, agricultural, and industrial water supply wells located within the ROI for the various Project components. Similarly, the discussion identifies the crossing areas for designated wellhead protection areas and the locations of springs (only applicable to Region 4).
- Groundwater Use: The discussion presents water use by county based on 2010 data published by the USGS. As noted in Section 3.7.2, this represents updated information compared to the Draft EIS, which presented USGS data for 2005. The USGS data are presented by use category and note whether the source is groundwater or surface water. To present a complete picture, a county's entire water use is presented together in a single table.

Several route variations for the Applicant Proposed Route in Regions 2 to 7 were developed in response to public comments on the Draft EIS and are described in Appendix M and summarized in Section 2.4.2.1 to 2.4.2.7. Brief descriptions of the groundwater elements that could be affected by the route variations by Project region, including accompanying adjustments to HVDC alternative routes, are provided below. The variations are presented graphically in Exhibit 1 of Appendix M.

3.7.5 Regional Description

Because this EIS considers a linear project that covers a long distance, the area analyzed crosses many groundwater features. Rather than identifying individual features along the more than 700-mile route, the following sections present Regions 1–7 in terms of the compiled area or number of elements (Section 3.7.4) within the ROI. Only the more important or significant groundwater features or feature locations within each region are identified individually. The individual regional discussions identify the important aquifers that underlie that portion of the route. Figure 3.7-1 (located in Appendix A) depicts the locations of the aquifers beneath all seven of the regions.

The regional descriptions in this section also identify groundwater features and elements found within a representative ROW consisting of a 200-foot-wide corridor within the 1,000-foot-wide ROI of the HVDC transmission line routes. This information is used in evaluating potential impacts of the Project in Section 3.7.6. The ROW features and elements are included here in the affected environment in order to provide the reader an easy comparison between features in the ROI and what would be expected in a smaller ROW. Consistent with the ROI discussion of Section 3.7.3, well data for the ROW are based on a 500-foot-wide corridor (i.e., 150 feet added to each side of the 200-foot-wide ROW) to incorporate wells or well systems that potentially could be impacted if blasting were done in the ROW.

3.7.5.1 Region 1

No route variations were proposed in Region 1.

3.7.5.1.1 Region 1 Principal Aquifers and Their Characteristics

Much of Region 1 overlies the High Plains aquifer, one of five principal aquifers or aquifer systems along the ROI. The High Plains aquifer underlies a large area that includes parts of Texas, Colorado, Kansas, Nebraska, New Mexico, South Dakota, and Wyoming as well as western Oklahoma (GIS Data Sources: OWRB 2011a; USGS 2003). The aquifer, often referred to as the Ogallala Aquifer, consists of poorly consolidated layers of sand, silt, clay, and gravel with intermittent well-cemented zones of the Ogallala Formation (OWRB 2012). As shown in Figure 3.7-1 in Appendix A, the High Plains aquifer underlies the AC collection system routes as well as the Oklahoma Converter Station Siting Area. The eastern end of Region 1 is outside the general bounds of the High Plains aquifer. At its eastern end, Region 1 overlies an alluvial aquifer associated with the Beaver or North Canadian River. This aquifer is considered a major alluvial aquifer by the state (GIS Data Source: OWRB 2011a). As indicated by its name, the North Canadian River alluvial aquifer follows the path of the North Canadian River, which in this area is roughly from the northwest to the southeast.

In Oklahoma, the depth below ground surface (BGS) to the water table of the High Plains aquifer ranges from less than 10 feet to greater than 300 feet and the thickness of the saturated zone can range from nearly zero to almost 430 feet. Wells tapping into the High Plains aquifer commonly yield 500 to 1,000 gallons per minute and, in thick highly permeable areas, can yield up to 2,000 gallons per minute. Pumping rates throughout the aquifer, however, have typically exceeded recharge rates and declining groundwater levels have been common (OWRB 2012).

3.7.5.1.1.1 Aquifer Annual Yield

The maximum annual yield of an aquifer is the maximum amount of water that can be removed from a groundwater basin on an annual basis without degrading the groundwater resource. In Oklahoma, the concept of maximum annual yield carries the stipulation that the amount of groundwater removed must allow a minimum 20-year life for the basin. The state estimates the maximum annual yield of the portion of the High Plains aquifer that underlies the Oklahoma Panhandle at about 2.29 million acre-feet (OWRB 2014), which equates to an average daily removal rate of just over 2,000 million gallons per day. When a maximum annual yield value is established and approved by the Oklahoma Water Resources Board, the state then distributes that yield across the groundwater basin to determine an equal proportionate share on a per-acre basis for overlying landowners. Within the Oklahoma Panhandle, the equal proportionate share for the High Plains aquifer is set at 2 acre-feet of water per year per acre of land (OWRB 2014) or an average daily removal rate of about 1,790 gallons per acre.

With regard to the North Canadian River alluvial aquifer, the state has determined a maximum annual yield of 426,000 acre-feet for the section of the aquifer that extends roughly from the western border of Harper County, through Woodward County, and to the southern border of Major County (OWRB 2014). The eastern end of Region 1 overlies a small portion of the alluvial aquifer in Harper County. This annual yield equates to a removal rate of about 380 million gallons per day. The equal proportionate share for this section of the alluvial aquifer is set at 1 acre-foot of water per year per acre of land (OWRB 2014) or an average daily removal rate of about 890 gallons per acre.

3.7.5.1.1.2 Depths to Water Table

The USGS National Water Information System contains groundwater level information for most of the nation, including each of the four Oklahoma counties that are included within Region 1. To ensure the data were reflective of current groundwater levels, DOE first queried the USGS data system for information collected since the start of 2012. If no recent county data were available, as was the case for some counties along the transmission line routes, the query criteria were modified to include entries back through 2005. Based on water level measurements taken since the start of 2012, the water table in Texas County is typically about 94 to 370 feet BGS, and in Beaver County it ranges from 15 to 240 feet BGS. The water table in Harper and Woodward counties can be shallower, ranging from 3 to 170 feet BGS (USGS 2014a).

According to recent (since 2012) data in the USGS data system, the five counties in which the AC collection system routes could be located (i.e., Beaver and Texas counties in Oklahoma and Sherman, Hansford, and Ochiltree counties in Texas) have depths to groundwater that range from 15 to 479 feet, with only Beaver County including a few wells with water table depths less than 30 feet (USGS 2014a). But even in Beaver County, the average depth to groundwater for the reporting locations is greater than 100 feet and the averages in the other four counties are all greater than 200 feet.

3.7.5.1.1.3 Groundwater Quality

Groundwater quality of the High Plains aquifer in Oklahoma is considered generally good, although localized areas contain high nitrate levels (OWRB 2012). In general, water in the aquifer south of the Canadian River (roughly 40 to 50 miles south of the Region 1 area of the Oklahoma Panhandle) begins having diminishing water quality in terms of increasing concentrations of total dissolved solids. North of the river, total dissolved solids concentrations are typically less than 400 milligrams per liter; the National Secondary Drinking Water Regulations (40 CFR Part 143, for aesthetic qualities) standard is 500 milligrams per liter. South of the river, large areas have concentrations more than twice the standard (George et al. 2011).

3.7.5.1.2 Region 1 Groundwater of Special Interest

Within Oklahoma, groundwater of special interest that could be crossed by the HVDC transmission line routes or underlie other Project components includes groundwater areas designated by the state as a Class I Special Source Groundwater or a Nutrient Vulnerable Groundwater. Class I groundwaters are areas with exceptional water quality, an irreplaceable source of water, a need to maintain an outstanding resource, or ecologically important groundwater. Class I groundwaters are also considered to be very vulnerable to contamination. Oklahoma further divides Class I into Subclass A for groundwater underneath watersheds of “Scenic Rivers,” Subclass B for groundwater underneath lands designated by regulation (specifically, Appendix B of Oklahoma Administrative Code (OAC) 785-45), and Subclass C for groundwater underneath state approved wellhead or source water protection areas (OAC 785-45-7-3). This section’s discussion is limited to Subclass A and B groundwater; wellhead protection areas are discussed in Section 3.7.5.1.3. Oklahoma also classifies groundwater areas with Class II, III, or IV designations, which are not considered to be of special interest for the current discussion because Class II is for general use groundwater, and Classes III and IV are for groundwater that is naturally of poor quality.

“Nutrient-vulnerable groundwater” is a designation Oklahoma gives to certain hydrogeologic basins considered to have a high or very high vulnerability to contamination from surface sources of pollution. The groundwater basins for the North Canadian, Cimarron, and Arkansas rivers in the ROI in Oklahoma have been designated Nutrient Vulnerable.

No Class I groundwater occurs in Region 1, although several thousand acres of land overlying nutrient-vulnerable groundwater do occur as shown Table 3.7-2. Also shown in parentheses in Table 3.7-2 are reduced areas of land in the 200-foot-wide corridor of the representative ROW that overlie groundwater of special interest.

Table 3.7-2:
Land Area in the 1,000-Foot-Wide Corridor (and the 200-Foot-Wide Representative ROW) of the HVDC Transmission Line Routes Overlying Groundwater of Special Interest—Region 1

Route—Proposed and Alternatives[1, 2]	Link 1	Link 2	Link 3	Link 4	Link 5	Total
Land Area Over Oklahoma Class 1 Special Source Groundwater—No groundwater of Class 1, Subclass A or B is within Region 1.						
Land Area Over Oklahoma Nutrient Vulnerable Groundwater						
APR (acres)	0	475 (96)	0	6 (0)	2,367 (474)	2,848 (570)
With AR 1-A (acres)	0	4,426 (884)				4,426 (884)
With AR 1-B (acres)	0	498 (101)		6 (0)	2,367 (474)	2,871 (575)

Table 3.7-2:
Land Area in the 1,000-Foot-Wide Corridor (and the 200-Foot-Wide Representative ROW) of the HVDC Transmission Line Routes Overlying Groundwater of Special Interest—Region 1

Route—Proposed and Alternatives[1, 2]	Link 1	Link 2	Link 3	Link 4	Link 5	Total
With AR 1-C (acres)	0	730 (147)		6 (0)	2,367 (474)	3,103 (621)
With AR 1-D (acres)	0	475 (96)	6 (0)		2,367 (474)	2,848 (570)

1 Each region of the Applicant Proposed Route (APR) is divided into links that lie between points, or nodes, where the APR is intersected by alternative routes (ARs). ARs bypass specific links of the APR as shown in the table.
2 For the ARs, the unshaded portion of the rows provides the data for the length of the AR. The shaded portion of the rows provides the data for the balance of the APR, thereby providing perspective across the region.
GIS Data Sources: OWRB (2011b, 2011c)

Using the same groundwater categories as those described for Table 3.7-2, the acreage of lands within the total 2-mile-wide ROI corridors (and 200-foot-wide representative ROWs) of the AC collection system routes that overlie groundwater of special interest is as follows (routes not shown overlie no groundwater of special interest) (GIS Data Sources: OWRB 2011b, 2011c):

- Land area over Class 1 Special Source Groundwater: 1,003 acres (0 acres) total
  - Route E-1 in Texas and Beaver counties, Oklahoma: 967 acres (0 acres)
  - Route E-2 in Texas and Beaver counties, Oklahoma: 18 acres (0 acres)
  - Route NE-1 in Texas County, Oklahoma: 18 acres (0 acres)
- Land area over Nutrient-Vulnerable Groundwater: 27,093 acres (482 acres) total
  - Route E-1 in Texas and Beaver counties, Oklahoma: 9,893 acres (174 acres)
  - Route E-2 in Texas and Beaver counties, Oklahoma: 5,184 acres (97 acres)
  - Route E-3 in Texas and Beaver counties, Oklahoma: 5,369 acres (100 acres)
  - Route SE-1, the portion in Texas County, Oklahoma: 1,463 acres (14 acres)
  - Route SE-3, the portion in Texas and Beaver counties, Oklahoma: 5,184 acres (97 acres)

The above numbers for nutrient-vulnerable groundwater within the ROIs are large in comparison to the values shown in Table 3.7-2 for the HVDC transmission line route, primarily because of the wider ROI (2 miles) associated with the AC collection system routes. No groundwater areas of special interest underlie the AC collection system routes in Texas (TCEQ 2013), which include all or parts of AC Collection System Route SW-2 in Sherman and Hansford counties, AC Collection System Route SW-1 in Hansford County, AC Collection System Route SE-2 in Hansford County, AC Collection System Route SE-1 in Hansford and Ochiltree counties, and AC Collection System Route SE-3 in Ochiltree County.

No groundwaters of special interest are underneath the Oklahoma Converter Station Siting Area or the associated AC interconnection (GIS Data Sources: OWRB 2011b, 2011c).

3.7.5.1.3 Region 1 Wells and Wellhead Protection Areas

Because water supply wells or well systems could potentially be impacted by the Project, the affected environment for each region includes consideration of private or public water supply wells and agricultural and industrial water wells located in the ROI. The description of the affected environment also addresses areas that have been designated by the applicable state as wellhead protection areas. Oklahoma identifies three somewhat concentric zones within wellhead protection areas: a 300-foot fixed radius, a 2-year groundwater travel time boundary, and a 10-year groundwater travel time boundary. To be reasonably conservative, data analyzed for the EIS represent the total area within the boundary of the outermost zones.

Table 3.7-3 summarizes the number of private, public, agricultural, and industrial water supply wells in the Region 1 expanded ROIs (and 200-foot-wide representative ROWs plus 150-foot buffers). The table also provides the wellhead protection areas in the baseline ROIs (and 200-foot-wide representative ROWs). There are private, domestic water supply wells along the HVDC transmission line routes, but there are no public water supply wells within Region 1. The ROI for HVDC Alternative Routes 1-B and 1-C cross wellhead protection areas.

Table 3.7-3:
Water Supply Wells and Wellhead Protection Areas within the HVDC Transmission Line Routes—Region 1

Route—Proposed and Alternatives[1, 2]	Link 1	Link 2	Link 3	Link 4	Link 5	Total

Source: GIS Data Sources: ODEQ (2012), OWRB (2011a)

Again, the great number of wells and, to a lesser extent, the acreage of wellhead protection area are attributed to the much greater ROI width (2 miles) associated with the AC collection system routes.

No wells or wellhead protection areas are associated with the Oklahoma Converter Station Siting Area and one industrial well is located within the ROW of the AC interconnection.

3.7.5.1.4 Region 1 Groundwater Use

Groundwater and surface water uses in the counties crossed by the Region 1 ROI are summarized in Table 3.7-5. The average use of groundwater in the four-county area of Beaver, Harper, Texas, and Woodward counties in Oklahoma was about 372 million gallons per day in 2010 and the greatest share of that use, at about 62 percent, was attributed to irrigation. Mining, public water supplies, and livestock were the other notable use categories for groundwater in the four-county area. The use of 372 million gallons of groundwater per day is compared to the use of only 5.1 million gallons per day of surface water. Groundwater accounts for about 99 percent of area's total water usage, and all of the area's public water supplies consist of water from groundwater sources. This use is consistent with the characterization of the area being one where intermittent streams are much more frequently encountered than are perennial streams (Section 3.15.5.1).

Table 3.7-5:
Average 2010 Water Use by Water Source and Category in Region 1 Counties (in million gallons per day)

County Source	Public Water Supply	Domestic Self-Supplied	Industrial Self-Supplied	Irrigation	Live-stock	Aqua-culture	Mining	Thermo-electric	Totals
Groundwater Sources									
Beaver, OK	0.49	0.23	0	24.60	2.54	0	14.07	0	41.93
Harper, OK	0.94	0.07	0	2.30	1.29	0	0.33	0	7.93
Texas, OK	7.46	0.19	0.02	198.00	8.74	0	87.13	0	301.54
Woodward, OK	6.63	0.35	0.40	5.50	1.98	0	8.02	1.02	23.90
Subtotals	15.52	0.84	0.42	230.40	14.55	0	109.55[1]	1.02	372.30
Surface Water Sources									
Beaver, OK	0	0	0	0.10	0	0	0	0	0.10
Harper, OK	0	0	0	4.02	0	0	0	0	4.02
Texas, OK	0	0	0	0.40	0	0	0	0	0.40
Woodward, OK	0	0	0	0.54	0	0	0	0	0.54

Totals	15.52	0.84	0.42	235.46	14.55	0	109.55	1.02	377.36

1 Of the 109.55 million gallons per day, 109.02 million gallons are identified as coming from saline groundwater sources, compared to only 9.27 million gallons per day coming from saline groundwater sources and used for mining in 2005.

Source: USGS (2014b)

Table 3.7-6 summarizes the average 2010 water use in the five-county area of Beaver and Texas counties in Oklahoma, and Hansford, Ochiltree, and Sherman counties in Texas that encompass the AC collection system routes. The predominant use of groundwater in the five-county area is even more apparent than for the four-county area described above. In the five-county area, surface water use at about 2.0 million gallons per day is less than 0.3 percent of the area’s total water use of 736 million gallons per day. Of the 734 million gallons per day of groundwater used in the area, irrigation is by far the predominant use category. Irrigation is followed by the use categories of mining, livestock, and public water supplies.

Table 3.7-6:
Average 2010 Water Use by Water Source and Category in the Counties of the AC Collection System Routes (in million gallons per day)

County Source	Public Water Supply	Domestic Self-Supplied	Industrial Self-Supplied	Irrigation	Live-stock	Aqua-culture	Mining	Thermo-electric	Totals

1 Of the 102.88 million gallons per day, 102.23 million gallons is identified as coming from saline groundwater sources, compared to only 8.96 million gallons per day coming from saline groundwater sources and used for mining in 2005.

Source: USGS (2014b)

3.7.5.2 Region 2

Two route variations to the Applicant Proposed Route were developed in Region 2 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.2. The variations (Applicant Proposed Route Link 1, Variation 1, and Applicant Proposed Route Link 2, Variation 2) are illustrated in Exhibit 1 of Appendix M. The discussion of Region 2 groundwater elements that follows includes identification of differences, if any, that would be expected with the route variations as compared to the original Applicant Proposed Route.

3.7.5.2.1 Region 2 Principal Aquifers and Their Characteristics

As shown in Figure 3.7-1 in Appendix A, no principal aquifers are present under Region 2, but the region does include two alluvial aquifers as well as an area of “other rocks,” which designates areas where there are only minor aquifers or no delineated aquifers. The western half of Region 2 overlies the North Canadian River alluvial aquifer that follows the Beaver/North Canadian River as mentioned in Section 3.7.5.1.1. This aquifer is considered a major alluvial aquifer by the state. Further to the east, Region 2 crosses over the Cimarron River alluvial aquifer that follows the Cimarron River, which the state also considers a major alluvial aquifer. The state identifies several minor alluvial and bedrock aquifers in between the two major alluvial aquifers and to the east of the Cimarron River alluvial aquifer that are crossed by the eastern half of Region 2 (GIS Data Source: OWRB 2011a). Neither of the two route variations to the Applicant Proposed Route developed in Region 2 would change the aquifers that would be crossed.

3.7.5.2.1.1 Aquifer Annual Yield

Oklahoma has determined a maximum annual yield of 426,000 acre-feet for the section of the North Canadian alluvial aquifer that extends roughly from the western border of Harper County, through Woodward County, and to the southern border of Major County (OWRB 2014). This annual yield equates to a removal rate of about 380 million gallons per day. Based on this yield, the state developed an equal proportionate share for area landowners of 1 acre-foot of water per year per acre of land or an average daily removal rate of about 890 gallons per acre.

The state has not finalized a maximum annual yield for the Cimarron River alluvial aquifer (OWRB 2014a), but has assigned a temporary equal proportionate share for area landowners of 2 acre-feet of water per year per acre of land (OWRB 2013a) or an average daily removal rate of about 1,790 gallons per acre.

3.7.5.2.1.2 Depths to Water Table

In the Oklahoma counties that contain Region 2, the USGS National Water Information System data collected in 2012 or later show the water table ranges from 3 to 170 feet BGS in Woodward County and ranges from 7 to 78 feet BGS in Major County. The USGS data system contained no recent (2012 or earlier) information for Garfield County, but searching the data back to 2005 shows water table depths in the county ranging from 4 to 41 feet below the surface (USGS 2014a).

3.7.5.2.1.3 Groundwater Quality

Water in Oklahoma's alluvial aquifers is generally of good quality, but in some western areas has high concentrations for chloride and sulfate and these aquifers are vulnerable to contamination from surface activities (OWRB 2012).

3.7.5.2.2 Region 2 Groundwater of Special Interest

Table 3.7-7 summarizes the acreage of land overlying groundwater of special interest in Region 2. No Class I groundwater areas occur within Region 2, but nutrient-vulnerable groundwater areas are present. Also shown in parentheses in Table 3.7-7 are the smaller land areas within the 200-foot-wide corridor of the representative ROW that overlie groundwater of special interest.

Table 3.7-7:
Land Area in the 1,000-Foot-Wide Corridor (and the 200-Foot-Wide Representative ROW) of the HVDC Transmission Line Routes Overlying Groundwater of Special Interest—Region 2

Route—Proposed and Alternatives[1, 2, 3]	Link 1	Link 2	Link 3	Region 2 Total
Land Area Over Oklahoma Class 1 Special Source Groundwater—No groundwater of Class 1, Subclass A or B is within Region 2				
Land Area Over Oklahoma Nutrient Vulnerable Groundwater				
APR (acres)	2,485 (494)	3,962 (780)	1,797 (361)	8,244 (1,635)
With AR 2-A (acres)	2,485 (494)	4,316 (861)	1,797 (361)	8,598 (1,716)
With AR 2-B (acres)	2,485 (494)	3,962 (780)	1,024 (206)	7,471 (1,480)

1 The values in the table do not reflect the minor changes that would result from application of the minor route variations and adjustments.
2 Each region of the Applicant Proposed Route (APR) is divided into links that lie between points, or nodes, where the APR is intersected by alternative routes (ARs). ARs bypass specific links of the APR as shown in the table.
3 For the ARs, the unshaded portion of the rows provides the data for the length of the AR. The shaded portion of the rows provides the data for the balance of the APR, thereby providing perspective across the region.
GIS Data Source: OWRB (2011c)

The two variations to the Applicant Proposed Route in Region 2 would involve very minor changes in the amount of nutrient-vulnerable groundwater area that would be crossed by the original Applicant Proposed Route. Link 1, Variation 1, would increase the area crossed by the 200-foot-wide ROW by about 1.5 acres, and Link 2, Variation 2, would decrease the area crossed by less than 1 acre.

3.7.5.2.3 Region 2 Wells and Wellhead Protection Areas

Table 3.7-8 summarizes the number of private (domestic), public, agricultural, and industrial water supply wells in the Region 2 expanded ROIs and expanded representative ROWs (with 150-foot buffers added to each side). The table also provides the wellhead protection areas in the baseline ROIs (and 200-foot-wide ROWs). Public water supply wells are only found in the ROI of HVDC Alternative Route 2-A.

Table 3.7-8:
Water Supply Wells and Wellhead Protection Areas within the HVDC Transmission Line Routes—Region 2

Route—Proposed and Alternatives[1, 2, 3]	Link 1	Link 2	Link 3	Region 2 Total
Private (Domestic) Water Supply Wells within a 1,300-Foot-Wide Corridor (and 500-Foot-Wide Corridor)				
APR	1 (1)	7 (1)	2 (0)	10 (2)
With AR 2-A	1 (1)	8 (2)	2 (0)	11 (3)
With AR 2-B	1 (1)	7 (1)	1 (1)	9 (3)
Public Water Supply Wells within a 1,300-Foot-Wide Corridor (and 500-Foot-Wide Corridor)				
APR	0	0	0	0
With AR 2-A	0	10 (2)	0	10 (2)
With AR 2-B	0	0	0	0
Agricultural Water Wells within a 1,300-Foot-Wide Corridor (and 500-Foot-Wide Corridor)				
APR	0	3 (2)	4 (3)	7 (5)
With AR 2-A	0	3 (0)	4 (3)	7 (3)
With AR 2-B	0	3 (2)	3 (1)	6 (3)
Industrial Water Wells within a 1,300-Foot-Wide Corridor (and 500-Foot-Wide Corridor)				
Applicant Proposed Route	3 (1)	2 (1)	1 (1)	6 (3)
With AR 2-A	3 (1)	2 (1)	1 (1)	6 (3)
With AR 2-B	3 (1)	2 (1)	0	5 (2)
Wellhead Protection Areas within a 1,000-foot-wide Corridor (and 200-foot-wide ROW)				
APR (acres)	0	0	34 (7)	34 (7)
With AR 2-A (acres)	0	116 (21)	34 (7)	150 (28)
With AR 2-B (acres)	0	0	0	0

1 The values in the table do not reflect the minor changes that would result from application of the minor route variations and adjustments.
2 Each region of the Applicant Proposed Route (APR) is divided into links that lie between points, or nodes, where the APR is intersected by alternative routes (ARs). ARs bypass specific links of the APR as shown in the table.
3 For the ARs, the unshaded portion of the rows provides the data for the length of the AR. The shaded portion of the rows provides the data for the balance of the APR, thereby providing perspective across the region.
GIS Data Sources: ODEQ (2012) OWRB (2014)

The two variations to the Applicant Proposed Route in Region 2 would involve a minimal change to the number of wells within the 500-foot-wide corridor of the end-to-end route—at most by one well. Neither of the Region 2 route variations involve wellhead protection area.

3.7.5.2.4 Region 2 Groundwater Use

Groundwater and surface water uses in the ROI in Region 2 are summarized in Table 3.7-9. The average use of groundwater in the three-county area of Garfield, Major, and Woodward counties in Oklahoma was about 49 million gallons per day in 2010, and the largest use category was public water supplies. Irrigation, mining, and livestock were the other notable uses of groundwater in the area. The amount of surface water used in the three-county area was much less at only about 2.6 million gallons per day. Groundwater accounts for about 95 percent of area's total water usage, and all of the area's public water supplies are taken from groundwater sources.

Table 3.7-9:
Average 2010 Water Use by Water Source and Category in Region 2 Counties (in million gallons per day)

County Source	Public Water Supply	Domestic Self-Supplied	Industrial Self-Supplied	Irrigation	Live-stock	Aqua-culture	Mining	Thermo-electric	Totals
Groundwater Sources									
Garfield, OK	4.77	0.13	0	1.10	0.12	0	2.44	0	8.56
Major, OK	6.12	0.18	0	7.60	1.78	0.01	0.83	0	16.52

1 Of the 11.29 million gallons per day, 11.18 million gallons are identified as coming from saline groundwater sources.
Source: USGS (2014b)

3.7.5.3 Region 3

Five route variations to the Applicant Proposed Route were developed in Region 3 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.3. The Applicant Proposed Route variations (Link 1, Variation 2; Links 1 and 2, Variation 1; Link 4, Variation 1; Link 4, Variation 2; and Link 5, Variation 2) are illustrated in Exhibit 1 of Appendix M. It should be noted that a route adjustment was made for HVDC Alternative Route 3-A to maintain an end-to-end route with the Links 1 and 2 variations. The discussion of Region 3 groundwater elements that follows includes identification of differences, if any, that would be expected with the route variations as compared to the original Applicant Proposed Route. The element discussions also address any changes attributed to the adjustment to HVDC Alternative Route 3-A.

3.7.5.3.1 Region 3 Principal Aquifers and Their Characteristics

As shown in Figure 3.7-1 in Appendix A, Region 3 crosses over two principal aquifers. HVDC Alternative Route 3-C passes over a small portion of the Central Oklahoma aquifer and the Applicant Proposed Route crosses the Ada-Vamoosa aquifer (or Vamoosa-Ada aquifer in some references). The Central Oklahoma aquifer underlies about 2,900 square miles, entirely in Oklahoma. The aquifer consists primarily of the Garber Sandstone in the Wellington Formation and is generally designated the Gabner-Wellington aquifer by the state. This bedrock aquifer is overlain in some places by the North Canadian River and Canadian River alluvial aquifers.

The Ada-Vamoosa aquifer underlies about 2,300 miles in east-central Oklahoma and extends northward into Kansas. It consists primarily of layers of fine- to coarse-grained sandstone of the Ada and Vamoosa groups. Its maximum thickness is about 900 feet, and the aquifer is confined at its western extent, but unconfined at its eastern extent, where it is near land surface.

Figure 3.7-1 in Appendix A identifies areas of no principal aquifers with an “other rocks” designation to the west of the Central Oklahoma aquifer, to the east of the Ada-Vamoosa aquifer, and in between the two aquifer areas. The state identifies no major or minor aquifers in these areas; on a state map, they are designated as areas with “no delineated aquifer boundary” (GIS Data Source: OWRB 2011a). The very eastern end of Region 3 may be over the Arkansas River alluvial aquifer, which is considered to be a major alluvial aquifer by the state, but for purposes of this discussion, it is assumed this aquifer starts beneath the western end of Region 4 as discussed in Section 3.7.5.4.1.

Neither the route variations to the Applicant Proposed Route developed in Region 3 nor the adjustment to HVDC Alternative Route 3-A would change the aquifers that would be crossed.

3.7.5.3.1.1 Aquifer Annual Yield

The state has not finalized a maximum annual yield for the Central Oklahoma (or Garber-Wellington) aquifer (OWRB 2014), but has assigned a temporary equal proportionate share for area landowners of 2 acre-feet of water per year per acre of land (OWRB 2013a) or an average daily removal rate of about 1,790 gallons per acre.

The state has determined a maximum annual yield of about 2.97 million acre-feet for the Oklahoma portion of the Ada-Vamoosa aquifer (OWRB 2014), which equates to a removal rate of about 2,650 million gallons per day. Based on this yield, the state developed an equal proportionate share for area landowners of 2 acre-feet of water per year per acre of land, which equates to an average daily removal rate of about 1,790 gallons per acre.

3.7.5.3.1.2 Depths to Water Table

Depth to water in the Central Oklahoma aquifer varies from less than 100 feet to 350 feet BGS (OWRB 2012). For the Ada-Vamoosa aquifer, a 1986 study by the USGS and Oklahoma Geological Survey reported depths in Creek, Lincoln, and Payne counties ranging from 3 to 280 feet BGS (D’Lugosz et al. 1986). Of the eight Oklahoma counties that encompass Region 3, the USGS National Water Information System has very limited data as recent as 2012; in one Creek County well the depth to the water table is 37 feet BGS and in two Lincoln County wells the depth is about 100 feet BGS. Considering data in the USGS system back through 2005, depths to groundwater range from 4 to 41 feet below the ground surface in Garfield County, from 1 to 39 feet in Kingfisher County, from 3 to 140 feet in Logan County, from 12 to 36 feet in Payne County, and 130 to 160 feet in Okmulgee County. Even going back to 2005, there were no data available for Muskogee County (USGS 2014a).

3.7.5.3.1.3 Groundwater Quality

Water quality in the Central Oklahoma aquifer is considered good, but nitrate is reported in some shallow portions of the aquifer and high concentrations of arsenic, chromium, and selenium can be found in some deep parts. Water quality in the Ada-Vamoosa aquifer is also considered good, but iron filtration and hardness are issues in some areas (OWRB 2013a).

3.7.5.3.2 Region 3 Groundwater of Special Interest

Table 3.7-10 summarizes the acreage of land overlying groundwater of special interest in Region 3. No Class I groundwater areas occur within Region 3, but nutrient-vulnerable groundwater areas are present. Also shown in parentheses in Table 3.7-10 are the smaller land areas of the 200-foot-wide ROW corridor that overlie groundwater of special interest.

Table 3.7-10:
Land Area in the 1,000-Foot-Wide Corridor (and the 200-Foot-Wide Representative ROW) of the HVDC Transmission Line Routes Overlying Groundwater of Special Interest—Region 3

Route—Proposed and Alternatives[1, 2, 3]	Link 1	Link 2	Link 3	Link 4	Link 5	Link 6	Region 3 Total
Land Area Over Oklahoma Class 1 Special Source Groundwater—No groundwater of Class 1, Subclass A or B is within Region 3							
Land Area Over Oklahoma Nutrient Vulnerable Groundwater							
APR (acres)	303 (63)	55 (12)	245 (49)	698 (137)	0	0	1,301 (261)
With AR 3-A (acres)	23 (5)	55 (12)	245 (49)	698 (137)	0	0	1,039 (203)
With AR 3-B (acres)	112 (21)			698 (137)	0	0	810 (158)
With AR 3-C (acres)	303 (63)	55 (12)	651 (130)				1,009 (205)
With AR 3-D (acres)	303 (63)	55 (12)	245 (49)	698 (137)	0		1,301 (261)
With AR 3-E (acres)	303 (63)	55 (12)	245 (49)	698 (137)	0	0	1,301 (261)

1 The values in the table do not reflect the minor changes that would result from application of the minor route variations and adjustments.
2 Each region of the Applicant Proposed Route (APR) is divided into links that lie between points, or nodes, where the APR is intersected by alternative routes (ARs). ARs bypass specific links of the APR as shown in the table.
3 For the ARs, the unshaded portion of the rows provides the data for the length of the AR. The shaded portion of the rows provides the data for the balance of the APR, thereby providing perspective across the region.
GIS Data Sources: OWRB (2011b, 2011c)

Of the five variations to the Applicant Proposed Route in Region 3, only one variation, Links 1 and 2, Variation 1, would cross over nutrient-vulnerable groundwater area. This variation would increase the area crossed by the 200-foot-wide ROW by about 16 acres. The adjustment to HVDC Alternative Route 3-A would also cross over nutrient-vulnerable groundwater area, but its 200-foot-wide ROW would cross 0.4 acre less than the original HVDC alternative.

3.7.5.3.3 Region 3 Wells and Wellhead Protection Areas

Table 3.7-11 summarizes the number of private, public, agricultural, and industrial water supply wells in the Region 3 expanded ROI and the expanded ROW. The table also provides the wellhead protection areas in the baseline ROIs and 200-foot-wide representative ROWs. There are many private water supply wells in the region, but no public water supply wells or industrial wells and few agricultural wells. There are also only limited wellhead protection areas in the region.

Table 3.7-11:
Water Supply Wells and Wellhead Protection Areas of the HVDC Transmission Line Routes—Region 3

Route—Proposed and Alternatives[1, 2, 3]	Link 1	Link 2	Link 3	Link 4	Link 5	Link 6	Region 3 Total
Private (Domestic) Water Supply Wells within a 1,300-Foot-Wide Corridor (and 500-Foot-Wide Corridor)							
APR	5 (0)	3 (0)	24 (7)	10 (5)	0	0	42 (12)
With AR 3-A	6 (1)	3 (0)	24 (7)	10 (5)	0	0	43 (13)
With AR 3-B	22 (7)			10 (5)	0	0	32 (12)
With AR 3-C	5 (0)	3 (0)	23 (7)				31 (7)

Table 3.7-11:
Water Supply Wells and Wellhead Protection Areas of the HVDC Transmission Line Routes—Region 3

Route—Proposed and Alternatives[1, 2, 3]	Link 1	Link 2	Link 3	Link 4	Link 5	Link 6	Region 3 Total
With AR 3-D	5 (0)	3 (0)	24 (7)	10 (5)	1 (0)		43 (12)
With AR 3-E	5 (0)	3 (0)	24 (7)	10 (5)	0	0	42 (12)
Public Water Supply Wells within a 1,300-Foot-Wide Corridor—No public water supply wells are within Region 3.							
Agricultural Water Wells within a 1,300-Foot-Wide Corridor (and 500-Foot-Wide Corridor)							
APR	0	0	0	1 (0)	0	0	1 (0)
With AR 3-A	0	0	0	1 (0)	0	0	1 (0)
With AR 3-B	0			1 (0)	0	0	1 (0)

Industrial Water Wells within a 1,300-Foot-Wide Corridor—No industrial water wells are within Region 3.							
Wellhead Protection Areas within a 1,000-foot-wide corridor (and 200-foot-wide ROW)							
APR (acres)	0	0	0	0	0	0	0
With AR 3-A (acres)	0	0	0	0	0	0	0
With AR 3-B (acres)	4 (0)			0	0	0	4 (0)
With AR 3-C (acres)	0	0	53 (11)				53 (11)
With AR 3-D (acres)	0	0	0	0	0		0
With AR 3-E (acres)	0	0	0	0	0	0	0

1 The values in the table do not reflect the minor changes that would result from application of the minor route variations and adjustments.
2 Each region of the Applicant Proposed Route (APR) is divided into links that lie between points, or nodes, where the APR is intersected by alternative routes (ARs). ARs bypass specific links of the APR as shown in the table.
3 For the ARs, the unshaded portion of the rows provides the data for the length of the AR. The shaded portion of the rows provides the data for the balance of the APR, thereby providing perspective across the region.
GIS Data Sources: ODEQ (2012), OWRB (2014)

Wells are present in three of the five route variations in Region 3 (Links 1 and 2, Variation 1; Link 4, Variation 2; and Link 5, Variation 2), but the number of wells would increase at the most by six wells within the 500-foot-wide corridor of the end-to-end route. No wells are present in the 500-foot-wide corridor of the adjustment to HVDC Alternative Route 3-A. Neither the variations nor the adjustment would involve wellhead protection areas.

3.7.5.3.4 Region 3 Groundwater Use

Groundwater and surface water uses in the ROI in Region 3 are summarized in Table 3.7-12. A shift occurs in the use of surface water in this region as compared to Regions 1 and 2. The average use of groundwater in the eight-county area of Creek, Garfield, Kingfisher, Lincoln, Logan, Muskogee, Okmulgee, and Payne counties in Oklahoma was about 267 million gallons per day in 2010, compared to about 81 million gallons per day of surface water used in the same area. Groundwater accounts for about 77 percent of area’s total water usage. The largest use of groundwater in the eight-county area is for mining activities at 242 million gallons per day. Public water supplies, irrigation, and self-supplied domestic are the other notable uses of groundwater in the area.

Table 3.7-12:
Average 2010 Water Use by Water Source and Category in Region 3 Counties (in million gallons per day)

County Source	Public Water Supply	Domestic Self-Supplied	Industrial Self-Supplied	Irrigation	Live-stock	Aqua-culture	Mining	Thermo-electric	Row Totals
Groundwater Sources									
Creek, OK	1.24	0.62	0	0	0.06	0	209.82	0	211.74

Totals	49.96	5.39	9.57	17.28	7.85	0.26	241.69	15.90	347.90

1 Of the 241.55 million gallons per day, 240.54 million gallons are identified as coming from saline groundwater sources, compared to only 32.12 million gallons per day coming from saline groundwater sources and used for mining in 2005.

Source: USGS (2014b)

3.7.5.4 Region 4

Seven route variations to the Applicant Proposed Route were developed in Region 4 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.4. The Applicant Proposed Route variations (Link 3, Variation 1; Link 3, Variation 2; Link 3, Variation 3; Link 6, Variation 1; Link 6, Variation 2; Link 6, Variation 3; and Link 9, Variation 1) are illustrated in Exhibit 1 of Appendix M. The discussion of Region 4 groundwater elements that follows includes identification of differences, if any, that would be expected with the route variations as compared to the original Applicant Proposed Route.

3.7.5.4.1 Region 4 Principal Aquifers and Their Characteristics

As shown in Figure 3.7-1 in Appendix A, no principal aquifers underlie Region 4; rather, the figure identifies an area of “other rocks.” However, the western end of Region 4 overlies the Arkansas River alluvial aquifer that follows the Arkansas River as it traverses from northwest to southeast in this part of its reach. This aquifer is considered a major alluvial aquifer by the state. Past the Arkansas River alluvial aquifer to the east, Region 4 passes over a minor bedrock aquifer that extends to the Oklahoma-Arkansas border (GIS Data Source: OWRB 2011a).

In Arkansas, Region 4 proceeds through the Arkansas Valley. The geology of the valley has a predominance of shale and many subsurface interbeds are of similar low porosity. As a result, few rocks qualify as aquifers. Most wells in the area have poor yield (less than 10 gallons per minute), so communities rely heavily on surface water sources. The alluvium along the Arkansas River is an exception and represents a consistent source of groundwater, which is used primarily for irrigation (AGS 2014). In this area, the Arkansas River flows roughly west to east and lies to the south of the HVDC transmission line routes, also aligned in a west-east direction.

The route variations to the Applicant Proposed Route developed in Region 4 would not change the aquifers crossed.

3.7.5.4.1.1 Aquifer Annual Yield

Oklahoma has not finalized a maximum annual yield for the Arkansas River alluvial aquifer (OWRB 2014a), but has assigned a temporary equal proportionate share for area landowners of 2 acre-feet of water per year per acre of land (OWRB 2013b) or an average daily removal rate of about 1,790 gallons per acre. As noted above, aquifer yield within the Region 4 area of Arkansas is low.

3.7.5.4.1.2 Depths to Water Table

The USGS National Water Information System has no recent (2012 or newer) depth to groundwater information for the Oklahoma and Arkansas counties that encompass Region 4. The query was extended to 2005 or newer and available data indicate that the water table in two of the counties (Sequoyah County, Oklahoma, and Crawford County, Arkansas) ranges from 4 to 28 feet BGS (USGS 2014a). Even with the extended search timeframe, no data were available for the other four counties.

3.7.5.4.1.3 Groundwater Quality

Water in Oklahoma’s alluvial aquifers, such as the Arkansas River alluvial aquifer, is generally of good quality, but it is vulnerable to contamination from surface activities (OWRB 2012). On the Arkansas side of Region 4, few rock formations produce sufficient water to qualify as aquifers (AGS 2014).

3.7.5.4.2 Region 4 Groundwater of Special Interest

Table 3.7-13 summarizes the acreage of land overlying groundwater of special interest in Region 4. Both Class I groundwater areas and nutrient-vulnerable groundwater areas are present within Region 4. The Applicant Proposed Route passes over the Oklahoma-Arkansas state line within Link 3 of Region 4. No groundwater of special interest is crossed in Links 4 through 9. The Oklahoma designations of groundwater of special interest stop at the state line; Arkansas groundwater designations of special interest are not present underneath Region 4.

The Applicant has proposed a route variation in Region 4, the Lee Creek Variation, that is not included in Table 3.7-13. The Lee Creek Variation would move a short segment, slightly more than 3 miles in length, of Link 3 of the Applicant Proposed Route less than 0.5 mile to the north in the area of the Lee Creek Reservoir, which is roughly on the Oklahoma-Arkansas border. The variation then drops back south to join the Applicant Proposed Route. Land area of the Lee Creek Variation that overlies groundwater of special interest is estimated as follows:

- Land area over Oklahoma Class 1 Special Source Groundwater: approximately 170 acres in the 1,000-foot-wide corridor and 30 acres in the 200-foot-wide ROW

- Land area over Oklahoma Nutrient-Vulnerable Groundwater: approximately 250 acres in the 1,000-foot-wide corridor and 50 acres in the 200-foot-wide ROW
- The amount land overlying groundwater of special interest within the avoided segment of the Applicant Proposed Route would be very similar to the above values

Table 3.7-13:
Land Area in the 1,000-Foot-Wide Corridor (and the 200-Foot-Wide Representative ROW) of the HVDC Transmission Line Routes Overlying Groundwater of Special Interest—Region 4

Route Proposed and Alternatives[1, 2, 3]	Link 1	Link 2	Link 3[4]	Link 4	Link 5	Link 6	Link 7	Link 8	Link 9	Region 4 Total

With AR 4-D (acres)	22 (4)	109 (19)	402 (76)	0			0	0	0	533 (99)
With AR 4-E (acres)	22 (4)	109 (19)	402 (76)	0	0	0	0	0		533 (99)

1 The values in the table do not reflect the minor changes that would result from application of the minor route variations and adjustments.
2 Each region of the Applicant Proposed Route (APR) is divided into links that lie between points, or nodes, where the APR is intersected by alternative routes (ARs). ARs bypass specific links of the APR as shown in the table.
3 For the ARs, the unshaded portion of the rows provides the data for the length of the AR. The shaded portion of the rows provides the data for the balance of the APR, thereby providing perspective across the region.
4 Link 3 of Region 4 spans Oklahoma and Arkansas, so beyond Link 3 there are no Oklahoma groundwater designations. Region 4 does not cross over specially designated groundwater in Arkansas.
GIS Data Sources: OWRB (2011b, 2011c)

Within Arkansas, groundwaters of special interest are those areas designated by the state as “Critical Groundwater Areas.” These are areas where aquifers are experiencing significant declines in water table elevations or water quality degradation (ANRC 2005). The critical designation establishes authority for the state to initiate additional regulation of the groundwater area, but to date, no additional regulations have been proposed for any of the state’s designated groundwater areas (ANRC 2014). In the areas of Arkansas crossed by the HVDC transmission line routes, Region 6 traverses the Cache Critical Groundwater Area, which is described further in the Region 6 discussion (Section 3.7.5.6.2).

None of the seven route variations to the Applicant Proposed Route in Region 4 would cross over groundwater of special interest.

3.7.5.4.3 Region 4 Wells and Wellhead Protection Areas

Table 3.7-14 summarizes the number of private, public, agricultural, and industrial water supply wells in the Region 4 expanded ROI and the expanded ROW. The table also provides the wellhead protection areas in the baseline ROIs and the 200-foot-wide representative ROWs. There are private domestic water wells along the ROI of the HVDC transmission line routes. Only a few agricultural or industrial wells are encountered by any of the route ROIs. The Lee Creek Variation, not shown in the table, would not include any wells.

Source: Clean Line (2013); GIS Data Sources: ODEQ (2012), OWRB (2014), AWWCC (2014),

The seven route variations to the Applicant Proposed Route in Region 4 would have no effect on the number of wells within a 500-foot-wide corridor of the route.

It should be noted that the Arkansas well data included in Table 3.7-14, as well as in the corresponding tables for Regions 5, 6, and 7, came from a source (GIS Data Source: AWWCC 2014) that included a number of wells in the search area with no use designations. Wells with a blank designation were not included in the evaluations presented in this document because it was not known whether they were of possible concern if damaged, such as for the well categories shown in the table, or if they were abandoned or of some other limited value.

The only spring identified within any Project ROI is within Region 4. Dripping Spring is located just inside the 1,000-foot-wide corridor of HVDC Alternative Route 4-D in the area where it departs from the Applicant Proposed Route in Crawford County, Arkansas.

3.7.5.4.4 Region 4 Groundwater Use

Groundwater and surface water uses in the ROI in Region 4 are summarized in Table 3.7-15. Water use in this region has shifted further in favor of surface water than described in Region 3. The average use of groundwater in the six-county area of Muskogee and Sequoyah counties in Oklahoma, and Crawford, Franklin, Johnson, and Pope counties in Arkansas, was about 9.4 million gallons per day in 2010. Conversely, surface water use was almost 1,100 million gallons per day in the same area. Groundwater accounts for only about 0.9 percent of area's total water usage. The largest use of groundwater in the six-county area is for irrigation at an average of about 4.3 million gallons per day and the second largest use category is for mining, but it is followed closely by self-supplied domestic water use.

Table 3.7-15:
Average 2010 Water Use by Water Source and Category in Region 4 Counties (in million gallons per day)

Source: USGS (2014b)

3.7.5.5 Region 5

Five route variations to the Applicant Proposed Route were developed in Region 5 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.5. The Applicant Proposed Route variations (Link 1, Variation 2; Link 2, Variation 2; Links 2 and 3, Variation 1; Links 3 and 4, Variation 2; and Link 7, Variation 1) are illustrated in Exhibit 1 of Appendix M. It should be noted that route adjustments were made for HVDC Alternative Route 5-B to maintain an end-to-end route with Links 2 and 3, Variation 1, and for HVDC Alternative Route 5-E to maintain an end-to-end route with Links 3 and 4, Variation 2. The discussion of Region 5 groundwater elements that follows includes identification of differences, if any, that would be expected with the route variations as compared to the original Applicant Proposed Route. The element discussions also address any changes attributed to the adjustments to HVDC Alternative Route 5-B and HVDC Alternative Route 5-E.

3.7.5.5.1 Region 5 Principal Aquifers and Their Characteristics

Principal aquifers underlie Region 5 of the Project's ROI, but only at the very eastern end of the region. As shown in Figure 3.7-1 in Appendix A, the eastern end of Applicant Proposed Route in Region 5 overlies the Mississippi River Valley alluvial aquifer; all other portions of the route in this region are identified as an area of "other rocks." The largest portion of Region 5 is within the Arkansas Valley area described in Section 3.7.5.4.1, where there are few subsurface strata that yield sufficient water to qualify as aquifers. The exception is the Arkansas River alluvial aquifer, which follows the Arkansas River, although in Region 5 the river moves further away as the ROI progresses to the east.

The Mississippi River Valley alluvial aquifer at the eastern end of Region 5 is a principal aquifer that underlies about 33,000 square miles in Missouri, Kentucky, Tennessee, northwestern Mississippi, northeastern Louisiana, and eastern Arkansas. The aquifer consists primarily of a coarse sand and gravel layer that is overlain with silt, clay, and fine sand confining unit that hinders movement of water down into the aquifer. The confining unit ranges from less than 20 to more than 60 feet thick and the aquifer ranges from 25 to 150 feet thick (Renken 1998). In Arkansas, depth to the water table of the aquifer ranges from 0 to 115 feet (ANRC 2013). Wells pulling water from the Mississippi River Valley alluvial aquifer can have high yields, 500 gallons per minute is typical, some can yield 1,000 to 5,000 gallons per minute (Renken 1998).

Neither the route variations to the Applicant Proposed Route developed in Region 5 nor the adjustments to HVDC Alternative Route 5-B and HVDC Alternative Route 5-E would change the aquifers that would be crossed.

3.7.5.5.1.1 Aquifer Annual Yield

Aquifer yields in most of Region 5 are low as was described in Section 3.7.5.4.1. The estimated sustainable yield of the Mississippi River Valley alluvial aquifer (within the state) is 2,987 million gallons per day (ARNC 2012), which equates to about 3.3 million acre-feet per year.

3.7.5.5.1.2 Depths to Water Table

The USGS National Water Information System data collected in 2012 or later include well data in three of the seven Arkansas counties that compose Region 5. The depth to the water table in the single well in Faulkner County is 6 feet BGS, the water table ranges from less than 1 to 84 feet BGS in White County and the water table ranges from 11 to 73 feet BGS in Jackson County (USGS 2014a). For the other four counties, the data search was expanded to 2005 or later, but no data were available.

3.7.5.5.1.3 Groundwater Quality

Water from the Mississippi River Valley alluvial aquifer is generally of sufficient quality for most uses. Dissolved-solids concentrations are usually less than 500 milligrams per liter (the limit for esthetic qualities per 40 CFR Part 143), but in some areas, concentrations can range from 1,000 to 3,000 milligrams per liter (Renken 1998). Naturally occurring arsenic is found in some areas of the Mississippi River Valley alluvial aquifer and low concentrations (below drinking water standards) of pesticides are often detected in samples from the aquifer (EPA 2009).

3.7.5.5.2 Region 5 Groundwater of Special Interest

Region 5 of the Applicant Proposed Route crosses no Arkansas-designated critical groundwater areas.

3.7.5.5.3 Region 5 Wells and Wellhead Protection Areas

Table 3.7-16 summarizes the number of private, public, agricultural, and industrial water supply wells in the Region 5 expanded ROIs and the expanded ROWs. The table also provides the wellhead protection areas in the baseline ROIs and 200-foot-wide representative ROWs. Small numbers of private and agricultural wells are present in the region, but no public water supply wells or industrial wells. The amount of wellhead protection area in the region is also very small.

Table 3.7-16:

1 The values in the table do not reflect the minor changes that would result from application of the minor route variations and adjustments.
2 Each region of the Applicant Proposed Route (APR) is divided into links that lie between points, or nodes, where the APR is intersected by alternative routes (ARs). ARs bypass specific links of the APR as shown in the table.
3 For the ARs, the unshaded portion of the rows provides the data for the length of the AR. The shaded portion of the rows provides the data for the balance of the APR, thereby providing perspective across the region.
4 Arkansas considers the locations of wellhead protection areas to be confidential information and as such are not shown on any figures associated with this document. The entry in this table is presented because it provides only very general location information and is of value to the analysis.
Source: Clean Line (2013); GIS Data Source: AWWCC (2014)

There are no wells or wellhead protection areas in the Arkansas Converter Station Alternative Siting Area or in the associated AC Interconnection Siting Area, including the site of the new substation.

Wells are present in three of the five route variations proposed for the Applicant Proposed Route in Region 3 (Link 1, Variation 1; Links 2 and 3, Variation 1; and Links 3 and 4, Variation 2), but number of wells would increase at most by two wells within the 500-foot-wide corridor of the end-to-end route. No wells are present in the 500-foot-wide corridor of the adjustments to HVDC Alternative Route 5-B or HVDC Alternative Route 5-E. Neither the variations nor the adjustments would involve wellhead protection areas.

3.7.5.5.4 Region 5 Groundwater Use

Groundwater and surface water uses in the ROI in Region 5 are summarized in Table 3.7-17. Water use in this region is more evenly divided between groundwater and surface water than in Region 4, but surface water is the predominant source. The average use of groundwater in the seven-county area of Cleburne, Conway, Faulkner, Jackson, Pope, Van Buren, and White counties in Arkansas was about 460 million gallons per day in 2010. Surface water use was approximately 1,120 million gallons per day in the same area. Groundwater accounts for about 29 percent of area's total water usage. The largest use of groundwater in the six-county area is for irrigation at an average of about 450 million gallons per day. Public water supplies, aquaculture, livestock, and self-supplied domestic water are the other groundwater use categories of note. It should be noted that if the amount of surface water used for thermoelectric power plant cooling (Table 3.7-17) was dropped from the equation, groundwater would be the predominant source for water use in the area.

Table 3.7-17:
Average 2010 Water Use by Water Source and Category in Region 5 Counties (in million gallons per day)

3.7.5.6 Region 6

One route variation to the Applicant Proposed Route was developed in Region 6 in response to comments on the Draft EIS to parallel more parcel boundaries to minimize impacts to agricultural operations and is illustrated in Exhibit 1 of Appendix M. It should be noted that a route adjustment was made for HVDC Alternative Route 6-A to maintain an end-to-end route with Link 2, Variation 1. The discussion of Region 6 groundwater elements that follows includes identification of differences, if any, that would be expected with the route variation as compared to the original Applicant Proposed Route. The element discussions also address any changes attributed to the adjustment to HVDC Alternative Route 6-A.

3.7.5.6.1 Region 6 Principal Aquifers and Their Characteristics

As shown in Figure 3.7-1 in Appendix A, principal aquifers underlie all of Region 6. Most of the region is over the Mississippi River Valley alluvial aquifer, but in the central part of the region, the ROI crosses a narrow band of the Mississippi embayment aquifer system. In most areas, the Mississippi River Valley alluvial aquifer overlies the Mississippi embayment system. The Mississippi River Valley alluvial aquifer was described in Section 3.7.5.5.1. The description below focuses on the Mississippi embayment aquifer system.

The Mississippi embayment aquifer system is a system of regional aquifers, consisting primarily of semi-consolidated sand that underlies parts of Louisiana, Arkansas, Missouri, Illinois, Kentucky, Tennessee, Mississippi, Alabama, and Florida. The system comprises nine hydrogeologic units made up of six regional aquifers and three confining units, and can be up to 6,000 feet thick (Renken 1998). Within Arkansas, the state refers to the Sparta and Memphis Sands of the Mississippi embayment aquifer system as the Sparta/Memphis aquifer. Throughout the Mississippi embayment aquifer system, depth to water ranges from 37 to about 320 feet BGS (ANRC 2013). Yield from this aquifer system varies greatly depending on location and which regional aquifer is being pumped, but well production on the order of 300 to 1,000 gallons per minute are common and yields occasionally exceed 2,000 gallons per minute (Renken 1998).

Neither the route variation to the Applicant Proposed Route developed in Region 6 nor the adjustment to HVDC Alternative Route 6-A would change the aquifers that would be crossed.

3.7.5.6.1.1 Aquifer Annual Yield

As indicated in Section 3.7.5.5.1, the sustainable yield of the Mississippi River Valley alluvial aquifer (within the state) is estimated to be 2,987 million gallons per day (ANRC 2012), which equates to about 3.3 million acre-feet per year. The state estimates the sustainable yield for the Sparta/Memphis aquifer at 87 million gallons per day (ANRC 2012), which equates to about 97,500 acre-feet per year.

3.7.5.6.1.2 Depths to Water Table

The USGS National Water Information System includes 2012 or later data for all three of the Arkansas counties that compose Region 6. The depth to the water table in Jackson County ranges from 11 to 73 feet BGS, the water table ranges from 7 to 150 feet BGS in Poinsett County, and the water table ranges from 17 to 210 feet BGS in Cross County (USGS 2014a).

3.7.5.6.1.3 Groundwater Quality

Water quality in the Region 6 area of the Mississippi embayment aquifer system is generally good; dissolved-solids concentrations are less than 500 milligrams per liter (Renken 1998). Groundwater quality in the Mississippi River alluvial aquifer was described in Section 3.7.5.5.1.

3.7.5.6.2 Region 6 Groundwater of Special Interest

Table 3.7-18 summarizes the acreage of land overlying Arkansas critical groundwater areas in Region 6. The feature of interest in Region 6 is the Cache Critical Groundwater Area, which is crossed by the HVDC transmission line routes in Poinsett and Cross counties. The Cache Critical Groundwater Area, however, is much larger in extent than the counties, encompassing the Mississippi River Valley alluvial aquifer and the Memphis Sand aquifer and extending into seven Arkansas counties. The critical groundwater designation is attributed to significant groundwater depletion and the associated decrease in saturated thickness has the potential to cause salt water intrusion (ANRC 2009).

Table 3.7-18:
Land Area in the 1,000-Foot-Wide Corridor (and the 200-Foot-Wide Representative ROW) of the HVDC Transmission Line Routes Overlying Groundwater of Special Interest—Region 6

Route—Proposed and Alternatives[1, 2, 3]	Link 1	Link 2	Link 3	Link 4	Link 5	Link 6	Link 7	Link 8	Region 6 Total
Land Area Over Arkansas Critical Groundwater									
APR (acres)	0	0	64 (14)	798 (155)	236 (46)	1,519 (301)	0	0	2,617 (516)
With AR 6-A (acres)	0	711 (145)			236 (46)	1,519 (301)	0	0	2,466 (492)
With AR 6-B (acres)	0	0	70 (16)	798 (155)	236 (46)	1,519 (301)	0	0	2,623 (518)
With AR 6-C (acres)	0	0	64 (14)	798 (155)	236 (46)	1,511 (301)		0	2,609 (516)
With AR 6-D (acres)	0	0	64 (14)	798 (155)	236 (46)	1,519 (301)	0	0	2,617 (516)

1 The values in the table do not reflect the minor changes that would result from application of the minor route variations and adjustments.
2 Each region of the Applicant Proposed Route (APR) is divided into links that lie between points, or nodes, where the APR is intersected by alternative routes (ARs). ARs bypass specific links of the APR as shown in the table.
3 For the ARs, the unshaded portion of the rows provides the data for the length of the AR. The shaded portion of the rows provides the data for the balance of the APR, thereby providing perspective across the region.
GIS Data Source: ANRC (2014)

Neither the route variation to the Applicant Proposed Route developed in Region 6 nor the adjustment to HVDC Alternative Route 6-A overlie groundwater of special interest.

3.7.5.6.3 Region 6 Wells and Wellhead Protection Areas

Table 3.7-19 summarizes the number of private, public, agricultural, and industrial water supply wells in the Region 6 expanded ROIs and the expanded ROW. The table also provides the wellhead protection areas in the baseline ROIs and 200-foot-wide representative ROWs. None of the HVDC transmission line routes in Region 6 contain private or public water supply wells or industrial water supply wells. The 1,000-foot-wide corridors for all of the routes do, however, contain roughly the same number of agricultural wells, ranging from 28 to 31 wells. Only the ROI of HVDC Alternative Route 6-B would cross any wellhead protection areas.

Table 3.7-19:
Water Supply Wells and Wellhead Protection Areas within the HVDC Transmission Line Routes—Region 6

Route—Proposed and Alternatives[1, 2, 3]	Link 1	Link 2	Link 3	Link 4	Link 5	Link 6	Link 7	Link 8	Region 6 Total
Private (Domestic) Water Supply Wells within a 1,300-Foot-Wide Corridor—No domestic water supply wells are within Region 6									
Public Water Supply Wells within a 1,300-Foot-Wide Corridor—No public water supply wells are within Region 6									
Agricultural Water Wells within a 1,300-Foot-Wide Corridor (and 500-Foot-Wide Corridor)

With AR 6-C (acres)	0	0	0	0	0	0		0	0
With AR 6-D (acres)	0	0	0	0	0	0	0	0	0

1 The values in the table do not reflect the minor changes that would result from application of the minor route variations and adjustments.
2 Each region of the Applicant Proposed Route (APR) is divided into links that lie between points, or nodes, where the APR is intersected by alternative routes (ARs). ARs bypass specific links of the APR as shown in the table.
3 For the ARs, the unshaded portion of the rows provides the data for the length of the AR. The shaded portion of the rows provides the data for the balance of the APR, thereby providing perspective across the region.
4 Arkansas considers the locations of wellhead protection areas to be confidential information and as such are not shown on any figures associated with this document. The entry in this table is presented because it provides only very general location information and is of value to the analysis.
Source: Clean Line (2013); GIS Data Source: AWWCC (2014)

3.7.5.6.4 Region 6 Groundwater Use

Groundwater and surface water uses in the ROI in Region 6 are summarized in Table 3.7-20. The distribution of water use in this region has shifted back to groundwater as being the predominant source. The average use of groundwater in the three-county area of Cross, Jackson, and Poinsett counties in Arkansas was approximately 1,790 million gallons per day in 2010. About 152 million gallons per day of surface water were used in the same area. Groundwater accounts for about 92 percent of area's total water usage. Groundwater use was attributed primarily to irrigation; public water supplies and aquaculture were the other notable uses.

Table 3.7-20:
Average 2010 Water Use by Water Source and Category in Region 6 Counties (in million gallons per day)

3.7.5.7 Region 7

Three route variations to the Applicant Proposed Route were developed in Region 7 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.7. The Applicant Proposed Route variations (Link 1, Variation 1; Link 1, Variation 2; and Link 5, Variation 1) are illustrated in Exhibit 1 of Appendix M. The discussion of Region 7 groundwater elements that follows includes identification of differences, if any, that would be expected with the route variations as compared to the original Applicant Proposed Route.

3.7.5.7.1 Region 7 Principal Aquifers and Their Characteristics

As with Region 6, Region 7 passes over the Mississippi River Valley alluvial aquifer and the Mississippi embayment aquifer system (Figure 3.7-1 in Appendix A); the alluvial aquifer in the western and central portions of the region and the aquifer system in the eastern portion. Since both of these principal aquifers were described in the preceding discussions of Region 5 and 6 (Sections 3.7.5.5.1 and 3.7.5.6.1, respectively), the information will not be repeated here. The route variations to the Applicant Proposed Route developed in Region 7 would not change the aquifers crossed.

The eastern end of Region 7 is in Tennessee, so the information below is specific to the portion of Region 7 that is in Tennessee. Similar information for Arkansas was presented in the Region 5 and 6 discussions.

3.7.5.7.1.1 Aquifer Annual Yield

Tennessee has not yet developed estimates of sustainable yield for the aquifer underlying the eastern end of Region 7.

3.7.5.7.1.2 Depths to Water Table

The USGS National Water Information System includes 2012 or later data for both of the Arkansas counties and both of the Tennessee counties that compose Region 7. The depth to water table in Poinsett County, Arkansas, ranges from 7 to 150 feet BGS and from 7 to 54 feet BGS in Mississippi County, Arkansas. The single well in Tipton County, Tennessee, has a water table 34 feet BGS and, in Shelby County, Tennessee, the depth ranges from 11 to 170 feet BGS (USGS 2014a).

3.7.5.7.1.3 Groundwater Quality

The general quality of water in the Mississippi River Valley alluvial aquifer and the Mississippi embayment aquifer system was described in Sections 3.7.5.5.1 and 3.7.5.6.1.

3.7.5.7.2 Region 7 Groundwater of Special Interest

The Applicant Proposed Route passes over the Arkansas-Tennessee state line within Link 1 of Region 7. The Arkansas portion of Region 7 of the Applicant Proposed Route crosses over no critical groundwater areas. Similarly, the Tennessee portion of Region 7 crosses over no groundwater areas designated by the state as a Special Source Water (a groundwater with exceptional quality or quantity that may serve as a valuable source for water supply or which is ecologically significant) or a Site-Specific Impaired Groundwater (one that has been contaminated by human activity and for which remediation is not reasonable or technically feasible). As indicated above, groundwater of either designation was not found within Region 7. Tennessee also uses classifications of General Use Groundwater and Unusable Groundwater, which were not considered to be of special interest for the current discussion.

3.7.5.7.3 Region 7 Wells and Wellhead Protection Areas

Table 3.7-21 summarizes the number of private, public, agricultural, and industrial water supply wells in the Region 7 expanded ROIs and the expanded ROWs. There are no wellhead protection areas in the Region 7 ROI. The ROI corridor for HVDC Alternative Route 7-D is the only one containing private domestic water supply wells and is the only one that contains no agricultural wells.

Table 3.7-21:
Water Supply Wells and Wellhead Protection Areas within the HVDC Transmission Line Routes—Region 7

Route—Proposed and Alternatives[1, 2, 3]	Link 1	Link 2	Link 3	Link 4	Link 5	Region 7 Total
Private (Domestic) Water Supply Wells within a 1,300-Foot-Wide Corridor (and 500-Foot-Wide Corridor)						
APR	0	0	0	0	0	0
With AR 7-A	0	0	0	0	0	0
With AR 7-B	0	0	0		0	0
With AR 7-C	0	0	0			0
With AR 7-D	0	0	0	2 (0)		2
Public Water Supply Wells within a 1,300-Foot-Wide Corridor—No public water supply wells are within Region 7.						
Agricultural Water Wells within a 1,300-Foot-Wide Corridor (and 500-Foot-Wide Corridor)						
APR	11 (5)	0	0	0	0	11 (5)
With AR 7-A	18 (10)	0	0	0	0	18 (10)
With AR 7-B	11 (5)	0	1 (0)		0	12 (5)
With AR 7-C	11 (5)	0	1 (0)			12 (5)
With AR 7-D	11 (5)	0	0	0		11 (5)
Industrial Water Wells within a 1,300-Foot-Wide Corridor—No industrial water wells are within Region 7.						
Wellhead Protection Areas within a 1,000-foot-wide corridor—No wellhead protection areas are within Region 7.						

1 The values in the table do not reflect the minor changes that would result from application of the minor route variations and adjustments.
2 Each region of the Applicant Proposed Route (APR) is divided into links that lie between points, or nodes, where the APR is intersected by alternative routes (ARs). ARs bypass specific links of the APR as shown in the table.
3 For the ARs, the unshaded portion of the rows provides the data for the length of the AR. The shaded portion of the rows provides the data for the balance of the APR, thereby providing perspective across the region.
GIS Data Sources: AWWCC (2014), Clean Line (2013a, 2013b)

As can be seen in the table, there are no public or industrial water wells in Region 7. The table also shows no wellhead protection areas within Region 7, but in this case it is the result of insufficient information to determine any acreage values. The Millington Water Department and Naval Support Activity Mid-South in Shelby County, along with the Poplar Grove Utility District in Tipton County, are named community water systems in the Region 7 vicinity that utilize wells as water sources (TDEC 2003). Wells supplying community water systems would be associated with wellhead protection areas, but there was not sufficient location information to develop any estimates of crossing acreage. No wells or wellhead protection areas are located within the Tennessee Converter Station Siting Area and AC Interconnection Tie.

Two of the variations (Link 1, Variation 1, and Link 1, Variation 2) to the Applicant Proposed Route in Region 7 could increase the number of wells within the route corridor at most by two wells.

3.7.5.7.4 Region 7 Groundwater Use

Groundwater and surface water uses in the ROI in Region 7 are summarized in Table 3.7-22. The distribution of water use in this region again shows groundwater as the predominant source. The average use of groundwater in the four-county area of Mississippi and Poinsett counties in Arkansas, and Shelby and Tipton counties in Tennessee, was 1,440 million gallons per day in 2010. About 540 million gallons per day of surface water are used in the same area. Groundwater accounts for about 73 percent of area's total water usage. The largest use of groundwater in the four-county area is for irrigation at an average of approximately 1,210 million gallons per day and the second largest use category is for public water supplies at 190 million gallons per day. Public water supplies in the area were identified as coming entirely from groundwater sources.

Table 3.7-22:
Average 2010 Water Use by Water Source and Category in Region 7 Counties (in million gallons per day)

3.7.5.8 Connected Actions

3.7.5.8.1 Wind Energy Generation

3.7.5.8.1.1 Principal Aquifers and Their Characteristics

Wind energy generation would likely occur within WDZs. The WDZs are located within the Oklahoma and Texas Panhandles that overlie the High Plains aquifer, also known as the Ogallala aquifer, as shown in Figure 3.7-1 (located in Appendix A). Portions of Zones D and J are exceptions as they fall over the area of "Other Rocks" shown in Figure 3.7-1 in Appendix A that extends across Beaver County and into Texas County along the general course of the Beaver (or North Canadian) River. Alluvial materials along the general course of the Beaver River in Beaver and Texas counties may contain usable quantities of groundwater as in the North Canadian River alluvial aquifer just to the east, but the state of Oklahoma does not consider the Beaver and Texas county portions to be a major, or even a minor alluvial aquifer (OWRB 2012). The extent and characteristics of the High Plains aquifer were described in Section 3.7.5.1.1.

As described in Section 3.7.5.1.1, the maximum annual yield of the portion of the High Plains aquifer that underlies the Oklahoma Panhandle is estimated at about 2.29 million acre-feet per year. In Texas, the WDZs are located within the North Plains Groundwater Conservation District, which has set the allowable annual production for groundwater, beginning January 1, 2012, at 1.5 acre-feet per acre of land (North Plains Groundwater Conservation District 2013). Also as described in Section 3.7.5.1.1, groundwater in the portions of the High Plains aquifer north of the Canadian River, which includes all of the WDZs, is generally considered to be of good quality.

With regard to depths to the water table, the USGS National Water Information System contains groundwater level information for each of the three Oklahoma and three Texas counties that encompass the WDZs. Table 3.7-23 provides a summary of the depth to groundwater data for measurements taken since the beginning of 2012. As indicated in the table, the more shallow water tables occur in the eastern-most counties (that is, Beaver County in Oklahoma and Ochiltree County in Texas), but even in these counties, some areas have quite deep water tables.

Table 3.7-23:
Depths to Groundwater in the Oklahoma and Texas Counties with Wind Development Zones

County	Wind Development Zones within County	Groundwater Level Measurements Since 1-1-2012 in USGS Database		
		Number of Monitored Sites/Wells	Minimum Depth BGS (feet)	Maximum Depth BGS (feet)
Beaver, OK	J, K	26	16	238
Cimarron, OK	G	30	77	353
Texas, OK	D, E, F, G, H, I, J	68	94	367
Hansford, TX	A, B, C, F, L	58	39	453
Ochiltree, TX	A, K, L	42	30	479
Sherman, TX	C, F	45	229	369

Source: USGS (2014a)

3.7.5.8.1.2 Groundwater of Special Interest

Groundwater areas of special interest within Oklahoma are Class I Special Source Groundwater and Nutrient Vulnerable Groundwater as described in Section 3.7.5.1.2. In Texas, groundwater areas of special interest are those designated as Priority Groundwater Management Areas. Texas uses this designation for groundwater areas experiencing, or expected to experience, critical groundwater problems. However, the three Texas counties containing WDZs have no Priority Groundwater Management Areas (TCEQ 2013). Table 3.7-24 summarizes the acreage of land overlying groundwater of special interest within the WDZs. For comparison, the table also shows the total acreage of each WDZ.

Table 3.7-24:
Wind Development Zone Acreage over Groundwater of Special Interest

Wind Development Zone	Total Acreage of Zone	Special Interest Categories	
		Acreage Over Oklahoma Class I Special Source Groundwater	Acreage Over Oklahoma Nutrient Vulnerable Groundwater
A	109,747	NA[1]	NA[1]
B	125,479	NA[1]	NA[1]
C	161,048	NA[1]	NA[1]
D	69,189	319	1,743
E	47,092	0	0
F	112,461	0	0
G	187,315	0	0
H	116,226	0	0
I	105,203	0	2,496
J	92,567	0	20,081
K	92,894	0	0
L	165,848	NA[1]	NA[1]

1 NA = Not Applicable. WDZs A, B, C, and L are located in Texas, so would not be applicable to Oklahoma groundwater designations. The three Texas counties in which WDZs A, B, C, and L are located do not contain groundwater areas with special interest designations.
GIS Data Sources: OWRB (2011b, 2011c)

As can be seen in Table 3.7-24, with the exception of Zone J, there are either no groundwater areas of special interest underlying the WDZs or they are very small in comparison to the zone's total area. With regard to Zone J, almost 22 percent of the zone's total area is over Nutrient Vulnerable Groundwater. The single area of Oklahoma Class 1 Special Source Groundwater in Zone D has a Subclass B designation for groundwater underneath lands designated by regulation (specifically, Appendix B of OAC 785.45). In this case, the designation is because of the overlying Optima Wildlife Management Area.

3.7.5.8.1.3 Wells and Wellhead Protection Areas

Table 3.7-25 summarizes the number of private (domestic), public, agricultural, and industrial water supply wells and wellhead protection areas in each of the WDZs. In the first column, the table also includes the total area of each WDZ for comparison to the wellhead protection area. As can be seen in the table, all of the zones contain relatively large numbers of wells; four of the zones (WDZs E, F, I, and K) in excess of 250 water wells each. Possibly of more significance, three of the zones (WDZs A, F, and I) each contain 8 or 9 public water supply wells. Most of the WDZs contain wellhead protection areas, but in all cases the protected areas are small in comparison to the total zone acreage.

Table 3.7-25:
Water Wells and Wellhead Protection Areas within Each of the Wind Development Zones

Wind Development Zone Number—Acreage	Number of Wells by Use Category				Total Number of Wells	Wellhead Protection Area - Acreage
	Domestic Water Supply	Public Water Supply	Agricultural	Industrial

3.7.5.8.1.4 Groundwater Use

Groundwater and surface water uses in the three Oklahoma counties and three Texas counties that contain WDZs are summarized in Table 3.7-26. Also shown in the table are WDZs within each of the counties, many extending across more than one county and in some cases by very small amounts (for example, the portions of Zones F and K that extend into Texas counties). The average use of water in the six-county area was about 791 million gallons per day in 2010 and the vast majority (99.7 percent) came from groundwater sources. All of the area's public and private drinking water supplies were taken from groundwater. The predominant use for groundwater in the six-county area was irrigation with mining a distant second.

Table 3.7-26:
Average 2010 Water Use by Water Source and Category in Oklahoma and Texas Counties Containing Wind Development Zones (in million gallons per day)

County Source	Wind Development Zone within County	Water Use Categories[1]						Totals
		Public Water Supply	Domestic Self-Supplied	Industrial Self-Supplied	Irrigation	Livestock	Mining

1 The data source includes water use categories for aquaculture and thermoelectric power production, but there was no water use in those categories for the counties in the table.
2 Of the 103.54 million gallons per day, 102.89 million gallons are identified as coming from saline groundwater sources.
Source: USGS (2014b)

3.7.5.8.2 Optima Substation

The future Optima Substation would be on a 160-acre site located just east of the Oklahoma Converter Station and AC Interconnection Siting Areas. Groundwater features in the ROI for the Optima Substation would be as described in the Region 1 discussion above (Section 3.7.5.1) for the Oklahoma converter station and AC interconnection. The Optima Substation would overlie the High Plains Aquifer. The depth to groundwater in the vicinity (Texas County) is typically 94 to 370 feet BGS. No groundwater of special interest is present and no wells or wellhead protection areas are expected to be present.

3.7.5.8.3 TVA Upgrades

The ROI for the direct assignment facilities (which are included in the Applicant Proposed Project) would occur within the Tennessee Converter Station Siting Area and more specifically within the Shelby Substation. The ROI for the network upgrades, and in particular TVA's future 500kV transmission line, cannot be fully determined at this time. The new 500kV transmission line would be constructed in western Tennessee. The upgrades to existing facilities would mostly be in western and central Tennessee. Principal aquifers in this area include the unconfined Mississippi River Valley alluvial aquifer (described in Section 3.7.5.5.1) in the floodplains of major rivers and confined Tertiary and Cretaceous sand aquifers. Groundwater yields can be high and groundwater is the major source for public water supplies (Bohac and Bowen 2012; Webbers 2003).

Upgrades to existing infrastructure would include upgrading terminal equipment at three existing 500kV substations and six existing 161kV substations; making appropriate upgrades to increase heights on 16 existing 161kV transmission lines to increase line ratings, and replacing the conductors on eight existing 161kV transmission lines. Where possible, general impacts associated with the required TVA upgrades are discussed in the impact sections that follow.

3.7.6 Impacts to Groundwater

3.7.6.1 Methodology

This section addresses potential impacts to groundwater that would be expected from typical construction actions for Project components. Potential impacts to groundwater during operations and maintenance, which would be minor in comparison to those during construction, are addressed in the individual Project component discussions in Sections 3.7.6.2 and 3.7.6.3. Decommissioning impacts are also discussed by individual Project component, but are described in terms of their similarity to construction impacts. Typical construction impacts from construction activities include potential impacts related to release of contaminants directly to groundwater or that could infiltrate the ground and reach groundwater, changes to infiltration and recharge rates, effects on water availability, and physical damage to well systems as described below.

3.7.6.1.1 Potential for Groundwater Contamination

Project-related contaminants, primarily in the form of fuels and lubricants, would be present in equipment or storage containers at locations where construction activities would occur and at construction staging or storage yards. Additional potential contaminants would be associated with concrete operations, including at temporary concrete batch plants that would be needed for construction areas that are too far from commercial batch plants. In any of these locations there would be the potential for contaminants to leak, spill, or otherwise accidently release to the environment. If the released quantity were large enough and not cleaned up quickly, or if infiltrating precipitation or runoff carried the release downward, contamination could reach groundwater. If a release occurred, groundwater quality could be threatened and local agricultural or drinking water wells could become contaminated. Project-related chemicals and minerals would also come into direct contact with groundwater in instances where excavation and drilling used in foundation construction went below the water table. However, as explained further below, because of the plans and permitting requirements that the Applicant would follow when conducting construction activities and because of the non-toxic nature of relevant additives, it is unlikely that construction activities would result in contaminated groundwater.

Potential water contaminants, as well as the construction actions in which they would be used, would be managed in accordance with plans and procedures that the Applicant would be required to develop and implement. The construction would require a stormwater discharge permit under the EPA’s NPDES program (Appendix C). Each of the states in which construction actions would occur has been given the authority by EPA to implement a state program. Arkansas and Tennessee implement their own state programs pursuant to this authority; Oklahoma and Texas implement their own programs except in Indian country and for specific discharges (not applicable to the Project) where EPA implements the permitting program for stormwater discharges during construction (EPA 2013). Each of these states implements its National Pollutant Discharge Elimination System (NPDES) stormwater discharge permit program through a general permit, referred to here simply as the construction general permit. Common to all of the construction general permits is the requirement for the Applicant to prepare a SWPPP, which would describe and ensure implementation of practices to reduce pollutants in stormwater discharges associated with the construction activities.

The same permit requirements that address measures to prevent stormwater contamination would act to prevent groundwater contamination because they include measures to prevent releases. These measures may include items such as using secondary containment for onsite fueling tanks or containers; providing cover, containment, and protection for chemicals, liquid products, petroleum products, and other potentially hazardous materials; using spill prevention and control measures when conducting maintenance, fueling, and repair of equipment and vehicles; and providing immediate response to any spill incident. Similarly, Clean Line would develop and follow its own SPCCP (Section 2.1.7) to minimize the potential for accidental discharge of hazardous or controlled substances. Should such a discharge occur, the elements of the SPCCP would also minimize the potential for contaminants to leave the site or reach groundwater.

Concrete operations are mentioned separately because they are common to construction actions and involve equipment carrying materials of concern in addition to fuels and lubricants. Clean Line would perform washout of concrete trucks and equipment, either at the construction site or at a temporary batch plant, at storage tanks, plastic-lined berms, or some similar containment structure. Captured liquids would not be discharged; rather, they would be allowed to evaporate or removed for disposal at an approved offsite location. Dried concrete would similarly be hauled off for proper disposal or recycling, or be broken up and used as clean fill. Clean Line may also bury hardened concrete in onsite embankments in accordance with applicable permit requirements (see Appendix F).

The deepest foundations would be those for the transmission line structures. In most instances, foundation depths for lattice structures would be about 15 feet, and for pole structures, the depths would be about 30 feet. Within the Mississippi floodplain, foundation depths generally would be greater: from 17 to 158 feet deep for lattice structures (with most foundation depths not exceeding 40 feet) and from 26 to 115 feet deep for pole structures (with most not exceeding 56 feet). Structure foundations would have to be deeper in the floodplain areas given the expected soil conditions. In the floodplain, pole structures are identified as having a more shallow range of foundations than lattice structures because, due to engineering constraints, the Applicant would need to limit the height of poles in floodplains to 130 feet to minimize the foundation depth (Thomas 2014). Lattice structures would be used exclusively in floodplain locations requiring greater heights than 130 feet. Other than possibly in the Texas and Oklahoma Panhandles, these foundation depths could reach the water table in some areas of each region of the Project. The Applicant has identified (Appendix F) two types of Project-related materials expected to come into contact with groundwater in areas where foundation construction would include work below the water table: Super Mud™ and high yield bentonite gel, both products of PDSCo. Inc. (Polymer Drilling Systems) of El Dorado, Arkansas.

Super Mud™ is described as a synthetic polymer used to create high viscosity slurries for stabilizing excavations (see Appendix F). The safety data sheet for the product provides the chemical name as anionic polyacrylamide in a water-in-oil emulsion. The only Occupational Safety & Health Administration-regulated component identified on the safety data sheet, which makes up 24 percent of the product, is "hydrotreated light petroleum distillate" (CAS No. 64742-47-8). EPA identifies this distillate as an inert material cleared for food, nonfood, and fragrance use (EPA 2014). High Yield Bentonite Gel is described as a polymer extended sodium bentonite, which is a naturally occurring clay material. It is designed for use in drilling applications and acts to stabilize the borehole walls as it circulates back to the surface, cooling the drill bit and transporting drill cuttings. The safety data sheet for this product identifies the crystalline quartz contaminants along with the nuisance dust as respirable hazards, but lists no other specific concerns. The slurries with either product would be pumped or otherwise removed from the hole prior to foundation construction, but residues would remain behind and contact with groundwater would occur during excavation or drilling. Because the materials used in these slurries do not contain contaminants of concern, impacts to groundwater would not be expected to occur.

Considering the requirements of the construction general permits, the measures that the Applicant would implement per its internal plans and procedures (Section 3.7.6.1.5), and the non-toxic nature of additives used in excavating or drilling below the water table, it is unlikely that construction activities would result in contaminated groundwater.

3.7.6.1.2 Changes to Infiltration Rates

During construction, soils at the sites of the transmission line structures and converter stations would be broken up and loosened for some period of time, either in areas of disturbed soils or in soil stockpiles, and would be expected to have lower runoff rates, and correspondingly higher infiltration rates, than before the disturbance. Higher infiltration rates would mean more water soaking into the ground that could potentially reach groundwater as recharge. At the same time, the soil in unpaved areas where heavy equipment traveled to, from, or around construction sites and in the temporary staging or storage areas could become more compacted than natural conditions and result in increased runoff and correspondingly lower infiltration rates. Conditions of loosened soil, however, would be relatively short-term and, for the most part, the disturbed areas would be restored to a pre-disturbance condition once the foundations and structures were in place. With regard to soils that may become compacted as a byproduct of equipment traffic, the Applicant would take measures to prevent serious issues such as the use of low ground pressure equipment and, as appropriate, use of temporary equipment mats. If necessary, the Applicant would also work with the landowners or tenants to determine the need for soil remediation and, as appropriate, undertake actions including decompaction, particularly in agricultural areas, to return soils to pre-disturbance conditions (Section 3.7.6.1.5). There is no evidence to suggest that the relatively small and short-term changes in infiltration rates associated with the proposed construction actions would cause noticeable changes in the area's natural groundwater recharge rates.

3.7.6.1.3 Effects on Water Availability

Adverse effects on water availability could result if the Project hindered the use of a local water well or reduced the amount of water available for other existing users. The former situation could result from the Project causing physical damage to a well or its equipment so that it was no longer operable, by taking actions such as blasting that altered local aquifer properties, or by causing contamination in a local well. As discussed further in Section 3.7.6.1.4 below, the Applicant would work with property owners or tenants to identify well locations, which would minimize the potential to inadvertently cause damage to well components, would monitor wells within 150 feet of any blasting location for changes in quality or yield, and control the use of hazardous materials. These actions would minimize the potential to release or cause contamination that could reach area wells.

Water would be needed to support construction activities, but the activities would not involve major demands for water. Water would be needed to facilitate soil compaction on access roads and at construction sites and then periodically for controlling dust on those surfaces. Slurries used in drilling and, as necessary, in stabilizing excavations would require water for their formulation. Whether mixed at commercial batch plants or at temporary portable batch plants in remote areas, water would be needed to make the concrete that would be used in foundations and for washing out concrete trucks and mixing equipment. Site restoration actions involving re-seeding or landscaping would include a water demand and some water may be required for fire prevention activities. The Applicant has considered the various construction actions that would require water and estimates the Project would require approximately 110 million gallons of water over a construction period of about 36 months (Appendix F). The Applicant would seek to obtain the water from municipal water providers along the transmission-line route where such water supplies are within a reasonable haul distance. Any other water required would be obtained through permitted sources or through supply agreements with landowners. The Applicant does not anticipate the need to drill wells to obtain water to support construction actions, but if new wells became necessary to support operational facilities, the Applicant would obtain the necessary approvals and limit withdrawal volumes so as to not adversely affect supplies for other uses (see Appendix F).

Although 110 million gallons is a substantial amount of water, when averaged over the entire construction period, it equates to about 100,000 gallons or 0.1 million gallons per day. In addition, this water demand would be spread out over a large geographic area, so the average demand of 0.1 million gallons per day would be experienced in different areas along the 700-mile route as construction progressed. Construction of the proposed converter stations, however, would be expected to cause their portions of the overall HVDC transmission line route to be associated with a higher percentage of the water demand than those sections with only transmission lines being constructed. As summarized in the average water use tables in Section 3.7.5, regional groundwater use varies from about 9 to 1,790 million gallons per day within the seven regions along the HVDC transmission line route. Because water for the Project is expected to come from municipal providers, its source could be groundwater or surface water depending on which part of the route is being worked. In any case, a water demand of 0.1 million gallons per day over the relatively short duration of construction is minor compared to quantities of groundwater already being used. Perennial or sustainable yields of aquifers along the route, where values are available, range from 87 to 2,987 million gallons per day, so in comparison to these numbers, the water demand of the Project represents an even smaller portion. Water demand associated with the Project is therefore not expected to have noticeable effects on groundwater resources beyond those resulting from existing water usage in Regions 1 through 7.

3.7.6.1.4 Physical Damage to Well Systems

If water wells or their associated piping systems were damaged due to construction activities, it could result in water availability issues for the local water user and breaks or other openings in the system could even provide an avenue for contamination to travel down the well and reach groundwater. Well system damage could occur as a result of direct impacts from equipment traffic or during excavations, and could also occur at locations more remote from construction if blasting was used at excavation sites. Blasting would only be used if determined to be the best way to deal with hard rock in an excavation site. The shock wave or ejected materials from blasting actions could cause damage to well systems at some distance from the excavation site.

To minimize potential impacts to wells, from either physical damage or from potential contaminants, the Applicant would work with landowners and tenants prior to construction to identify and mark locations of existing and planned wells and irrigation systems. If blasting were required within 150 feet of a spring or groundwater well, the Applicant would work with the landowner to perform preconstruction monitoring of yield and water quality and, if there was damage, would arrange for a temporary water supply until a permanent solution was identified (see EPMs in Section 3.7.6.1.5).

3.7.6.1.5 Environmental Protection Measures for Groundwater

The Applicant has developed and would adopt a comprehensive list of EPMs to avoid or minimize impacts to groundwater. Implementation of these EPMs is assumed throughout the impact analysis that follows for the Project. A complete list of EPMs for the Project is provided in Appendix F. The EPMs associated with groundwater are presented below in three general potential impact categories: (1) contamination, (2) runoff and infiltration rates, and

(3) water availability, including from well system damage. Each EPM is identified by its Applicant-designated reference number.

Practices would be implemented to minimize the potential for release or mismanagement of hazardous materials that could eventually result in groundwater contamination. These EPMs include the following:

- GE-1: Clean Line will train personnel on health, safety, and environmental matters. Training will include practices, techniques, and protocols required by federal and state regulations and applicable permits.
- GE-5: Any herbicides used during construction and operations and maintenance will be applied according to label instructions and any federal, state, and local regulations.
- GE-13: Emergency and spill response equipment will be kept on hand during construction.
- GE-14: Clean Line will restrict the refueling and maintenance of vehicles and the storage of fuels and hazardous chemicals within at least 100 feet from wetlands, surface waterbodies, and groundwater wells, or as otherwise required by federal, state, or local regulations.
- GE-28: Hazardous materials and chemicals will be transported, stored, and disposed of according to federal, state, or local regulations or permit requirements.
- GE-31: Clean Line will provide sanitary toilets convenient to construction; these will be located greater than 100 feet from any stream or tributary or to any wetland. These facilities will be regularly serviced and maintained; waste disposal will be properly manifested. Employees will be notified of sanitation regulations and will be required to use sanitary facilities.
- W-14: Clean Line will ensure that there is no off-site discharge of wastewater from temporary batch plant sites.

Practices would be implemented to minimize changes to stormwater runoff and infiltration rates that could potentially change quantities and locations of groundwater recharge. Such EPMs would include the following:

- GE-3: Clean Line will minimize clearing vegetation within the ROW, consistent with a Transmission Vegetation Management Plan filed with NERC, and applicable federal, state, and local regulations. The TVMP may require additional analysis under NEPA depending on whether and under what conditions DOE decides to participate in the Project.
- GE-6: Clean Line will restrict vehicular travel to the ROW and other established areas within the construction, access, or maintenance easements(s).
- GE-7: Roads not otherwise needed for maintenance and operations will be restored to preconstruction conditions. Restoration practices may include decompacting, recontouring, and re-seeding. Roads needed for maintenance and operations will be retained.
- GE-9: Clean Line will avoid and/or minimize damage to drainage features and other improvements such as ditches, culverts, levees, tiles, and terraces; however, if these features or improvements are inadvertently damaged, they will be repaired and/or restored.
- GE-27: Clean Line will minimize compaction of soils and rutting through appropriate use of construction equipment (e.g., low ground pressure equipment and temporary equipment mats).
- GE-30: Clean Line will minimize the amount of time than any excavations remain open.
- AG-2: Agricultural soils temporarily impacted by construction, operation, or maintenance activities will be restored to pre-activity conditions. For example, soil remediation efforts may include decompaction, recontouring, liming, tillage, fertilization, or use of other soil amendments.
- GEO-1: Clean Line will stabilize slopes exposed by its activities to minimize erosion.

Practices would be implemented to minimize changes to existing groundwater availability, including avoiding damage to water wells and utilities. Such EPMs would include the following:

- GE-29: Clean Line will work with landowners and operators of active oil and gas wells, utilities, and other infrastructure to identify and verify the location of facilities and to minimize adverse impacts. Identification may include use of the One Call system and surveying of existing facilities.
- W-5: Clean Line will construct access roads to minimize disruption of natural drainage patterns including perennial, intermittent, and ephemeral streams.
- W-11: Clean Line will locate and minimize impacts to groundwater wells and springs within the construction ROW.
- W-12: If blasting is required within 150 feet of a spring or groundwater well, Clean Line will conduct preconstruction monitoring of yield and water quality in cooperation with the landowner. In the event of damage, Clean Line will arrange for a temporary water supply through a local supplier until a permanent solution is identified.
- W-13: If any groundwater wells are needed to support operational facilities, withdrawal volumes will be limited so as not to adversely affect supplies for other uses.
- W-15: Clean Line will seek to procure water from municipal water systems where such water supplies are within a reasonable haul distance; any other water required will be obtained through permitted sources or through supply agreements with landowners.

3.7.6.2 Impacts Associated with the Applicant Proposed Project

3.7.6.2.1 Converter Stations and AC Interconnection Siting Areas

3.7.6.2.1.1 Construction Impacts

3.7.6.2.1.1.1 Oklahoma Converter Station Siting Area and AC Interconnection Siting Area

The Oklahoma converter station and the AC interconnection siting areas would be located over the High Plains aquifer, but not in an area with designations of special interest. No wells or wellhead protection area are located within the station siting area and a single industrial well is within the ROW of the AC interconnection. It is expected the well would be avoided by the transmission line, but in any case, potential impacts to wells would be minimized as described in Section 3.7.6.1. Potential impacts associated with construction of the station and AC interconnection line would be the same as those common impacts described in Section 3.7.6.1. In Texas County, where the depth to groundwater is great enough (about 94 to 370 feet BGS) that construction would not include work below the water table, work materials would not come into contact with groundwater during construction. Water needed to support construction of the converter station and AC interconnection—although expected to be obtained from a municipal provider—would likely come from groundwater, since groundwater is the predominant source of water in Texas County (Table 3.7-5). The amount of water required for construction of the converter station and AC interconnection would be spread over a couple of years and would not be expected to have an impact on the availability of groundwater for other uses.

3.7.6.2.1.1.2 Tennessee Converter Station Siting Area and AC Interconnection Tie

The Tennessee converter station and the AC interconnection tie would be located over the Mississippi embayment aquifer system, but not in an area with designations of special interest. No wellhead protection area or wells occur within the siting areas. Potential impacts associated with construction of the station and AC interconnection tie would be the same as those common impacts described in Section 3.7.6.1. As shown in Table 3.7-22, surface water is used heavily in Shelby County, most for thermo-electric power plant cooling, but public water supplies in Shelby County come entirely from groundwater, so water to support construction of the converter station would be expected to come from groundwater. The depth to water in Shelby County is as shallow as about 11 feet. At this depth, construction of the converter station might not encounter groundwater. If foundation construction extended below the water table, materials described in Section 3.7.6.1.1 could come into contact with groundwater. As described in that section, however, groundwater contamination would not be expected to occur.

3.7.6.2.1.2 Operations and Maintenance Impacts

Operation and maintenance of the converter stations and the AC interconnections in Oklahoma and Tennessee would not be expected to have any impacts on groundwater. No water would be needed other than the minor amount of drinking water required to support fewer than 15 full-time workers at each station; the Applicant's plans are for the stations to be connected to the municipal water system. However, the Applicant's plans also note that if a new well is required, quantities of water withdrawn would be limited so as not to adversely affect existing groundwater uses.

3.7.6.2.1.3 Decommissioning Impacts

Decommissioning of converter stations and AC interconnection lines or ties would be expected to have impacts similar to those described in Section 3.7.6.1 for common construction activities, i.e., measures would be required to manage the fuel and lubricants that would be present in equipment and actions to protect stormwater runoff at the site would ensure that contaminants did not reach groundwater. Water demand during decommissioning would be limited to that needed for actions such as dust suppression, soil compaction, and possibly re-seeding or landscaping to put the ground back into suitable condition. Water demand would be less than for construction and would not adversely impact groundwater resources.

3.7.6.2.2 AC Collection System

3.7.6.2.2.1 Construction Impacts

Evaluation of the potential impacts of the AC collection system routes is based on a representative 200-foot-wide ROW for each route. Groundwater features and elements within the ROWs were presented in Section 3.7.5.1 along with the information for the 2-mile-wide ROI.

As described in Section 3.7.6.1.1, the deepest foundations for transmission line structures would be in the range of 30 to 44 feet BGS. Based on the typical depths to groundwater (Section 3.7.5.1.1.2) in the five counties in which the AC collection system routes would be located (i.e., Beaver and Texas counties in Oklahoma and Sherman, Hansford, and Ochiltree counties in Texas), it is expected that construction of foundations for transmission line structures would not reach groundwater. Accordingly, potential impacts associated with excavating or drilling to groundwater would not be applicable.

3.7.6.2.2.1.1 Route E-1

AC Collection System Route E-1 would be located over the High Plains aquifer and includes areas over groundwater of special interest. As described in Section 3.7.5.1.2, this route would be the only AC collection system route for which the ROI would cross over any notable amount of special source groundwater area (967 acres); however, the 200-foot-wide ROW would avoid the area. The E-1 ROW would be one of the five routes that cross over groundwater with the nutrient-vulnerable designation. Of the five, AC Collection System Route E-1 would encompass the largest area (174 acres), almost twice that of the next highest route. The E-1 ROW would miss the wellhead protection area that would be in the wider ROI. As shown in Table 3.7-4, the 200-foot-wide E-1 ROW would contain only two wells, both used for industrial water supplies. Potential impacts associated with construction of the AC Collection System Route E-1 would be the same as those common impacts described in Section 3.7.6.1.

3.7.6.2.2.1.2 Route E-2

AC Collection System Route E-2 would be located over the High Plains aquifer and include area with designations of special interest. As described in Section 3.7.5.1.2, the 200-foot-wide ROW of E-2 would avoid the special source groundwater area in the ROI and would be one of five system routes that cross over groundwater with the nutrient-vulnerable designation (at 97 acres), but would go over no wellhead protection area. As shown in Table 3.7-4, the E-2 ROW would contain eight wells, including two domestic water supply wells, but no public supply wells. Potential impacts associated with construction of AC Collection System Route E-2 would be the same as those common impacts described in Section 3.7.6.1.

3.7.6.2.2.1.3 Route E-3

AC Collection System Route E-3 would be located over the High Plains aquifer and include area with designations of special interest. As described in Section 3.7.5.1.2, the 200-foot-wide ROW of E-3 would be one of five routes that cross over groundwater with the nutrient-vulnerable designation (at 100 acres), but would miss the small amount of wellhead protection area in the wider ROI. As shown in Table 3.7-4, the E-3 ROW would contain eight wells, including four agricultural wells and four industrial wells. Potential impacts associated with construction of AC Collection System Route E-3 would be the same as those common impacts described in Section 3.7.6.1.

3.7.6.2.2.1.4 Route NE-1

AC Collection System Route NE-1 would be located over the High Plains aquifer and its 200-foot-wide ROW would be avoid the small amounts of special source groundwater and wellhead protection area that are in the wider ROI. As summarized in Table 3.7-4, the NE-1 ROW would contain no public water supply wells, but would contain five wells, including four agricultural wells and one industrial well. Potential impacts associated with construction of AC Collection System Route NE-1 would be the same as those common impacts described in Section 3.7.6.1.

3.7.6.2.2.1.5 Route NE-2

AC Collection System Route NE-2 would be located over the High Plains aquifer, but not in an area with designations of special interest. As summarized in Table 3.7-4, the 200-foot-wide ROW of NE-2 would contain six wells, including two domestic water supply wells, two agricultural wells, and two industrial wells. Potential impacts associated with construction of AC Collection System Route NE-2 would be the same as those common impacts described in Section 3.7.6.1.

3.7.6.2.2.1.6 Route NW-1

AC Collection System Route NW-1 would be located over the High Plains aquifer, but not in an area with designations of special interest. As summarized in Table 3.7-4, the 200-foot-wide ROW of NW-1 would contain almost three wells, including one agricultural well and two industrial wells. Potential impacts associated with construction of AC Collection System Route NW-1 would be the same as those common impacts described in Section 3.7.6.1.

3.7.6.2.2.1.7 Route NW-2

AC Collection System Route NW-2 would be located over the High Plains aquifer, but not in an area with designations of special interest. As summarized in Table 3.7-4, the 200-foot-wide ROW of NW-2 would contain eight wells, including one domestic water supply well and seven agricultural wells. Potential impacts associated with construction of AC Collection System Route NW-2 would be the same as those common impacts described in Section 3.7.6.1.

3.7.6.2.2.1.8 Route SE-1

AC Collection System Route SE-1 would be located over the High Plains aquifer and includes area with designations of special interest. As summarized in Section 3.7.5.1.2, the 200-foot-wide ROW of SE-1 is one of five routes that would cross over groundwater with the nutrient-vulnerable designation (at 14 acres), but would not pass through wellhead protection area. As shown in Table 3.7-4, the SE-1 ROW would contain five wells, including one domestic water supply well, three agricultural wells, and one industrial well. Potential impacts associated with construction of the AC Collection System Route SE-1 would be the same as those common impacts described in Section 3.7.6.1.

3.7.6.2.2.1.9 Route SE-2

The AC Collection System Route SE-2 would be located over the High Plains aquifer, but not in an area with designations of special interest. As summarized in Table 3.7-4, the 200-foot-wide ROW of SE-2 would contain no wells. Potential impacts associated with construction of AC Collection System Route SE-2 would be the same as those common impacts described in Section 3.7.6.1.

3.7.6.2.2.1.10 Route SE-3

The AC Collection System Route SE-3 would be located over the High Plains aquifer and includes area with designations of special interest. As summarized in Section 3.7.5.1.2, the 200-foot-wide ROW of SE-3 would be one of five routes that cross over groundwater with the nutrient-vulnerable designation (at 97 acres), but would not pass through wellhead protection area. As shown in Table 3.7-4, the SE-3 ROW would contain eight wells, including one domestic water supply well, six agricultural wells, and one industrial well. Potential impacts associated with construction of AC Collection System Route SE-3 would be the same as those common impacts described in Section 3.7.6.1.

3.7.6.2.2.1.11 Route SW-1

AC Collection System Route SW-1 would be located over the High Plains aquifer, but not in an area with designations of special interest. As summarized in Table 3.7-4, the 200-foot-wide ROW of SW-1 would contain no wells. Potential impacts associated with construction of AC Collection System Route SW-1 would be the same as those common impacts described in Section 3.7.6.1.

3.7.6.2.2.1.12 Route SW-2

AC Collection System Route SW-2 would be located over the High Plains aquifer, but not in an area with designations of special interest. As summarized in Table 3.7-4, the 200-foot-wide ROW of SW-2 would contain no wells. Potential impacts associated with construction of AC Collection System Route SW-2 would be the same as those common impacts described in Section 3.7.6.1.

3.7.6.2.2.1.13 Route W-1

AC Collection System Route W-1 would be located over the High Plains aquifer, but not in an area with designations of special interest. As summarized in Table 3.7-4, the 200-foot-wide ROW of W-1 would contain seven wells, including three domestic water supply wells, the largest number of any of the route ROWs, and four agricultural wells. Potential impacts associated with construction of AC Collection System Route W-1 would be the same as those common impacts described in Section 3.7.6.1.

3.7.6.2.2.2 Operations and Maintenance Impacts

Operation and maintenance of AC collection system routes would not impact groundwater. During operations and maintenance, no notable sources of contaminants would be in use other than the typical fuels and lubricants found in vehicles and equipment, no soil disturbance would occur, and water needs would be limited to personal needs of the few workers that would be associated with maintenance of facilities and equipment.

3.7.6.2.2.3 Decommissioning Impacts

Decommissioning of AC collection system routes would be expected to have impacts similar to those described in Section 3.7.6.1 for common construction activities, i.e., the same types of measures would be required to manage the fuel and lubricants that would be present in equipment and actions to protect stormwater runoff at the site would ensure that contaminants did not reach groundwater. Water demand during decommissioning would be limited to that needed for actions such as dust suppression, soil compaction, and possibly re-seeding or landscaping to put the ground back into suitable condition. Water demand would be less than for construction and would not adversely impact groundwater resources.

3.7.6.2.3 HVDC Applicant Proposed Route

3.7.6.2.3.1 Construction Impacts

This section addresses potential impacts from construction of the HVDC transmission line within each of the seven regions. The groundwater features considered in the evaluation for each region are those located within a representative 200-foot-wide ROW for the Applicant Proposed Route. Groundwater features and elements within the ROWs were presented in the regional discussions of Section 3.7.5 along with the information for the 1,000-foot-wide ROIs. Additionally, the ROWs were expanded by 150 feet on either side, forming 500-foot-wide corridors for use in identifying wells to account for possible physical damage from blasting (Section 3.7.6.1.4) within the ROW. Changes to impacts due to route variations and adjustments developed in response to public comments on the Draft EIS are described at the end of the applicable sections.

Considering the descriptions of the depth to groundwater in Sections 3.7.5.1 through 3.7.5.7, groundwater could be encountered during construction of the foundations for transmission line structures all along the Applicant Proposed Route, with the possible exception of the western and central portions of Region 1. Accordingly, the common impacts described in Section 3.7.6.1.1 that are associated with encountering groundwater during construction excavations or drilling could be applicable for each of the regions.

3.7.6.2.3.1.1 Region 1

Much of the Applicant Proposed Route in Region 1 would be located over the High Plains aquifer; the eastern end of the Applicant Proposed Route would pass over the North Canadian River alluvial aquifer. Groundwater designations of special interest along the Applicant Proposed Route are special source groundwater and nutrient-vulnerable groundwater. As summarized in Table 3.7-2, the 200-foot-wide ROW of the Applicant Proposed Route would encompass no special source groundwater, but would overlie 570 acres of nutrient-vulnerable groundwater. As shown in Table 3.7-3, an expanded 500-foot-wide corridor for the Applicant Proposed Route would contain 11 wells, including 2 domestic water supply wells, 8 agricultural wells, and 3 industrial wells. The Applicant Proposed Route also would not pass through wellhead protection area. Potential impacts associated with construction of the Applicant Proposed Route would be the same as those common impacts described in Section 3.7.6.1.

No route variations were proposed in Region 1.

3.7.6.2.3.1.2 Region 2

The most significant aquifers along the Applicant Proposed Route in Region 2 are the North Canadian River and Cimarron River alluvial aquifers. Groundwater designations of special interest along the Applicant Proposed Route are special source groundwater and nutrient-vulnerable groundwater. As summarized in Table 3.7-7, the 200-foot-wide ROW of the Applicant Proposed Route would encompass no special source groundwater, but would overlie 1,635 acres of nutrient-vulnerable groundwater. The Region 2 ROW would encompass only 7 acres of wellhead protection area. As shown in Table 3.7-8, the expanded ROW for the Applicant Proposed Route would contain 10 wells, including 2 domestic water supply wells, 5 agricultural wells, 3 three industrial wells. Potential impacts associated with construction of the Applicant Proposed Route would be the same as those common impacts described in Section 3.7.6.1.

The variations involve very minor changes in the amount of nutrient-vulnerable groundwater that would be crossed and, at most, one additional well within the 500-foot-wide corridor of the end-to-end route would be present. These minor changes in the groundwater elements would not affect the potential impacts associated with construction.

3.7.6.2.3.1.3 Region 3

The Applicant Proposed Route in Region 3 would pass over only one principal aquifer, the Ada-Vamoosa aquifer. Groundwater designations of special interest along the Applicant Proposed Route are special source groundwater and nutrient-vulnerable groundwater. As summarized in Table 3.7-10, the 200-foot-wide ROW of the Applicant Proposed Route would encompass no special source groundwater, but would overlie 261 acres of nutrient-vulnerable groundwater. No wellhead protection area would be located along the Applicant Proposed Route. As shown in Table 3.7-11, the expanded ROW for the Applicant Proposed Route would contain twelve wells, all domestic water supply wells. Potential impacts associated with construction of the Applicant Proposed Route would be the same as those common impacts described in Section 3.7.6.1.

The variations involve a small 16-acre increase (all attributed to Applicant Proposed Route Links 1 and 2, Variation 1) in the amount of nutrient-vulnerable groundwater that would be crossed and, at most, six additional wells within the 500-foot-wide corridor of the end-to-end route would be present. As indicated in Section 3.7.6.1.5, the Applicant would work with landowners and tenants to minimize impacts to wells as necessary. These minor changes in the groundwater elements would not affect the potential impacts associated with construction.

3.7.6.2.3.1.4 Region 4

The western end of the Applicant Proposed Route in Region 4 would pass over the Arkansas River alluvial aquifer, but that is the only principal or major aquifer in the region. Groundwater designations of special interest along the Applicant Proposed Route are special source groundwater and nutrient-vulnerable groundwater in Oklahoma and critical groundwater area in Arkansas. As summarized in Table 3.7-13, the 200-foot-wide ROW for the Applicant Proposed Route would encompass 159 acres of special source groundwater, 99 acres of nutrient-vulnerable groundwater, and no critical groundwater area. No wellhead protection areas would be located along the Applicant Proposed Route. As shown in Table 3.7-14, the expanded ROW for the Applicant Proposed Route would contain only one well, a domestic water supply well. If the Applicant were to use the Lee Creek Variation, the route ROW would cross very similar areas of special source groundwater and nutrient-vulnerable groundwater; there would be no difference in the number of wells encountered. Potential impacts associated with construction of the Applicant Proposed Route would be the same as those common impacts described in Section 3.7.6.1.

The route variations would cross no areas overlying groundwater of special interest and there would be no changes in the number of wells within the 500-foot-wide corridor of the end-to-end route. These minor changes in the groundwater elements would not affect the potential impacts associated with construction.

3.7.6.2.3.1.5 Region 5

The eastern end of the Applicant Proposed Route in Region 5 would pass over the Mississippi River Valley alluvial aquifer, and it is the only principal or major aquifer in the region. The groundwater designation of special interest along the Applicant Proposed Route is critical groundwater area, but there are no groundwater designations of special interest or wellhead protection area along the 200-foot-wide ROW of the Applicant Proposed Route. As shown in Table 3.7-16, the expanded ROW for the Applicant Proposed Route would contain four wells, including one domestic water supply well and three wells used for agricultural purposes. Potential impacts associated with construction of the Applicant Proposed Route would be the same as those common impacts described in Section 3.7.6.1.

The variations would cross no areas overlying groundwater of special interest and at most two additional wells would be encountered within the 500-foot-wide corridor of the end-to-end route. These minor changes in the groundwater elements would not affect the potential impacts associated with construction.

3.7.6.2.3.1.6 Region 6

The Applicant Proposed Route in Region 6 would traverse two principal aquifers in its path from west to east. From the west, it would cross the Mississippi River Valley alluvial aquifer, the Mississippi embayment aquifer system (crossing Crowley's Ridge in eastern Arkansas), and the Mississippi River Valley alluvial aquifer again in the east. The groundwater designation of special interest along the Applicant Proposed Route is critical groundwater area. As summarized in Table 3.7-18, the 200-foot-wide ROW of the Applicant Proposed Route would cross over 516 acres of critical groundwater area and per Table 3.7-19, would not cross wellhead protection area. Also as shown in Table 3.7-19, the expanded ROW for the Applicant Proposed Route would contain nine wells, all agricultural wells. Potential impacts associated with construction of the Applicant Proposed Route would be the same as those common impacts described in Section 3.7.6.1.

The variation would cross no areas overlying groundwater of special interest and at most encounter an additional three wells within the 500-foot-wide corridor of the end-to-end route. These minor changes in the groundwater elements would not affect the potential impacts associated with construction.

3.7.6.2.3.1.7 Region 7

The Applicant Proposed Route in Region 7 would traverse two principal aquifers in its path from west to east, the Mississippi River Valley alluvial aquifer in the west and the Mississippi embayment aquifer system to the east. Groundwater designations of special interest along the Applicant Proposed Route are critical groundwater areas in Arkansas and special source water and site-specific impaired groundwater in Tennessee. No groundwater designations of special interest or wellhead protection area were identified along the Applicant Proposed Route. As shown in Table 3.7-21, the expanded ROW (i.e., a 500-foot-wide corridor) for the Applicant Proposed Route would contain 15 wells, all identified as being used for agricultural purposes. Potential impacts associated with construction of the Applicant Proposed Route would be the same as those common impacts described in Section 3.7.6.1.

The variations would cross no areas overlying groundwater of special interest and at most would encounter an additional two wells within the 500-foot-wide corridor of the end-to-end route. These minor changes in the groundwater elements would not affect the potential impacts associated with construction.

3.7.6.2.3.2 Operations and Maintenance Impacts

Operations and maintenance of the HVDC transmission line in Regions 1 through 7, using the Applicant Proposed Route, would not impact groundwater. During operations and maintenance, no notable sources of contaminants would be in use other than the typical fuels and lubricants found in vehicles and equipment, no soil disturbance would occur, and water needs would be limited to personal needs of the few workers that would be associated with maintenance of facilities and equipment.

3.7.6.2.3.3 Decommissioning Impacts

Decommissioning of HVDC transmission lines would be expected to have impacts similar to those described in Section 3.7.6.1 for common construction activities, i.e., the same types of measures would be required to manage the fuel and lubricants that would be present in equipment and actions to protect stormwater runoff at the site would ensure that contaminants did not reach groundwater. Water demand during decommissioning would be limited to that needed for actions such as dust suppression, soil compaction, and possibly re-seeding or landscaping to put the ground back into suitable condition. Water demand primarily would be for dust suppression, soil compaction, and possibly re-seeding or landscaping to put the ground back into suitable condition. Water demand would be expected to be less than for construction and would not adversely impact groundwater resources.

3.7.6.3 Impacts Associated with the DOE Alternatives

3.7.6.3.1 Arkansas Converter Station Alternative Siting Area and AC Interconnection Siting Area

3.7.6.3.1.1 Construction Impacts

The Arkansas Converter Station Alternative Siting Area and Alternative AC Interconnection Siting Area, including the site of the new substation at the southern end of the AC Interconnection Siting Area, would be located over an area that has no principal aquifer. This area has few subsurface strata that yield sufficient water to qualify as aquifers. No wellhead protection area or wells are present in the siting areas. Potential impacts associated with construction of the converter station, AC interconnection line, and substation would be the same as those common impacts described in Section 3.7.6.1. Surface water is the predominant source of water in Pope County (Table 3.7-17), where the siting areas are located, so water to support construction of the converter station, AC interconnection line, and substation would likely not come from groundwater even though it is expected to be obtained from a municipal provider. Although water depth measurements were not available for Pope County, water tables in other portions of Region 5 of the HVDC transmission line route are often shallow, so construction actions could encounter groundwater even though the water-bearing strata may not qualify as an aquifer.

3.7.6.3.1.2 Operations and Maintenance Impacts

Operation and maintenance of the Arkansas converter station, AC interconnection line, and substation would not be expected to have any impacts on groundwater. There would be no water demand other than the minor amount of drinking water required to support fewer than 15 full-time workers and the station would be connected to the municipal water system.

3.7.6.3.1.3 Decommissioning Impacts

Decommissioning of Arkansas converter station, AC interconnection line, and substation would be expected to have impacts similar to those described in Section 3.7.6.1 for common construction activities, i.e., the same types of measures would be required to manage the fuel and lubricants that would be present in equipment and actions to protect stormwater runoff at the site would ensure that contaminants did not reach groundwater. Water demand during decommissioning would be limited to that needed for actions such as dust suppression, soil compaction, and possibly re-seeding or landscaping to put the ground back into suitable condition. Water demand would be less than for construction and would not adversely impact groundwater resources.

3.7.6.3.2 HVDC Alternative Routes

3.7.6.3.2.1 Construction Impacts

This section addresses potential impacts from construction of the HVDC transmission line within the HVDC alternative routes identified for each of the same seven regions considered for the Applicant Proposed Route. The groundwater features considered in the evaluation of the HVDC alternative routes are those located within a representative 200-foot-wide ROW corridor (i.e., 100 feet on either side of the centerline of the alternative route). Groundwater features and elements within the ROWs were presented in the regional discussions of Section 3.7.5 along with the information for the 1,000 foot-wide ROIs. Additionally, the ROWs were expanded by 150 feet on either side, forming 500-foot-wide corridors for use in identifying wells to account for possible physical damage from blasting (Section 3.7.6.1.4) within the ROW.

As identified for the Applicant Proposed Route, depths to groundwater in each of the regions (Sections 3.7.5.1 through 3.7.5.7) indicate that groundwater could be encountered during construction of the foundations for transmission line structures all along the various HVDC alternative routes, with the possible exception of those in the western and central portions of Region 1. Accordingly, the common impacts described in Section 3.7.6.1.1 that are associated with encountering groundwater during construction excavations or drilling could be applicable for each of the regions.

3.7.6.3.2.1.1 Region 1

HVDC Alternative Routes 1-A through 1-D would be located largely over the High Plains aquifer and the eastern ends pass over the North Canadian River alluvial aquifer. The ROIs of HVDC alternative routes in Region 1 would encompass areas with groundwater designations of special interest and wellhead protection areas. As shown in Table 3.7-2, the 200-foot-wide ROWs of HVDC Alternative Routes 1-A, 1-B, and 1-C would cross 314, 5, and 51 more acres, respectively, of nutrient-vulnerable groundwater area than the corresponding links of the Region 1 Applicant Proposed Route, and HVDC Alternative Route 1-D would cross the same amount of area. Like the Applicant Proposed Route, none of the Region 1 HVDC alternative routes would cross wellhead protection areas. As shown in Table 3.7-3, the combined number of wells (domestic, agricultural, and industrial) encompassed by the expanded (500-foot-wide) ROWs of HVDC Alternative Routes 1-A, 1-B, and 1-C would be fewer by four, four, and six wells, respectively, than encompassed by the corresponding links of the Region 1 Applicant Proposed Route, while the combined number of wells within the expanded ROW of HVDC Alternative Route 1-D would be eight greater than the Applicant Proposed Route. Potential impacts associated with construction of an HVDC alternative route in Region 1 would be the same as those common impacts described in Section 3.7.6.1.

3.7.6.3.2.1.2 Region 2

The most significant aquifers along the Region 2 HVDC alternative routes are the North Canadian River and Cimarron River alluvial aquifers. As summarized in Tables 3.7-7 and 3.7-8, the HVDC alternative routes in Region 2 would encompass areas with two groundwater designations of special interest: nutrient-vulnerable groundwater and wellhead protection area. The 200-foot-wide ROW of HVDC Alternative Route 2-A would cross 81 more acres of nutrient-vulnerable groundwater than the corresponding links of the Region 2 Applicant Proposed Route, while 2-B would cross 155 fewer acres. With respect to well head protection area, the ROW of HVDC Alternative Route 2-A would cross 21 more acres than the corresponding links of the Applicant Proposed Route and 2-B would cross none compared to 7 acres by the Applicant Proposed Route. As shown in Table 3.7-8, the combined number of wells (domestic, agricultural, and industrial) encompassed by the expanded (500-foot-wide) ROW of HVDC Alternative Route 2-A would be one more than encompassed by the corresponding links of the Region 2 Applicant Proposed Route, while the total number of wells within the expanded ROW of HVDC Alternative Route 2-B would be two less. Of note in these numbers, HVDC Alternative Route 2-A would encompass two public water supplies wells compared to none in the corresponding links of the Applicant Proposed Route. Potential impacts associated with construction of any of the HVDC alternative routes in Region 2 would be the same as those common impacts described in Section 3.7.6.1.

3.7.6.3.2.1.3 Region 3

The HVDC alternative routes in Region 3 would pass over the principal aquifer, the Ada-Vamoosa aquifer, and HVDC Alternative Route 3-C also would pass over the edge of a second principal aquifer, the Central Oklahoma aquifer. As summarized in Tables 3.7-10 and 3.7-11, the HVDC alternative routes in Region 3 would encompass areas with two groundwater designations of special interest: nutrient-vulnerable groundwater and wellhead protection area. As shown in Table 3.7-10, the 200-foot-wide ROWs of HVDC Alternative Routes 3-A, 3-B, and 3-C would cross 58, 103, and 56 fewer acres, respectively, of nutrient-vulnerable groundwater area than the corresponding links of the Region 3 Applicant Proposed Route, and HVDC Alternative Routes 3-D and 3-E would cross the same amount of area. With respect to wellhead protection area, the ROW of HVDC Alternative Route 3-C would cross 11 acres while the ROWs of the other HVDC alternative routes as well as the Applicant Proposed Route would encompass none. As shown in Table 3.7-11, the combined number of wells (domestic, agricultural, and industrial) encompassed by the expanded (500-foot-wide) ROW of HVDC Alternative Route 3-A would be one more than encompassed by the corresponding links of the Region 3 Applicant Proposed Route, while the total number of wells within the expanded ROW of HVDC Alternative Route 3-C would be four less; the expanded ROWs of HVDC Alternative Routes 3-B, 3-D, and 3-E would be the same as the corresponding links of the Applicant Proposed Route. Potential impacts associated with construction of an HVDC alternative routes in Region 3 would be the same as those common impacts described in Section 3.7.6.1.

As described in Appendix M and summarized in Section 2.4.2.3, a route adjustment was developed for HVDC Alternative Route 3-A to maintain an end-to-end route with the Applicant Proposed Route Links 1 and 2, Variation 1. The adjustment to HVDC Alternative Route 3-A would involve a very small decrease (0.4 acre) in the amount of nutrient-vulnerable groundwater crossed by the alternative and would involve no change in the number of wells within the 500-foot-wide corridor. These minor changes in the groundwater elements would not affect the potential impacts associated with construction.

3.7.6.3.2.1.4 Region 4

The only principal or major aquifer passed over by the HVDC alternative routes in Region 4 would be the Arkansas River alluvial aquifer. As summarized in Table 3.7-13, groundwater designations of special interest along the Region 4 HVDC alternative routes are special source groundwater and nutrient-vulnerable groundwater. The 200-foot-wide ROWs of HVDC Alternative Routes 4-A and 4-B would cross 108 and 90 more acres, respectively, of special source groundwater than the corresponding links of the Region 4 Applicant Proposed Route. With respect to nutrient-vulnerable groundwater, the ROWs of HVDC Alternative Routes 4-A and 4-B would cross no designated areas, but the corresponding links of the Applicant Proposed Route would cross 76 and 95 acres, respectively. The ROWs of HVDC Alternative Routes 4-C, 4-D, and 4-E, being in Arkansas, would cross no area of special source groundwater or nutrient-vulnerable groundwater just as the corresponding links of the Applicant Proposed Route would cross none. As shown in Table 3.7-14, the combined number of wells (domestic, agricultural, and industrial) encompassed by the expanded (500-foot-wide) ROWs of HVDC Alternative Routes 4-A, 4-B, and 4-D would be more by 6, 12, and 1, respectively, than encompassed by the corresponding links of the Region 4 Applicant Proposed Route. No wells would be within the expanded ROW of HVDC Alternative Routes 4-C and 4-E, just as there would be no wells in corresponding links of the Applicant Proposed Route. Potential impacts associated with construction of an HVDC alternative route in Region 4 would be the same as those common impacts described in Section 3.7.6.1.

HVDC Alternative Route 4-B passes through national forest land. The greater amount of special source groundwater and number of wells that would be encompassed by this alternative route, as compared to the corresponding links of the Applicant Proposed Route, might be considered to represent more potential for environment impact. However, the potential would still remain low.

3.7.6.3.2.1.5 Region 5

The eastern end of the HVDC alternative routes in Region 5 would pass over the Mississippi River Valley alluvial aquifer, the only principal or major aquifer in the region. No groundwater designations of special interest are present along HVDC alternative routes in Region 5 and the 200-foot-wide ROWs of all alternative routes avoid wellhead protection area. As shown in Table 3.7-16, the combined number of wells (domestic, agricultural, and industrial) encompassed by the expanded (500-foot-wide) ROWs of HVDC Alternative Routes 5-A, 5-B, and 5-E would be more by one, two, and one, respectively, than the number of wells in the corresponding links of the Region 5 Applicant Proposed Route. The ROWs of HVDC Alternative Routes 5-C and 5-F would contain the same number of wells as the corresponding links of the Applicant Proposed Route, and the ROW of HVDC Alternative Route 5-D would contain two fewer wells than the corresponding links of the Applicant Proposed Route. Potential impacts associated with construction of an HVDC alternative route in Region 5 would be the same as those common impacts described in Section 3.7.6.1.

As described in Appendix M and summarized in Section 2.4.2.5, a route adjustment was developed for HVDC Alternative Route 5-B to maintain an end-to-end route with the Applicant Proposed Route Links 2 and 3, Variation 1. Another route adjustment was developed for HVDC Alternative Route 5-E to maintain an end-to-end route with the Applicant Proposed Route Links 3 and 4, Variation 2. The adjustments to HVDC Alternative Routes 5-B and 5-E would not overlie groundwater of special interest and they would result in no change in the number of wells within the 500-foot-wide corridor of either alternative. The minor changes in HVDC Alternative Routes 5-B and 5-E would not affect the potential impacts associated with construction.

3.7.6.3.2.1.6 Region 6

The HVDC alternative routes in Region 6 would traverse two principal aquifers in their paths from west to east. From the west, they would cross the Mississippi River Valley alluvial aquifer, the Mississippi embayment aquifer system (crossing Crowley's Ridge in eastern Arkansas), and the Mississippi River Valley alluvial aquifer again in the east. The only groundwater designation of special interest along the HVDC alternative routes in Region 6 is critical groundwater area. As shown in Table 3.7-18, the 200-foot-wide ROW of HVDC Alternative Route 6-A would cross 24 fewer acres of critical groundwater area than the corresponding links of the Region 6 Applicant Proposed Route, and HVDC Alternative Route 6-B would cross 2 more acres than the corresponding links of the Applicant Proposed Route. The ROWs of HVDC Alternative Routes 6-C and 6-D would cross the same amount of designated area as the corresponding links of the Applicant Proposed Route. The 200-foot-wide ROWs of all alternative routes avoid wellhead protection area. As shown in Table 3.7-19, the combined number of wells (domestic, agricultural, and industrial) encompassed by the expanded (500-foot-wide) ROWs of HVDC Alternative Routes 6-A, 6-B, and 6-C would each be one more well than encompassed by the corresponding links of the Region 6 Applicant Proposed Route, while the total number of wells within the expanded ROW of HVDC Alternative Route 6-D would be two less. Potential impacts associated with construction of an HVDC alternative route in Region 6 would be the same as those common impacts described in Section 3.7.6.1.

As described in Appendix M and summarized in Section 2.4.2.6, a route adjustment was developed for HVDC Alternative Route 6-A to maintain an end-to-end route with the Applicant Proposed Route Links 2, Variation 1. The adjustment to HVDC Alternative Route 6-A underlies no groundwater of special interest and would involve no change in the number of wells within the 500-foot-wide corridor of the alternative. The minor adjustment in HVDC Alternative Route 3-A would not affect the potential impacts associated with construction.

3.7.6.3.2.1.7 Region 7

The HVDC alternative routes in Region 7 would traverse two principal aquifers in their path from west to east, the Mississippi River Valley alluvial aquifer in the west and the Mississippi embayment aquifer system to the east. Like the Applicant Proposed Route, no groundwater designations of special interest—or wellhead protection area—are identified along the Region 7 HVDC alternative routes. As shown in Table 3.7-21, the combined number of wells (domestic, agricultural, and industrial) encompassed by the expanded (500-foot-wide) ROW of HVDC Alternative Route 7-A would be five more than encompassed by the corresponding links of the Region 7 Applicant Proposed Route and they are all agricultural wells. There are no wells in the expanded ROWs of HVDC Alternative Routes 7-B, 7-C, and 7-D, the same as for the corresponding links of the Applicant Proposed Route. Potential impacts associated with construction of an HVDC alternative route in Region 7 would be the same as those common impacts described in Section 3.7.6.1.

3.7.6.3.2.2 Operations and Maintenance Impacts

Operation and maintenance of an HVDC transmission line in Regions 1 through 7, using any of the HVDC alternative routes, would not impact groundwater. During operations and maintenance, no notable sources of contaminants would be in use other than the typical fuels and lubricants found in vehicles and equipment, no soil disturbance would occur, and water needs would be limited to personal needs of the few workers that would be associated with maintenance of facilities and equipment.

3.7.6.3.2.3 Decommissioning Impacts

Decommissioning of HVDC transmission lines, with the Applicant Proposed Route or any of the HVDC alternative routes, would be expected to have impacts similar to those described in Section 3.7.6.1 for common construction activities, i.e., the same types of measures would be required to manage the fuel and lubricants that would be present in equipment and actions to protect stormwater runoff at the site would ensure that contaminants did not reach groundwater. Water demand during decommissioning would be limited to that needed for actions such as dust suppression, soil compaction, and possibly re-seeding or landscaping to put the ground back into suitable condition. Water demand would be expected to be less than for construction and would not adversely impact groundwater resources.

3.7.6.4 Best Management Practices

The Applicant has developed a comprehensive list of EPMs that would avoid and minimize impacts to groundwater. A complete list of EPMs for the Project is provided in Appendix F; those EPMs that would minimize the potential for release or mismanagement of hazardous materials, changes to stormwater runoff and infiltration rates, and changes to existing groundwater availability are identified in Section 3.7.6.1.5. The EPMs are sufficiently comprehensive to minimize or avoid potential adverse impacts to groundwater. DOE has therefore not identified any additional groundwater-related best management practices.

3.7.6.5 Unavoidable Adverse Impacts

Standard construction practices along with the EPMs to which the Applicant has committed (Section 3.7.6.1.5) should avoid adverse impacts to groundwater with the exception that water resources would be required to support the construction. Although the water needed for the Project is expected to come from municipal water systems, some of that municipal water would undoubtedly come from groundwater sources. To the extent that groundwater resources are replenished by cyclic, seasonal recharge, adverse impacts would be small and relatively short-term, but there would be a minor reduction in groundwater available for other uses or natural features while the construction took place.

As described in Section 3.7.6.1.1, common materials present during construction would be considered groundwater contaminants were those materials to be spilled, leaked, or otherwise released and eventually reach groundwater. The potential for groundwater quality problems is minor because measures required by permits as well as the additional measures that would be implemented by the Applicant (i.e., the EPMs of Section 3.7.1.6.5) would ensure proper management of such materials and appropriate responses to any releases should they occur, but the potential would not be eliminated.

Water (some likely from groundwater sources) would also be needed to support operations and maintenance of the transmission lines and converter stations, but the quantities would be minor in comparison to quantities currently used in the region.

3.7.6.6 Irreversible and Irretrievable Commitment of Resources

The Project would involve a commitment of groundwater resources, but at least to some extent, those resources would be replenished by cyclic seasonal recharge. The commitment of groundwater resources would be irreversible in that it would limit, in the short term, other options for use of that resource. Over time, however, the amounts of groundwater used to support construction would be expected to have a negligible effect on groundwater resources. In sum, the groundwater resource would be renewable or recoverable, so the commitment would not be considered irretrievable.

3.7.6.7 Relationship between Local Short-term Uses and Long-term Productivity

Groundwater required to support the Project would represent a new, short-term use of the resource, but would have negligible effect on its long-term productivity.

3.7.6.8 Impacts from Connected Actions

3.7.6.8.1 Wind Energy Generation

3.7.6.8.1.1 Construction Impacts

Construction of wind farms in the Oklahoma and Texas Panhandle regions would be expected to involve potential impacts to groundwater similar to those described in Section 3.7.6.1 for common construction activities under the Project. Sources of contamination, primarily in the form of fuels and lubricants, would be present at construction sites and at associated construction staging and storage yards. Soils in construction areas, access routes, and support areas would be disturbed and, for at least some period of time, would be expected to experience changes in stormwater infiltration and runoff rates as compared to undisturbed conditions. Water needs to support construction activities could affect the availability of groundwater resources for other users in the region. The construction actions could also affect local groundwater availability by causing damage to existing wells or piping systems.

The groundwater features that could be affected by construction or that could alter construction approaches due to added requirements are presented in Section 3.7.5.8.1 by WDZ. Although there are differences in groundwater features between the WDZs, DOE has no way of predicting precisely where wind farms might be constructed within the WDZs and therefore cannot address whether those features would be of concern to a specific wind farm proposal. Further, it is estimated that future wind farm developments utilizing the Applicant’s transmission line would include only 20 to 30 percent of any WDZ (Clean Line 2014) and the nature of wind farm developments is that large areas are required, but only relatively small areas are physically impacted. As a result, wind farm design would be expected to have flexibility on where roads and facilities were placed and what locations, specifically those with environmental concerns, could be avoided. Because of these factors, DOE has not identified potential groundwater impacts for individual WDZs; rather the discussion that follows provides more detail on the typical impacts that would be expected from the construction of wind farms within any of the WDZs.

3.7.6.8.1.1.1 Potential for Groundwater Contamination

Construction of even one large wind turbine would involve land disturbance of more than 1 acre (BLM 2005), which is the trigger in both Oklahoma and Texas for requiring a construction general permit for stormwater discharges under the EPA NPDES program as implemented by each state. Accordingly, construction of a wind farm in either state would be subject to the requirements of a construction general permit and the standard permit provisions described in Section 3.7.6.1.1. The future wind farm developer would be required to prepare and implement a SWPPP, which would in turn act to prevent groundwater contamination by requiring actions to prevent contaminant releases. If wind farm construction required setup of a temporary concrete batch plant, its operation would also be subject to permit requirements. Since wind farm developments require relatively small amounts of permanently disturbed or dedicated land (or restated, large areas of land remain unused between individual wind turbines) (Denholm et al. 2009), it is typical for them to be located on private land under lease agreements with landowners. Since some type of formal agreement with landowners would be expected, it is unlikely that wind farm construction would take place without knowing the exact locations of existing features such as wells that are important to the landowner. It is reasonable to assume that any actions that might damage or contaminate any wells (and groundwater) would be avoided.

Wind farm construction activities could involve foundation depths up to 40 feet if pier foundations are used, but the often-used mat foundations, while requiring more land area, generally do not require excavations of more than 10 feet in depth (DOE 2013). As shown by the water table depths in Table 3.7-23, construction of pier foundations in WDZs in Beaver County, Oklahoma, or in Ochiltree County, Texas (i.e., WDZ-A, -J, -K, and -L), could encounter groundwater, but in the other counties, construction would be unlikely to reach groundwater. Construction of mat foundations would be unlikely to encounter groundwater in any of the WDZs. As described in Section 3.7.6.1.1 for the Project, if foundations for wind turbines or other facilities involve excavations or drillings that reach groundwater, materials such as drilling muds or bentonite could be used to help stabilize excavation or borehole walls. Although they would come into contact with groundwater, these materials are formulated to be relatively immobile in groundwater (they adhere to and stabilize soil surfaces), are non-toxic, and would be used for their intended purposes.

With the wind farm development elements described above, it is expected that construction of the connected action would involve the same minor potential for groundwater contamination impacts as described in Section 3.7.6.1.1 for general construction under the Project.

3.7.6.8.1.1.2 Changes to Infiltration Rates

As described in Section 3.7.6.1.2 for the Project, soils at connected action construction sites would be broken up, loosened, and stockpiled for some period of time during which such soils would have higher infiltration rates, possibly with higher groundwater recharge, than undisturbed soils. Similarly, soil in some areas could be compacted intentionally to improve its stability or indirectly through equipment traffic and have lower infiltration rates as a result. However, such conditions would be expected to be relatively short-term, with most soils being restored to a pre-disturbance condition once foundations and structures were in place. Also, areas of permanent or long-term disturbance would be relatively small compared to surrounding areas not disturbed by the connected action; it is estimated that the footprint of all wind farm facilities and structures, including maintained access roads, would be approximately 1 percent of the total wind farm area (Denholm et al. 2009). The relatively small and short-term changes in infiltration rates would not be expected to result in any noticeable changes in the area's natural groundwater recharge rates.

3.7.6.8.1.1.3 Effects on Water Availability

Water would be needed to support construction of the connected action wind farms. As shown in Table 3.7-26, the majority of water used in the six-county area of the WDZs comes from groundwater. Accordingly, it is assumed that whatever water is needed to support construction of the connected action wind farms would be from groundwater sources. Primary water needs would include use for soil compaction during road, substation, and wind turbine foundation construction; as a component of concrete; and for dust suppression.

The BLM (2010) estimated that 9.8 million gallons of water would be required over an 8-month construction period for a typical wind farm of 34 to 52 wind turbines, each with a capacity of 3MW. For the current evaluation, it is conservatively assumed that this would be the water demand for 34 such wind turbines, which equates to a construction water demand of 96,000 gallons/MW of wind farm generating capacity. The Applicant assumes that the total capacity of the wind farms in the WDZs would have to be 4,000 to 4,550MW to achieve the Project's full utilization of 3,500 to 4,000MW. The Applicant also assumes that 90 percent of this total capacity can be constructed in a 2-year time frame leading up to the operation date of the Project, with the remaining 10 percent constructed in the following year (Clean Line 2014). At 90 percent of 4,550MW and an estimated construction water demand of 96,000 gallons/MW, it is estimated that 363 million gallons of water would be needed during 2 years of peak wind farm construction, or an average water demand of 0.54 million gallons per day during the 2-year period.

The Applicant estimates the maximum wind development for the individual WDZs ranges from a minimum of 300MW (for WDZ-D and WDZ-E) to a maximum of 1,300MW (for WDZ-G). To construct wind farms with a combined capacity of 4,095MW (i.e., 90 percent of 4,550MW) in two years, it is clear that the estimated water demand of 0.54 million gallons per day would be spread out over multiple WDZs. At any given time, the water demand could be focused in a small number of the zones, but over time the average demand in any single zone would be expected to be only a fraction of the 0.54 million gallons per day. Although a notable amount of water, 0.54 million gallons per day is only 0.07 percent of the 791 million gallons per day (Table 3.7-26) used in the six-county area in which the WDZs are located. On a county-by-county basis, however, 0.54 million gallons per day represents as much as 1.3 percent of a county's water use (in the case of Beaver County, Oklahoma). As noted above, however, over the two-year construction period, the total water demand would have to be spread out over multiple WDZs and multiple counties.

Since groundwater is the predominant source of water used in the six-county region of the WDZs (Table 3.7-26), it is assumed that water to support construction of the connected action wind farms would be obtained from new wells or, more likely, from existing wells and existing water rights holders. Irrigation is the predominant water use in all six counties (Table 3.7-26) and there are large numbers of agricultural wells in each of the WDZs (Table 3.7-25). It seems less likely that any significant portion of the water demand would be obtained from public water systems because the public water systems in all six counties produce less than 12 million gallons per day, with three of the counties producing about 0.5 million gallons per day each. It is important to note that the water needed to support the primary construction demands would not have to be of drinking water quality.

3.7.6.8.1.2 Operations and Maintenance Impacts

Operations and maintenance of wind farm facilities in any of the WDZs would not impact groundwater. During operations and maintenance, no notable sources of contaminants would be in use other than the typical fuels and lubricants found in vehicles and equipment, no soil disturbance would occur, and water needs would be limited to personal needs of the few workers that would be associated with maintenance of facilities and equipment.

3.7.6.8.1.3 Decommissioning Impacts

Decommissioning of wind farms would be expected to have impacts similar to those described in Section 3.7.6.8.1 and in more detail in Section 3.7.6.1 for common construction activities. Measures would be required to manage the fuel and lubricants that would be present in equipment and actions would be taken to protect stormwater runoff at the site to ensure that contaminants did not reach groundwater. Water demand during decommissioning would be limited to the amounts needed for actions such as dust suppression, soil compaction, and possibly re-seeding or landscaping to put the ground back into suitable condition. Water demand would be expected to be less than for construction and would not adversely impact groundwater resources.

3.7.6.8.2 Optima Substation

Groundwater impacts from construction of the Optima Substation would be the same as described in Section 3.7.6.2.1 for the Oklahoma converter station and AC interconnection and the common construction impacts described in Section 3.7.6.1. Depths to groundwater are great enough that it is unlikely that groundwater would be reached during excavation for the substation’s foundation. Impacts during operations and maintenance would be expected to be similar to those described for the Oklahoma converter station and AC interconnection in Section 3.7.6.2.1.

3.7.6.8.3 TVA Upgrades

Groundwater impacts of concern for the required TVA upgrades, like the Project, are associated with the potential for groundwater contamination, changes to infiltration rates, effects on water availability, and physical damage to well systems. These concerns would be limited primarily to construction activities associated with the new transmission line. The TVA upgrades would not be expected to use large quantities of water during long-term operations.

The new transmission line would be expected to involve the presence of the same type of potential contaminants (primarily fuels and lubricants in equipment) during construction and to implement the same type of measures to ensure those contaminants were not released. The construction would be expected to involve relatively minor changes to infiltration rates and, to minimize potential liability, TVA would take precautions to ensure that equipment movement and excavations did not unknowingly damage well systems. Water needs for dust suppression, soil compaction, equipment cleaning, and concrete formulation would be relatively minor and short term. There would be little potential for impacts to groundwater during upgrades involving modifications to existing facilities. A possible exception would be if replacement of structures was required as part of the upgrades to existing transmission lines. These type activities could involve new ground disturbances and potential for impacts to groundwater similar to those described for typical construction.

3.7.6.9 Impacts Associated with the No Action Alternative

Under the No Action Alternative, DOE assumes for analytical purposes that the Project would not move forward. Groundwater conditions would remain as described in the affected environment descriptions of Section 3.7.5.

3.8 Health, Safety, and Intentional Destructive Acts

This section presents the results of DOE's analysis of potential health and safety impacts associated with the Project. Some additional health and safety concerns regarding members of the public are addressed in individual resource area discussions elsewhere in this EIS including electrical environment (Section 3.4), surface and subsurface instability (Section 3.6), noise (Section 3.11), surface water resources (Section 3.15), and transportation (Section 3.16).

3.8.1 Regulatory Background

3.8.1.1 Federal Requirements

Transmission line projects must be designed to meet or exceed applicable safety and reliability criteria and requirements outlined by organizations and standards such as NERC, the National Electrical Safety Code (NESC), the Southwest Power Pool, TVA, the American Society of Chemical Engineers, and other applicable federal, state, or local requirements. Appendix B of the NESC contains detailed requirements to ensure the safe design, construction, and operations and maintenance of transmission line projects. The NESC is published by the IEEE (IEEE 2011). Worker safety during construction and operations is regulated by workplace safety rules established by the Occupational Safety and Health Administration (OSHA) and/or equivalent workplace safety rules established by each state (Clean Line 2013a). The OSHA standards and NESC rules work together to create a comprehensive set of standards and practices designed to protect the health and safety of workers engaged in the construction, operations, and maintenance of a project. Industrial construction and routine workplace operations are governed by the Occupational Safety and Health Act of 1970, specifically 29 CFR Part 1910 (general industry standards) and 29 CFR Part 1926 (construction industry standards).

EO 13045, Protection of Children from Environmental Health Risks and Safety Risks (62 FR 19885, April 23, 1997), dictates that each federal agency ensure that its policies, programs, activities, and standards address disproportionate risks to children that result from environmental health or safety risks; children are defined as populations under the age of 18. This EO is relevant if it is determined that there may be disproportionate health and safety impacts to children from construction or operations and maintenance of the Project.

Management of hazardous waste is governed by RCRA, which establishes a program administered by the EPA that regulates the generation, transportation, treatment, storage, and disposal of hazardous waste. Section 3.8.4.1 identifies the hazardous materials that could be used and the potential hazardous waste that could be generated on the Project. Title III of the Superfund Amendments and Reauthorization Act also known as the Emergency Planning and Community Right-to-Know Act requires states to promote outreach for developing local emergency preparedness programs to respond to chemical releases, receive reports from the regulated community, and to analyze and disseminate the resulting information on hazardous chemicals to local governments and the public.

Security of the components of the Project facilities can involve a variety of different regulatory and reporting structures, authorities, and agencies. Intentional destructive acts, sabotage, vandalism, theft, or other mischief, whether from terrorist activities or other criminal behavior, would be addressed through law enforcement and Project design protocols.

Presidential Policy Directive 21, "Critical Infrastructure Security and Resilience," identifies 16 critical infrastructure sectors, including energy, and identifies the national goal to advance a national policy to strengthen and maintain secure, functioning, and resilient critical infrastructure. This Project would fall under the energy sector's definition of critical infrastructure. This directive includes measures that address public-private partnerships to reduce vulnerability and guidelines to address vulnerability, and the directive establishes federal government roles and responsibilities for protecting critical infrastructure.

The NERC is a not-for-profit entity whose mission is to ensure the reliability of the bulk-power system in North America. The NERC develops and enforces reliability standards; assesses seasonal and long-term reliability; monitors the bulk-power system through system awareness; and educates, trains, and certifies industry personnel. The NERC's reliability standards include requirements for physical and cyber security of bulk-power system facilities, including major transmission lines (NERC 2014). In November 2013, the Federal Energy Regulatory Commission issued Order Number 791 (FERC 2013), approving Version 5 Critical Infrastructure Protection Reliability Standards submitted for approval by the NERC. There are 10 reliability standards that require certain users, owners, and operators of the bulk-power system to comply with specific requirements to safeguard critical cyber assets. In the area of security, the NERC reliability standards have focused on cyber security for operational systems; however, related requirements apply to security risk assessment and physical security and protection of critical facilities.

The U.S. Department of Homeland Security Homeland Infrastructure Threat and Risk Analysis Center, which conducts integrated threat analysis for all critical infrastructure and key resources, works in partnership with owners and operators and other federal, state, and local government agencies to ensure that suitable threat information is made available (DHS 2010).

3.8.1.2 State Requirements

State health and safety requirements are designed to be generally consistent with the federal requirements to ensure comparable standards for the workplace. Workplace health and safety requirements for Oklahoma, Arkansas, Tennessee, and Texas are summarized in Table 3.8-1. Although Oklahoma, Arkansas, and Tennessee have adopted the federal OSHA requirements, some exceptions may apply in cases where further information or more stringent requirements were deemed necessary by the state; exceptions are identified within each state's OSHA program.

Table 3.8-1:
State Occupational Health and Safety Information

State	Workplace Health and Safety Authority	Responsible State Agency	Additional Information
Oklahoma	Oklahoma Occupational Health and Safety Standards Act, codified in the Oklahoma Statutes, Title 40, Sec. 401, et seq.	Oklahoma Department of Labor; OSHA, Consultation Division	The state has adopted the U.S. Department of Labor OSHA health and safety standards
Arkansas	Arkansas Department of Labor Safety Code 11 on Electrical Safety	Arkansas Department of Labor, Occupational Safety and Health Division	The state has adopted the U.S. Department of Labor OSHA health and safety standards
Tennessee	Tennessee Occupational Safety and Health Act of 1972 as codified in Tennessee Code Annotated Sec. 50-3-101 through 50-3-919	Tennessee Occupational Health and Safety Administration	The state has adopted the U.S. Department of Labor OSHA health and safety standards
Texas	No comprehensive workplace health and safety legislation	Texas Department of Insurance, Division of Workers Compensation	Texas does not have its own occupational health and safety regulatory program, but all private-sector workplaces must comply with federal OSHA regulations

Source: Clean Line (2013a)

The ODEQ manages hazardous waste in Oklahoma under the Oklahoma Hazardous Waste Management Act (27A Oklahoma Statutes Sec. 2-7-101 et seq.), which applies to construction and operations and maintenance activities. The Oklahoma Emergency Response Act (27A Oklahoma Statutes Sec. 4-2-102) governs emergency response to hazardous material incidents that may present a threat to public health and safety throughout the state. This act applies in the event of a release of a hazardous material caused by construction, operations, or decommissioning activities in Oklahoma. Oklahoma's Emergency Planning and Community Right-to-Know regulation (Oklahoma Administrative Code 252-020) requires reporting for the use or generation of hazardous chemicals. Projects that include handling of hazardous chemicals during construction or operations and maintenance and that meet regulatory thresholds would require reporting under this regulation.

Under the Arkansas Hazardous Waste Management Act (Arkansas Code, Sec. 8-7 202 et seq.), the Arkansas State Hazardous Waste Division manages hazardous waste in Arkansas through the state's RCRA Subtitle C waste management program. This program provides specific requirements for the management and disposal of hazardous wastes, used oils, and universal wastes (ADEQ 2013).

The TDEC manages hazardous materials in accordance with the Tennessee Hazardous Waste Program. The TDEC's administrative rules for hazardous waste management (Chapter 0400-12-01) provide specific requirements for the management and disposal of hazardous waste (TDEC 2012). Projects that include transport, handling, storage, or disposal activities of hazardous chemicals identified during construction or operations and maintenance activities would trigger the need to meet state reporting and waste management requirements under these rules.

The Texas Hazard Communication Act (Texas Health and Safety Code 502.001 et seq.), as amended in 1993, sets the minimum requirements employers must meet for providing information about hazardous chemicals in the workplace to employees and other interested parties and is enforced by the Texas Department of Health. The rules require project developers to compile workplace chemical lists for work sites, train all exposed employees regarding the hazards associated with the chemicals they use, maintain a file of safety data sheets (formerly known as material safety data sheets), and supply the appropriate emergency response personnel with information.

3.8.2 Data Sources

Much of the information presented herein for the health, safety, and intentional destructive acts resource areas relies on the Safety, Security, and Hazards Technical Report for the Project and associated, independently verified references (Clean Line 2013a). The connected actions discussion addressing potential wind energy generation facility development and related substation or transmission upgrades utilizes information and references from the Wind Generation Technical Report for the Project (Clean Line 2014a). The health, safety, and intentional destructive acts analysis herein relies on relevant publicly available information and reports to provide information on the existing affected environment. Sources of information include federal, state, and municipal governments, as well as non-governmental organizations. Security risk- and hazard-related data were obtained through official agency websites or directly from government agencies. In addition, health and safety, security, and hazard information was received from regulatory agencies and other stakeholders during the DOE scoping process.

Noise, traffic, electrical environment, land use, geology, and water resources information was reviewed from other sections of this EIS for applicability to the health and safety resource area. The U.S. Bureau of Labor Statistics' (BLS) website was consulted for worker fatality and injury data. The BLS, like OSHA, is part of the U.S. Department of Labor.

3.8.3 Region of Influence

The ROI for the health, safety, and intentional destructive acts resource area for the Project and connected actions is described in Section 3.1.1 and does not differ for purposes of impact analyses for this resource area.

3.8.4 Affected Environment

This section includes a description of the existing environment for health, safety, and intentional destructive acts such that impacts may be effectively evaluated. The affected environment includes descriptions of worker health and safety, hazardous materials and waste, aircraft and rail operations, fire hazards, natural events and disasters, and intentional destructive acts.

3.8.4.1 Worker Health and Safety

Worker safety in construction and industrial settings is regulated by OSHA. The Project would be subject to OSHA standards during construction and operations and maintenance (e.g., OSHA General Industry Standards [29 CFR Part 1910] and the OSHA Construction Industry Standards [29 CFR Part 1926]). OSHA standards are designed to protect workers from potential construction and industrial accidents, as well as to minimize exposure to workplace hazards (e.g., noise, chemicals).

Industrial health and safety is concerned with occupational and worker hazards during routine operations. The BLS maintains statistics on the incidence of workplace injuries, illnesses, and fatalities. The health and safety incident categories are defined as follows:

- Total recordable cases: The total number of work-related deaths, illnesses, or injuries that result in the loss of consciousness, days away from work, restricted work activity or job transfer, or required medical treatment beyond first aid.
- Days away from work, or days of restricted work activity or job transfer: Cases that involve days away from work, or days of restricted activity or job transfer, or both.
- Worker fatality: Cases that involve the death of a worker.

The incidence rates (cases per 100 full-time workers for non-fatality statistics and cases per 100,000 full-time workers for fatality statistics) maintained by the BLS are calculated separately for different industries based on the reported health and safety cases for that particular industry.

To minimize the effect of industrial health and safety hazards, industries must comply with all applicable regulations that relate to industrial health and safety. Table 3.8-2 summarizes 2012 national safety statistics from the BLS for industry categories that are relevant to the Project.

Table 3.8-2:
2012 National Statistics for Workplace Hazards

Industry	Nonfatal Recordable Incidents (Per 100 FTE Workers)[1]	Lost Workdays (Per 100 FTE Workers)	Fatalities (Per 100,000 FTE Workers)
Construction (all)	3.7	2.0	9.9
Utilities (electric power generation, transmission, control, and distribution)	2.8	1.4	2.5

FTE = Full-time equivalent
1 Nonfatal occupational injury and illness cases requiring days away from work to recuperate.
Source: BLS (2012a, 2012b)

Of the 4,175 worker fatalities that occurred nationally in private industry in calendar year 2012, 806 (19.3 percent) were in construction. The leading causes of worker deaths on construction sites were falls, followed by struck by object, electrocution, and caught-in/between. These "fatal four" were responsible for more than half (54.2 percent) the construction worker deaths in 2012. Eliminating the fatal four would save 437 workers' lives in America every year (OSHA 2013a). Details for these fatal four include the following:

- Falls: 279 out of 806 total deaths in construction in 2012 (34.6 percent)
- Struck by object: 79 (9.8 percent)
- Electrocutions: 66 (8.1 percent)
- Caught-in/between: 13 (1.6 percent)

By comparison, there were 14 fatalities nationally in the private utility industry (electric power transmission, control, and distribution) in calendar year 2012. Causes of worker death in this industry include transportation incidents, exposure to harmful substances or environments, and contact with objects and equipment (OSHA 2013b).

Construction, operations and maintenance, and decommissioning of a transmission line and associated facilities may result in a variety of conditions that present a risk to worker health and safety. A recent article on safety risk management for electrical transmission and distribution line construction found that: “construction contractors account for the highest rate of electrocutions. Within the construction trade, electricians accounted for about 17% of the electrocution fatalities; construction laborers accounted for 9%...and maintenance workers incurred a total of 7%... ” (Albert and Hallowell 2012).

Exposure to certain chemicals can adversely affect human health through toxic reactions, carcinogenic effects, or both. Chemical exposure can occur from chemicals present in water or in soil from past industrial activities. EPA hazardous materials data sources were used to determine known contaminated sites within the ROI. The Applicant conducted site and route selection activities to avoid known contamination sites, so no Superfund sites or brownfield sites are located in the ROI. However, contamination may be encountered where not previously known to occur and is more likely in areas where land uses may have involved the use and/or storage of hazardous materials, including at oil and gas wells, abandoned or active mine sites, oil/gas pipelines, railroads, aerial pesticide application airstrips, and agricultural/commercial/industrial structure sites (Clean Line 2013a).

During construction and operations and maintenance activities, hazardous materials including vehicle fuels, oils, and other vehicle maintenance fluids would be stored and used in construction staging areas and necessary operational work areas. During these activities, mismanagement or accidental releases of these materials could contaminate soil and/or water resources and have adverse effects on human health and the environment. Examples of hazardous wastes include spent hazardous materials and by-products from their use.

A number of hazardous substances are used in the construction, operation, and maintenance of electrical transmission lines and associated facilities. Table 3.8-3 lists common types of materials that could be used, but is not a comprehensive list. Generation of hazardous waste is not anticipated; however, the Applicant would implement applicable EPMs and follow regulatory processes if construction and industrial processes resulted in the generation of hazardous waste.

Table 3.8-3:
Hazardous Materials Typically Used for Transmission Line Construction

Hazardous Material			
2-cycle oil (contains distillates and hydro-treated heavy paraffinic)	ABC fire extinguisher	Acetylene gas	Air tool oil Insulating oil (inhibited, non-polychlorinated biphenyl)
Ammonium hydroxide	Antifreeze (ethylene glycol)	Automatic transmission fluid	Battery acid (in vehicles and in the meter house of the substations)
Bottled oxygen	Brake fluid	Canned spray paint	Chain lubricant (contains methylene chloride)
Connector grease (penotox)	Contact Cleaner 2000 (1,1,1-trichloroethene)	Diesel deicer	Diesel fuel
Diesel fuel additive	Gasoline	Gasoline treatment	Hot stick cleaner (cloth treated with polydimethylsiloxane)
Hydraulic fluid	Lubricating grease	Mastic coating	Methyl alcohol
Motor oils	Paint thinner	Pesticide	Propane
Puncture seal tire inflator	Safety fuses, implosive connectors, conductor splices, deadend assemblies	Starter fluid	Sulfur hexafluoride (within the circuit breakers in the substations)
Potassium hydroxide—nickel-cadmium batteries	WD-40 (penetrating oil)	Edisol XT—insulating oil used in capacitor banks	Transformer oil—insulates and cools transformers

Source: Clean Line (2014b)

3.8.4.2 Aircraft and Rail Operations

Fifty-two known aircraft facilities (airports, airstrips, and heliports) are located within the ROI for transportation impact analyses, which includes a 4-mile-wide corridor from the HVDC transmission line and AC collection system transmission line centerlines (see Section 3.16.3.1). It is possible, however, that unknown private or unofficial airstrips may be located within the ROI or nearby. In addition, the Project is located within agricultural areas where aerial application of pesticides, and fertilizers is a common practice for certain crops (commonly known as crop dusting). Section 3.16.4.4 and Section 3.16.5 (by region) present detailed airport and aircraft operation information applicable to health and safety impact analyses discussed later.

Numerous rail lines are located within the transportation resource area ROI (6-mile area around Project components) as shown on Figures 3.16-1a through 3.16-1f in Appendix A. Railroads are more specifically discussed in Section 3.16.5 by region. Railroads were identified based on the potential encroachment within the ROI, which refers to areas where railroads and railroad ROWs might be affected because the Project would cross the railroad ROW or be located in close proximity to the railroad.

3.8.4.3 Fire Hazards

A wildfire is an uncontrolled fire spreading through vegetative fuels and could occur at any point within the ROI. Oklahoma has a significant wildfire hazard given its climate and the types of vegetative fuels present. Fire season in Oklahoma has been identified as lasting from July through April (ODEM 2011). Wildfires have occurred in every county in Arkansas, but they are most common in the south-central and southwestern parts of the state within the heavily forested Gulf Coastal Plain and southern Ouachita Province (ADEM 2013). The Project would be located in the northern portion of Arkansas, which is primarily categorized as having a low to medium occurrence of wildfire events over the period 1997 to 2012 (ADEM 2013).

3.8.4.4 Natural Events and Disasters

Natural events and disasters consisting of extreme weather, ground surface and subsurface instabilities (e.g., earthquakes), and flooding have the potential to cause damage to Project facilities with resultant impacts to worker and public health and safety.

Severe weather such as thunderstorms, lightning, high winds, ice storms, and tornadoes may occur during all phases of the Project since activities would be conducted year-round. Tornadoes and thunderstorms are most likely to occur during spring, summer, and fall; ice storms could occur during late fall, winter, and early spring; and high winds may occur at any time of year. Weather forecasts are generally accurate at predicting potential periods when severe weather may occur and forecasts would be monitored during construction. Tornadoes are a particular concern in the ROI and have occurred in each Oklahoma County approximately two to three times per year on average based on data from 1950 to 2013; the majority of the tornadoes recorded were in lower strength categories measuring less than F-3 on the Fujita scale[1] (THP 2014). In Arkansas and western Tennessee, tornadoes occur in the vicinity of the ROI approximately once or twice per year on average during the same reporting period identified above, and the majority also were in lower strength categories (THP 2014).

Surface and subsurface ground instabilities such as earthquakes, faulting, liquefaction, landslides, and subsidence could have an effect on the health and safety of workers and the public. Section 3.6 describes the affected environment and impact analyses for geology, paleontology, minerals, and soils including locations of active faults and seismic risk scenarios for the various components, facilities, and routing locations of the Project.

Flooding is another natural event that could have an effect on Project components with resultant impacts to the health and safety primarily of workers. Section 3.15 describes the affected environment and impact analyses for surface water resources including watersheds, surface water features, water quality, and water use. Section 3.19 describes the affected environment and impact analyses for wetlands, floodplains, and riparian areas including definitions and locations of floodplains applicable to the Project.

3.8.4.5 Intentional Destructive Acts

There are not any specific sources of information regarding acts of terrorism specific to the ROI; however, three incidents of intentional destructive acts, alleged to be sabotage, occurred in September and October 2013 to a high-voltage transmission line in Arkansas and are under investigation by the Federal Bureau of Investigation (Blinder 2013).

Equipment theft is also a growing concern that is very costly to construction projects. According to the National Insurance Crime Bureau, between $300 million to $1 billion a year is lost nationwide to the theft of construction equipment (NICB 2012). A 2008 industry research study commissioned by LoJack Corporation and the National Insurance Crime Bureau showed that 71 percent of equipment owners have experienced the theft of equipment in the previous year (LoJack 2012). According to LoJack, the types of equipment most frequently stolen are light utility work trucks and trailers, loaders, skid steers, and generators/air compressors/welders.

---

[1] The Fujita scale, more popularly known as the F scale is used to measure the intensity of a tornado based on the amount of damage done by a passing tornado over an area. The F scale rates a tornado from F-0 to F-5 with a F-5 tornado having the fastest wind speeds and causing the most damage

Energy transmission has become increasingly reliant on computer-based control systems that operate and monitor energy infrastructure. The following points were extracted from a DOE-sponsored report through the Energy Sector Control Systems Working Group (ESCSWG 2012) addressing cyber security threats to energy delivery systems:

- “Because the private sector owns and operates most of the energy sector’s critical assets and infrastructure, and governments are responsible for national security, securing energy delivery systems against cyber threats is a shared responsibility of both the public and private sectors.”
- “Smart technologies (e.g., smart meters, phasor measurement units), new infrastructure components, the increased use of mobile devices, and new applications are changing the way that energy information is communicated and controlled while introducing new vulnerabilities and creating new needs for the protection of consumer and energy market information.”
- “Adversaries have pursued progressively innovative techniques to exploit flaws in system components, telecommunication methods, and common operating systems found in modern energy delivery systems with the intent to infiltrate and sabotage them.”

3.8.4.6 Protection of Children

Electrical and magnetic fields are known to occur around transmission lines, distribution lines and electric appliances. Extensive scientific research has been conducted in the United States and around the world to determine whether exposure to power-frequency AC electric and magnetic fields has any potential to produce human health effects among adults and children. Section 3.4.11.2.1.2.2.7 presents an overview of the scientific literature on potential health effects of AC electric and magnetic fields, including epidemiology studies on potential health effects on children. Sections 3.4.11.2.2.2.1 and 3.4.11.2.2.2.2 present AC electric and magnetic field calculations for the various structure and transmission line configurations for the Project.

3.8.4.7 Connected Actions

3.8.4.7.1 Wind Energy Generation

Worker activities occurring during construction and operation of wind energy generation facilities typically involve major actions such as establishing site access, excavating and installing structure foundations, working at heights (e.g., erecting turbines, nacelle and blade placement, and turbine maintenance), constructing support buildings and electrical substations, assembling and erecting meteorological towers, constructing access roads, and routine maintenance of ancillary facilities and components. Decommissioning presents many of the same hazards to the workforce as construction. Construction and operations workers at any facility are subject to risks of injuries and fatalities from physical hazards. While such occupational hazards can be minimized when workers adhere to safety standards and use appropriate protective equipment, fatalities and injuries from accidents can still occur with rates consistent with the data presented in Table 3.8-2. Many of the occupational hazards associated with wind energy generation projects are similar to those of the heavy construction and electric power industries.

A potential physical effect of operating wind turbines is shadow flicker and blade glint and glare. These terms refer to the phenomenon that occurs when the moving blades of wind turbines cast moving shadows (shadow flicker) or reflections (blade glint or glare) that cause a flickering effect. When the sun is in such a position in relation to the blades, and the shadow or reflection falls across occupied buildings, the light passing through windows can disturb the occupants. This can be viewed by observers as either brief changes in brightness in an indoor environment or by moving shadows on the ground in an outdoor environment. The type of turbine, landscape features, latitude, weather, and wind energy generation facility layout are all factors that would impact shadow flicker and blade glint and glare (Bos et al. 2013).

Construction, routine operations and maintenance, and decommissioning of wind turbines would include the use of some hazardous materials such as fuels, greases, lubricants, coolants, paints, and/or coatings for corrosion control. Hazardous materials, such as insulating fluids in electrical transformers, may also be present at substations. Information and data regarding potential existing soil contamination within WDZs are based on available information from regulatory databases including EPA's Facility Registry Services database, which lists facilities that are required to report hazardous waste management activities but does not necessarily identify sites where soil contamination has occurred. Table 3.6.2-18 lists Facility Registry Services sites within WDZs; one site in WDZ-A and one in WDZ-D are indicated as having soil contamination and are in some stage of clean up (see Section 3.6.2.5.1). It is possible; however, that other unknown hazardous waste sites may be encountered during potential wind energy generation facility development especially during foundation and cable trench excavations.

Wind turbines, generation tie lines, substations, and associated facilities could be targets of intentional destructive acts, such as sabotage, terrorism, vandalism, and theft. Such acts include cyber-attack; gunfire at turbines, generation tie lines, transmission structures, or substation and support building equipment; vandalism; and theft of equipment, supplies, tools, or materials. Theft is the most likely threat during wind energy generation facility construction, operations and maintenance, and decommissioning. There are no sources of information regarding acts of terrorism specific to specific wind energy generation facility development areas. However, there is anecdotal evidence that this should be a concern to wind energy generation facility developers. An investigation into a recent turbine collapse in the United Kingdom revealed that bolts were missing from the base (Collins 2013). Though the turbine collapsed during a high wind event, it is being speculated that it could be the result of an intentional act (Collins 2013).

3.8.4.7.2 Optima Substation

The future Optima Substation would be constructed on approximately 160 acres partially within the area identified on Figure 2.1-3 in Appendix A as the AC Interconnection Siting Area. The descriptions of the affected environment in Sections 3.8.4.1 through 3.8.4.6 are applicable to the future Optima Substation. The same worker health and safety accident statistics for the construction and operational electric utility industry would apply to the construction and operations and maintenance of the future Optima Substation.

3.8.4.7.3 TVA Upgrades

The ROI for the direct assignment facilities (which are included in the Applicant Proposed Project) would occur within the Tennessee Converter Station Siting Area, and more specifically within the Shelby Substation in Shelby County. The ROI for the network upgrades, and in particular TVA's future 500kV transmission line, cannot be fully determined at this time. The new 500kV transmission line would be constructed in western Tennessee. The upgrades to existing facilities would mostly be in western and central Tennessee. Upgrades to existing infrastructure would include upgrading terminal equipment at three existing 500kV substations and six existing 161kV substations, making appropriate upgrades to increase heights on 16 existing 161kV transmission lines to increase line ratings, and replacing the conductors on eight existing 161kV transmission lines. Where possible, general impacts associated with the required TVA upgrades are discussed in the impact sections that follow.

3.8.4.8 Regional Description

The description of the affected environment provided in Section 3.8.4 is applicable to all seven regions across Oklahoma, Arkansas, Texas, and Tennessee and to areas associated with connected actions in these states.

3.8.5 Impacts to Health and Safety

Electric transmission projects may affect worker and public health and safety during construction, operations and maintenance, and decommissioning. Additionally, project components could become the target of intentional destructive acts or sabotage (e.g., terrorist attack or mischievous actions). Potential health and safety concerns related to power transmission during construction include worker injuries; exposure to hazardous materials, contaminated sites, or excessive noise; and other risks to workers and the surrounding community from technological and natural hazards that could result in accidents within the ROI (Section 3.8.3). Health and safety concerns associated with operations and maintenance include electrical shock, electric and magnetic fields, corona, stray and induced voltage, collision hazards, fire risk, and public access to transmission structures and substation equipment.

Specific Project-related activities that could cause impacts include:

- Operating equipment near energized lines
- Energized lines/equipment put in service
- Excavation/trenching and installing foundations
- Climbing poles/operating aerial lifts
- Grounding/removing grounding
- Framing of temporary and permanent structures
- Inspecting/troubleshooting power lines/equipment
- Splicing, repairing, and installing conductors and wiring
- Clearing/trimming trees and bushes
- Moving energized conductors
- Assembling/repairing equipment and hardware
- Traffic control
- Hanging and installing transformers and vaults
- Installing and connecting busses, switches, circuit breakers, and regulators
- Installing conduit or cable trough
- Installing insulators
- Assembling and erecting substations
- Removing/replacing existing line
- Installing lightning arrestors
- Sagging to provide clearance between wires
- Attaching/replacing insulators
- Replacing shield wire
- Installing/removing dampers
- Installing/removing spacers
- Metering, testing, and measuring

3.8.5.1 Methodology

The methodology for evaluating impacts on health and safety and from intentional destructive acts involves identifying and assessing Project design, construction, operational and maintenance standards, and decommissioning guidelines for electric transmission lines and associated components. The Applicant has conducted research and evaluations addressing potential health and safety impacts associated with the Project (Clean Line 2013a). DOE has reviewed and verified these evaluations for applicability and where appropriate, has summarized them and other applicable information in the impact analyses in the following sections.

The Applicant has developed, and would implement, the EPMs listed in Appendix F to avoid or minimize potential impacts from construction and operations and maintenance of the Project. Activities described in Appendix F would incorporate and be subject to the EPMs as well as measures/requirements imposed as part of federal or state permits and authorizations. The measures that would specifically minimize the potential for impacts on health and safety are listed below:

- GE-1: Clean Line will train personnel on health, safety, and environmental matters. Training will include practices, techniques, and protocols required by federal and state regulations and applicable permits.
- GE-3: Clean Line will minimize clearing vegetation within the ROW, consistent with a Transmission Vegetation Management Plan filed with NERC, and applicable federal, state, and local regulations. The TVMP may require additional analysis under NEPA depending on whether and under what conditions DOE decides to participate in the Project.
- GE-5: Any herbicides used during construction and operations and maintenance will be applied according to label instructions and any federal, state, and local regulations.
- GE-6: Clean Line will restrict vehicular travel to the ROW and other established areas within the construction, access, or maintenance easement(s).
- GE-8: Access controls (e.g., cattle guards, fences, gates) will be installed, maintained, repaired, replaced, or restored as required by regulation, road authority, or as agreed to by landowner.
- GE-12: Clean Line will avoid remedial structures (e.g., capped areas, monitoring equipment, or treatment wells) on contaminated sites, Superfund sites, CERCLA remediation areas, and other similar areas. Workers will use appropriate protective equipment and appropriate safe working techniques when working at or near contaminated sites.
- GE-13: Emergency and spill response equipment will be kept on hand during construction.
- GE-15: Waste generated during construction or maintenance, including solid waste, petroleum waste, and any potentially hazardous materials will be removed and taken to an authorized disposal facility.
- GE-16: Where required by FAA, or in certain areas to protect aviator safety, Clean Line will mark structures and/or conductors and/or shield wires with high-visibility markers (i.e., marker balls or other FAA-approved devices).
- GE-19: Clean Line will properly ground permanent structures (e.g., fences, gates) to reduce the potential for induced voltage and currents onto conductive objects in the ROW.
- GE-21: Clean Line will maintain construction equipment in good working order. Equipment and vehicles that show excessive emissions of exhaust gasses and particulates due to poor engine adjustments or other inefficient operating conditions will be repaired or adjusted.
- GE-22: Clean Line will impose speed limits during construction for access roads (e.g., to reduce dust emissions, for safety reasons, and for protection of wildlife).

- GE-25: Clean Line will turn off idling equipment when not in use.
- GE-28: Hazardous materials and chemicals will be transported, stored, and disposed of according to federal, state, or local regulations or permit requirements.
- GE-29: Clean Line will work with landowners and operators of active oil and gas wells, utilities, and other infrastructure to identify and verify the location of facilities and to minimize adverse impacts. Identification may include use of the One Call system and surveying of existing facilities.
- AG-5: Clean Line will work with landowners and/or tenants to consider potential impacts to current aerial spraying or application (i.e., crop dusting) of herbicides, fungicides, pesticides, and fertilizers within or near the transmission ROW. Clean Line will avoid or minimize impacts to aerial spraying practices when routing and siting the transmission line and related infrastructure.

Clean Line will also develop the following plans or procedures to implement the EPMs:

- Blasting Plan. This plan will describe measures designed to minimize adverse effects due to blasting.
- Spill Prevention, Control and Countermeasures (SPCC) Plan. This plan will describe the measures designed to prevent, control, and clean up spills of hazardous materials.
- Transmission Vegetation Management Plan (TVMP). This plan would be developed and implemented pursuant to the North American Electric Reliability Corporation (NERC) Reliability Standard FAC-003 and will describe how Clean Line will conduct work on its right-of-way to prevent outages due to vegetation. The TVMP may require additional analysis under NEPA depending on whether and under what conditions DOE decides to participate in the Project.
- Construction Security Plan. This plan will describe measures designed to avoid and/or minimize adverse effects associated with breaches in Project security during construction including terrorism, sabotage, vandalism, and theft. The plan will include provisions describing how the Project construction team will coordinate with state and local law enforcement agencies during construction to improve Project security and facilitate security incident response, if required.
- Transportation and Traffic Management Plan. This plan would include railroad crossing protocols and construction and post-construction practices to avoid vehicle, railroad, and transmission line conflicts. Typically, stoppage of railroad traffic is not required during construction or conductor stringing and tensioning activities. Crossing activities are similar to those for road crossings and typically involve the use of guard structures. Stringing and tensioning activities would be performed in coordination with the appropriate railroad authorities as required.

3.8.5.2 Impacts Associated with the Project

The impacts discussed below are common to all components of the Project within Oklahoma, Arkansas, Tennessee, and Texas, including converter stations and AC interconnections, the HVDC transmission line, AC collection system transmission lines, access roads, multi-use construction yards and other temporary construction areas, and communications sites. There are no appreciable differences in health and safety impacts between the Applicant Proposed Project and DOE Alternatives unless otherwise stated in specific sections below because Project components, construction and operation processes, and facility footprints would be the same or similar.

Several route variations to the Applicant Proposed Route in Regions 2–7 were developed in response to public comments on the Draft EIS and are described in Appendix M and summarized in Sections 2.4.2.1–2.4.2.7. Assessments of the health and safety impacts related to the route variations, including accompanying HVDC alternative route adjustments, do not differ across the regions, routes, or variations. The variations are presented graphically in Exhibit 1 of Appendix M.

3.8.5.2.1 Construction Impacts

Construction activities could pose hazards that affect worker and public health and safety. In addition, natural disasters, accidents, or intentional destructive acts or mischief could impact the health and safety of construction workers and the public. The following sections include a qualitative summary of each hazard and its relative frequency, severity, potential impacts, and avoidance and minimization measures for the construction phase.

3.8.5.2.1.1 Worker and Public Health and Safety

Accidents during construction that could present a worker and public health and safety risk include heavy equipment and commuting vehicle accidents, electrocution, personal accidents (e.g., slips, trips, and falls), hazardous materials spills, construction-induced fires, and aircraft accidents.

Construction activities pose various health and safety risks to workers that are considered typical for large construction projects involving electrical components, working at height, and operating heavy machinery. The following potential risks could be associated with the Project:

- Falls from working at height
- Crush injuries in excavation work
- Slips and trips
- Cuts and scrapes from sharp tools or construction materials or debris
- Receiving injuries from hand tools and/or rotating machinery
- Electrocution
- Being struck by falling objects
- Manually lifting heavy loads
- Bad working positions, possibly in confined spaces
- Being struck or crushed by a workplace vehicle
- Inhalation of dust
- Handling of rough materials
- Exposure to dangerous substances (chemical and biological)
- Working near, in, or over water
- Hearing damage from loud noises
- Sustaining injuries as a result of an on-road or off-road accident involving a motor vehicle or construction equipment

Based on BLS data reported nationally within the construction industry (BLS 2012a), there were 3.7 non-fatal recordable incidents per 100 full-time equivalent workers. A full-time equivalent worker equates to 2,080 labor hours annually. Using the BLS data, based on an average full-time equivalent construction workforce of approximately 1,260 workers (Appendix F) working for an assumed 36 months on all components of the Applicant Proposed Project, it is estimated there would be approximately 140 non-fatal recordable incidents associated with the construction phase. Also, BLS data reported nationally within the construction industry identify 9.9 fatal incidents per

100,000 full-time equivalent workers (BLS 2012b). Using the average construction workforce of 1,260 workers, it is estimated that there would be approximately 0.4 fatalities during the assumed 36-month construction phase.

3.8.5.2.1.2 Aircraft and Rail Operations

Airports and associated air traffic in the vicinity of the components of the Project have the potential to result in impacts to workers, aircraft occupants, and Project components if an aircraft collides with a structure. The use of helicopters during Project surveying, structure installation, and line and conductor stringing could result in accidents that cause health and safety impacts to workers. Low-altitude aircraft that apply pesticides, herbicides, and fertilizers on nearby agricultural operations could result in an increased risk of collision with Project components, especially lines and conductors, which aircraft operators have more difficulty seeing. An aircraft collision is possible and would be expected to result in major injury or death—more likely to the aircraft occupants but possibly people on the ground. Additionally, an aircraft collision with Project facilities or components could cause significant damage to Project assets during construction. Environmental Protection Measure GE-16 would ensure Project structures and components are appropriately marked with devices to help aviators identify potential dangers to aircraft operations.

As identified in Section 3.16, railroads cross at several points or are in close proximity to the Applicant Proposed Route and the various DOE alternative routes. No increase in railroad traffic is expected to occur as a result of the construction of the Project, and therefore no additional health and safety risk would result. Structure heights and placement, span lengths, and vertical clearance would be determined in accordance with the NESC, the Applicant's design criteria, and applicable standards and laws. The NESC provides for minimum distances between the conductors and the ground, crossing points of other lines and the transmission support structure, and other conductors, and minimum working clearances for vehicles and personnel.

3.8.5.2.1.3 Fire Hazards

Wildfires in the vicinity of the ROI as a result of lightning strikes or accidental events can cause risks to Project components and personnel during construction. Although not necessarily caused by construction activities of the Project, once ignited, a wildfire could spread causing injuries to workers or the public and damage to Project facilities, construction equipment, and construction materials. A wildfire during the construction phase of the Project is considered possible, but it would not be expected to result in permanent or significant damage to Project components or health and safety of workers or members of the public since emergency reporting and response actions coupled with identified EPMs would minimize impacts.

The potential for construction activities to start a fire represents a potential safety hazard for workers or nearby residents. Fire hazards could result from workers welding, operating motorized construction equipment, smoking, refueling, electrical mishaps while energizing components, and operating or parking vehicles in areas with dry vegetation. With implementation of adequate preparedness and response measures, the potential for a fire to cause major damage to Project components or to result in injuries or death to workers or members of the public is considered unlikely.

3.8.5.2.1.4 Natural Events and Disasters

Project facilities and components may be susceptible to natural events and disasters and could be damaged by extreme weather, ground surface and subsurface instabilities (e.g., earthquakes), and flooding. Failure of partially constructed transmission line components from natural events can result in structures and lines falling to the ground;

impacts would generally be limited to the Project ROW. Damage to Project infrastructure may result in temporary adverse impacts to worker and public health and safety and nearby property. Natural events and disasters may occur on a relatively frequent basis; however, severe events would be less likely to result in structural damage or downed lines and conductors since the Project would be designed and built according to federal, state, and industry building codes and standards, which are intended to avoid or minimize safety risks posed by natural events and disasters.

Sudden severe weather during construction could result in hazardous conditions for workers including difficulty in controlling equipment and structural components, difficulty working at heights, reduced visibility, poor road conditions, impaired footing, and increased possibility of electrocution.

Surface and subsurface instabilities and displacement from earthquakes, faulting, liquefaction, landslides, and subsidence is a possibility during construction activities. Collapse of structures or falling objects pose potential risks to workers or nearby members of the public. Ground instability or failure associated with events described above occurs with little or no notice and preparation by onsite personnel would be minimal. Based on USGS earthquake-risk scenarios, seismic hazards are low for the entire Project area except for the eastern portion of the ROI in Region 5 and all of Regions 6 and 7 as the Project routes approach a relatively active seismic zone (see Sections 3.6.1.5.3 through 3.6.1.5.7). While the area's seismic hazard increases south of the ROI in Regions 2 and 3, the hazard for the ROI in these regions is low. Some areas within the regions have a range of susceptibility and incidence rates for ground instability events (see Table 3.6.1-11 through 3.6.1-19). Compliance with federal and state earthquake preparedness and response procedures would help ensure risks to workers and the public during seismic events would be minimized.

The occurrence of flooding during construction could put workers at risk of drowning. Flooding may also cause erosion that may damage construction sites and access routes or create spills of hazardous materials with resulting human exposure to environmental contamination or injury. However, flood events can often be forecast, which allows time to prepare, so the most severe impacts of flooding can more likely be avoided. Although construction and placement of structures in 100-year floodplains would be avoided as much as possible, all seven regions contain several 100-year floodplains that would potentially be crossed by the Applicant Proposed Route or the DOE alternative routes (see applicable discussions in Section 3.19). Placement of some structures within 100-year floodplains would be unavoidable in some areas (e.g., approaches to the Mississippi River).

3.8.5.2.1.5 Intentional Destructive Acts

Although it is not possible to predict whether acts of terrorism or sabotage events would occur, or the nature of such events if they did occur, DOE has considered the potential for events involving terrorism, sabotage, or criminal mischief that could result in health and safety impacts to workers and members of the public. Also, sabotage of onsite equipment or placement of explosive devices that could disrupt the Project is a remote possibility. Impacts to health and safety from intentional destructive acts would be unlikely to be greater than events involving extreme weather. A more likely scenario would involve mischievous or criminal acts of theft or vandalism, which would generally pose lower safety risks. Theft of tools, equipment, and construction materials is a relatively common occurrence at large sites, especially when spread across large geographic areas where security is more difficult to maintain. Impacts could result in schedule and cost delays to the construction effort. Although the possibility of some theft or vandalism is considered likely, related health and safety impacts to workers or the public are negligible.

As identified earlier, the Applicant would prepare a comprehensive Construction Security Plan that would describe measures designed to avoid and/or minimize adverse effects associated with breaches in Project security during construction, including terrorism, sabotage, vandalism, and theft. This plan would include provisions describing how the Project construction team and operations and maintenance personnel would coordinate with state and local law enforcement agencies to improve Project security and facilitate security incident response if required.

3.8.5.2.1.6 Protection of Children

While the potential for effects on members of the public from construction activities cannot be dismissed, the Project is not expected to cause any disproportionate effects on people less than 18 years of age. (Children are factored into construction impact analyses as members of the general public.)

3.8.5.2.2 Operations and Maintenance Impacts

Operations and maintenance activities could pose hazards that affect worker and public health and safety. In addition, natural disasters, accidents, or intentional destructive acts or mischief could impact the health and safety of operational workers and the public. The following sections include a qualitative summary of each hazard and its relative frequency, severity, potential impacts, and avoidance and minimization measures for the operations and maintenance phase.

3.8.5.2.2.1 Worker and Public Health and Safety

During the operations and maintenance phase of the Project, potential health and safety impacts to workers would be similar to those described during the construction phase. Electrocution remains a safety concern during operations and maintenance activities that occur in close proximity to or under transmission lines or at converter stations. The Project components would be designed and built to NESC guidelines, minimizing the risk of electrocution (IEEE 2011). Potential injuries or fatalities to workers could also occur from falls from heights, equipment and vehicle accidents, and other operational and maintenance activities. Because day-to-day activities with regard to operating equipment and vehicles and hazardous materials management would be less during operational activities than during construction, the frequency of accidents that could affect members of the public would also be less. Electrical and magnetic field impacts and potential health effects are discussed in Section 3.4.6.

Based on BLS data reported nationally within the electric utility industry (BLS 2012a), there were 2.8 non-fatal recordable incidents per 100 full-time equivalent workers annually. Using the BLS data, based on an average full-time equivalent operations workforce of approximately 72 individuals (See Section 2.1.5) working over the assumed 80-year operational phase of the Applicant Proposed Project, it is estimated there would be approximately 2.0 non-fatal recordable incidents annually. Also, BLS data reported nationally within the utility industry identify 2.5 fatal incidents per 100,000 full-time equivalent workers (BLS 2012b). Using the average operations workforce of 72 workers, it is estimated that there would be approximately 0.002 fatalities annually during the operational phase.

3.8.5.2.2.2 Aircraft and Rail Operations

A fully constructed and operating transmission system could pose long-term hazards to low-flying aircraft in the vicinity of the Project. Structure heights are not expected to exceed 180 feet along the majority of the Project, but could reach heights of approximately 380 feet at the Mississippi River crossing to maintain necessary clearance over the navigable channels. Potential health and safety impacts to workers, members of the public, and aircraft operators and passengers could occur from low-flying aircraft that use nearby airports and landing strips or that conduct aerial application of herbicides, pesticides, and/or fertilizers on nearby croplands. Low-flying aircraft would present a potential hazard to worker and public health and safety, Project assets, and the power supply for the life of the Project up until the facilities are decommissioned and removed. EPM GE-16 would ensure Project structures and components are appropriately marked with devices to help aviators identify potential dangers to aircraft operations.

As explained in Section 3.8.5.2.1.2, no increase in railroad operations is expected to occur as a result of any phase of the Project, so no increased health and safety risk would result.

3.8.5.2.2.3 Fire Hazards

Potential fire hazards would remain during the operations and maintenance phase of the Project. Events that may cause fires include ignition from airborne debris that comes in contact with electrical system components, natural debris buildup on insulators, vegetation contact with transmission lines, and incidents involving firearms. Wildlife interactions with Project components (e.g., perching birds) are not expected to cause bridging between two electrical conductors given the large separation between components which, depending on the type of structure used, would provide a minimum conductor separation distance of approximately 21 feet (see Figures 3.4-21 and 3.4-22 for typical 345kV configuration, Figures 3.4-29 and 3.4-30 for typical ±600kV configuration). Higher-voltage transmission lines (like the Project), where conductors are separated by relatively large distances, makes electrical arcing between components and resultant ignition of fires much less likely.

3.8.5.2.2.4 Natural Events and Disasters

Given the relatively long timeframe of the operations and maintenance phase (assumed to be 80 years), natural events and disasters consisting of severe weather (e.g., ice and windstorms and tornadoes) and ground instability events (e.g., earthquakes) are possible. Project components could fail in a manner that would result in collapse of structures with resultant health and safety concerns and disruption of electrical service. Impacts would typically remain within the ROW but may extend beyond in extreme cases (e.g., a tornado with sufficient strength to transport dislodged structural material from the Project beyond the ROW). The Applicant has designed robust structures that incorporate the appropriate NESC requirements. The Project's design criteria contemplate a wind-loading scenario on a structure without wires of wind speeds equivalent to an F-2/EF3 tornado[2]. While these loading scenarios would not eliminate the potential for damage to the line, they would decrease the likelihood of structure damage or a major outage. The transmission system would be designed according to applicable engineering standards to withstand, to the maximum extent practicable, natural disasters that could result in system failures. In general, the potential for tornadoes to occur can be forecast; however, the actual severity of tornadoes cannot be accurately predicted. The Applicant plans to utilize weather monitoring systems currently in place in the regions of the Project to track tornadic activity and to communicate elevated risk levels to interconnecting utilities to ensure operational readiness. Forecasting potential severe weather would generally allow adequate time to alert, prepare, and mobilize response teams to be ready to respond if needed (see Appendix F).

As with the construction phase, natural events and disasters may occur relatively frequently, but an event severe enough to result in structural damage or downed lines with resultant health and safety hazards or significant

[2] The Enhanced Fujita scale (EF-Scale) was implemented in place of the F-Scale in the United States in 2007 and has the same basic design as the F-Scale. It was revised to reflect better examinations of tornado damage surveys to align wind speeds more closely with associated wind damage.

disruption of electrical service is less likely since the Project would be designed, built, and operated according to federal, state, and industry building codes and standards, which are intended to avoid or minimize safety risks posed by natural events and disasters. The Applicant would take all prudent measures to site transmission towers at safe distances from residences and other structures to provide safety buffers.

3.8.5.2.2.5 Intentional Destructive Acts

Although it is not possible to predict if acts of terrorism or sabotage events would occur, or the nature of such events if they did occur, DOE has considered the potential for events involving terrorism, sabotage, or criminal mischief that could result in health and safety impacts to workers and members of the public. Impacts would be similar to those described for construction. The impacts of terrorism or sabotage of structures or other equipment could range from no noticeable effect to loss of electrical service to some service areas for a period of time. A terrorist cyber-attack could potentially impact operating and communications systems leading to a disruption in service. Although such an attack is possible, the consequences would not be considered major regarding health and safety concerns, although they would be considered critical due to potential impact to the local energy system and grid.

Theft, vandalism, or other mischievous acts could cause safety risks to perpetrators as well as workers and members of the public. Destructive acts such as firearm use near the Project components, including shooting at Project equipment, components, and structures, may cause fires, electrical hazards, personal injury, or death to people in the area. Theft of equipment, supplies, tools, or materials is also a possibility, although less likely than during construction when more equipment would be accessible.

3.8.5.2.2.6 Protection of Children

Electric and magnetic fields are known to occur around transmission lines, distribution lines, and electric appliances. As discussed in detail in Section 3.4.11.2.1.2.2.7, research has been conducted in the United States and around the world to determine whether exposure to power-frequency AC electric and magnetic fields has human health effects.

The general consensus among researchers and the medical and scientific communities is that there is insufficient evidence at this time to conclude whether magnetic fields are a cause of adverse health issues. A review of available literature on the health risk posed by AC electric and magnetic fields was conducted by the World Health Organization (WHO) Task Group (other studies and reviews are discussed in detail in the section cited above). The WHO report, *Environmental Health Criteria 238* (WHO 2007), concluded that:

> Scientific evidence suggesting that every day, chronic low-intensity (above 3–4 mG) power-frequency magnetic field exposure poses a health risk is based on epidemiological studies demonstrating a consistent pattern of increased risk for childhood leukemia. Uncertainties in the hazard assessment include the role that control selection bias and exposure misclassification might have on the observed relationship between magnetic fields and childhood leukemia. In addition, virtually all of the laboratory evidence and the mechanistic evidence fail to support a relationship between low-level power-frequency magnetic fields and changes in biological function or disease status. Thus, on balance, the evidence is not strong enough to be considered causal, but sufficiently strong to remain a concern.

In addition, The National Institute of Environmental Health Sciences (NIEHS) report to the United States Congress, at the conclusion of its multi-year Electric and Magnetic Fields (EMF) Rapid Program, summarized its research and concluded that “The scientific evidence suggesting that extremely low frequency EMF exposures pose any health risk is weak” (NIEHS and NIH 2002).

3.8.5.2.3 Decommissioning Impacts

Potential impacts related to worker and public health and safety and hazards during the decommissioning phase of the Project are expected to be similar to those that could occur during the construction phase. As indicated in Section 2.1.6, a comprehensive decommissioning plan would be prepared prior to decommissioning the Project. This plan would include procedures to minimize safety risks to workers and the public.

3.8.5.3 Impacts Associated with the DOE Alternatives

Potential impacts associated with the Project with the DOE Alternatives within Oklahoma, Arkansas, and Tennessee, including the Arkansas converter station and AC interconnection, the HVDC transmission line alternative routes, access roads, multi-use construction yards and other temporary construction areas, and communications sites, would be similar to those discussed above for the Applicant Proposed Project (Section 3.8.5.2) except for potential injury and fatality statistics, which are discussed below.

The construction impacts to worker health and safety from the Project with the DOE Alternatives would depend on the number of workers, which is related to the length of the routes, ruggedness of terrain, and other factors. The ruggedness of the terrain would also increase the potential health and safety risk associated with construction of the HVDC transmission line. Approximately half of the alternative routes are equal to or shorter than the Applicant Proposed Route; the other half are somewhat longer. The total length of the alternative routes is roughly equivalent to that of the corresponding links of the Applicant Proposed Route. Therefore, the number of workers required for construction of the alternative routes would not be substantially different than the estimate calculated for the Applicant Proposed Project discussed above. This would result in no appreciable change in health and safety impacts to workers from construction of the HVDC transmission line.

The addition of the Arkansas converter station and interconnection would increase the required construction workforce by approximately 10 percent based on the contribution of a typical converter station to the total workforce required for the Applicant Proposed Project (see Appendix F). Because the addition of the Arkansas converter station and interconnection would not replace any elements of the Applicant Proposed Project, the estimated health and safety impacts associated with construction of the Arkansas converter station and interconnection would increase the number of workers and thus the number of non-fatal recordable incidents and potential fatalities by roughly 10 percent over that estimated for the Applicant Proposed Project.

The addition of the Arkansas converter station and interconnection would increase the number of operational workers by 15 over that of the Applicant Proposed Project of 72 operational workers. Based on BLS data reported nationally within the electric utility industry (BLS 2012a), there were 2.8 non-fatal recordable incidents per 100 full-time equivalent workers. Using the BLS data, based on an average full-time equivalent operations workforce of approximately 87 individuals (Clean Line 2013b; Thomas 2014) working over the assumed 80-year operational phase of the Project, it is estimated there would be approximately 2.4 non-fatal recordable incidents annually. Also, BLS data reported nationally within the utility industry identify 2.5 fatal incidents per 100,000 full-time equivalent workers (BLS 2012b). Using the average operations workforce of 87 workers, it is estimated that there would be approximately 0.002 fatalities annually during the operational phase.

3.8.5.4 Best Management Practices

Each of the phases of the Project would be planned, coordinated, and conducted in a manner that protects worker and public health and safety and mitigates or minimizes impacts as described above. Specific EPMs and Project plans and procedures (see Section 3.8.5.1) would be implemented to help ensure protection of workers and the public from identified hazards and intentional destructive acts. Additional practices identified by DOE would minimize the safety risks and consequences posed during construction and operations and maintenance of the Project. However, despite preparedness planning, worker training, and application of safety procedures, accidents may still occur. Although there may be some overlap or inclusion within Applicant-identified EPMs and Project plans, the following BMPs identify additional measures to further ensure impacts are minimized:

- Develop and implement a Health and Safety Plan that describes regulatory requirements, procedures, and practices for conducting activities to help ensure a safe working environment, which for purposes of health and safety measures should include:
  - Fire prevention, suppression, and emergency responder contact procedures
  - Natural disaster and severe weather reporting and contact procedures
  - Law enforcement contact procedures
  - Procedures for addressing hazardous materials spills and other mishaps
  - Helicopter flight safety measures
- Develop and implement a Communications Plan. Section 3.1.2 describes the elements of this plan, which for purposes of health and safety should include:
  - Liaison and public outreach activities with local airports, aviation communities, aviation regulatory bodies, aerial agricultural spraying operations, and railroad operators.
  - Local media and public outreach procedures for applicable hazard communication notices

3.8.5.5 Unavoidable Adverse Impacts

Based on national nonfatal and fatal workplace injury statistics tracked by the BLS (see Table 3.8-2), accidents resulting in worker injuries and possibly death could occur during the construction and/or operations and maintenance phases of the Project. The hazardous nature of the work, the complexity of the electrical system, and the size and areal extent of the Project all would contribute to a potential for worker injuries or death and would be considered unavoidable adverse impacts. These unavoidable adverse impacts could be as a result of common personnel-involved injuries (e.g., slips, trips, or falls), hazardous materials or waste accidents, aircraft incidents, fire hazards, natural events or disasters, or intentional destructive acts.

3.8.5.6 Irreversible and Irretrievable Commitment of Resources

The health of workers and the public are important resources that must be protected. Through the implementation of safety plans, procedures, and required design elements, irreversible commitment of these resources would be kept to a minimum.

3.8.5.7 Relationship between Local Short-term Uses and Long-term Productivity

While there would be a short-term temporary increase in potential health and safety impacts associated with construction, long-term impacts in the region would not increase and would not affect the productivity of the region.

3.8.5.8 Impacts from Connected Actions

3.8.5.8.1 Wind Energy Generation

During construction and operations and maintenance of wind energy generation facilities, potential health and safety impacts to workers and the public would be similar to those described for the Project. Wind energy generation facility developers would be expected to adopt and implement common industry practices and to comply with applicable regulations to protect worker and public health and safety. Installation and operation of wind turbines and associated components present many of the same types of health and safety impacts from working at heights and in an electrically charged environment that are associated with transmission system installations with some exceptions, which are discussed below.

Depending on the alternative selected, the electrical power delivery capacity of the Project would range between 3,500 and 4,000MW. To achieve full utilization of the 3,500 to 4,000MW delivery capacity of the Project, actual wind capacity build-out would be expected to range between 4,200 to 4,550MW, which takes into account line losses, equipment outages, variation in wind turbine power generation, and other operational conditions (Clean Line 2014a, 2014c). Construction of typical, commercial-scale wind energy generation facilities in the Oklahoma or Texas panhandle regions[3] would employ approximately 57 to 515 full-time equivalent workers (Clean Line 2014a) over a 2-year construction period. The minimum full-time equivalent workforce is based on a small-scale wind generation facility with a combined turbine nameplate rating of approximately 53MW (fifteen 3.5MW turbines) and the maximum value is based on a large-scale wind energy generation facility with a combined turbine nameplate rating of 975MW (six hundred fifty1.5MW turbines). Operation of typical commercial-scale wind energy generation facilities in the Oklahoma or Texas panhandle regions would employ approximately 4 to 44 workers annually (Clean Line 2014a).

For purposes of analyses, the following construction and operational calculations are based on the maximum wind capacity build-out of 4,550MW to supply the Project, which could consist of 12 small-scale and 4 large-scale wind energy generation facilities. Worker injury and fatality rates would be expected to be lower if the wind capacity build-out were less than 4,550MW.

Based on BLS data reported nationally within the construction industry (BLS 2012a), there were 3.7 non-fatal recordable incidents per 100 full-time equivalent workers annually. Using the BLS data, based on a full-time equivalent construction workforce (16 wind energy generation facilities) of approximately 2,744 workers working for 2 years, it is estimated there would be approximately 203 non-fatal recordable incidents associated with the construction of the wind energy generation facilities. Also, BLS data reported nationally within the construction industry (BLS 2012b) identify 9.9 fatal incidents per 100,000 full-time equivalent workers. Using the representative construction workforce of 2,744 workers, it is estimated that there would be approximately 0.5 fatalities during a 2-year construction phase.

Operational accident statistics for the 16 wind energy generation facilities is based on BLS data reported nationally within the electric utility industry (BLS 2012a), which identifies 2.8 non-fatal recordable incidents per 100 full-time

---

[3] Although wind generation facility development could occur in Oklahoma or Texas, Oklahoma employment estimates from Clean Line 2014a are used in this EIS for Texas. (The employment estimate for Texas identified in Clean Line 2014a is 56 to 494 full-time equivalent workers over a 2-year construction period and is similar to the Oklahoma estimate. Using the Oklahoma estimate for Texas in this EIS is reasonably conservative.)

equivalent workers. Using the BLS data, based on a full-time equivalent operations workforce of approximately 224 people working over the long-term operational phases of the 16 wind energy generation facilities associated with the maximum 4,550MW build-out capacity, it is estimated there would be approximately 6.3 non-fatal recordable incidents annually. Also, BLS data reported nationally within the utility industry (BLS 2012b) identify 2.5 fatal incidents per 100,000 full-time equivalent workers. Using the operations workforce of 224 workers, it is estimated that there would be approximately 0.006 fatalities annually during the combined operations and maintenance phases of the 16 wind energy generation facilities.

Because of the expected establishment of adequate access controls that prevent entry to hazardous areas by unauthorized individuals, the majority of adverse impacts during construction, operations and maintenance, and decommissioning of wind energy generation facilities have the potential to impact only the respective workforces of those phases (WAPA and USFWS 2013). A primary physical safety hazard of wind turbines occurs if a rotor blade fails and pieces are ejected. Ejection could occur as a result of rotor overspeed, although such occurrences have been extremely rare and have happened mostly with older and smaller turbines (Hau 2000). A related issue, ice throw, can occur if ice builds up on the turbine blades. Although weather conditions relatively near the ground, where the blades would be working, rarely result in ice buildup on the blades, such buildup can and has occurred (WAPA and USFWS 2013). The portion of the ROI in Oklahoma and the Texas Panhandle experience extreme temperature changes, especially in the winter months, from cold fronts moving west to east after crossing the Rocky Mountains. In most instances, ice pieces simply fall from the blade as the air temperature warms and land on the ground near the base of the structure. However, ice pieces as large as 2.2 pounds have been found several hundreds of feet from the structure base (WAPA and USFWS 2013). The extent of impacts from these physical hazards and component failures would typically remain within the wind generation facility site or transmission line ROW, but could extend beyond in extreme cases.

Wind energy generation facility development has the potential to result in health and safety impacts through the handling and use of hazardous materials and the potential to disturb existing known or unknown contaminated sites during construction in the vicinity of WDZs. The types of impacts that may occur are the same as those described for the Project and are considered temporary and minor.

Potential wind energy generation facility development may be located in areas where airports and airstrips are located in the vicinity, which could cause added hazards to workers and the public, aircraft occupants, and wind energy generation facility components from air operations and possible collisions with structures. Wind energy generation facility use of helicopters during construction and operation could cause added risk to occupants, personnel on the ground, and facility structures if a collision were to occur. Table 3.16-7 in Section 3.16 identifies airports or airstrips within or in close proximity to the WDZs. Additionally, potential wind energy generation areas are located within agricultural areas where aerial application of pesticides, herbicides, or fertilizers is a common practice for some crops. Downwind turbulence from rotor airstreams may also cause potential hazards to lighter aircraft (e.g., small private aircraft, aerial spraying aircraft, or helicopters) operating at low altitudes in the area of wind energy generation facilities (Airspace & Safety Initiative 2013).

Fire hazards and natural events and disasters such as severe weather (e.g., tornadoes, ice storms, and flooding), and ground instabilities (e.g., earthquakes) in the vicinity of potential wind energy generation facility developments pose the same types of risks and hazards to workers and members of the public as those described for the transmission Project. Severe weather is known to occur in the WDZs.

Shadow flicker and blade glint and glare are not concerns during construction of wind farm facilities, although operating the wind turbines could cause impacts from such phenomena. Shadow flicker and blade glint and glare would not be an issue during cloudy periods or when turbines are not operating. While there have been studies that have found that shadow flicker may result in the potential for epileptic seizures for those suffering from photosensitive epilepsy (Bos et al. 2013), the AWEA has refuted that finding, noting that "shadow flicker from wind turbines occurs much more slowly than the 'light strobing' associated with seizures" (AWEA 2009). One study (Harding et al. 2008) reported that flickers with a frequency greater than 3 hertz could pose a potential for inducing photosensitive seizures, i.e., a light flashing at a rate of more than 3 times per second. The American Epilepsy Foundation reports that lights flashing in the range of 5 to 30 hertz are most likely to trigger seizures (Epilepsy Foundation 2013). A wind turbine with three blades would have to make a full revolution every second (or 60 revolutions per minute) to reach a frequency of 1 hertz; however, large turbines (like the ones likely for the connected action) operate at 18–45 revolutions per minute or 0.3–0.75 hertz (Bos et al. 2013).

Intentional destructive acts most likely to impact the construction of the wind energy generation facilities are theft and vandalism, which generally pose lower safety risks to individuals but could cause temporary disruptions to electrical service. Wind energy generation facilities are generally designed and constructed to minimize the potential for their destruction or displacement. For example, countermeasures such as regular inspections, security patrols, fencing, signs, and video cameras are commonly used to deter or prevent theft, vandalism, and unauthorized access. Although intentional destructive acts could still occur, implementation of these preventative measures would discourage perpetrators and minimize the potential for such events (Clean Line 2014a).

3.8.5.8.2 Optima Substation

The health and safety impacts associated with the future Optima Substation would be similar to the impacts described for other Project components, including other converter stations and associated transmission lines and components; however, the addition of this substation is anticipated to have a smaller potential for effects due to the relatively smaller scale of the future Optima Substation compared to other substations associated with the Project. There would also be fewer construction and operations workers and therefore lower probabilities for injuries and fatalities.

3.8.5.8.3 TVA Upgrades

Interconnection of the Project with TVA's transmission grid would require construction of approximately 37 miles of new 500kV transmission line in western Tennessee and upgrades to approximately 350 miles of existing transmission lines, mostly in central and western Tennessee (as described in Section 2.5.2). Modifications to several substations also would be required. TVA has identified the types and general sizes (e.g., lengths of transmission lines) of upgrades that would be affected by the Project, but has not yet identified the specific locations of the upgrade activities.

The required TVA upgrades are anticipated to have a similar but smaller potential for health and safety effects than the Project because the upgrades would involve similar activities and workforces and cover a smaller total area, which would likely require less time to construct, potentially resulting in less risk exposure time for workers. TVA would implement measures similar to those listed in Section 3.8.5.1 to minimize or avoid these effects.

3.8.5.9 Impacts Associated with the No Action Alternative

Under the No Action Alternative, DOE assumes for analytical purposes that the Project would not proceed. No impacts to worker and public health and safety or from intentional destructive acts would occur.

3.9 Historic and Cultural Resources

3.9.1 Regulatory Background

The federal and state requirements that address identifying, evaluating and considering mitigation measures for cultural and historic resources are identified in Table 3.9-1 and are discussed below.

Table 3.9-1:
Key Statutes and Regulations Related to Historic and Cultural Resources

Jurisdiction	Statute	Legal Code Citation	Key Historic/Cultural Provisions
Federal actions and undertakings	National Environmental Policy Act of 1969, as amended (NEPA)	42 USC §§ 4321–4370 (implementing regulations: 40 CFR Parts 1500–1508) DOE NEPA implementing regulations (10 CFR Part 1021)	Federal law requires evaluation of the potential impacts of major federal actions on historic and cultural resources as a component of the human environment.
	National Historic Preservation Act of 1966, as amended (NHPA)	54 USC § 300101 et seq. (implementing regulations: 36 CFR Part 60 and 36 CFR Part 800)	Federal law requires federal agencies to consider the effects of a federal undertaking on NRHP-listed and NRHP-eligible properties.
Federal and tribal lands	Archaeological Resources Protection Act of 1979, as amended (ARPA)	16 USC §§ 470aa–470mm (implementing regulations: 36 CFR Part 296)	Federal law that prohibits unauthorized collection, excavation of or damage to archaeological resources on federal and tribal lands.
	Native American Graves Protection and Repatriation Act of 1990, as amended (NAGPRA)	25 USC §§ 3001–3013 (implementing regulations: 43 CFR Part 10)	Federal law that protects Native American human remains, funerary objects, and items of cultural patrimony found on federal and tribal lands.
	American Indian Religious Freedom Act	42 USC § 1996	Federal law that protects and preserves for American Indians their inherent right of freedom to believe, express, and exercise traditional religions, including access to sites, use and possession of sacred objects, and freedom to worship through ceremonials and traditional rites.
	Cultural and Heritage Cooperation Authority1	25 USC §§ 3051–3057	Authorizes Secretary of Agriculture to ensure access to National Forest land by Indians and Indian Tribes and Nations for traditional and cultural purposes; authorizes reburial of human remains and cultural items on National Forest land; and prohibits unauthorized disclosure of information regarding reburial sites and locations of sites.
Arkansas public lands	Arkansas Antiquities Act of 1967, as amended	ACA Chap. 13-6-301–13-6-308	Prohibits unauthorized excavation on public lands in Arkansas; specifies excavation and reporting standards; provides penalties for violations; discourages excavations on private lands except in accordance with the provisions and spirit of the act.
Arkansas public and private lands and waters	Arkansas Grave Protection Act of 1991, as amended	ACA Chap. 13-6-401–13-6-409	Protects all human burials and human skeletal burial remains from desecration, without reference to ethnicity, cultural or religious affiliation, or date of burial; establishes a permit system for legitimate excavation; provides penalties for violations; specifies provisions apply to state and federal agencies as well as private individuals and firms.

Table 3.9-1:
Key Statutes and Regulations Related to Historic and Cultural Resources

Jurisdiction	Statute	Legal Code Citation	Key Historic/Cultural Provisions
Historic preservation reviews in Arkansas	Arkansas Historic Preservation Program (AHPP) Act of 1977, as amended	ACA Chap. 13-7-101–13-7-111	Establishes the AHPP; authorizes cooperation with the Arkansas Archaeological Survey (AAS); assigns AHPP and AAS responsibilities for administration of state role in NHPA.
Oklahoma public lands	Oklahoma Antiquities Law of 1985	53 OS 361	Prohibits unauthorized excavation on public lands in Oklahoma; specifies excavation and reporting standards; provides penalties for violations.
Oklahoma public and private lands and waters	Oklahoma Burial Desecration Law of 1987, as amended	21 OS 1168.0–1168.6	Protects all human burials, skeletal remains, and burial furniture from desecration; establishes a permit system for legitimate excavation; provides penalties for violations; specifies provisions apply to state and federal agencies as well as private individuals and firms.
Historic preservation reviews in Oklahoma	Oklahoma State Register of Historic Places Act of 1983	53 OS 351–355	Designates the Executive Director of the Oklahoma Historical Society (OHS) as the State Historic Preservation Officer and directs OHS to work with the federal government and other states concerning matters of historic preservation; establishes a State Register of Historic Places.
Texas public lands	Antiquities Code of Texas	9 TX NRC 191 (implementing regulations at 13 TX AC 24–26)	Protects archaeological and historic sites on state and local public property and establishes the designation of State Antiquities Landmarks.
Cemeteries in Texas	Texas Cemetery Law	8 TX H&SC Chap. 711 (implementing regulations at 13 TX AC 22)	Cemeteries protected from desecration; a person who discovers an unknown or abandoned cemetery shall file notice of the cemetery with the county clerk of the county in which it is located.
Historic preservation reviews in Texas	Texas Historical Commission Act	4 TX GC Chap. 442 (implementing regulations at 13 TX AC 2)	Established the Texas Historical Commission; defines its purpose, powers, and duties; assigns Commission responsibility for administration of state role in NHPA.
Tennessee public lands and waters	Tennessee Archaeology Code	TCA 11-6-101–11-6-106	Establishes the Tennessee Division of Archaeology; protects archaeological sites on public lands and waters from vandalism and unauthorized excavation.
Graves and cemeteries in Tennessee	Tennessee Archaeology Code	TCA 11-6-107 and 11-6-116–11-6-119	Requires notification to Tennessee Division of Archaeology when human remains are discovered on public or private lands; provides for notification of Indian Tribes and Nations when Native American human remains are excavated and grants Native American observers the privilege of presence during such excavations; provides for repatriation and burial.
Places of burial in Tennessee	Tennessee Criminal Code	TCA 39-17-311–39-17-312	Protects places of burial from desecration and the unauthorized disinterment of human remains and their sale.
Historic preservation reviews in Tennessee	Tennessee State Code: State Historian and Historical Commission	TCA 4-11-111	Provides that state agencies consult with Tennessee Historical Commission prior to altering or demolishing state buildings and further provides that Commission staff shall assist agencies, institutions and entities in determining if property is or may be of historical, architectural, or cultural significance.

1 Only relevant to National Forest land.

ACA—Arkansas Code Annotated; OS—Oklahoma Statutes; TCA—Tennessee Code Annotated; TX AC—Texas Administrative Code; TX GC—Texas Government Code; TX H&SC—Texas Health and Safety Code; TX NRC—Texas Natural Resources Code

3.9.1.1 Federal Requirements

For purposes of this EIS, the major federal requirements addressing, identifying, evaluating, and mitigating impacts to cultural and historic resources are in NEPA and the NHPA. These two federal laws are discussed below.

3.9.1.1.1 National Environmental Policy Act

NEPA is a federal law that requires all federal agencies to consider the potential environmental impacts of their proposed major federal actions (42 USC § 4332(C)(i)). The CEQ implementing regulations for NEPA require that EISs discuss the potential environmental consequences to historic and cultural resources (40 CFR 1508.8). Historic and cultural resources under NEPA cover a wide range, including collections, sacred sites, and non-National Register of Historic Places (NRHP)-eligible sites that may be affected by major federal actions that may include activities entirely or partially financed, assisted, conducted, or approved by federal agencies. NEPA's focus is on the environment of the area(s) to be affected by the alternatives under consideration.

In December 2012, DOE published the NOI to prepare an EIS to analyze the potential environmental impacts of the Project. Several of the scoping comments received in response to this NOI addressed potential effects of the Project on specific cultural resources and/or historic resources, including burial sites and a ceremonial ground important to two Tribes, the Honey Springs Battlefield National Historic Landmark identified in consultation with the Oklahoma SHPO, and the potential for effects to portions of the Trail of Tears identified by the NPS.

3.9.1.1.2 National Historic Preservation Act

Section 106 of the NHPA, (54 USC § 306108) requires federal agencies to take into account the effects on historic properties of their undertakings and to provide the ACHP with a reasonable opportunity to comment on such undertakings. A federal undertaking is defined as a federal action, expenditure of funds or issuance of permit, license, or other approval. Under NHPA, historic properties include any prehistoric or historic district, site, building, structure, or object that is included in or eligible for inclusion in the NRHP. Historic properties of traditional religious and cultural importance to Indian Tribes and Native Hawaiian organizations may also be determined to be eligible for inclusion in the NRHP. The ACHP's NHPA implementing regulations (36 CFR Part 800) describe the process for compliance with Section 106 and provide the steps a federal agency must take to determine the Area of Potential Effects (APE) of a proposed undertaking; identify historic properties within the APE; assess potential effects of the proposed undertaking on historic properties; and conduct consultation regarding measures to avoid, minimize, or mitigate any adverse effects of the undertaking on historic properties. These steps are carried out in consultation with SHPOs, Tribal Historic Preservation Officers (THPOs) and/or representatives from Indian Tribes and Nations on whose tribal lands the undertaking may occur or that may attach religious and cultural significance to historic properties that may be affected by the Project undertaking, and other consulting parties (36 CFR 800.2). SHPOs involved in consultation for this Project comprise those of Arkansas, Oklahoma, Tennessee, and Texas; participating Indian Tribes and Nations are enumerated below. During the public comment period for the Draft EIS, the Applicant requested that DOE clarify that the language of Section 106 specifically enjoins federal agencies to take into account the effects of undertakings on historic properties that are listed on or eligible for the NRHP; in addition, while avoidance of Project impacts is often ideally the most desirable alternative, the NHPA implementing regulations use the phrase "avoid, minimize or mitigate" to describe the means by which adverse effects may be resolved (e.g., 36 CFR 800.6). The DOE has determined that participation in Clean Line's Project is an undertaking under the NHPA. Implementing regulations for both the NEPA and the NHPA encourage agencies to integrate the reviews of potential Project impacts that are required under each law (40 CFR 1500.2(c) and 1502.25, for NEPA; 36 CFR 800.8(a) and

800.8(c), for NHPA). DOE informed the ACHP by letter dated November 20, 2012, that pursuant to the NHPA implementing regulation at 36 CFR 800.8(c), it intended to use substitution, under which DOE is authorized to use the NEPA process and documentation required for the preparation of the EIS for the Plains & Eastern Clean Line Project to comply with Section 106 of the NHPA in lieu of the procedures set forth in 36 CFR 800.3 through 800.6.

In November 2012, DOE invited a number of federal agencies to participate in the Section 106 process and related consultation in this combined NEPA/NHPA evaluation. The following agencies are participating as consulting parties in the Section 106 process: BIA, NPS, USFWS, and TVA. DOE is the lead agency for the Section 106 consultation process as indicated in DOE's Memoranda of Understanding with the above-listed federal agencies.

DOE is developing a Programmatic Agreement (PA) pursuant to 36 CFR 800.14(b) to address its obligations under NHPA Section 106, including government-to-government consultation with Indian Tribes and Nations on whose tribal lands the undertaking may occur or that may attach religious and cultural significance to historic properties that may be affected by the undertaking, and consultation with the Arkansas, Oklahoma, Tennessee, and Texas SHPOs as well as the federal agencies listed above. The draft PA is included in Appendix P. DOE intends to execute the PA prior to issuance of the ROD or otherwise comply with procedures set forth in 36 CFR Part 800.

Clean Line will also be a party to the PA. The PA addresses resource identification and evaluation, assessment of effects, and resolution of effects, including avoidance, minimization, and mitigation. Development of a PA under 36 CFR 800.14(b) is appropriate for the Project because its potential effects on historic properties are multi-state and regional in scope, because of the complex nature of the undertaking, and because effects on historic properties cannot be fully determined prior to approval of the undertaking. In such situations, the regulations allow development of a PA to address the identification of historic properties and resolution of adverse effects in a phased approach (36 CFR 800.14(b)). Federal agencies that do not sign or concur in the PA, but whose involvement with the Project constitutes an undertaking pursuant to 36 CFR 800.16(y), would conduct consultation with SHPOs and/or THPOs and/or other appropriate parties according to the regular process described by 36 CFR 800 Subpart B.

DOE initiated consultation with the SHPOs from Arkansas, Oklahoma, and Tennessee in November 2012, when DOE informed the SHPOs about its intention to integrate NEPA and NHPA Section 106 consultation. In January 2013, DOE notified the SHPOs that it authorized Clean Line to initiate the Section 106 consultation, while reaffirming that DOE would remain responsible for government-to-government consultation with Indian Tribes and Nations. DOE's government-to-government consultation with Indian Tribes and Nations is described in greater detail below. After the NEPA public scoping period ended in March 2013, DOE sent a letter to the Oklahoma, Arkansas and Tennessee SHPOs in April 2013, updating them on the status of DOE's public scoping process and tribal consultation. DOE met with the Oklahoma, Arkansas, and Tennessee SHPOs in June 2013. DOE initiated consultation with the SHPO from Texas in January 2014 in a letter that informed the SHPO about DOE's intention to integrate NEPA and NHPA Section 106 consultation by using the substitution process (36 CFR 800.8(c)). On February 19, 2014, the ACHP notified the DOE that ACHP would participate in consultation to develop a PA for the Project given the Project's potential to impact historic properties and the potential that procedural questions might arise because DOE proposed to use a substitution process (36 CFR 800.8(c)) to address certain obligations under both NEPA and NHPA simultaneously. Throughout development of the draft PA, DOE was in contact with individual consulting parties as circumstances required and also invited the participation of all parties, including the Indian Tribes and Nations, in several in-person meetings (September and November 2014 and January 2015), telephone conference calls (October and December 2014), and invitations to comment on the draft PA (May and August 2015).

The consulting parties also had the opportunity to comment on various aspects of the Section 106 process, including the development and general stipulations of the draft PA, during the public comment period for the Draft EIS. The draft PA is provided in Appendix P. The PA will be signed and executed before DOE issues the ROD.

As part of the Section 106 process, DOE also initiated government-to-government consultation with Indian Tribes and Nations in accordance with 36 CFR 800.2. DOE identified Indian Tribes and Nations that may attach religious and cultural significance to historic properties potentially affected by the undertaking and initiated consultation with them in January 2013. DOE has subsequently invited the participation of additional Indian Tribes and Nations as Section 106 consultation identified other Tribes and Nations that also may attach religious and cultural significance to historic properties potentially affected by the undertaking or on whose tribal lands the undertaking may occur. Table 3.9-2 lists Indian Tribes and Nations that DOE has consulted or sought to consult with as part of the coordinated NEPA-NHPA review. Following the NEPA public scoping period, DOE sent a second letter to each Indian Tribe and Nation in April 2013 to provide updates on the status of the NEPA process and the NHPA Section 106 and government-to-government consultation. In July 2013, DOE sent a third letter to Indian Tribes and Nations, in which DOE requested a meeting to discuss the potential development of the PA. Indian Tribes and Nations that have agreed to be consulting parties in the PA are the Absentee-Shawnee Tribe of Indians of Oklahoma, the Cherokee Nation, the Chickasaw Nation, the Choctaw Nation of Oklahoma, the Iowa Tribe of Oklahoma, the Muscogee (Creek) Nation, the Osage Nation, the Quapaw Tribe of Oklahoma, the Sac and Fox Nation, the Thlopthlocco Tribal Town, the United Keetoowah Band of Cherokee Indians in Oklahoma, and the Wichita and Affiliated Tribes (Appendix P).

Table 3.9-2:
Indian Tribes and Nations Consulted under NHPA Section 106

Tribe	Tribe	Tribe
Absentee-Shawnee Tribe of Indians of Oklahoma	Delaware Nation, Oklahoma	Osage Nation
Alabama Quassarte Tribal Town	Delaware Tribe of Indians	Quapaw Tribe of Indians
Apache Tribe of Oklahoma	Eastern Band of Cherokee Indians	Sac and Fox Nation, Oklahoma
Caddo Nation of Oklahoma	Iowa Tribe of Oklahoma	Santee Sioux Nation, Nebraska
Cherokee Nation	Kaw Nation, Oklahoma	Seneca-Cayuga Nation
Cheyenne and Arapaho Tribes, Oklahoma	Kialegee Tribal Town	Thlopthlocco Tribal Town
Chickasaw Nation	Kiowa Indian Tribe of Oklahoma	Tonkawa Tribe of Indians, Oklahoma
Choctaw Nation of Oklahoma	Modoc Tribe of Oklahoma	United Keetoowah Band of Cherokee Indians in Oklahoma
Comanche Nation, Oklahoma	Muscogee (Creek) Nation	Wichita and Affiliated Tribes (Wichita, Keechi, Waco and Tawakonie), Oklahoma

As of late August 2015, one local government, Woodward County, is included as a consulting party in the PA under 36 CFR 800.3(f). However, the county did not wish to be a concurring party and as a result does not have a signature page in the draft PA. No other local government, non-governmental organizations (NGOs) or individuals have requested to be included in the PA as a consulting party under 36 CFR 800.3(f). DOE has issued several invitations to local governments and NGOs to participate in the Section 106 consultation and PA development process, most recently on August 17, 2015, via an e-mail to approximately 70 recipients. On August 15, 2015, DOE also invited the Trail of Tears Association to participate as a consulting party to the Section 106 process, but to date the Association has not notified DOE that it wishes to consult.

3.9.1.1.3 Other Federal and State Laws

Other federal laws that concern the evaluation and management of historic and cultural resources within the Project ROI include Archaeological Resources Protection Act (ARPA), Native American Graves Protection and Repatriation Act (NAGPRA), American Indian Religious Freedom Act (AIRFA), and Cultural and Heritage Cooperation Authority, which only applies to National Forest lands (Table 3.9-1). Very little of the Applicant Proposed Route and only one alternative route, HVDC Alternative Route 4-B, crosses National Forest land. ARPA (16 USC §§ 470aa–470mm) protects archaeological sites and resources on federal and tribal lands from unauthorized damage or impacts, establishes procedures for obtaining permits for archaeological excavation on federal and tribal lands by qualified individuals, and sets criminal and civil penalties for violations of the law. NAGPRA (25 USC §§ 3001–3013) protects Native American human remains, funerary objects, and other items of cultural patrimony found on federal and tribal lands and requires that such materials are treated respectfully if encountered on federal or tribal lands during Project development, construction, operation, or decommissioning. AIRFA (42 USC § 1996 et seq.) protects and preserves for American Indians their inherent right of freedom to believe, express, and exercise their traditional religions, including but not limited to access to sites, use and possession of sacred objects, and the freedom to worship through ceremonials and traditional rites. No tribal lands, as defined by 25 CFR 169.1(d) or 36 CFR 800.16(x), outside of the Arkansas River, are crossed by the Project. The only location along the Project involving tribal lands is in the vicinity of a crossing of the Arkansas River south of Webbers Falls Lock and Dam 16. Tribal interests here are managed by the Arkansas Riverbed Authority, an entity created jointly by the Chickasaw, Choctaw and Cherokee Nations (Title 25 USC §§ 1779-1779f) to administer tribal interests in this section of the river.

State laws and regulations complement federal law on historic and cultural resources. These laws and regulations vary by state (Table 3.9-1). In general, however, all four states in which the Project would be located have laws protecting marked and unmarked graves and cemeteries, and all four states assert control over archaeological and historic resources on state and local public lands. Administrative rules or other standards issued by the respective SHPOs provide specifications and guidance for archaeological and historic architectural surveys, particularly when such studies are completed as part of Section 106 consultation.

3.9.2 Data Sources

To date, evaluation of cultural resources has relied upon background reviews of existing inventories and related information, primarily from SHPO and other state-maintained files. No Project-specific field surveys have been conducted; instead, this analysis relies on data compiled as part of studies, surveys, and reviews that were completed for unrelated projects independent of this EIS in portions of the ROI.

The Applicant and its contractors, SWCA Environmental Consultants (SWCA) and Panamerican Consultants, assembled data on cultural resources from various state agencies in the ROI for the Project. These data and the reports developed from them (Clean Line 2013, 2014) serve as the principal sources of information for the description of the affected environment and the analysis of potential effects related to the Project. Data have been assembled from the following state agencies, some of which are SHPOs (Clean Line 2013):

- Arkansas Archaeological Survey, University of Arkansas, Fayetteville
- Arkansas Historic Preservation Program, Little Rock
- Oklahoma Archaeological Survey, University of Oklahoma, Norman
- Oklahoma State Historic Preservation Office, Oklahoma City

- Tennessee Division of Archaeology, Nashville
- Tennessee Historical Commission, Nashville
- Texas Archaeological Research Laboratory, University of Texas, Austin
- Texas Historical Commission, Austin

In addition to the aforementioned state agency sources, SWCA also examined NRHP online records from the NPS. DOE also conducted its own review of the NRHP-online records (NPS 2014b) for this EIS.

To develop the background sections of their report on the Project, SWCA also reviewed standard scholarly treatments and selected historic preservation planning documents from pertinent SHPOs. DOE is conducting an ongoing consultation with Indian Tribes and Nations on whose tribal lands the undertaking may occur or that may attach religious and cultural significance to historic properties that may be affected by the Project undertaking to identify tribal cultural resources that could be affected by the Project. Clean Line in 2011 and 2012 conducted outreach to Indian Tribes and Nations in the vicinity of the Project.

During the public comment period for the Draft EIS, DOE received information about the locations of several potential archaeological and cultural resources, including Native American camps and other types of sites, burial localities, and historic graves and cemeteries. DOE provided this information to the Applicant for future consideration during micrositing and cultural resource surveys.

In response to public comments on the Draft EIS, DOE reviewed lists of honorees for the Century Farm programs in Oklahoma, Texas, Arkansas, and Tennessee to assess the potential presence of such properties in the ROI for the Project. The lists identify properties that have been honored by the programs by county, but to protect the privacy of property owners, location maps are not available. Lists of honorees were consulted online via the program webpages (Arkansas Agriculture Department 2015; OKSHPO 2015; Texas Department of Agriculture 2015; Middle Tennessee State University Center for Historic Preservation 2015). Comments also expressed concerns about Centennial Trees, but a query by the Applicant to the Oklahoma Forestry Services determined that no database of trees so honored exists. They are therefore not specifically considered in the Final EIS.

The information reported in this section is the best available at the present time concerning historic and cultural resources. DOE has independently reviewed information provided by the Applicant. Additional information on historic and cultural resources that could be impacted by the Project will be obtained through field surveys to be conducted prior to construction.

3.9.3 Region of Influence

As described in Section 3.1.1, this EIS defines the area potentially affected by the Project as the ROI. DOE defines the APE (see Section 3.9.1.1.2), which is the geographic area within which an undertaking may directly or indirectly cause alterations in the character or use of historic properties, in the draft PA (Appendix P). The extent of the APE is influenced by the scale and nature of an undertaking and may be different for different types of effects caused by the undertaking.

For historic and cultural resources, the ROI for the Project is as defined in Section 3.1.

For purposes of this EIS, the ROI for potential visual effects to historic and cultural resources is defined as follows:

- A 1-mile-wide corridor along the Applicant Proposed Route or along the HVDC alternative routes, and the AC collection system routes (i.e., a 0.5-mile zone on either side of the centerline).
- Each converter station siting area and AC interconnection siting area with the area extending outward 0.5 mile.[1]
- A 1,000-foot-wide corridor ROI (500 feet on either side of the centerline of the Applicant Proposed Route and HVDC alternative route) is used to characterize and assess potential effects on archaeological sites, which are largely belowground and therefore less likely to experience visual effects; the larger ROI is used to characterize and assess potential effects on aboveground historic properties and historic routes. It is possible that some archaeological sites could have aboveground expressions, but for the purpose of this analysis, archaeological sites were evaluated in the 1,000-foot-wide corridor ROI.

The ROI for historic and cultural resources for wind energy development, the future Optima Substation, and TVA upgrades are as described in Section 3.1.

3.9.4 Affected Environment

The Project encompasses a geographic transect stretching approximately 720 miles across central North America. This transect extends from the grasslands of the High Plains on the west to the forested eastern flank of the Mississippi Valley on the east. It contains a diverse range of climatic zones, terrain, flora, and fauna whose character has gradually altered with global climatic change and with the effects of human activities on local environments over a period of more than 12 millennia. These environmental factors in turn helped shape the different cultures of people who lived in various places at various times throughout central North America in which the ROI is located.

Human occupation in the region began with the arrival of the early ancestors of modern Native Americans, who are known to archaeologists as Paleoindians. Paleoindians specialized in hunting large now-extinct Pleistocene megafauna, and herd animals such as bison, and are believed to have travelled over wide regions to secure their livelihood. With environmental change at the end of the last glacial epoch, forested lands became more widespread and environmental stresses related to warming and drying climatic conditions appeared. While the Plains dwellers of the western end of the Project region continued to depend on bison and other herd animals, further east, Native American peoples developed new subsistence strategies that aimed to exploit the more solitary animals of forests and woodlands, as well as abundant resources found in and around rivers, ponds, and wetlands. This Archaic period, as it is known, lasted for many thousands of years, and in some places Native Americans still practiced what were essentially Archaic period lifeways up to the disruptions caused by the arrival of Euroamerican explorers, traders, and settlers.

Some two to three thousand years ago, innovations originating among the Native Americans of Mexico and Central America reached the Southeast and Plains regions of the United States. Key innovations included the practice of horticulture involving cultivation of corn, beans, and squash, and the manufacture of earthenware pottery. These new practices mark the emergence of the Woodland period. In the eastern part of the ROI, the rise of horticulture was probably one factor in the development of large villages and towns with increasingly complex social and political

[1] Since completion of the Draft EIS, the Applicant has reduced the footprints of the Arkansas Converter Station and the Tennessee Converter Station Siting Areas, has added a substation at the Arkansas AC interconnection, and has eliminated a 1-mile ROW for the Tennessee interconnection. The net effect of these changes is to reduce the total study area footprint. All changes, however, are located within areas studied in the Draft EIS.

organizations, which characterize the final period of prehistory in the eastern Arkansas-western Tennessee region, known as the Mississippian period. To the west, a cultural tradition known to archaeologists as Plains Villager appeared. This tradition was characterized by small semi-permanent settlements and a mixed hunting, gathering, and horticultural way of life; social complexity was less intensely developed than in the Mississippian cultures to the east.

Beginning in the mid-sixteenth century, European explorers started traversing the region. Traders and settlers followed, generally moving west up major valleys from the Mississippi River, causing vast disruption to the traditional cultures and ways of life of the Native American peoples of the region. In the nineteenth century, policies of the federal government relocated many Tribes from the eastern United States into Oklahoma, parts of which then comprised Indian Territory. As the United States grew in population and economic and industrial power, the Project region was drawn into the modern nation-state. Dates of statehood indicate the historical trajectory of this process: Tennessee became a state in 1796, followed by Arkansas in 1834, and Oklahoma in 1907.

Historic and cultural resources preserve traces of this long history for archaeological study and illustrate it for modern Americans. In general, traces of the Native American past prior to the arrival of Euroamericans (conventionally referred to as the prehistoric period of human history in North America) are largely preserved belowground as archaeological sites. Extant, mostly aboveground, buildings and structures, in contrast, serve as important witnesses to colonial and post-colonial American history, mostly of the nineteenth and twentieth centuries, and these standing structures are complemented by archaeological sites of the period.

The discussion below uses only counts of archaeological resources in the Project ROI to maintain the confidentiality of the geographic locations of the sites provided by the SHPOs or state archaeological surveys. Site location confidentiality helps to protect sites from vandalism.

The ROI contains more than 100 inventoried archaeological sites and a roughly similar number of architectural resources. Most cultural resources have been identified only, and their integrity, significance, and potential eligibility for listing in the NRHP remain unevaluated. However, the ROI also contain 13 identified historic properties that are listed on the NRHP. Figure 3.9-1 in Appendix A shows the NRHP sites that are located within Regions 1 through 7. Unlike the majority of inventoried cultural resources in the ROI whose integrity, significance, and eligibility remain unevaluated, these 19 properties have a clearly established level of cultural or historical significance and are identified individually in Tables 3.9-3 and 3.9-12 and in the text below.

Table 3.9-3:
NRHP-Listed Properties in the 1-mile ROI for the Project—All Regions

Region	Project Segment(s)	Property Name	NRIS No.	Location	Distance from Centerline (miles)
1	AC Collection Line NW 2	Tracey [or Tracy] Wood-Frame Grain Elevator[1]	83002137	Muncy, Texas County, Oklahoma	0.03
3	AR 3-C and AR 3-D	Oktaha School	78002242	Oktaha, Muskogee County, Oklahoma	0.29
3	AR 3-C and AR 3-D	Honey Springs Battlefield NHL	70000848	Oktaha vicinity, Muskogee and Macintosh Counties, Oklahoma	0.10
4	APR Link 6	Mulberry River Bridge	06001272	Pleasant Hill vicinity, Crawford County, Arkansas	0.28

Table 3.9-3:
NRHP-Listed Properties in the 1-mile ROI for the Project—All Regions

Region	Project Segment(s)	Property Name	NRIS No.	Location	Distance from Centerline (miles)
4	AR 4-B	Butterfield Overland Mail Route—Lucian Wood Road Segment	09000771	Cedarville vicinity, Crawford County, Arkansas	0.08
4	AR 4-E	Lutherville School	99000228	Lamar vicinity, Johnson County, Arkansas	0.09
4	AR 4-E	Munger House	96001174	Lutherville vicinity, Johnson County, Arkansas	0.05
5	APR Link 9	William Henry Watson Homestead	91001308	Denmark Township, White County, Arkansas	0.34
5	AR 5-B	Charlie Hall House	05000492	Twin Groves vicinity, Faulkner County, Arkansas	0.05
5	AR 5-B, AR 5-E, and AR 5-F	New Mt. Pisgah School	91001331	Mt. Pisgah vicinity, White County, Arkansas	0.29
5	AR 5-C, APR Link 5, and APR Link 6	Wesley Marsh House	91001328	Letona vicinity, White County, Arkansas	0.34 mi (AR 5-C and APR Link 5); 0.41 mi (APR Link 6)

7	AR 7-A	Nodena Site NHL	66000201	Wilson Vicinity, Mississippi County, Arkansas	>0.10

NRIS—National Register Information System.
NHL—National Historic Landmark
1 Examination of aerial imagery available from Google Earth indicates that the Tracey Wood-Frame Grain Elevator is no longer extant. Field survey would be required to verify its disappearance.
Source: NPS (2014b), OKSHPO (2014b)

In addition to the historical dimension of the resources present in the ROI, there may be additional resources including burial sites, individual homestead allotments, and ceremonial grounds important to present-day Indian Tribal identity or lifeways, or cultural significance. Tribal resources conceptually overlap in part with archaeological and architectural resources, but tribal resources have not yet been formally identified or documented. As part of the process of identifying and evaluating historic and cultural resources in this region, and as noted above, DOE is conducting ongoing consultation with Indian Tribes and Nations. Concerns for specific burial and ceremonial ground areas have been expressed in consultation meetings in relation to the ROI.

State-level Century Farms programs provide recognition to self-nominated agricultural operators who can document at least 100 years of continuous operation of a farm or ranch by a single family. These programs are honorary, voluntary, and do not afford legal protections (Arkansas Agriculture Department 2015; OKSHPO 2015; Texas Department of Agriculture 2015; Middle Tennessee State University Center for Historic Preservation 2015). In most of the 33 counties included in the study area for this Project (Tables 2.1-3, 2.1-5, and 2.4-1), around 1 percent (the median) of active farms and ranches have been honored as Century Farms. Most counties have participation rates in their state's Century Farm program of between 0.1 and 3.0 percent. Two counties, Crawford and Cleburne counties, Arkansas, have no Century Farm honorees, and three, Major, Garfield, and Kingfisher counties, Oklahoma, have over 3 percent (7.2, 11.5, and 12.8 percent Century Farms, respectively).

Assessment of effects (including visual effects) on historic properties is based in part on the evaluation of integrity and is related to the characteristics of each property that make it NRHP-eligible. According to the NRHP guidelines, integrity is defined as the ability of an historic property to convey its own significance; evaluations of integrity must always be grounded in an understanding of a property's physical features and whether they remain sufficiently intact to convey its significance. A historic property's integrity includes seven unique aspects: location, setting, design, materials, feeling, workmanship, and association. Based on these aspects, the types of sites considered visually sensitive include, but are not limited to, National Historic Monuments, Districts, Landmarks, and Trails; sites eligible under criteria A, B, or C and Traditional Cultural Properties (36 CFR 800.5). In the Section 106 consultation process, the lead federal agency typically makes a determination about the NRHP eligibility of each identified historic property within the APE of the undertaking; the pertinent SHPO provides concurrence, as appropriate, with the agency's determinations.

Several route variations to the Applicant Proposed Route in Regions 2–7 were developed in response to public comments on the Draft EIS and are described in Appendix M and summarized in Sections 2.4.2.1–2.4.2.7. Exhibit 2 of Appendix M tabulates available information on previously recorded historic and cultural resources, which was obtained from the sources listed above in Section 3.9.2. Assessments of the impacts related to the route variations by Project region, including accompanying HVDC alternative route adjustments, are provided below. The variations are presented graphically in Exhibit 1 of Appendix M.

3.9.5 Regional Description

Geographic and cultural features relevant to the characteristics and distribution of historic and cultural resources are described by region in the sections below. The region names and the Applicant Proposed Route and HVDC alternative routes by region are listed in Table 2.4-1.

3.9.5.1 Region 1

The western end of Region 1 is the location of the AC collection system centered in Texas County, Oklahoma, and including areas in adjoining counties in Oklahoma and Texas. In addition, Region 1 includes the Applicant Proposed Route, HVDC alternative routes, and the Oklahoma Converter Station.

Region 1 is situated in western Oklahoma, including the eastern and central portions of the Oklahoma Panhandle. It also includes the north-central border region of the adjoining Texas Panhandle. The region is part of the Plains culture area as defined by ethnographers for indigenous Native American peoples of the late prehistoric and historical periods (after roughly 1650 AD) (DeMallie 2001). The Oklahoma Archaeological Survey (OAS) places the region within its Southern Plains Adaptations research region for Native American archaeology (OAS 2011). Region 1 spans portions of two historic preservation planning and management regions defined by the Oklahoma State Historic Preservation Office (OKSHPO): OKSHPO Region 1 (the Oklahoma Panhandle) and OKSPHO Region 2 (Northwestern Oklahoma) (OKSHPO 2014a). In Texas, Region 1 is part of the Texas Historical Commission's Archaeology Region 1 and its Plains Trail heritage tourism region (Texas Historical Commission 2014a, 2014b). Texas archaeologists and historians identify Region 1 as part of the Panhandle region of the state (Perttula 2004, Figure 1.1; Rathjen 2010).

Geographically, Region 1 lies within the High Plains physiographic province (Wedel and Frison 2001, Figure 1). It is characterized by level and irregular, rolling to broken plains that grade into dissected canyons, escarpments, hills, buttes, terraces, and dunes. There are scattered playas on the plains of the region. The natural vegetation is mostly short grass prairie (Griffith et al. 2004; Woods et al. 2005). The region today is primarily agricultural and is dominated by cattle ranching. The archaeological record of the region spans over 12,000 years, extending from the sites of early Native American hunter-gatherers of the Paleoindian period through the small pithouse villages of Native American horticulturalists in late prehistory to the remains of dugouts, ranches, and farmsteads of late nineteenth- and twentieth-century non-Indian settlers, ranchers, and farmers (Clean Line 2013). According to the OAS (2011), prehistoric, protohistoric, and early historic period archaeological sites in the region are "characterized by the remains of special activity sites, camps, and villages of Native Americans whose lives were focused around the bison (buffalo)." Historic property types associated with the occupation of the region by Euroamericans and other non-Indian groups from the late nineteenth century onwards include townsites; commercial buildings and structures; non-commercial and governmental buildings; homesteads, farms, and ranches; churches; schools; and cemeteries (Smith 1986a). Such property types occur both as extant standing structures and as archaeological sites.

No historic or cultural resources have been identified within the Oklahoma Converter Station Siting Area or associated AC Interconnection Siting Area (Clean Line 2013). Information about historic and cultural resources in the AC collection system and HVDC transmission facilities in Region 1 is presented in the following sections.

3.9.5.1.1 Region 1 AC Collection System

The proposed AC collection system in Region 1 primarily occupies vast upland regions of the Oklahoma and Texas Panhandles. Terrain in the region is varied, and climate is semi-arid. Inventoried archaeological sites are few in comparison to the acreages involved. Nonetheless, available information shows that archaeological sites typically occur in the vicinity of principal drainages and major tributaries, as well as in the vicinity of terrain features such as escarpments and buttes. Several historic transportation routes cross the area, but no cultural resources have been documented as associated.

The Applicant's initial analysis of potential impacts to historic and cultural resources for the AC collection system routes considered 2-mile-wide siting corridors (the ROI), which represented a combined area of over 440,000 acres. In all, these corridors contain a total of 71 separate sites, but due to overlaps between adjacent 2-mile siting corridors, some of these sites are counted more than once in Table 3.9-4, which shows the numbers of previously inventoried historic and cultural resources associated with the corridors. Among the 71 sites, 46 are prehistoric archaeological sites, 11 are historic period sites, 5 are multicomponent (prehistoric and historic period) sites, and 9 lack a record as to period. Over 80 percent (59 of 71) of the inventoried archaeological sites have not been evaluated for NRHP eligibility. To date, nine of the sites have been determined ineligible for the NRHP, while three are categorized as NRHP-eligible. No previously recorded archaeological sites in the ROI for the AC collection system routes in Region 1 are listed on the NRHP. Prehistoric archaeological site types that may be anticipated within the ROI include open camps, general artifact scatters, isolated burials, and a bison kill sites. Historic archaeological sites may include farmsteads, general artifact scatters, cemeteries (which could also be categorized as historic architectural features), isolated structures, and railroad-related ruins (Clean Line 2013). Only one aboveground historic structure, an NRHP-listed early twentieth-century grain elevator, has been inventoried in the ROI of the AC collection system routes in Region 1. Four historic transportation routes are known in the region, including two railroad lines, a military road, and a cattle trail, and the ROI intersects these historic transportation routes in multiple locations. The region contains few farms or ranches that have been honored as Century Farms.

No route variations were proposed for the AC Collection System in Region 1.

Table 3.9-4:
Previously Inventoried Historic and Cultural Resources in the ROI for the AC Collection System Routes in Region 1

		AC Collection System Route

Century Farms (estimated)[5, 6]		0	0	0	0	0	0	0	0	1	1	0	0	0

1 “Unique” sites are counted only once in this table. They are within the 2-mile siting corridor for only a single collection line.
2 “Duplicate” sites are counted two or more times in this table. They are overlapping portions areas of the 2-mile siting corridors for two or more collection lines.
3 Due to the low number of aboveground historic properties, duplicate counts do not arise.
4 Trail intersections per 2-mile corridor; includes a combination of several different trails that may intersect a given corridor once or more than once.
5 Estimated number of Century Farms crossed by centerline of the route, rounded to the nearest whole number, based upon per-county data for total number of farms, average size of farms, and percentage county area in farmland (Table 3.13-9); number of Century Farm honorees (OKSHPO 2015; Texas Department of Agriculture 2015); and lengths of route segments. The estimate assumes an unbiased distribution of Century Farms across each county.
6 Century Farms Programs are honorary, voluntary, and do not afford legal protections (Arkansas Agriculture Department 2015; OKSHPO 2015; Texas Department of Agriculture 2015; Middle Tennessee State University Center for Historic Preservation 2015).
Source: Clean Line (2013, Table 3-42B), supplemented by data referenced in Footnote 5.

3.9.5.1.2 Region 1 HVDC Transmission Facilities

Available information for the proposed transmission line corridors of the Applicant Proposed Route and HVDC Alternative Routes 1-A through 1-D in Region 1 indicates that inventoried prehistoric and historic archaeological sites typically occur along the principal drainages and their major tributaries; these increase in prominence toward the eastern end of the region. Historical settlement was dispersed across the region; documented historic standing structures occur in the western end of the ROI in a clustering that results from the low density of historic properties in Region 1 and the limited extent of survey to date (Clean Line 2013). The clustering is not historically meaningful.

Including duplicate counts, 11 prehistoric archaeological sites and five historic archaeological sites are documented for the ROI associated with the HVDC transmission facilities in Region 1 (Table 3.9-5). None of the sites has been determined to be eligible for or is listed on the NRHP. Documented prehistoric archaeological site types in the ROI include general artifact scatters, open camps, and a bison kill site. Documented historic archaeological site types in Region 1 are farmsteads, along with an isolated structure and an unspecified site type. The Applicant Proposed Route and HVDC alternative routes cross several nineteenth-century cattle trails, military roads, and early railroad lines, but no archaeological sites or standing structures have been recorded as specifically associated with these routes in the region. Among the historic trail alignments crossed by the Project route is that of the Western or Great Western Trail, which was recently identified as a potential National Historic Trail NPS 2014d). The intersection of the Project with this historic trail alignment is approximately 2.6 miles west-southwest of May, Harper County, Oklahoma. No historic or cultural resources have been identified as associated with the trail alignment in the vicinity of the intersection. The ROI for potential visual impacts for the Applicant Proposed Route and HVDC alternative routes includes three buildings that are reported to be eligible for the NRHP (Clean Line 2013). The Applicant Proposed Route is estimated to cross approximately one Century Farm, while most HVDC alternative routes are estimated to cross one or two such operations.

No route variations were proposed for the Applicant Proposed Route in Region 1.

Table 3.9-5:
Previously Inventoried Historic and Cultural Resources in the ROI for the Applicant Proposed Route and HVDC Alternative Routes in Region 1

	APR	AR 1-A	AR 1-B	AR 1-C	AR 1-D
Archaeological Sites[1]					
Prehistoric	2[2]	7	1	0	12
Historic	2	2	1	0	0

Historic Routes, Trails, and Roads[1]	6	6	2	2	0
Century Farms (estimated)[5, 6]	1	2	1	1	0

1 ROI for archaeological sites is a 1,000-foot-wide corridor; ROI for aboveground historic properties and historic routes is a 1-mile corridor.
2 Includes one site that is counted twice because its location is known only to a half quarter-section, and the identified area is intersected by both Applicant Proposed Route Link 4 and HVDC Alternative Route 1-D.
3 Identified by OKSHPO records as NRHP eligible.
4 Duplicate count. Building or structure occurs in conterminous ROI for HVDC Alternative Routes 1-B and 1-C.
5 Estimated number of Century Farms crossed by centerline of the route. See Table 3.9-4 Footnote 5 for basis of estimate.
6 Century Farms Programs are honorary, voluntary, and do not afford legal protections (Arkansas Agriculture Department 2015; OKSHPO 2015; Texas Department of Agriculture 2015; Middle Tennessee State University Center for Historic Preservation 2015).
Source: Clean Line (2013, Table 3-9), supplemented by data from OKSHPO (2015).

3.9.5.2 Region 2

The history of Region 2 includes the Plains culture area as defined by ethnographers for Native American peoples of the late prehistoric and historical periods (after roughly 1650 AD). The OAS (2011) places the region within its Southern Plains Adaptations research region for Native American archaeology (OAS 2011). Region 2 is situated within OKSHPO (2014a) historic preservation planning and management Region 2 (Northwestern Oklahoma).

Geographically, Region 2 lies within the Osage Plains physiographic province (Wedel and Frison 2001, Figure 1). It is characterized by a variety of landforms, including stabilized and active dune fields, gypsum karst terrain, breaks, escarpments, gorges, ledges, canyons, and nearly level prairieland. The natural vegetation of upland areas is predominantly mixed grass prairie. Characteristic soils and hydrological conditions mean that dune and karst areas each support distinct vegetation communities of mixed grasslands, shrubs, and trees. Throughout the region, ravines and stream valleys support woodlands, and woodlands are more extensive to the east, where annual rainfall tends to be greater and less variable (Woods et al. 2005). Cattle ranching dominates the western half of Region 2, and small grain farming is predominant in the eastern half. The archaeological record of Region 2 spans over 12,000 years, extending from the sites of early Native American hunter-gatherers of the Paleoindian period through the small pithouse villages of Native American horticulturalists in late prehistory to the remains of dugouts, ranches, and farmsteads of late nineteenth- and twentieth-century non-Indian settlers, ranchers, and farmers (Clean Line 2013). According to the OAS (2011), prehistoric, protohistoric, and early historic period archaeological sites in the region are “characterized by the remains of special activity sites, camps, and villages of Native Americans whose lives were focused around the bison (buffalo).” Historic property types associated with the occupation of the region by Euroamericans and other non-Indian groups from the late nineteenth century onwards include townsites; commercial buildings and structures; non-commercial and governmental buildings; homesteads, farms, and ranches; churches; schools; and cemeteries (Smith 1986b). Such property types occur both as extant standing structures and as archaeological sites.

Available information indicates that, in general, prehistoric and historic archaeological sites occur most frequently along the region’s principal drainages and their major tributaries, which are more numerous in its central and eastern sections. Historical settlement was dispersed across the region, and the region was crossed by several historical transportation corridors (Clean Line 2013). Among these was the Chisholm Trail, the alignment of which was recently identified by NPS as a potential National Historic Trail (NPS 2014d), and was identified as a potentially significant resource by commenters on the Draft EIS. Approximately 1.6 miles south of Bison, Oklahoma, Link 2 of the Region 2 Applicant Proposed Route passes approximately 200 feet south of a field containing relict wagon ruts from this trail; the property owner is working with the Oklahoma SHPO to develop an NRHP nomination for the property.

Only two archaeological sites have been documented within the ROI in Region 2 (Table 3.9-6), and the available information does not indicate the time period of either. Neither has been determined to be eligible for or is listed on the NRHP. No historic standing structures have been documented in the ROI for potential visual impacts for the Applicant Proposed Route and HVDC alternative routes (Clean Line 2013). The counties of Region 2 have by far both the greatest number and the highest percentage of Century Farms of any region of the Project (OKSHPO 2015). The reasons for the high participation rate are not known, and it is not known whether the high rate reflects notable longevity among family farming enterprises in the region or if it is a result of particular enthusiasm for or strong local promotion of Oklahoma’s Century Farm program. Whatever the reason, it is estimated that the Applicant Proposed Route may cross approximately seven Century Farms, while the shorter HVDC alternative routes may each cross approximately three Century Farms. Consistent with the high estimates for the frequency of Century Farms in this region, three comments on the Draft EIS noted the presence of specific examples along the Applicant Proposed Route in Garfield County or in its vicinity.

Two route variations to the Applicant Proposed Route were developed in Region 2 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.2. The variations are illustrated in Exhibit 1 of Appendix M. These variations represent minor adjustments to the Applicant Proposed Route, and their potential to involve historic and cultural resources appears similar to those segments analyzed for the Draft EIS. Both Link 1, Variation 1, and Link 2, Variation 2, cross similar terrain to the original Applicant Proposed Route considered in the Draft EIS with similar potential to contain archaeological sites and historic resources. There are no recorded historic or cultural resources in the ROIs for either route variation segment (Appendix M).

Table 3.9-6:
Previously Inventoried Historic and Cultural Resources in the ROI for the Applicant Proposed Route and HVDC Alternative Routes in Region 2

Century Farms (estimated)[3, 4]	7	3	3

1 The values in the table do not reflect the minor changes that would result from application of route variations and adjustments.
2 ROI for archaeological sites is a 1,000-foot-wide corridor; ROI for aboveground historic properties and historic routes is a 1-mile corridor.
3 Estimated number of Century Farms crossed by centerline of the route. See Table 3.9-4 Footnote 5 for basis of estimate.
4 Century Farms Programs are honorary, voluntary, and do not afford legal protections (Arkansas Agriculture Department 2015; OKSHPO 2015; Texas Department of Agriculture 2015; Middle Tennessee State University Center for Historic Preservation 2015).
Source: Clean Line (2013, Table 3-14), supplemented by data from OKSHPO (2015).

3.9.5.3 Region 3

The history of Region 3 includes the Plains culture area as defined by ethnographers for Native American peoples of the late prehistoric and historical periods (after roughly 1650 AD). The OAS (2011) places the region within its Cross Timbers research region for Native American archaeology (OAS 2011). Region 3 is situated within OKSHPO's (2014a) historic preservation planning and management Regions 2 (Northwestern Oklahoma), 3 (Northeastern Oklahoma), and 6 (Central Oklahoma).

Geographically, Region 3 lies within the Osage Plains and Central Lowland physiographic provinces (Wedel and Frison 2001, Figure 1). "Terrain and vegetation are transitional between the less rugged grass-covered ecoregions to the west and the hilly, oak savanna… to the east" (Woods et al. 2005). It is characterized by rough, undulating, and irregular plains, hills, and typically asymmetrical ridges. The natural vegetation varies from west to east. To the west, the characteristic natural vegetation is prairie grasses with scattered trees and light woodlands, while to the east natural vegetation consists of a mosaic of oak savanna, scrubby oak forest, eastern redcedar, and tall grass prairie. Modern land use is varied and includes rangeland, cultivated crops, forests, and commercial and residential development. The archaeological record of Region 3 spans over 12,000 years, extending from the sites of early Native American hunter-gatherers of the Paleoindian period through the small pithouse villages of Native American horticulturalists in late prehistory to the remains of dugouts, ranches, and farmsteads of late nineteenth- and twentieth-century non-Indian settlers, ranchers, and farmers (Clean Line 2013). According to the OAS (2011), the prehistoric archaeology of the Cross Timbers region offers a glimpse into the continual adjustments that Native American peoples made to changing environmental conditions over the 12 millennia during which they occupied the area. A variety of prehistoric Native American site types occur, including special activity sites, camps, and villages. From the 1830s, northeastern Oklahoma (OKSHPO Planning and Management Region 3) was the home of the Creek and Cherokee Nations following the forced removal of Native Americans from the eastern states to Indian Territory. The OKSHPO's historic context for historic Native Americans in northeastern Oklahoma identifies 11 associated classes of properties, described as buildings, structures, objects, sites, and districts related to tribal government; spirit life; education; agriculture, ranching, commerce, and industry; pre-railroad transportation; dwellings and home places; townsites; recreation and encampments; health care; military; and the federal Indian Agency (Baird and Gebhard 1991). Historic property types associated with the occupation of the region by Euroamericans and other non-Indian groups from the late nineteenth century onwards include townsites; commercial buildings and structures; non-commercial and governmental buildings; homesteads, farms, and ranches; churches; schools; and cemeteries (Smith 1984, 1986b, 1986c). Such property types occur both as extant standing structures and as archaeological sites.

Available information indicates that, in general, prehistoric and historic archaeological sites occur most frequently along the region's principal drainages and their major tributaries, which are more numerous than in Regions 1 and 2 to the west. Historical settlement was dispersed across the region, and the region was crossed by several historical transportation corridors, including portions of historic U.S. Route 66 (Clean Line 2013). Congress has recognized the national historical significance of Route 66 and encourages preservation of historic properties along it through the NPS's Route 66 Corridor Preservation Program, which provides leadership for a diverse group of public and private stakeholders (NPS 2014a). Oklahoma has completed historic resource surveys of resources associated with the highway within its borders (Anderson et al. 2002; Cassity 2002).

Including duplicate counts, eight archaeological sites have been documented for the ROI in Region 3, including four prehistoric period sites, three historic period sites, and one site whose age is not specified (Table 3.9-7). None of these has been determined to be eligible for or is listed on the NRHP, and one historic period farmstead is described as not NRHP eligible. General artifact scatters are the only type of prehistoric archaeological site that have been documented in Region 3, while farmsteads are the only type of historic archaeological site type documented for the region. The Applicant Proposed Route and HVDC alternative routes cross several nineteenth-century cattle trails, military roads, and early railroad lines, but no archaeological sites or standing structures have been recorded as specifically associated with these routes in the region.

Table 3.9-7:
Previously Inventoried Historic and Cultural Resources in the ROI for the Applicant Proposed Route and HVDC Alternative Routes in Region 3

Resource[1]	APR	AR 3-A	AR 3-B	AR 3-C	AR 3-D	AR 3-E

Total Aboveground Properties	2	0	0	2	2	0
Historic Routes, Trails, and Roads[2]	20	4	6	19	14	2
Century Farms (estimated)[6, 7]	2	2	2	1	0	0

1 The values in the table do not reflect the minor changes that would result from application of route variations and adjustments.
2 ROI for archaeological sites is a 1,000-foot-wide corridor; ROI for aboveground historic properties and historic routes is a 1-mile corridor.
3 Duplicate count—the same site occurs in conterminous sections of HVDC Alternative Routes 3-C and 3-D.
4 Includes one structure consultant-recommended as NRHP eligible.
5 Duplicate counts—the same two properties occur in conterminous sections of HVDC Alternative Routes 3-C and 3-D.
6 Estimated number of Century Farms crossed by centerline of the route. See Table 3.9-4 Footnote 5 for basis of estimate.
7 Century Farms Programs are honorary, voluntary, and do not afford legal protections (Arkansas Agriculture Department 2015; OKSHPO 2015; Texas Department of Agriculture 2015; Middle Tennessee State University Center for Historic Preservation 2015).

Source: Modified from Clean Line (2013, Table 3-15), supplemented by data from OKSHPO (2015).

The Applicant Proposed Route and HVDC Alternative Route 3-C both intersect the historic U.S. Route 66 corridor in Creek County near the midpoint of Region 3. The Applicant Proposed Route intersects the historic U.S. Route 66 corridor approximately 5 miles northeast of Bristow. HVDC Alternative Route 3-C intersects the historic U.S. Route 66 corridor approximately 5.3 miles west-southwest of Bristow. The Applicant Proposed Route passes within approximately 0.5 mile south of a 1.8 mile segment of the 1926 Portland Concrete-paved alignment of U.S. Route 66, which is the longest privately owned section of unaltered first-generation paving in Oklahoma. This segment is recommended as eligible for the NRHP; information on OKSHPO concurrence (if any) is not available. No historic resources associated with historic U.S. Route 66 have been documented within at least 1.3 miles of HVDC Alternative 3-C (Anderson et al. 2002, Maps 22–23; OKDOT 2012).

The ROI for potential visual impacts for HVDC Alternative Routes 3-C and 3-D contains two NRHP-listed properties (Table 3.9-3), both situated in the vicinity of Oktaha, Muskogee County, Oklahoma, which is located toward the eastern end of the ROI. The listed properties are the Oktaha School and the Honey Springs Battlefield, which is also listed as a National Historic Landmark (NHL) as of 2013. Oktaha School is situated approximately 0.29 mile north of HVDC Alternative Routes 3-C and 3-D conterminous centerlines. The boundaries of Honey Springs Battlefield as defined in the nomination by which the property was listed on the NRHP in 1970 are approximately 0.10 to 3.54 miles south of the same two alternatives. The NHL nomination, which reflects an additional 40 years of historical and archaeological research on the battle as well as a more refined assessment of the current integrity of the battlefield, delineates boundaries approximately 0.41 mile to 3.44 miles south of the alternatives (Fischer and Ruth 1970; NPS 2013, 2014b; Clean Line 2013; Warde et al. 2012). Both properties are also important to the history of Native Americans in Oklahoma.

Aside from the two NRHP-listed properties, no aboveground buildings, structures, districts, sites, or objects properties have been inventoried as historic resources in the 1-mile ROI for Region 3. The estimated number of Century Farms crossed by Applicant Proposed Route is two, which is also the estimate for HVDC Alternative Routes 3-A and 3-B. The western end of this region lies within an area of Oklahoma with a notably high participation rate in Century Farms program (OKSHPO 2015).

Five route variations to the Applicant Proposed Route were developed in Region 3 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.3. The variations are illustrated in Exhibit 1 of Appendix M. These variations represent minor adjustments to the Applicant Proposed Route, and their potential to involve historic and cultural resources appears similar to the original Applicant Proposed Route analyzed for the Draft EIS. Link 1, Variation 2, crosses similar terrain and has similar potential for containing historic and cultural resources as the original Applicant Proposed Route Link 1. Links 1 and 2, Variation 1, crosses similar terrain and has similar potential for containing historic and cultural resources as the original Applicant Proposed Route Link 1. It should be noted that a route adjustment was made for HVDC Alternative Route 3-A to maintain an end-to-end route with the Links 1 and 2 variations. Link 4, Variation 1, and the original Applicant Proposed Route in this location have similar pre-modern terrain and originally had similar potential for containing historic and cultural resources; however, the proposed variation crosses generally undeveloped land, whereas the ROI for the original Applicant Proposed Route crosses a quarry operation, where there would be a lower potential for historic and cultural resources. Link 4, Variation 2, crosses similar terrain and has similar potential for containing historic and cultural resources as the original Applicant Proposed Route. Link 5, Variation 2, crosses similar terrain and has similar potential for containing historic and cultural resources as the original Applicant Proposed Route. There are no recorded historic or cultural resources in the ROIs for any of the five route variation segments, nor for the route adjustment in HVDC Alternative Route 3-A (Appendix M).

3.9.5.4 Region 4

Occupied by the Osage, a Siouan-speaking people, in late prehistory and the historical period, the region is part of the Plains culture area as defined by ethnographers for Native American peoples (after roughly 1650 AD) (Bailey 2001; DeMallie 2001). The western part of Region 4 is part of the OAS's Caddoan Origins research region for Native American archaeology (OAS 2011). Region 4 is situated within OKSHPO's (2014a) historic preservation planning and management Region 3 (Northeastern Oklahoma). In Arkansas, Region 4 is part of the Ozark Plateau/Arkansas Valley geographic region (Clean Line 2013).

Geographically, Region 4 skirts the border between the Ozark Plateau physiographic province to the north and the Ouachita Mountain province to the south (Wedel and Frison 2001, Figure 1). It is characterized by undulating to hilly terrain, with some sections of the alternative alignments crossing the rugged terrain of the southern edge of the Boston Mountains. The natural vegetation is a mosaic of prairie, savanna, woodland, and forest and includes pine–oak savanna, oak–hickory forest, and oak–hickory–pine forest (Woods et al. 2004, 2005). Modern land use is varied and includes haylands, pasture, and forest. The archaeological record of Region 4 spans over 12,000 years, extending from the sites of early Native American hunter-gatherers of the Paleoindian period through the small villages of round or elongate at-grade, earthfast sapling-frame dwellings built by Native American horticulturalists in late prehistory to the remains of homesteads and other structures of nineteenth- and twentieth-century non-Indian settlers (Clean Line 2013). The archaeology of the Region 4 in eastern Oklahoma and western Arkansas reflects the transitional character of the region, with trends characteristic of the Eastern Woodlands and Southeast developing in concert with trends more characteristic of the Plains region (OAS 2011; Clean Line 2013). Prehistoric Native American site types include isolated finds (artifacts), lithic scatters, camps and villages, mounds, rock art localities, and quarries. Historic period property types include residences and farmsteads, commercial properties, small- and large-scale industrial enterprises, military facilities, transportation-related structures, cemeteries, and religious properties (AHPP 2013; Clean Line 2013). Property types associated with the Bell-Drane Cherokee Removal Route of the Trail of Tears (1838–1839) (described below) potentially include roadbed segments; ferry crossings, landings, and fords; campsites; buildings, structures, and building sites; and gravesites (Thomason and Parker 2003, Appendix F). Available information indicates that no historic properties associated with the Trail of Tears have been identified at any of the intersections of the Applicant Proposed Route or the HVDC route alternatives with the Trail of Tears.

Available information indicates that, in general in Region 4, prehistoric and historic archaeological sites occur most frequently “in undulating hills and at stream basins.” Historical settlement was dispersed across the region, and the region was crossed by several historical transportation corridors, including a segment of the Trail of Tears National Historic Trail (Clean Line 2013).

The Trail of Tears in Region 4 is a multi-branched linear resource management corridor, rather than a single continuous historic resource or discontinuous historic district. This network of trails was used during the forced relocation of Native American peoples indigenous to the southeastern United States to Indian Territory (now Oklahoma) in the 1830s. The NPS leads a group of federal, state, local, non-governmental, and private stakeholders in the identification, preservation, interpretation, and promotion of the Trail of Tears National Historic Trail and associated properties. Greatly expanded in 2009, the Trail of Tears National Historic Trail consists of several separate branches that cross, and in one case terminate in, Arkansas. Public comments received on the Draft EIS indicated that the Trail of Tears is of particular historical and cultural interest to the Cherokee Nation and other Indian Tribes and Nations. The ROI for the Project intersects the branch of the Trail of Tears now called the Bell-Drane Route between western Crawford County and south-central Johnson County. Generally following the old Little Rock-to-Fort Gibson Road up the northern side of the Arkansas Valley as far west as Fort Smith, this trail segment is typically described as approximating the present route of U.S. Route 64. From the vicinity of Fort Smith, the Bell-Drane Route turns north and approximates State Route 59 to Evansville, in southwestern Washington County near the Arkansas-Oklahoma line. Between late July 1838 and early January 1839, three groups of Cherokee numbering from around 660 to 1,000 each followed the Bell-Drane Route through the ROI to exile in eastern Indian Territory (Horne 2006; NPS 2007, 2014c; Thomason and Parker 2003, Appendix E).

Including duplicate counts, 62 archaeological sites have been documented for the ROI in Region 4 (Table 3.9-8). This count comprises 24 occurrences of prehistoric period sites, 28 occurrences of historic period sites, and 10 multicomponent (most of which are prehistoric and historic period) sites. Prehistoric archaeological site types include general artifact scatters, open camps, and rockshelters. Historic period archaeological sites include building ruins and foundations (“structures” and “isolated structures”), farmsteads, markers, general artifact scatters, and unspecified. Three individual archaeological sites have been determined to be eligible for the NRHP, including one prehistoric period site and two multicomponent sites. Prehistoric components at the NRHP-eligible sites are described as either general artifact scatters or open camps, while the two historic period components (both at the multicomponent sites) represent farmsteads. Nine sites, three each prehistoric, historic, and multicomponent, have been determined not

NRHP eligible; the remaining sites are unevaluated (Clean Line 2013). While tribal resources have not been delineated across the Project ROI, tribal consultation with DOE in September 2013 indicated the "potential for a burial site location and a ceremonial grounds location" along the Region 4 Applicant Proposed Route (Clean Line 2013). During the public comment period for the Draft EIS, the Applicant explicitly stated that no known burial site locations and no ceremonial grounds are intersected by the Applicant Proposed Route or the HVDC route alternatives in Region 4. In addition, on March 17, 2015, DOE specifically advised the Council of the Cherokee Nation that the Stokes Smith Ceremonial Grounds would not be crossed by the Applicant Proposed Route or HVDC Alternative Route 4-A. The Stokes Smith grounds is an important location of regular cultural activities for the Cherokee Nation. The Applicant Proposed Route is approximately 1.4 miles south of the ceremonial grounds, while the alternative route is approximately 1.6 miles to the northwest (DOE 2015).

Table 3.9-8:
Previously Inventoried Historic and Cultural Resources in the ROI for the Applicant Proposed Route and HVDC Alternative Routes in Region 4

Resource[1]	APR	AR 4-A	AR 4-B	AR 4-C	AR 4-D	AR 4-E

Historic Routes, Trails, and Roads[2,7]	8	7	8	1	1	1
Century Farms (estimated)[8, 9]	0	0	0	0	0	0

1 The values in the table do not reflect the minor changes that would result from application of route variations and adjustments.
2 ROI for archaeological sites is a 1,000-foot-wide corridor; ROI for aboveground historic properties and historic routes is a 1-mile corridor.
3 Includes two duplicate counts—the same two sites occur in conterminous sections of HVDC Alternative Routes 4-A and 4-B.
4 Includes one triplicate count—the same site occurs in conterminous sections of HVDC Alternative Routes 4-A, 4-B, and 4-D.
5 Includes one duplicate count—the same historic property occurs in conterminous sections of HVDC Alternative Routes 4-A and 4-B.
6 Includes one triplicate count—the same historic property occurs in conterminous sections of HVDC Alternative Routes 4-A, 4-B, and 4-D.
7 Most historic routes enumerated in this table are located in Oklahoma. Considerably less readily accessible public information is available for the Arkansas portion of Region 4 than for Oklahoma.
8 Estimated number of Century Farms crossed by centerline of the route. See Table 3.9-4 Footnote 5 for basis of estimate.
9 Century Farms Programs are honorary, voluntary, and do not afford legal protections (Arkansas Agriculture Department 2015; OKSHPO 2015; Texas Department of Agriculture 2015; Middle Tennessee State University Center for Historic Preservation 2015).
Source: Modified from Clean Line (2013, Table 3-19), supplemented by data from Arkansas Agriculture Department (2015) and the Oklahoma SHPO (OKSHPO 2015)

The Applicant Proposed Route and HVDC alternative routes intersect the Bell-Drane Route of the Trail of Tears in the east-central section of Region 4. Intersections occur at roughly 11 locations between the vicinity of State Route 59 north of Fort Smith, Arkansas, on the west, and approximately 6.5 miles west of Clarksville, Arkansas, on the east.

Five intersections occur close to the north-south-aligned State Route 59 at the western end of this area. No historic properties associated with the Trail of Tears have been inventoried in the vicinity of any of these intersections. In addition to the Trail of Tears, the ROI is reported to cross several other historic transportation corridors in different places along the Applicant Proposed Route and HVDC alternative routes, but no historic properties are known to be associated with any of these intersections (Clean Line 2013).

Including duplicate counts, 18 historic buildings and structures have been inventoried at various locations along the Applicant Proposed Route and HVDC alternative routes (Table 3.9-8). The majority of the buildings and structures are unevaluated for NRHP eligibility. One has been determined ineligible, and two have been determined NRHP eligible. Within the 1-mile ROI for aboveground historic properties for the Applicant Proposed Route and HVDC alternative routes, four buildings and structures have been listed on the NRHP (Table 3.9-3). All are located in the Arkansas portion of Region 4 and include the Mulberry River Bridge, 0.28 mile from the Applicant Proposed Route in Crawford County; Lucian Wood Road Segment of the Butterfield Overland Mail Route, 0.08 mile from HVDC Alternative Route 4-B, also in Crawford County; and Lutherville School and the Munger House, 0.09 and 0.05 mile from HVDC Route Alternative 4-E in Johnson County (Clean Line 2013; NPS 2014b).

Based on lists of farms and ranches in Oklahoma and Arkansas that have been honored by their respective states' Century Farms programs, it is estimated that no such agricultural operations would be crossed by the Applicant Proposed Route or any of the HVDC alternative routes. This estimate reflects the small number of Century Farms that have been honored in eastern Oklahoma and western Arkansas, which in the latter area is due in part to the recent establishment of a Century Farms program in Arkansas (Arkansas Agriculture Department 2015; OKSHPO 2015). Two comments on the Draft EIS report that HVDC Alternative Route 4E crosses a Century Farm in western Pope County, Arkansas.

Seven route variations to the Applicant Proposed Route were developed in Region 4 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.4. The variations are illustrated in Exhibit 1 of Appendix M. These variations represent minor adjustments to the Applicant Proposed Route, and their potential to involve historic and cultural resources appears to be generally similar to original Applicant Proposed Route analyzed for the Draft EIS. Link 3, Variation 1, generally has similar terrain and similar potential to contain historic and cultural resources as the original Applicant Proposed Route. Appendix M notes that one cemetery of unknown age and significance falls within the ROI for this route variation segment; this feature is also within the ROI of the original Applicant Proposed Route.

Link 3, Variation 2, crosses somewhat hillier terrain than the original Applicant Proposed Route Link 3, which could indicate minor overall differences in their respective potential to contain historic and cultural resources. This variation passes approximately 0.6 mile south of the Stokes Smith Ceremonial Grounds, which is roughly 1 mile closer than either the original Applicant Proposed Route or HVDC Alternative Route 4-A. There are no recorded historic or cultural resources in the ROI for this route variation segment (Appendix M).

Link 3, Variation 3, crosses less rugged terrain and fewer minor drainages than the Applicant proposed Route, but passes through a small, broad stream valley. These terrain differences could produce minor differences in the presence or absence of historic and cultural resources between the previously analyzed route and the proposed variation. There are no recorded historic or cultural resources in the ROI for this route variation segment (Appendix M).

Link 6, Variations 1, 2, and 3, and Link 9, Variation 1, cross generally similar terrain as the as the links of the original Applicant Proposed Route and appear to have similar potential to contain historic and cultural resources. Although there are no recorded historic or cultural resources in the ROI for the three Link 6 variations, Link 9, Variation 1, is reported to contain one cemetery of unknown age and significance (Appendix M).

3.9.5.5 Region 5

Occupied by the Quapaw, a Siouan-speaking people, in late prehistory and the historical period, the region lies at the eastern edge of the Plains culture area as defined by ethnographers for Native American peoples (after roughly 1650 AD) (DeMallie 2001). Though the Quapaw are regarded as a Plains people on the basis of language and other cultural traits, their settlement and subsistence practices closely resembled those of the Eastern Woodlands peoples to the east more than those of the Plains peoples to the west, due to the predominantly forested environment of their homeland (Young and Hoffman 2001). Region 5 is part of the Ozark Plateau/Arkansas Valley geographic region used for archaeological and historic resources management in Arkansas (Clean Line 2013).

Geographically, Region 5 skirts the border between the Ozark Plateau physiographic province to the north and the Ouachita Mountain province to the south. It is characterized by hilly terrain that flanks the Arkansas Valley to the south. The eastern end of this region lies just inside the Lower Mississippi Alluvial Valley, which comprises most of the eastern end of the ROI (Gremillion 2004, Figure 1; Wedel and Frison 2001, Figure 1). The natural vegetation of Region 5 consists predominantly of oak-hickory and oak-hickory-pine forests (Woods et al. 2004). Modern land use includes forested areas, open lands for pasture or cultivated crops, and rural residential development. The archaeological record of Region 5 spans over 12,000 years, extending from the sites of early Native American hunter-gatherers of the Paleoindian period through the small villages of round or elongate at-grade, earthfast sapling-frame dwellings built by Native American horticulturalists in late prehistory to the remains of homesteads and other structures of nineteenth- and twentieth-century non-Indian settlers (Clean Line 2013). Prehistoric Native American site types include isolated finds, lithic scatters, camps and villages, rock art localities, and quarries. Historic period property types include residences and farmsteads, commercial, small- and large-scale industrial, military, transportation, cemeteries, and religious (AHPP 2013; Clean Line 2013).

Available information indicates that, in general, prehistoric and historic archaeological sites occur most frequently along the region's principal drainages and their major tributaries. Historical settlement was dispersed across the region; initial background research identified no well-defined, named historic transportation corridors (Clean Line 2013).

The Draft EIS reported that 26 previously recorded cultural resources occur within the Arkansas Converter Station Alternative and AC Interconnect Siting Area (Clean Line 2013), which was then defined as a 25,500-acre area in total. The Applicant has since refined these siting areas to substantially smaller footprints within the areas studied by the Draft EIS. The size of the reduced areas for the Arkansas Converter Station Alternative and AC Interconnect Siting Area are discussed in Section 3.1. The cultural resources identified within the Draft EIS study area include 23 previously recorded archaeological sites (17 prehistoric sites, 4 historic sites, and 2 multicomponent sites). The prehistoric site types consist of general artifacts scatters, isolated artifacts, and open camps. The historic site types consist primarily of farmsteads. The multicomponent sites are farmsteads and prehistoric lithic scatters. Of the 23 archaeological sites, 2 are recommended eligible and 21 received no previous recommendation regarding eligibility for inclusion on the NRHP. This area includes no linear resources, no NRHP-eligible properties, and three historic historic-age buildings or structures that have not received a previous recommendation regarding eligibility for inclusion on the NRHP. Information about historic and cultural resources in the HVDC transmission facilities in Region 5 is presented below.

Including duplicate counts, 73 archaeological sites have been documented for the ROI in Region 5, including 41 occurrences of prehistoric period sites, 27 occurrences of historic period sites, and 3 occurrences of a single multicomponent site (Table 3.9-9). Prehistoric archaeological site types include general artifact scatters, open camps, and rockshelters. Historic period archaeological sites include building ruins and foundations ("structures" and "isolated structures"), farmsteads, isolated finds, and general artifact scatters. In addition, five localities are recorded as historic archaeological sites that might equally have been inventoried as historic architectural properties; these include four historic cemeteries and a Cold War-era missile complex. Three separate multicomponent archaeological sites, all of which are general artifact scatters containing both prehistoric and historic materials, are also documented for the Applicant Proposed Route and HVDC alternative routes in Region 5. Of the 50 individual archaeological sites included in the ROI for the Applicant Proposed Alternative and the HVDC alternative routes, two sites, a prehistoric period rockshelter and a historic period structure, have been determined to be eligible for the NRHP, while three prehistoric sites and eight historic sites are not eligible for the NRHP. The remaining 36 individual sites are unevaluated for NHRP eligibility (Clean Line 2013).

Including duplicate counts, a total of 89 buildings and structures are included in the Region 5 ROI. Aside from the four historic cemeteries and the Cold War missile complex that that have been inventoried as archaeological sites (see above), approximately 47 individual historic buildings and structures have been inventoried at various locations along the Applicant Proposed Route and HVDC alternative routes. The majority of the buildings and structures are unevaluated for NRHP eligibility. At least three, however, been determined NRHP ineligible. Four buildings in the 1-mile ROI for the Applicant Proposed Route and HVDC alternative routes are listed on the NRHP (Table 3.9-3). All are located in Arkansas. The listed properties are the William Henry Watson Homestead, White County, 0.34 mile from the Applicant Proposed Route; the Charlie Hall House, Faulkner County, 0.05 mile from HVDC Alternative Route 5-B; the New Mt. Pisgah School, White County, 0.29 mile from overlapping HVDC Alternative Routes 5-B, 5-E, and 5-F; and the Wesley Marsh House, a minimum of 0.34 mile from the Applicant Proposed Route and HVDC Alternative Route 5-C (Clean Line 2013; NPS 2014b). It is estimated that no agricultural operations that have been honored as Century Farms would be crossed by the Applicant Proposed Route and the HVDC alternative routes.

Five route variations to the Applicant Proposed Route were developed in Region 5 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.5. The variations are illustrated in Exhibit 1 of Appendix M. These variations represent minor adjustments to the Applicant Proposed Route, and their potential to involve historic and cultural resources appears similar to the original links of the Applicant Proposed Route that were analyzed for the Draft EIS. Link 1, Variation 2, crosses similar terrain and has similar potential to contain historic and cultural resources as the original Applicant Proposed Route Link 1. Link 2, Variation 2, crosses similar terrain and has similar potential to contain historic and cultural resources as the original Applicant Proposed Route Link 2. Links 2 and 3, Variation 1, crosses similar terrain and has similar potential to contain historic and cultural resources as the original Applicant Proposed Route ; it should be noted that a route adjustment was made for HVDC Alternative Route 5-B to maintain an end-to-end route with Links 2 and 3, Variation 1. Links 3 and 4, Variation 2, crosses similar terrain and has similar potential to contain historic and cultural resources as the original Applicant Proposed Route ; it should be noted that a route adjustment was made for HVDC Alternative Route 5-E to maintain an end-to-end route with this proposed variation. Link 7, Variation 1, crosses similar terrain and has similar potential to contain historic and cultural resources as the original Link 7 of the Applicant

Proposed Route. The ROIs for Link 1, Variation 2 and Links 3 and 4, Variation 2 are both reported to include one cemetery each of unknown age and significance (Appendix M). The cemetery included in the ROI for Links 3 and 4, Variation 2, is outside the ROI of the Applicant Proposed Route analyzed for the Draft EIS. Link 7, Variation 1, contains two previously recorded archaeological sites of unknown age and significance (Appendix M). Precise locations in relationship to the original Applicant Proposed Route analyzed in the Draft EIS are not known. Neither the ROI for the route adjustment for HVDC Alternative Route 5-B, nor that for HVDC Alternative Route 5-E, contains any recorded historic or cultural resources (Appendix M).

Table 3.9-9:
Previously Inventoried Historic and Cultural Resources in the ROI for the Applicant Proposed Route and HVDC Alternative Routes in Region 5

Resource[1]	APR	AR 5-A	AR 5-B	AR 5-C	AR 5-D	AR 5-E	AR 5-F
Archaeological Sites[2]							
Prehistoric	7	0	13[3]	2	3	8[3]	8[3]
Historic	3	0	12[4,5]	1	6	3[4,5]	2[5]
Multicomponent	2	0	1[6]	0	0	1[6]	1[6]
Not Specified	0	0	0	0	0	0	0
Total Archaeological Sites	12	0	26	3	9	12	11

Inventoried Buildings and Structures	16[7]	0	23[7,8,9]	3	3	20[7,8,9]	17[7,8]
NRHP-Listed Properties	2[10]	0	2[11]	1[10]	0	1[11]	1[11]
Total Aboveground Properties	18	0	25	4	3	21	18
Historic Routes, Trails, and Roads[2,12]	0	0	0	0	0	0	0
Century Farms (estimated)[13, 14]	0	0	0	0	0	0	0

1 The values in the table do not reflect the minor changes that would result from application of route variations and adjustments.
2 ROI for archaeological sites is a 1,000-foot-wide corridor; ROI for aboveground historic properties and historic routes is a 1-mile corridor.
3 Includes eight triplicate counts—the same eight sites occur in conterminous sections of HVDC Alternative Routes 5-B, 5-E, and 5-F.
4 Includes one duplicate count—the same site occurs in conterminous sections of HVDC Alternative Routes 5-B and 5-E.
5 Includes two triplicate counts—the same two sites occur in conterminous sections of HVDC Alternative Routes 5-B, 5-E, and 5-F.
6 Includes one triplicate count—the same site occurs in conterminous sections of HVDC Alternative Routes 5-B, 5-E, and 5-F.
7 Includes two quadruplicate counts—the same two historic properties occur in conterminous sections of HVDC Alternative Routes 5-B, 5-E, and 5-F and in the conterminous 1-mile ROI of Applicant Proposed Route Links 5 and 6.
8 Includes 15 triplicate counts—the same 15 historic properties occur in conterminous sections of HVDC Alternative Routes 5-B, 5-E, and 5-F.
9 Includes three duplicate counts—the same three historic properties occur in conterminous sections of HVDC Alternative Routes 5-B and 5-E.
10 Includes one duplicate count—the same NRHP-listed property occurs in the conterminous ROI of the Applicant Proposed Route and Alternative Route 5-C.
11 Includes one triplicate count—the same NRHP-listed property occurs in the conterminous sections of HVDC Alternative Routes 5-B, 5-E, and 5-F.
12 No readily accessible public information concerning historic routes, trails, and roads is available for Region 5.
13 Estimated number of Century Farms crossed by centerline of the route. See Table 3.9-4 Footnote 5 for basis of estimate.
14 Century Farms Programs are honorary, voluntary, and do not afford legal protections (Arkansas Agriculture Department 2015; OKSHPO 2015; Texas Department of Agriculture 2015; Middle Tennessee State University Center for Historic Preservation 2015).

Source: Clean Line (2013, Table 3-24), supplemented by data from Arkansas Agriculture Department (2015).

3.9.5.6 Region 6

Occupied in late prehistory and the protohistoric period by Tunica and subsequently the Quapaw, the region lies at the southwestern edge of the northeastern Woodlands culture area as defined by ethnographers for Native American peoples living in the region around the time of the arrival of European explorers and colonists (Brain et al. 2004; Callender 1978; Dye 2007; Trigger 1978). Region 6 is part of the Mississippi Alluvial Valley geographic region used for archaeological and historic resources management in Arkansas (Clean Line 2013).

Geographically, Region 6 is situated entirely within the Lower Mississippi Alluvial Valley physiographic province (Gremillion 2004, Figure 1). It is characterized by broad, flat to nearly flat meander belts associated with the modern Mississippi River and several of its important tributaries (the Cache and White rivers) with intervening older alluvial and wind-transported sediments comprising valley train materials deposited during the Pleistocene epoch, the most recent episode of worldwide continental glaciation. Region 6 also crosses Crowley's Ridge in the east-central portion of Region 6, a string of low hills covered by up to several tens of feet of fine wind-blown silt (loess). The natural vegetation of Region 6 is a complex mosaic locally shaped by the alluvial, Pleistocene, and relict landforms present. In better-drained alluvial bottomlands, oak-dominated hardwood forests predominate, while on active natural levees and wooded portions of backswamps and abandoned channels, there is less oak, and trees such as sugarberry, elm, ash, pecan, cottonwood, and sycamore are common. In less frequently flooded areas, such as Crowley's Ridge and portions of the Pleistocene valley trains, forests and woodlands of post oak-blackjack oak, southern red oak-white oak, beech-maple, and post oak-loblolly pine occur. Except for Crowley's Ridge, where substantial tracts of hardwood forest remain, most of the formerly forested lands of Region 6 have been cleared, and modern land use is principally agricultural. Crops such as rice, corn, and soybeans dominate (Woods et al. 2004).

The archaeological record of Region 6 spans over 12,000 years. For the period before European intrusion into the region, the archaeological record encompasses sites of the early Native American, herd-oriented hunters and gatherers of the Paleoindian period, as well as their successors, the efficient hunter-gatherer-fishers of the mast forests and southern rivers of the Archaic period. The archaeological record continues through the camps and villages of the pottery-making horticulturalists of the Woodland period to the farmsteads, hamlets, villages, and earthworks of the late prehistoric Mississippian period. The Mississippi Valley also contains traces of several hundred years of Euroamerican exploration, settlement, warfare, and development, beginning in the mid-seventeenth century. Prehistoric Native American site types include isolated finds, lithic scatters, camps, farmsteads, hamlets, and villages, earth burial and temple mounds, and cemeteries. Historic period property types include residences, farmsteads, and plantations; commercial and small-scale industrial properties; and military, transportation, cemeteries, and religious buildings, structures, and sites (AHPP 2013; Clean Line 2013).

Available information indicates that area "geomorphology and topography greatly influenced settlement patterns in this region. In this relatively flat landscape, minor differences in elevation greatly affect the character of the local floral and faunal communities…. [Sites] at high natural levee ridges between stream meander belts and higher interfluvial 'islands' on Pleistocene terraces" were apparently favored locations for habitation over thousands of years. Historical settlement was dispersed across the region; initial background research identified no well-defined, named historic transportation corridors (Clean Line 2013).

Fourteen archaeological sites (the count involves no duplicates) have been documented for the ROI in Region 6, including 13 prehistoric period sites and one historic period site (Table 3.9-10). Sites are recorded for the Applicant Proposed Route and each alternative except HVDC Alternative Route 6-D, for which no archaeological sites have been identified to date. Prehistoric archaeological site types include general artifact scatters, isolated finds, and villages. The historic period site is described as an “isolated enclosure.” None of the 14 inventoried sites has been evaluated for NRHP eligibility. Very few historic buildings and structures have been recorded in the ROI for potential visual impacts for the Applicant Proposed Route and HVDC alternative routes, and none has been assessed for NRHP eligibility. Of the four historic buildings and structures inventoried for the ROI in Region 6, one is located along the Applicant Proposed Route, one is found along HVDC Alternative Route 6-A, and two occur along HVDC Alternative Route 6-B. No NRHP-listed properties are recorded for Region 6 (Clean Line 2013). It is estimated that approximately one Century Farm would be crossed by the Applicant Proposed Route and that no such operations would be crossed by the HVDC alternative routes.

One route variation to the Applicant Proposed Route was developed for Region 6 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.6. The variations are illustrated in Exhibit 1 of Appendix M. The variation seeks to minimize impacts to agricultural operations and represents a minor adjustment to the Applicant Proposed Route. Link 2, Variation 1, covers similar terrain and has a similar potential for involvement of historic and cultural resources as the original Applicant Proposed Route. There are no recorded historic or cultural resources in the ROI for this route variation segment (Appendix M). It should be noted that a route adjustment was made for HVDC Alternative Route 6-A to maintain an end-to-end route with the Link 2, Variation 1. The ROI for this route adjustment is reported to contain one cemetery of unknown age and significance (Appendix M).

Table 3.9-10:
Previously Inventoried Historic and Cultural Resources in the ROI for the Applicant Proposed Route and HVDC Alternative Routes in Region 6

Resource[1]	APR	AR 6-A	AR 6-B	AR 6-C	AR 6-D

Historic Routes, Trails, and Roads[2,3]	0	0	0	0	0
Century Farms (estimated)[4, 5]	1	0	0	0	0

1 The values in the table do not reflect the minor changes that would result from application of route variations and adjustments.
2 ROI for archaeological sites is a 1,000-foot-wide corridor; ROI for aboveground historic properties and historic routes is a 1-mile corridor. There are no duplicate, triplicate, or quadruplicate resource counts in Region 6.
3 No readily accessible public information concerning historic routes, trails, and roads is available for Region 6.
4 Estimated number of Century Farms crossed by centerline of the route. See Table 3.9-4 Footnote 5 for basis of estimate.
5 Century Farms Programs are honorary, voluntary, and do not afford legal protections (Arkansas Agriculture Department 2015; OKSHPO 2015; Texas Department of Agriculture 2015; Middle Tennessee State University Center for Historic Preservation 2015).
Source: Clean Line (2013, Table 3-31), supplemented by data from Arkansas Agriculture Department (2015).

3.9.5.7 Region 7

Occupied in late prehistory and the protohistoric period by the Tunica and subsequently the Quapaw, the region lies at the southwestern edge of the northeastern Woodlands culture area for Native American peoples living in the region around the time of the arrival of European explorers and colonists (Brain et al. 2004; Callender 1978; Dye 2007; Trigger 1978). Region 7 is part of the Mississippi Alluvial Valley geographic region used for archaeological and historic resources management in Arkansas (Clean Line 2013). In Tennessee, Region 7 is located in Development District 1 (Memphis Area), one of nine multicounty planning regions mandated by the state legislature, whose functions have grown to encompass historic preservation outreach and planning (Tennessee Historical Commission 2013).

Geographically, Region 7 is mostly situated within the Lower Mississippi Alluvial Valley physiographic province, but the last 9 miles of the Applicant Proposed Route are located in the Southeastern Coastal Plain (locally called the West Tennessee Plateau Slope) province (Gremillion 2004, Figure 1). Overall, Region 7 is characterized by broad, flat to nearly flat meander belts associated with the modern Mississippi River with intervening Pleistocene alluvial and wind-transported sediments comprising valley train deposits. The eastern end of the ROI is characterized by a 150-foot bluff marking the edge of the Mississippi floodplain, east of which are located rolling, irregular plains; a thick blanket of Pleistocene-age wind-blown sediment (loess) caps the landscape at the eastern end of Region 7. In the Mississippi Valley, the natural vegetation of Region 7 is a complex mosaic locally shaped by the alluvial, Pleistocene, and relict landforms present. Broadly speaking, the natural vegetation of the Mississippi meander belts is the Southern floodplain forest (oak, tupelo, bald cypress). Swampy woodlands are often occupied by cypress-gum woodlands, while the uplands of the eastern end of Region 7 are dominated by oak-hickory forests, with abundant beech and sugar maple in some areas. Land use west of the Mississippi River consists chiefly of cultivated crops, while east of the river land use is a mix of agricultural land, hardwood forests, and residential and commercial development (Griffith et al. 1998; Woods et al. 2004).

The archaeological record of Region 7 spans over 12,000 years, extending from the sites of early Native American hunter-gatherers of the Paleoindian period to the farmsteads, hamlets, villages, and earthworks of the late prehistoric Mississippian period. The Mississippi Valley also contains traces of several hundred years of Euroamerican exploration, settlement, warfare, and development, beginning in the mid-seventeenth century. Prehistoric Native American site types include isolated finds, lithic scatters, camps, farmsteads, hamlets, and villages, earth burial and temple mounds, and cemeteries. Historic period property types include residences, farmsteads, and plantations; commercial and small-scale industrial properties, and military, transportation, cemeteries, and religious buildings, structures, and sites (AHPP 2013; Clean Line 2013).

Available information indicates that archaeological sites and historic buildings and structures occur mainly along major streams and focus toward the Mississippi. In the Mississippi meander belts “geomorphology and topography greatly influenced settlement patterns in this region. In this relatively flat landscape, minor differences in elevation greatly affect the character of the local floral and faunal communities…. [Sites] at high natural levee ridges between stream meander belts and higher interfluvial “islands” on Pleistocene terraces” were apparently favored locations for habitation over thousands of years. Historical settlement was dispersed across the region, except in the vicinity of Millington, Tennessee, and a few other small population centers (Clean Line 2013). Although the Mississippi River, which the ROI crosses near Island Number 35, has had vast historical significance for water transport since the mid-eighteenth century, the ROI intersects no well-defined, named historic land routes adjacent to the river. Bell’s Route of Trail of the Tears National Historic Trail crosses east-central Shelby County, Tennessee, several miles south of the ROI. Historians are highly confident that Bell's Detachment of approximately 660 exiled Cherokee travelled through the area on November 22, 1838 via Stage Road (Tennessee State Route 15) (Nance 2001; NPS 2007, Map 5; Thomason and Parker 2003, Appendix E). At its closest, Stage Road passes approximately 6.8 miles south of any portion of the Applicant Proposed Route or HVDC Route Alternatives.

Since completion of the Draft EIS, the Applicant has refined the location of the Tennessee Converter Station Siting Area and reduced its ROI. As currently defined, however, the siting area is still within the previously studied area, and no historic or cultural resources have been identified within it (Clean Line 2013). Information about historic and cultural resources in the HVDC transmission facilities in Region 7 is presented below.

Including duplicate counts, 37 archaeological sites have been documented for the 1,000-foot-wide corridor ROI in Region 7, including an estimated 20 occurrences of prehistoric period sites (17 individual sites), 9 historic period sites (no duplicates), 7 multicomponent sites (no duplicates), and 1 site with no period attributed to it (Table 3.9-11). Thirty individual archaeological sites, including all 17 unique prehistoric sites, 6 each of the historic and multicomponent sites, and the unattributed site have not been evaluated for NRHP eligibility. Four sites, including three historic period sites and one multicomponent site, have been determined not eligible for the NRHP (Clean Line 2013).

In addition to the archaeological sites documented as occurring within the 1,000-foot-wide corridor ROI for the Applicant Proposed Route and HVDC alternative routes, one important prehistoric archaeological site is situated within the 1-mile ROI for historic resources. This is the Nodena Site in Mississippi County, Arkansas. The site is both listed on the NRHP and as a National Historic Landmark (Table 3.9-3). HVDC Alternative Route 7-A crosses more than 0.1 mile to the east of the Nodena Site NHL, which is situated approximately 5 miles east-northeast of Wilson, Arkansas. The exact location of the site is not publicly available, because the property has a restricted address to prevent vandalism. The NRHP/NHL property covers approximately 305 acres and apparently includes several separately designated sites, including the Upper Nodena Site (3MS4) and the Middle Nodena Site (3MS3) (AHPP 2014; Mainfort et al. 2007; NPS 2014b). (Because it is outside the 1,000-foot-wide corridor ROI, the Nodena Site NHL is not included in the archaeological site count of Table 3.9-11.)

Prehistoric period archaeological site types in Region 7 include general artifact scatters, open camps, and village sites. The Mississippian period Nodena Site (ca. 1400 to 1650 AD) is a categorized as a village site. Historic period archaeological site types include farmsteads and general artifact scatters. Multicomponent site types include general artifact scatters and open camps in association with farmsteads (Clean Line 2013).

Including one duplicate count, but excluding the Nodena Site NHL, 82 buildings and structures have been inventoried to date within the 1-mile ROI for the Applicant Proposed Route and HVDC Alternative Routes 7-A and 7-C (Table 3.9-11). Thirty-nine (plus one duplicate) of the inventoried properties occur along the Applicant Proposed Route, and all are situated in the more densely developed Tennessee portion of the alignment. Thirty-eight (plus one duplicate) of the inventoried properties occur along HVDC Alternative Route 7-C, also in Tennessee. None of these properties has been evaluated for eligibility to the NRHP. The remaining two properties occur near HVDC Alternative Route 7-A, probably in Arkansas. One has been recommended as NRHP eligible (Clean Line 2013).

Aside from the Nodena Site NHL, one other NRHP-listed property occurs within the ROI for Region 7. This is the Highway A-7 Bridges Historic District, which is crossed by HVDC Alternative Route 7-A in the vicinity of Marked Tree, Poinsett County, Arkansas (Table 3.9-3).

It is estimated that no agricultural operations that have been honored as Century Farms would be crossed by the Applicant Proposed Route and the HVDC alternative routes.

Three route variations to the Applicant Proposed Route were developed in Region 7 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.7. The variations are illustrated in Exhibit 1 of Appendix M. These variations represent minor adjustments to the Applicant Proposed Route, and their potential to involve historic and cultural resources appears similar to the links of the original Applicant Proposed Route. Link 1, Variation 1; Link 1, Variation 2; Link 5, Variation 1, all cross terrain similar to that considered for the original Applicant Proposed Route and all have similar terrain to the original Applicant Proposed Route considered in the Draft EIS with similar potential to contain archaeological sites and historic properties. There are no recorded historic or cultural resources in the ROIs for any of these route variation segments (Appendix M).

Table 3.9-11:
Previously Inventoried Historic and Cultural Resources in the ROI for the Applicant Proposed Route and HVDC Alternative Routes in Region 7

Resource[1]	APR	AR 7-A	AR 7-B	AR 7-C	AR 7-D
Archaeological Sites[2]					
Prehistoric	8[3]	2	2[3]	6[3]	2
Historic	2	4	0	3	0
Multicomponent	3	1	0	3	0
Not Specified	0	0	0	1	0
Total Archaeological Sites	13	7	2	13	2
Aboveground Historic Properties[2]					
Inventoried Buildings and Structures	40[4]	2	0	39[4]	0
NRHP-Listed Properties	0	2[5]	0	0	0
Total Aboveground Properties	40	4	0	39	0
Historic Routes, Trails, and Roads[2, 6]	0	0	0	0	0
Century Farms (estimated)[7, 8]	0	0	0	0	0

1 The values in the table do not reflect the minor changes that would result from application of route variations and adjustments.
2 ROI for archaeological sites is a 1,000-foot-wide corridor; ROI for aboveground historic properties and historic routes is a 1-mile corridor.
3 Includes one quadruplicate count—the same site is counted twice for the Applicant Proposed Route and also once each in HVDC Alternative Routes 7-B and 7-C, because they are located at a junction for two links of the Applicant Proposed Route and in the adjoining conterminous sections of the alternative routes.
4 Includes one duplicate count—the same historic property occurs in the 1-mile ROI of corresponding link of the Applicant Proposed Route (Link 5) and the overlapping ROI for HVDC Alternative Route 7-C.
5 Includes the Nodena Site NHL, a belowground historic property, which is believed to be located outside the 1,000-foot-wide ROI but within the 1-mile ROI for HVDC Alternative Route 7-A.
6 No readily accessible public information concerning historic routes, trails, and roads is available for Region 7.
7 Estimated number of Century Farms crossed by centerline of the route. See Table 3.9-4 Footnote 5 for basis of estimate.
8 Century Farms Programs are honorary, voluntary, and do not afford legal protections (Arkansas Agriculture Department 2015; OKSHPO 2015; Texas Department of Agriculture 2015; Middle Tennessee State University Center for Historic Preservation 2015).

Source: Modified from Clean Line (2013, Table 3-34), supplemented by data from Arkansas Agriculture Department (2015) and Middle Tennessee State University Center for Historic Preservation (2015).

3.9.5.8 Connected Actions

3.9.5.8.1 Wind Energy Generation

Wind energy generation would likely occur within WDZs. The 12 WDZs contain a total of 155 prehistoric, historic, multicomponent, and indeterminate previously recorded archaeological sites (Table 3.9-12). The WDZs do not overlap, and frequencies of inventoried historic and archaeological resources given in Table 3.9-12 do not contain duplications. There are also 77 inventoried historic buildings and structures and 8 identified intersections of historic routes, trails, and roads (Table 3.9-12). Six historic buildings and structures and one archaeological site listed on the NRHP also occur in the WDZs (Table 3.9-13). Previously recorded sites within the WDZs have not been evaluated for their potential to be eligible to the NRHP. Analysis of the lists of agricultural operations that have been honored by the Oklahoma Centennial Farm and Ranch Program (OKSHPO 2015) and the Texas Family Land Heritage Program (Texas Department of Agriculture 2015) shows that the six counties within which the WDZs are located contain a total of 49 Century Farms. Based upon the number of farms and ranches in the six counties, the surface areas of the WDZs, the mean farm size and proportion of agricultural land per county, the number of active farms and ranches, and the number of Century Farms, it is estimated that each WDZ could potentially contain approximately one Century Farm.

As noted in the discussion of the Region 1 AC collection system routes, at least one of the NRHP-listed properties, the Tracey Wood-Frame Grain Elevator, appears to have suffered severe loss of integrity and may no longer be eligible for the register. It is unknown whether any other NRHP properties have experienced similar losses.

Table 3.9-12:
Previously Inventoried Historic and Cultural Resources by Wind Development Zone

	WDZ											
	A	B	C	D	E	F	G	H	I	J	K	L

Century Farms (estimated)[2]	1	1	1	1	1	1	1	1	1	1	1	1

1 The NRHP-listed historic property in WDZ-L is the Buried City Site (41OC1), a belowground prehistoric archaeological site. It is unknown whether the Buried City Site or any of its separately inventoried components are included in the prehistoric site count for WDZ-L.
2 Estimated number of Century Farms occurring in the WDZ. See Table 3.9-4 Footnote 5 for basis of estimate.
3 Century Farms Programs are honorary, voluntary, and do not afford legal protections (Arkansas Agriculture Department 2015; OKSHPO 2015; Texas Department of Agriculture 2015; Middle Tennessee State University Center for Historic Preservation 2015).
Source: Clean Line (2014, pp 201–204), supplemented by data from OKSHPO (2015) and Texas Department of Agriculture (2015).

Table 3.9-13:
NRHP-Listed Properties in the Wind Development Zones

WDZ	Property Name (Alternate Name)	NRIS No.	Location
A	Plainview Hardware Company Building	90000904	Perryton, Ochiltree County, Texas
F	Penick House (Raymond Choate House)	84003436	Texhoma, Texas County, Oklahoma
H	Eva Wood-Frame Grain Elevator (Wright Grain & Milling Co. Elevator)	83002132	Eva, Texas County, Oklahoma
H	Tracey [or Tracy] Wood-Frame Grain Elevator (Genco Grain Co. Elevator)	83002137	Muncy (Tracey), Texas County, Oklahoma
I	Adams Wood-Frame Grain Elevator (Old Tex-Co Elevator)	83002129	Adams, Texas County, Oklahoma
I	Hooker Wood-Frame Grain Elevator (Wheat Pool Elevator Company)	83002133	Hooker, Texas County, Oklahoma
L	Buried City Site (41OC1)	84001923	Perryton vicinity, Ochiltree County, Texas

NRIS—National Register Information System.
Note: Examination of aerial imagery available from Google Earth indicates that the Eva and Tracey wood-frame grain elevators are no longer extant. Field survey would be required to verify their disappearance.
Source: NPS (2014b)

3.9.5.8.1.1 WDZ-A

WDZ-A contains a total of six previously recorded archaeological sites (Table 3.9-12). These include four prehistoric-period sites representing two site types (artifact scatter and camp site). It also contains two historic period sites including an artifact scatter and a cemetery. These sites have not been evaluated for their potential to be eligible to the NRHP. Also previously recorded within WDZ-A are 25 historic buildings/structures and 1 historic transportation route. Of these, only the Plainview Hardware Company Building, Perryton, Texas, is NRHP-listed (Table 3.9-13), while 25 have not been evaluated for their potential to be eligible to the NRHP. The WDZ is estimated to contain one Century Farm.

3.9.5.8.1.2 WDZ-B

The three archaeological sites recorded within WDZ-B all date to the prehistoric time period (Table 3.9-12). These include a prehistoric artifact scatter and cairn sites. One of these sites was determined not eligible for the NRHP, while the remaining two sites have not been evaluated for their potential to be eligible to the NRHP. No historic period buildings and structures or mapped historic transportation routes have been previously recorded within WDZ-B. The WDZ is estimated to contain one Century Farm.

3.9.5.8.1.3 WDZ-C

There are no previously recorded archaeological sites within WDZ-C (Table 3.9-12). There are also no previously recorded historic period buildings, structures or mapped historic transportation routes recorded within WDZ-C. The WDZ is estimated to contain one Century Farm.

3.9.5.8.1.4 WDZ-D

WDZ-D contains 11 archaeological sites including 4 prehistoric, 6 historic and 1 multicomponent (Table 3.9-12). The range of site types includes prehistoric artifact scatter, camp site, historic artifact scatter, farmstead, cemetery, and abandoned railroad grade. Two of these sites have been determined to be eligible to the NRHP, six have not been evaluated for their potential to be eligible to the NRHP, and three are not eligible to the NRHP. No historic period buildings and structures or mapped historic transportation routes have been recorded within WDZ-D. The WDZ is estimated to contain one Century Farm.

3.9.5.8.1.5 WDZ-E

Two archaeological sites have been recorded within WDZ-E (Table 3.9-12). The one prehistoric artifact scatter and the one historic artifact scatter have not been evaluated for their potential to be eligible to the NRHP. No historic period buildings and structures or mapped historic transportation routes have been recorded within WDZ-E. The WDZ is estimated to contain one Century Farm.

3.9.5.8.1.6 WDZ-F

Previously recorded archaeological sites within WDZ-F include four prehistoric sites, one multicomponent site, and one temporally unspecified site (Table 3.9-12). The range of site types represented includes prehistoric camp, historic farmstead, and unspecified sites. Five of these sites have not been evaluated for their potential to be eligible to the NRHP while one site was determined not eligible for the NRHP. Within WDZ-F, 37 buildings/structures and 1 historic transportation route have been previously recorded. Of these, only the Penick House, Texhoma, Oklahoma, is listed in the NRHP (Table 3.9-13), while 37 have not been evaluated for their potential to be eligible to the NRHP. The WDZ is estimated to contain one Century Farm.

3.9.5.8.1.7 WDZ-G

Records reviewed indicated 26 archaeological sites within WDZ-G (Table 3.9-12). Of these, 22 are prehistoric, 2 historic and 2 are temporally unspecified. Site types represented include prehistoric artifact scatters, camps, historic farmsteads, and unspecified site types. Four of these sites were determined not eligible to the NRHP while 22 sites have not been evaluated for their potential to be eligible to the NRHP. One historic transportation route was previously recorded within WDZ-G, though this site has not been evaluated for its potential to be NRHP-eligible. The WDZ is estimated to contain one Century Farm.

3.9.5.8.1.8 WDZ-H

Within WDZ-H, 15 archaeological sites have been previously recorded, including 9 prehistoric sites, 1 historic site, and 5 temporally unspecified sites (Table 3.9-12). Site types represented include prehistoric artifact scatter, historic farmstead, and unspecified site types. Four of the sites have been evaluated as not eligible to the NRHP while 11 of the sites have not been evaluated for their potential to be NRHP-eligible. WDZ-H contains two NRHP-listed properties in Oklahoma, the Eva Wood-Frame Grain Elevator, Eva, and the Tracey Wood-Frame Grain Elevator, Muncy (Table 3.9-13). One historic transportation route is recorded from documentary sources, but additional property has been recorded but not evaluated for its potential to be eligible to the NRHP. The WDZ is estimated to contain one Century Farm.

3.9.5.8.1.9 WDZ-I

There are 14 previously recorded archaeological sites within WDZ-I (Table 3.9-12), including 9 prehistoric sites, 3 historic sites, 1 multicomponent site, and 1 unspecified site. Site types represented include prehistoric artifact scatter, camp, historic artifact scatter, and cemetery. Three of these sites have been determined to be not eligible for the NRHP while 11 have not been evaluated for their potential to be NRHP-eligible. WDZ-I contains the Adams Wood-Frame Grain Elevator, Adams, Oklahoma, and Hooker Wood-Frame Grain Elevator, Hooker, Oklahoma, both listed in the NRHP (Table 3.9-13). In addition, 13 buildings/structures and 2 historic transportation routes have been previously recorded but not evaluated for their potential to be eligible to the NRHP. The WDZ is estimated to contain one Century Farm.

3.9.5.8.1.10 WDZ-J

Within WDZ-J, 51 archaeological sites have been recorded previously (Table 3.9-13). Of these, 42 sites are prehistoric, 7 are historic, and 2 are multicomponent. Represented site types include prehistoric artifact scatter, camp, historic artifact scatter, farmstead sites, and an isolated prehistoric burial. Thirty-six of these sites have not been evaluated for their potential to be eligible to the NRHP while 14 sites have been determined to be not eligible to the NRHP. One previously recorded historic transportation route has not been evaluated for its potential to be eligible to the NRHP. The WDZ is estimated to contain one Century Farm.

3.9.5.8.1.11 WDZ-K

Five archaeological sites have been previously recorded within WDZ-K (Table 3.9-12). These include four historic period sites and one multicomponent site. Site types represented include prehistoric artifact scatter, camp, historic artifact scatter, and cemetery sites. The potential for these sites to be eligible to the NRHP is unknown. Three buildings/structures and one historic transportation route were previously recorded within WDZ-K. Three of these have been determined to be NRHP-eligible, and one has not been evaluated for its potential to be eligible to the NRHP. The WDZ is estimated to contain one Century Farm.

3.9.5.8.1.12 WDZ-L

Within WDZ-L, 16 archaeological sites have been previously recorded including 10 prehistoric, 2 historic, and 4 unspecified (Table 3.9-12). Site types represented include prehistoric camps, historic farmsteads, and unspecified site types. These sites have not been evaluated for their potential to be eligible to the NRHP. One prehistoric archaeological site is listed on the NRHP, the Buried City Site in Ochiltree County, Texas (Table 3.9-13). It is unknown whether the site is included in the prehistoric counts provided in Clean Line (2014), because site names are not available in the public record provided in that document. WDZ-L does not contain any previously recorded buildings/structures or historic transportation routes. The WDZ is estimated to contain one Century Farm.

3.9.5.8.2 Optima Substation

The future Optima Substation would be on a 160-acre site located just east of the Oklahoma Converter Station Siting Area and partially within the AC Interconnection Siting Area where no historic or cultural resources have been identified.

3.9.5.8.3 TVA Upgrades

The ROI for the direct assignment facilities (which are included in the Applicant Proposed Project) would occur within the Tennessee Converter Station Siting Area and more specifically within the Shelby Substation. The ROI for the network upgrades, and in particular TVA's future 500kV transmission line, cannot be fully determined at this time. The new 500kV transmission line would be constructed in western Tennessee within the Southeast Coastal Plain province. The upgrades to existing facilities would mostly be in western and central Tennessee. Upgrades to existing infrastructure would include upgrading terminal equipment at three existing 500kV substations and six existing 161kV substations, making appropriate upgrades to increase heights on 16 existing 161kV transmission lines to increase line ratings, and replacing the conductors on eight existing 161kV transmission lines. Where possible, general impacts associated with the required TVA upgrades are discussed in the impact sections that follow.

3.9.6 Impacts to Historical and Cultural Resources

3.9.6.1 Methodology

The analysis of potential effects to historic and cultural resources uses the same ROI described in Section 3.9.3 for archaeological sites, aboveground historic properties, and historic routes. Many other resources evaluated in this EIS evaluate 200-foot-wide representative ROWs for direct impacts, but this section uses a broader area because the APE (which DOE defines in the draft PA [Appendix P]) may vary from the typical 200-foot-wide final ROW for the Project transmission lines (Clean Line 2013). Also, for consistency with the HVDC transmission lines, potential effects to historic and cultural resources related to AC collection system routes are evaluated across a 1,000-foot-wide corridor instead of the larger 2-mile ROI.

The assessment of potential impacts to historic and cultural resources entailed a qualitative review of available information on these resources (following from the information described in Sections 3.9.4 and 3.9.5, above) in conjunction with consideration of potential effects of various Project activities (see Appendix F) on different types of historic and cultural resources. The strategy for assessing potential impacts from the Project resulted from the conceptual, preliminary, or non-Project-specific nature of much of the available information. Quantitative information presented below is therefore preliminary and may be refined as Project-specific cultural resources surveys are undertaken prior to construction. In particular, density calculations presented in impact tables are based on available records and may substantially underrepresent the actual resource density. As described in Section 3.9.2, field surveys will be undertaken prior to construction. The results of the surveys will provide specific information as to the presence or absence of cultural resources that may qualify as historic properties.

One proxy indicator of *potential* project interactions, impacts, or effects on historic and cultural resources is provided by considering the land cover of areas within which the Project would be constructed. Land cover is discussed and analyzed in detail in Section 3.10 using data extracted by GIS techniques from the 2006 release of the National Land Cover Database (NLCD) (GIS Data Source: Jin et al. 2013). As a proxy for assessment of *potential* Project effects, the 14 land cover classes observed in a 200-foot-wide representative ROW (consistent with results presented in Section 3.10) were placed into four groups, representing different possible constellations of Project effects (Table 3.9-14). Land cover Group A primarily is composed of terrain that is being actively manipulated, either through crop cultivation or development. Land cover Group B is composed of terrain that is predominantly covered by perennial grasses and herbaceous vegetation and so is relatively open. Land cover Group C comprises woodlands and forests and is relatively closed. Land cover Group W is the residual group of open water, which generally comprises a small percentage of the Project acreage.

Pursuant to the PA, in coordination with consulting parties, more detailed assessments of potential Project impacts to historic and cultural resources will be made prior to construction. Under the PA, the Applicant will also develop and implement plans to manage identification, assessment, and treatment of these resources. These plans would set forth the process that the Applicant would use to identify, evaluate, and treat unanticipated historic properties and cultural resources discovered during construction and operations and maintenance phases of the Project. The evaluation of potential impacts in the following sections assumes implementation of these plans. The draft PA is included in Appendix P.

Table 3.9-14:
Land Cover Groups and Potential Project Effects on Historic and Cultural Resources

Group	Constituent Land Cover Classification	General Characteristics	Potential Project Effects On Historic and Cultural Resources
A	Barren Land Cultivated Crops Developed—Low Intensity Developed—Medium Intensity Developed—Open Space	Typically artificially landscaped or manipulated terrain; generally open and covered in relatively low, often discontinuous vegetation; often contains existing roads or field drives.	<u>Ground Disturbance</u>: Large areas of extant cleared land and availability of roads limit need for extensive new construction to provide access to and work spaces around towers and other permanent facilities. <u>Visual Exposure</u>: Potential for distant views of permanent Project elements because of limited extent of tall vegetative screening.
B	Emergent Herbaceous Wetlands Grassland/Herbaceous Pasture/Hay Shrub/Scrub	Generally open terrain covered by grasslands, shrubs, and discontinuous patches of low trees; existing road access is variable.	<u>Ground Disturbance</u>: Large areas of open land tends to limit need for vegetation clearing and thus amount of ground disturbance outside towers, other permanent facilities, and their associated work spaces. However, limited availability of existing roads in some areas may result in need for construction of temporary or permanent roads. <u>Visual Exposure</u>: Potential for distant views of permanent Project elements because of limited extent of tall vegetative screening.
C	Deciduous Forest Evergreen Forest Mixed Forest Woody Wetlands	Generally closed terrain covered by woodland; access by existing roads tends to be limited.	<u>Ground Disturbance</u>: Probable need for extensive vegetation clearance, possibly resulting in ground disturbances, at towers and other facilities, in new transmission line ROWs between towers and in construction work areas. Access road construction may be necessary. <u>Visual Exposure</u>: Distant views of permanent Project elements tend to be limited in extent because of extensive of tall vegetative screening.
W	Open Water	Water bodies such as rivers, streams, ponds, and lakes.	Minor land cover type; not analyzed.

Source: GIS Data Source: Jin et al. (2013)

3.9.6.1.1 Impacts Common to All Project Components

This section describes potential Project impacts that could affect historic and cultural resources anywhere within the ROI.

The characteristics of specific historic and cultural resources fundamentally affect their susceptibility to different types of potential Project impacts. The discussion that follows focuses primarily on potential direct, physical impacts and on potential visual impacts, because these two types of impact are the most likely to affect the kinds of historic and cultural resources that likely occur in the ROI.

Archaeological sites, consisting of patterns of objects (artifacts) on or in the ground and traces of modifications to the soil and landscape by past peoples, are primarily vulnerable to Project activities that disturb the soil. Such disturbances relocate artifacts, altering archaeologically meaningful spatial relationships among these objects and between these objects and the soil matrix within which they are located; documentation of such spatial relationships is critical to meaningful interpretation of archaeological sites. In addition, some archaeological evidence exists only as contrasting layers of soil and soil boundaries, and ground disturbances can disrupt soil boundaries, mix layers, and obliterate such evidence. Occasionally, an archaeological site's relationship to its surrounding environment is an essential characteristic that contributes fundamentally to the site's significance, and in these instances, the site may also be subject to visual impacts from a project. Typically, however, the analysis of Project impacts on archaeological resources focuses on direct ground disturbance. In the case of archaeological sites that are eligible for listing in the NRHP, efforts would be made to resolve adverse effects by means of avoidance, minimization, or mitigation as per 36 CFR 800.6(a)(1).

Installation of utility systems in rural areas, including generating facilities, transmission lines, converter stations, and other infrastructure related to the construction and/or operation of the project, would typically avoid the demolition or relocation of buildings and other existing elements of the built environment. Factors such as the cost of real estate taking and project setback requirements generally mean that historic buildings, structures, objects, and landscape features (such as identifiable cemeteries) are not directly altered physically, damaged, or demolished by electrical generation and transmission projects in rural areas. Instead, such historic and cultural resources may be impacted by the introduction of non-historical visual or, occasionally, auditory elements into their setting. The identification and analysis of potential visual impacts to historic resources overlaps with that for potential visual and aesthetic impacts (Section 3.18), but the latter is concerned with many types of resources, of which historic and cultural resources are just one category. In the case of historic architectural resources located in the vicinity of the Project that are eligible for listing in the NRHP, visual impacts might constitute an adverse effect under 36 CFR 800.5(a)(2)(v). In this instance, efforts would be made to avoid, minimize, or mitigate effects. Introduction of structures such as the proposed transmission line and associated towers into an otherwise rural or natural setting could diminish the integrity of a property's significant historic features. Assessment of effects (including visual effects) on historic properties is based in part on the evaluation of integrity.

Historic properties of particular interest to Indian Tribes and Nations are varied in their characteristics and could be subject to direct physical disturbances or to disturbances resulting from alteration of the visual surroundings, auditory field, or other characteristics of their setting. As noted in Section 3.9.4, DOE has requested information from Indian Tribes that may attach religious and cultural significance to historic properties that may be affected by the undertaking, but these resources remain to be delineated for the ROI.

The Applicant will develop plans and employ various measures during the construction and operations and maintenance phases of the Project that, if executed effectively and consistently, will help to avoid or minimize impacts to historic and cultural resources. Key Project plans related to these resources include:

- Historic Properties Identification Plan for the early identification of historic and cultural resources within the Project footprint through appropriate surveys
- Historic Properties Treatment Plan for the avoidance, minimization, and mitigation of adverse effects on historic and cultural resources within the Project footprint
- Discovery Plan that outlines the steps to be followed in the event that a historic or cultural resource is discovered during construction

In addition, the Applicant has identified various EPMs that will help avoid or minimize impacts to historic and cultural resources. Applicable measures include:

- GE-1: Clean Line will train personnel on health, safety, and environmental matters. Training will include practices, techniques, and protocols required by federal and state regulations and applicable permits.
- GE-6: Clean Line will restrict vehicular travel to the ROW and other established areas within the construction, access, or maintenance easement(s).

- GE-27: Clean Line will minimize compaction of soils and rutting through appropriate use of construction equipment (e.g., low ground pressure equipment and temporary equipment mats).
- LU-5: Clean Line will make reasonable efforts, consistent with design criteria, to accommodate requests from individual landowners to adjust the siting of the ROW on their properties. These adjustments may include consideration of routes along or parallel to existing divisions of land (e.g., agricultural fields and parcel boundaries) and existing compatible linear infrastructure (e.g., roads, transmission lines, and pipelines), with the intent of reducing the impact of the ROW on private properties.
- GEO-1: Clean Line will stabilize slopes exposed by its activities to minimize erosion.

3.9.6.1.2 Construction Impacts

A wide range of activities associated with the construction of the Project has the potential to result in extensive ground disturbance. From the point of view of archaeological resources, Project-related ground disturbance is the alteration of the structure, composition, and/or texture of the soil and its contents from the air-ground interface to depth in excess of that which would occur in absence of Project activities. Such impacts may occur as a result of earth moving (cutting, filling, grading, foundation preparation, sub-roadbed construction, and similar construction activities) or movements of equipment and vehicles over unprotected ground surfaces. If such ground disturbance results in physical or visual impacts to historic properties that are eligible for listing in the NRHP, such impacts could constitute an NHPA Section 106 adverse effect under 36 CFR 800.5(a)(1), and, therefore, would require consultation with consulting parties to attempt to avoid, minimize, or mitigate adverse effects.

Construction could also cause temporary impacts to historic and cultural resources through the generation of dust, noise, and vibration, but such effects would be transient in nature.

Assuming that demolition of existing buildings, structures, and sites such as marked historic cemeteries would be avoided during construction through appropriate design and application of EPM LU-5 for micrositing, direct effects from constructing the Project would be transient and limited, and could include such temporary alterations of the environment as increased noise, vibration, and dust. Because of their transient nature, such effects would not usually require mitigation in relation to historic and cultural resources.

As indicated in Section 3.9.4, state-level Century Farm programs honor continuity of tenancy of one century or more and family farming. The Project has the potential to impact agricultural land in general during construction (see Section 3.2.6 for details). It is possible that affected agricultural land could include Century Farms.

Wooded terrain requires more ground disturbance because of the need to clear transmission line corridors and build roads, among other activities, but woodlands may also present possibilities for vegetative screening of nearby historic standing structures. Open terrain tends to reduce the need for extensive construction disturbances outside transmission towers and other ground-level facilities. At the same time, open terrain also somewhat increases the potential for adverse visual effects to historic standing structures in close proximity to the Project alignment resulting from the introduction of transmission towers and other facilities. However, with effective implementation of plans and measures such as those described in Section 3.9.6.1.1, adverse effects to historic properties would be resolved through consultation with consulting parties to develop means of avoidance, minimization, or mitigation.

As the types of tribal resources that may be present within the ROI remain to be determined, only a broad, generic description of potential impacts is possible at this time. In general, impacts to tribal resources would be similar to those that might occur to archaeological sites and historic architectural properties as described above.

3.9.6.1.3 Common Operations and Maintenance and Decommissioning Impacts

Adverse impacts to historic and cultural resources are not expected from operations and maintenance or decommissioning of the Project. Operations and maintenance activities and decommissioning would take place within areas that would have been surveyed for historic and cultural resources. DOE intends to address any potentially NRHP-eligible cultural resources that could be recorded in areas affected by the Project through the Section 106 process, as appropriate. DOE intends that compliance with Section 106 would address potential adverse effects to cultural resources that qualify as historic properties during operations and maintenance or decommissioning.

Following decommissioning, removal of Project transmission structures, conductors, and converter stations that may have caused visual alterations to aboveground historic and cultural resources such as buildings and structures would benefit those resources.

3.9.6.2 Impacts Associated with the Applicant Proposed Project

3.9.6.2.1 Converter Stations and AC Interconnection Siting Areas

3.9.6.2.1.1 Construction Impacts

The ROI for the Oklahoma Converter Station Siting Area and AC Interconnection Siting Area and the Tennessee Converter Station Siting Area and AC Interconnection Tie contain no previously recorded archaeological sites or other historic properties. Cultural resources surveys would be performed prior to construction to ascertain whether any unrecorded NRHP-eligible properties are present and to assess the possible impacts of construction on such resources if present. DOE will establish the timing and protocols for cultural resources surveys through the PA. A draft PA is included in Appendix P.

3.9.6.2.1.2 Operations and Maintenance Impacts

No impacts would result from operations and maintenance activities at the Oklahoma converter station and AC interconnection and the Tennessee converter station and AC interconnection tie (see Section 3.9.6.1.3).

3.9.6.2.1.3 Decommissioning Impacts

No impacts would result from decommissioning (see Section 3.9.6.1.3).

3.9.6.2.2 AC Collection System

The AC collection system is located in the high plains of the Oklahoma and Texas panhandles. The frequency of inventoried historic and cultural resources per mile of ROI appears to be low based on available information (Table 3.9-15). Land cover data show that the AC collection system is located in open terrain, which is divided between cultivated crops (in land cover Group A) and rangelands (in land cover Group B) (Table 3.9-16). Overall, available information appears to suggest that the potential for the Project to impact historic and cultural resources is relatively low.

Table 3.9-15:
Frequency Per Linear Mile of AC Collection System Route Centerline for Previously Inventoried Historic and Cultural Resources by Project Alternative in Region 1

	AC Collection System Routes												
	E-1	E-2	E-3	NE-1	NE-2	SE-1	SE-2	SE-3	NW-1	NW-2	SW-1	SW-2	W-1
Length (miles)	28.94	39.82	39.95	30.05	26.28	40.34	13.44	49.09	51.89	56.01	13.39	37.03	20.74
Total Archaeological Sites (n)[1]	1	1	1	0	0	0	0	1	2	2	0	3	2
Total Aboveground Historic Properties (n)[1]	0	0	0	0	0	0	0	0	0	1	0	0	0
Archaeological Sites per Mile[2]	0.03	0.03	0.03	0.00	0.00	0.00	0.00	0.02	0.04	0.04	0.00	0.08	0.10

1 Land cover percentages and acreages based on a 200-foot-wide representative ROW and including tensioning work sites, which typically extend outside the transmission line ROW. See Section 3.10 for discussion of source data quality and limitations. Percentages may not sum to 100 due to rounding error.
GIS Data Source: Jin et al. (2013)

3.9.6.2.2.1 Construction Impacts

Construction impacts are described in Section 3.9.6.1.1. Cultural resources survey within AC collection system would be performed prior to construction to assess the possible impacts of construction on such resources if present. DOE establishes the timing and protocols for cultural resources surveys in the draft PA (Appendix P). For sites discovered, the possible impacts of construction on such resources would be assessed. If NRHP-eligible historic properties are identified, efforts would be made to avoid, minimize or mitigate effects.

AC Collection System Routes NE-1, NE-2, SE-1, SE-2, and SW-1 contain no previously recorded archaeological sites or other historic properties.

AC Collection System Routes E-1, E-2, E-3, and SE-3 each contain one previously recorded archaeological site that has not been evaluated for NRHP eligibility. None contains previously recorded historic buildings.

AC Collection System Route NW-1 and NW-2 each contain two previously recorded archaeological sites, neither of which has been evaluated for NRHP eligibility. AC Collection System Route NW-1 contains no previously recorded historic buildings. The NRHP-listed Tracey Woodframe Grain Elevator is located in the vicinity of AC Collection System Route NW-2. Listed in 1983, aerial imagery (using Google Earth) from 2013 shows that the elevator has collapsed. Such severe loss of integrity may be sufficient to require delisting from the NRHP. The current condition of this property has not been field-verified, but if the elevator has collapsed, the loss of integrity would mean that any Project elements in the vicinity would not adversely affect the property.

AC Collection System Route SW-2 contains three previously recorded archaeological sites, none of which have been evaluated for NRHP eligibility. The route contains no previously recorded historic properties.

AC Collection System Route W-1 contains two previously recorded archaeological sites, neither of which has been evaluated for NRHP eligibility. The route contains no previously recorded historic properties.

A public comment received on the Draft EIS expressed concern that analysis of AC collection system impacts did not consider the Stamper Site (34TX1, NRIS 66000635), an NHL in the Beaver River valley of Texas County, Oklahoma. However, DOE determined that the site is located outside the conceptual study corridors of all AC collection system routes (specifically AC Collection System Routes NE-1 and NW-2), and therefore had been appropriately excluded from the impacts analysis.

3.9.6.2.2.2 Operations and Maintenance Impacts

No impacts would result from operations and maintenance of any of the AC collection system routes (see Section 3.9.6.1.3).

3.9.6.2.2.3 Decommissioning Impacts

No impacts would result from decommissioning (see Section 3.9.6.1.3).

3.9.6.2.3 HVDC Applicant Proposed Route

Based on available information, the frequency of inventoried historic and cultural resources per mile of centerline along the Applicant Proposed Route varies, with higher frequencies occurring toward the eastern end of the Project, notably in Regions 4, 5, and 7 (Table 3.9-17), as more cultural resources surveys have taken place and more incidental finds have been recorded in these areas. Cultural resources field surveys would be conducted in all regions of the Applicant Proposed Route prior to construction to assess the possible impacts of construction on such resources if present. DOE establishes the timing and protocols for cultural resources surveys in the draft PA (Appendix P).

Land cover data show the increased extent of woodlands from Region 4, in eastern Oklahoma (Table 3.9-18). However, it is also evident that large areas of agricultural land occur in Regions 6 and 7. The implications of the available data are that Regions 4, 5, and 7 appear likely to contain the greatest numbers of historic and cultural resources. For sites discovered, the possible impacts of construction on such resources would be assessed through the measures outlined in the PA. If historic properties are identified, adverse effects would be resolved through consultation with consulting parties to develop means of avoidance, minimization, or mitigation.

As discussed in Sections 3.9.4 and 3.9.5, as a result of public comment on the Draft EIS, the Applicant has proposed several minor variations to the Applicant Proposed Route. Review of these minor variants found that, based on the information currently available to DOE, there is generally similar potential for involvement with historic and cultural resources as compared to the original Applicant Proposed Route, and so the Project effects along these variations are also expected to be similar.

Table 3.9-17:
Frequency Per Linear Mile of the Applicant Proposed Route Centerline for Previously Inventoried Historic and Cultural Resources by Region

Length/Inventory[1]	Applicant Proposed Route (APR)						
	Region 1	Region 2	Region 3	Region 4	Region 5	Region 6	Region 7
Length (miles)	115.46	105.97	161.69	126.28	112.8	54.36	42.83
Total Archaeological Sites (n)[2]	4	0	2	20	13	5	14
Total Aboveground Historic Properties (n)[2]	6	9	20	8	0	0	0
Archaeological Sites per Mile[3]	0.03	0.00	0.01	0.16	0.12	0.09	0.33
Historic Properties per Mile[3]	0.01	0.00	0.01	0.05	0.20	0.02	0.93

1 The values in the table do not reflect the minor changes that would result from application of route variations and adjustments.
2 ROI for archaeological sites is a 1,000-foot-wide corridor; ROI for aboveground historic properties and historic routes is a 1-mile corridor.
3 Density calculations are based on statewide records available in SHPO and state archaeologist offices.

Table 3.9-18:
Percentage Comparison of Land Cover Groups for Assessment of Potential Project Effects on Historic and Cultural Resources for the HVDC Transmission Line by Region

Land Cover Group[1, 2]	Applicant Proposed Route (APR)						
	Region 1	Region 2	Region 3	Region 4	Region 5	Region 6	Region 7
A (Manipulated Terrain)	32.8%	39.7%	13.2%	5.6%	9.6%	85.8%	73.8%
B (Open Vegetation Patterns)	66.7%	50.5%	58.2%	50.6%	32.7%	0.4%	10.4%
C (Closed Vegetation Pattern)	0.2%	9.6%	28.3%	43.6%	57.3%	13.0%	13.7%
W (Water)	0.4%	0.2%	0.3%	0.2%	0.3%	0.9%	2.2%
Total Acres	2,926	2,687	4,328	3,570	3,051	1,448	1,221

1 The values in the table do not reflect the minor changes that would result from application of route variations and adjustments.
2 Land cover percentages and acreages based on a 200-foot-wide representative ROW and including tensioning work sites, which typically extend outside the transmission line ROW. See Section 3.10 for discussion of source data quality and limitations. Percentages may not sum to 100 due to rounding error.
GIS Data Source: Jin et al. (2013)

3.9.6.2.3.1 Construction Impacts

3.9.6.2.3.1.1 Region 1

Based upon information on archaeological, historical, and tribal resources available from background research as presented in Table 3.9-17, the Applicant Proposed Route appears to have an overall potential for containing a few to some historic and cultural resources in Region 1. Nearly all of the terrain is open (Table 3.9-18), which tends to reduce the need for extensive construction disturbances outside of transmission towers and other ground-level facilities. With effective implementation of plans and measures such as those described in Section 3.9.6.1.1, adverse effects to historic properties would be resolved by consultation with consulting parties to develop means of avoidance, minimization, or mitigation.

The approximate 115-mile Applicant Proposed Route primarily traverses the interfluve between the Beaver River to the north and Wolf Creek to the south, intersecting the headwaters of several widely spaced minor tributaries of the Beaver River. In settings like that of the Applicant Proposed Route on the High Plains, the frequencies of cultural resources tend to be low, except in the vicinity of water sources, such as washes, creeks, rivers, and playas, where cultural resources, particularly prehistoric archaeological sites, may be more common. In contrast, pioneer settlement-era and statehood-period archaeological sites, buildings, and structures tend to be located along road networks, which are generally based on 1-mile section lines; terrain and water sources are thus somewhat less relevant to the distribution of cultural resources of later historic periods than they are to sites of earlier times. The Applicant Proposed Route crosses several historic transportation corridors (trails and railroad lines), but no associated cultural resources have been inventoried in any of these corridors in the vicinity of Project route intersections.

Terrain features related to drainage tend to be infrequent along most sections of the Applicant Proposed Route; the most notable exception to this generalization is the crossing of the Beaver River, where a higher frequency of cultural resources, and consequently a greater potential for Project impacts, may occur. Information on file with state and federal agencies confirms the presence of archaeological sites and historic buildings along the Applicant Proposed Route: inventoried properties include four archaeological sites and six historic buildings and structures. The Applicant Proposed Route crosses several historic transportation corridors (trails and railroad lines), but no associated cultural resources have been inventoried in any of these corridors in the vicinity of their intersections with the Project. The Applicant Proposed Route contains no identified NRHP-listed or -eligible properties.

No route variations were proposed in Region 1.

3.9.6.2.3.1.2 Region 2

Based upon information on archaeological, historical, and tribal resources available from background research as presented in Table 3.9-17, the Applicant Proposed Route appears to have an overall potential to contain a few historic and cultural resources in Region 2. The great majority of terrain is open (Table 3.9-18), which tends to reduce the need for extensive construction disturbances outside of transmission towers and other ground-level facilities. With effective implementation of plans and measures such as those described in Section 3.9.6.1.1, adverse effects to historic properties would be resolved through consultation with consulting parties to develop means of avoidance, minimization, or mitigation.

The approximate 106-mile Applicant Proposed Route parallels the North Canadian River along its approximately 55 westernmost miles, generally staying distant from the river on rolling plains. Much of this distance is located along the drainage divide with the Cimarron River to the north and east. It then enters the Cimarron River drainage via the headwaters of several minor tributaries of the river, crosses the Cimarron River and valley floor, and intersects the middle reaches of two tributary creeks of the river. In settings like that of the Applicant Proposed Route on the High Plains, the frequencies of cultural resources tend to be low, except in the vicinity of water sources, such as washes, creeks, rivers, and playas, where cultural resources, particularly prehistoric archaeological sites, may be more common. In contrast, pioneer settlement-era and statehood-period archaeological sites, buildings, and structures tend to be located along road networks, which are generally based on 1-mile section lines; terrain and water sources are thus somewhat less relevant to the distribution of cultural resources of later historic period than they are to sites of earlier times. An exception to this rule-of-thumb is the location of trails and travel routes from the early historic period, such as the Chisholm Trail, which came into existence before the establishment of the township-and-range surveys and do not necessarily follow section lines.

While much of the Applicant Proposed Route is situated on rolling plains distant from such terrain features, the route does cross several drainages, including headwaters and middle reaches of several creeks and the Cimarron River itself. Such locations have a higher potential to contain cultural resources and a greater potential for Project impacts. Information on file with state and federal agencies, however, suggests the overall low frequency of cultural resources along the Applicant Proposed Route; there are no inventoried archaeological sites or historic buildings and structures (Table 3.9-17). The Applicant Proposed Route crosses several historic transportation corridors (trails and railroad lines), but no associated cultural resources or NRHP-listed or -eligible properties have been inventoried in any of these corridors in the vicinity of their intersections with the Project.

Two minor route variations were proposed in Region 2, as discussed in Section 3.9.5.2. Examination of these variations indicates similar potential for involvement with cultural resources as compared to the original Applicant Proposed Route analyzed in the Draft EIS. Adoption of such variations would not substantively alter the analysis of potential Project effects.

3.9.6.2.3.1.3 Region 3

Based upon information on archaeological, historical, and tribal resources available from background research as presented in Table 3.9-17, the Applicant Proposed Route appears to have an overall potential to contain a moderate number of cultural resources in Region 3. While much of the terrain is open, wooded areas compose around one-quarter of the terrain (Table 3.9-18).

The approximate 162-mile Applicant Proposed Route traverses gently rolling to broken terrain, intersecting numerous small drainages. The route also crosses the Cimarron River near Ripley, Oklahoma, and terminates on the western bank of the Arkansas by Webbers Falls Dam in Muskogee County, Oklahoma. The Applicant Proposed Route crosses several historic transportation corridors (trails and railroad lines), but with one exception associated with the U.S. Highway 66 National Historic Trail near Bristow, Oklahoma, no associated cultural resources have been inventoried in any of these corridors in the vicinity of the Applicant Proposed Route. Region 3 is the longest of the seven regions encompassing the Project—more than 25 percent longer than the second longest region, Region 4—and there are more inventoried historic and cultural resources in the Applicant Proposed Route in Region 3 than in the regions to the west. For any additional sites discovered, the possible impacts of construction on such resources would be assessed.

While there is reason to anticipate that cultural resources would be relatively common in Region 3, information on file with state and federal agencies does not reflect a high resource frequency (Table 3.9-17). Only two archaeological sites have been recorded within a portion of the ROI in this region to date, and no historic buildings have been inventoried. One historic structure, an NRHP-eligible segment of the 1926 original concrete-paved roadway (now abandoned) of U.S. Route 66, occurs as near as 0.5 mile from the Applicant Proposed Route near Bristow, Oklahoma.

Five minor route variations were proposed in Region 3, as discussed in Section 3.9.5.3. Examination of these variations indicates similar potential for involvement with cultural resources as compared to the original Applicant Proposed Route analyzed in the Draft EIS. Adoption of such variations would not substantively alter the analysis of potential Project effects.

3.9.6.2.3.1.4 Region 4

Based upon information on archaeological, historical, and tribal resources available from background research as presented in Table 3.9-17, the Applicant Proposed Route appears to have an overall potential to contain moderate numbers of historic and cultural resources in Region 4. The terrain is a roughly equal mix of open and wooded areas (Table 3.9-18).

The approximate 126-mile Applicant Proposed Route traverses undulating to hilly terrain along the northern edge of the Arkansas River valley. At the western end of Region 4, the Project alignment crosses the river itself at Webbers Falls Dam in Muskogee County, Oklahoma. The Arkansas riverbed would be spanned, and visual impacts would be moderate–low given the distance of the Project from the river and the presence of existing high-voltage transmission lines in close proximity to the Project, as described in Section 3.18.6.3.2.2.4 and Appendix K. Since the Arkansas riverbed would be spanned, there would be no ground disturbing activities and thus impacts would be limited to visual resources. The alignment then roughly parallels the river at a varying distance of approximately 2.25 to 17.5 miles. The route intersects numerous small drainages that flow from the rugged Boston Mountains to the north across the Arkansas Valley to confluences with the Arkansas River. In terrain such as that of Region 4, cultural resources may occur in a variety of settings. However, there is likely a tendency for the number of cultural resources, specifically prehistoric archaeological sites, to be greatest in the vicinity of water-related features, such as ravines, creeks, rivers, wetlands, and ponds. While water-related features might also have affected the locations of certain pioneer settlement-era and statehood-period archaeological sites, buildings, and structures, resources of the historic period tend to be located along road networks. Unlike Oklahoma, where local road networks are generally based on 1-mile section lines, in western Arkansas geographic features such as stream and river courses and the ruggedness of the terrain appear to have played a dominant role influencing the locations of roads and settlements. The Applicant Proposed Route crosses several historic transportation corridors (trails and railroad lines). The most prominent of these is the Trail of Tears National Historic Trail (a multi-branched resource management corridor), specifically the Bell-Drane Route of the trail, over which approximately 2,000 Native Americans traveled into exile in Indian Territory (the future state of Oklahoma) in three separate parties in 1838 and 1839. To date, no NRHP-listed or -eligible properties have been identified at crossings between the identified route of the Trail of Tears and any of the Project proposed or alternative routes. In addition, one property in the Applicant Proposed Route ROI is listed on the NRHP:

- Mulberry River Bridge, Pleasant Hill vicinity, Crawford County, Arkansas

The property is located 0.28 mile off the centerline of the Applicant Proposed Route. The property could be subject to visual impacts from the construction of the proposed HVDC transmission line, if it substantially alters the bridge's historic setting. Analysis of this potential impact would occur prior to construction. Adverse effects, if any, would be resolved by means of avoidance, minimization, or mitigation. Tribal consultation also suggested specific potential for the location of burials and ceremonial grounds along the Applicant Proposed Route.

Taken in combination, these factors suggest that the number of cultural resources is likely higher along the Applicant Proposed Route in Region 4 than in Regions 1 and 2, perhaps somewhat higher than in Region 3, and similar to or somewhat lower than in Regions 5, 6, and 7. For sites discovered, the possible impacts of construction on such resources would be assessed.

The archaeological sensitivity of the Applicant Proposed Route and of Region 4 in general is suggested by the 20 inventoried archaeological sites that have been documented for the Applicant's Proposed Route ROI (Table 3.9-17), all of which are located in the western half of the Applicant Proposed Route, as far east as approximately the Crawford-Franklin county line in Arkansas. These 20 sites span a variety of types and periods and include prehistoric period general artifact scatters (7) and open camps (3), historic period farmsteads (2) and unidentified features (1), and multicomponent (mixed historic and prehistoric period) artifact scatters (5) and prehistoric sites co-occurring with historic period farmsteads (2). There are also several inventoried historic buildings and structures, none of which is NRHP listed or known to be eligible for the Arkansas Register of Historic Places. The Applicant Proposed Route intersects the Bell-Drane Route of the Trail of Tears in approximately six places between western Crawford and eastern Franklin counties. No cultural resources have been previously documented in the vicinity of any of the intersections.

Seven minor route variations were proposed in Region 4, as discussed in Section 3.9.5.4. Examination of these variations indicates similar potential for involvement with cultural resources as compared to the original Applicant Proposed Route analyzed in the Draft EIS. Adoption of such variations would not substantively alter the analysis of potential Project effects.

3.9.6.2.3.1.5 Region 5

Based upon information on archaeological, historical, and tribal resources available from background research as presented in Table 3.9-17, the Applicant Proposed Route appears to have an overall potential to contain moderate numbers of historic and cultural resources in Region 5. A majority of the terrain is wooded, but open areas account for well over one-third of the alignment (Table 3.9-18).

The approximate 113-mile Applicant Proposed Route traverses hilly terrain along the southern fringe of the Ozark Plateau, which flanks northern edge of the Arkansas Valley. The alignment intersects numerous small and large drainages that flow off the Ozark Plateau toward Arkansas River or, at the eastern end of this region, more directly toward the Mississippi. While water-related features might also have affected the locations of certain pioneer settlement-era and statehood-period archaeological sites, buildings, and structures, resources of the historic period tend to be located along road networks. In western and central Arkansas, geographic features such as stream- and river courses and the ruggedness of the terrain appear to have played a dominant role influencing the locations of roads and settlements, rather than public lands section lines, as is characteristic of states to the west and north. Consequently, the intervals at which the Project alignment crosses roads—and thus has a somewhat increased chance of the presence of historic period cultural resources—are apt to be more irregular than in Regions 1, 2, and 3, where section line roads dominate. No historic transportation corridors (trails and railroad lines) have been identified in the ROI for Region 5. Taken in combination, these factors suggest that the number of historic and cultural resources is likely similar to that of Region 4. For sites discovered, the possible impacts of construction on such resources would be assessed. If historic properties are identified, adverse effects would be resolved through consultation with consulting parties to develop means of avoidance, minimization, or mitigation.

The archaeological sensitivity of the Applicant Proposed Route and of Region 5 generally is confirmed by the 12 inventoried archaeological sites that have been documented for the Applicant's Proposed Route ROI. These 12 sites span a variety of types and periods and include prehistoric period general artifact scatters (6), open camps (1), and rockshelters (1); historic period farmsteads (2) and other structures (2); and multicomponent (mixed historic and prehistoric period) artifact scatters (1). There are also 18 inventoried historic buildings and structures. The prehistoric rockshelter site and one of the inventoried historic buildings or structures, both at undisclosed locations, are reported to be NRHP-eligible (Clean Line 2013, Table 3-25). In addition, two properties in the Applicant Proposed Route ROI are listed on the NRHP:

- Wesley Marsh House, Letona vicinity, White County, Arkansas
- William Henry Watson Homestead, Bradford vicinity, White County, Arkansas

Each property is located about 0.34 mile off the centerline of the Applicant Proposed Route and could be subject to visual impacts from the construction of the proposed HVDC transmission line. Analysis of this potential impact would occur prior to construction. Adverse effects, if any, would be resolved through consultation with consulting parties to develop means of avoidance, minimization or mitigation.

Five minor route variations were proposed in Region 5, as discussed in Section 3.9.5.5. Examination of these variations indicates similar potential for involvement with cultural resources as compared to the original Applicant Proposed Route analyzed in the Draft EIS. Adoption of such variations would not substantively alter the analysis of potential Project effects.

3.9.6.2.3.1.6 Region 6

Based upon information on archaeological, historical, and tribal resources available from background research as presented in Table 3.9-17, the Applicant Proposed Route appears to have an overall potential to contain moderate numbers of historic and cultural resources in Region 6. This assessment is based upon information on file with the respective SHPOs and NPS, as no cultural resources surveys of this portion of the Project have been completed to date. This region contains the highest proportion of cultivated crops (Table 3.9-18), which are open and generally present good transportation access.

The approximate 54-mile Applicant Proposed Route traverses the Lower Mississippi Alluvial Valley and crosses Holocene epoch riverine meander belts; Pleistocene epoch valley train deposits; and Crowley's Ridge, a string of low hills. The alignment intersects the Cache and White rivers and numerous small low-order drainages. The pre-agricultural terrain of the region contained numerous wetlands, sloughs, and oxbows. In terrain such as that of Region 6, cultural resources may occur in a variety of settings. However, soil drainage is likely to be a critical factor in the frequently flooded lower Mississippi Valley, with areas of good drainage preferentially occupied over more poorly drained areas, during both prehistoric and historic times. While water-related features doubtless affected the locations of certain pioneer settlement-era and statehood-period archaeological sites, buildings, and structures, resources of the historic period tend to be located along road networks, which, while generally following a grid pattern in Region 6, tend to be irregularly spaced. Consequently, the intervals at which the Project alignment crosses roads are apt to be more irregular than in Regions 1, 2, and 3, where section line roads dominate. No historic transportation corridors (trails and railroad lines) have been identified in the ROI for Region 6. It should also be noted that the natural environment of this region is dynamic, with flooding from the Mississippi River and its major tributaries occurring frequently. Such alluvial activity may tend to remove or obscure archaeological resources, and the combination of the natural dynamism of the area and intensive agriculture may account for the decrease in the number of historic and cultural resources in Region 6 as compared to the regions to the east and west (Table 3.9-17).

For sites discovered, the possible impacts of construction on such resources would be assessed. If historic properties are identified, adverse effects would be resolved through consultation with consulting parties to develop means of avoidance, minimization, or mitigation.

The archaeological sensitivity of the Applicant Proposed Route and of Region 6 is evidenced by the five archaeological sites (four prehistoric archaeological sites and one historic period archaeological site) that have been documented for the route. In addition, one historic building or structure has been inventoried along the Applicant Proposed Route ROI. This alignment contains no NRHP-listed properties.

One minor route variation was proposed in Region 6, as discussed in Section 3.9.5.6. Examination of this variation indicates similar potential for involvement with cultural resources as compared to the original Applicant Proposed Route analyzed in the Draft EIS. Adoption of such variations would not substantively alter the analysis of potential Project effects.

3.9.6.2.3.1.7 Region 7

Based upon information on archaeological, historical, and tribal resources available from background research as presented in Table 3.9-17, the Applicant Proposed Route appears to have an overall potential to contain numerous cultural resources in Region 7. This assessment is based upon information on file with the respective SHPOs and NPS, as no cultural resources surveys of this portion of the Project have been completed to date. A majority of the Project alignment is cultivated crops or other open terrain, but wooded areas comprise around one-quarter of the Project ROI (Table 3.9-18).

The approximate 43-mile Applicant Proposed Route in Region 7 traverses the Lower Mississippi Alluvial Valley and crosses Holocene epoch riverine meander belts before climbing an escarpment on the right (eastern) side of the Mississippi River onto the West Tennessee Plateau Slope (part of the Southeastern Coastal Plain). This alignment crosses the Mississippi River and begins its climb onto the West Tennessee Plateau. Approximately three-quarters of the Applicant Proposed Route in Region 7 is located on Mississippi bottomlands. In bottomlands terrain like that found in the western and central portions of Region 7, cultural resources may occur in a variety of settings. However, soil drainage is likely to be a critical factor in the frequently flooded lower Mississippi valley, with areas of good drainage preferentially occupied over more poorly drained areas, during both prehistoric and historic times. In the hilly eastern portion of this region, there is likely a tendency for the number of cultural resources, specifically prehistoric archaeological sites, to be greatest in the vicinity of water-related features, such as ravines, creeks, rivers, wetlands, and ponds. While water-related features doubtless affected the locations of certain pioneer settlement-era and statehood-period archaeological sites, buildings, and structures, resources of the historic period tend to be located along road networks. In the western and central portions of Region 7, the road network tends to follow a grid pattern, while in the eastern portion, geographic features such as stream courses and the roughness of terrain strongly influence the form of the road network. In consequence, the intervals at which the Project alignment crosses roads are apt to be more irregular than in Regions 1, 2, and 3, where section line roads dominate. No historic transportation corridors (trails and railroad lines) have been identified in the ROI for Region 7. Such alluvial activity may tend to remove or obscure archaeological resources. Region 7 has the highest frequencies of both inventoried archaeological sites and inventoried aboveground historic properties (Table 3.9-17). For sites discovered, the possible impacts of construction on such resources would be assessed.

The archaeological sensitivity of the Applicant Proposed Route and of Region 7 generally is confirmed by the 14 inventoried archaeological sites and 40 inventoried historic buildings and structures that have been documented for The Applicant's Proposed Route in Region 7. The 14 archaeological sites include prehistoric period general artifact scatters (8) and villages (2), as well as general artifact scatters for the historic period (4, 2 of which also yield prehistoric artifacts). The large number of inventoried historic buildings and structures within the ROI for the Applicant Proposed Route in Region 7 reflects the location of the eastern end of the Project near the outskirts of Memphis, Tennessee; none has been evaluated for NRHP eligibility. The Applicant Proposed Route contains no NRHP-listed properties. The overall number or density of cultural resources that may be affected by the Project cannot be estimated from the available background information.

Three minor route variations were proposed in Region 7 as discussed in Section 3.9.5.7. Examination of these variations indicates similar potential for involvement with cultural resources as compared to the original Applicant Proposed Route analyzed in the Draft EIS. Adoption of such variations would not substantively alter the analysis of potential Project effects.

3.9.6.2.3.2 Operations and Maintenance Impacts

No impacts would result from operations and maintenance of the Applicant Proposed Route in Regions 1 through 7 (see Section 3.9.6.1.3).

3.9.6.2.3.3 Decommissioning Impacts

No impacts would result from decommissioning (see Section 3.9.6.1.3).

3.9.6.3 Impacts Associated with the DOE Alternatives

3.9.6.3.1 Arkansas Converter Station Alternative Siting Area and AC Interconnection Siting Area

3.9.6.3.1.1 Construction Impacts

The Arkansas Converter Station Alternative Siting Area ROI evaluated in the Draft EIS contains 23 previously recorded archaeological sites, including 2 that have been recommended as eligible for the NRHP and 21 that have no eligibility recommendation. There are also three previously recorded historic buildings, none of which has been evaluated for NRHP eligibility. The number of previously recorded cultural resources suggests a moderate to high sensitivity for the presence of sites that may be affected by the project construction. Design of the converter station would avoid currently known NRHP-eligible properties. The smaller Arkansas Converter Station Alternative and AC Interconnection Siting Area ROI evaluated in this Final EIS would have the potential to impact a smaller subset of these historic or cultural resources.

The cultural resources sensitivity of the Arkansas Converter Station AC interconnection is comparable to that described for the Arkansas Converter Station Alternative Siting Area ROI. Following cultural resources surveys, the Project design would attempt to avoid or minimize impacts to NRHP-eligible cultural resources. If avoidance or minimization is not possible, appropriate resolution of adverse impacts to NRHP-eligible cultural resources would be performed in consultation with the appropriate SHPOs and Indian Tribes that may attach religious and cultural significance to historic properties that may be affected by the undertaking.

3.9.6.3.1.2 Operations and Maintenance Impacts

No impacts would result from operations and maintenance of the Arkansas Converter Station or AC interconnection (see Section 3.9.6.1.3).

3.9.6.3.1.3 Decommissioning Impacts

No impacts would result from decommissioning (see Section 3.9.6.1.3).

3.9.6.3.2 HVDC Alternative Routes

3.9.6.3.2.1 Construction Impacts

Comparisons of the historic and cultural resources along the HVDC alternative routes with the Applicant Proposed Routes are presented in the sections that follow based on the data summarized by region in the associated tables. As described for the Applicant Proposed Route, cultural resources field surveys would be conducted in all HVDC alternative routes prior to construction to assess the possible impacts of construction on such resources if present. DOE establishes the timing and protocols for cultural resources surveys in the draft PA (Appendix P). Across all HVDC alternative routes, with effective implementation of plans and measures such as those described in Section 3.9.6.1.1, adverse effects to historic properties would be resolved through consultation with consulting parties to develop means of avoidance, minimization, or mitigation.

3.9.6.3.2.1.1 Region 1

3.9.6.3.2.1.1.1 Alternative Route 1-A

HVDC Alternative Route 1-A loops to the north of the Applicant Proposed Route, and the alternative route is longer (by 9.42 miles) than the corresponding links of the Applicant Proposed Route. While the greater length of the alternative route alone would somewhat increase its potential to impact cultural resources, its geographic location also contributes to its increased potential for impacting these resources. Unlike the corresponding links of the Applicant Proposed Route, which primarily traverses an interfluve between adjoining drainage basins, HVDC Alternative Route 1-A is located much closer to the Beaver River, where greater numbers of prehistoric archaeological sites and perhaps other types of cultural resources might be found. Information on file with state and federal agencies confirms the greater frequency of inventoried archaeological sites and shows an equal number of inventoried historic buildings and structures (Table 3.9-19). Neither contains identified NRHP-listed or -eligible properties.

Table 3.9-19:
Frequency of Previously Inventoried Historic and Cultural Resources Per Linear Mile of HVDC Alternative Route in Region 1

Length/Inventory[1]	Region 1 APR	AR 1-A		AR 1-B		AR 1-C		AR 1-D	
		AR	APR Links 2, 3, 4, 5	AR	APR Links 2, 3	AR	APR Links 2, 3	AR	APR Links 3, 4
Length (miles)	115.46	122.97	113.55	51.86	53.83	52.03	53.83	33.45	33.57
Total Archaeological Sites (n)[2]	4	9	4	2	3	0	3	1	1
Total Aboveground Historic Properties (n)[1]	6	0	1	1	0	1	0	0	1
Archaeological Sites per Mile[3]	0.03	0.07	0.04	0.04	0.06	0.00	0.06	0.03	0.03
Historic Properties per Mile[3]	0.01	0.00	0.01	0.02	0.00	0.02	0.00	0.00	0.03

1 The values in the table do not reflect the minor changes that would result from application of route variations and adjustments.
2 ROI for archaeological sites is a 1,000-foot-wide corridor; ROI for aboveground historic properties and historic routes is a 1-mile corridor.
3 Density calculations are based on statewide records available in SHPO and state archaeologist offices.
Source: Clean Line (2013)

While it appears that HVDC Alternative Route 1-A involves more cultivated crops than the equivalent links of the Applicant Proposed Route (Table 3.9-20), which might indicate an overall lower need for ground-disturbing terrain manipulation, the alternative appears to have a somewhat greater potential to contain historic and cultural resources than the corresponding links of the Applicant Proposed Route.

Table 3.9-20:
Region 1 HVDC Alternative Routes—Percentage Comparison of Land Cover Groups for Assessment of Potential Project Effects on Historic and Cultural Resources

Land Cover Group[1, 2]	Region 1 APR	AR 1-A AR	AR 1-A APR Links 2, 3, 4, 5	AR 1-B AR	AR 1-B APR Links 2, 3	AR 1-C AR	AR 1-C APR Links 2, 3	AR 1-D AR	AR 1-D APR Links 3, 4
A (Manipulated Terrain)	32.8%	19.8%	33.3%	23.0%	46.3%	23.3%	46.3%	25.3%	16.6%
B (Open Vegetation Patterns)	66.7%	79.6%	66.1%	77.0%	53.7%	76.6%	53.7%	74.2%	82.9%
C (Closed Vegetation Pattern)	0.2%	0.4%	0.2%	0.0%	0.0%	0.1%	0.0%	0.5%	0.4%
W (Water)	0.4%	0.2%	0.4%	0.0%	0.0%	0.0%	0.0%	0.0%	0.0%
Total Acres	2,926	3,168	2,875	1,315	1,361	1,333	1,361	848	845

1 The values in the table do not reflect the minor changes that would result from application of route variations and adjustments.
2 Land cover percentages and acreages based on a 200-foot-wide representative ROW and including tensioning work sites, which typically extend outside the transmission line ROW. See Section 3.10 for discussion of source data quality and limitations. Percentages may not sum to 100 due to rounding error.
GIS Data Source: Jin et al. (2013)

3.9.6.3.2.1.1.2 Alternative Route 1-B

HVDC Alternative Route 1-B parallels the corresponding links of the Applicant Proposed Route to the north at a distance of up to approximately 7 miles. HVDC Alternative Route 1-B is shorter (by 1.97 miles) than the corresponding links of the Applicant Proposed Route, but it traverses similar terrain. Information on file with state and federal agencies shows similar numbers of inventoried archaeological sites and historic buildings and structures (Table 3.9-19). Neither contains identified NRHP-listed or -eligible properties. The alternative route appears to cross more cultivated crops than the Applicant Proposed Route (Table 3.9-20), which may indicate that existing access is somewhat better for the alternative.

Given the small difference in length between the two routes and the detail of the available information, the likely number of historic and cultural resources in HVDC Alternative Route 1-B is similar to the estimated low to moderate frequencies of the corresponding links of the Applicant Proposed Route.

3.9.6.3.2.1.1.3 Alternative Route 1-C

HVDC Alternative Route 1-C parallels the Applicant Proposed Route to the north at distances of up to approximately 7 miles. HVDC Alternative Route 1-C is shorter (by 1.80 miles) than the corresponding links of the Applicant Proposed Route, but it similar terrain. Information on file with state and federal agencies shows a non-substantial difference in the number of inventoried archaeological sites and a similar number of inventoried historic buildings and structures (Table 3.9-19). Neither contains identified NRHP-listed or -eligible properties. The alternative route appears to cross more cultivated crops than the Applicant Proposed Route (Table 3.9-20), which may indicate that existing access is somewhat better for the alternative.

Given the small difference in length between the two routes and the available information, the potential for HVDC Alternative Route 1-C to contain cultural resources is similar to the estimated low to moderate frequencies of the corresponding links of the Applicant Proposed Route.

3.9.6.3.2.1.1.4 Alternative Route 1-D

HVDC Alternative Route 1-D parallels the Applicant Proposed Route to the south by approximately 0.5 mile. HVDC Alternative Route 1-D is approximately the same length (shorter by just 0.12 mile) as the corresponding links of the Applicant Proposed Route and traverses the same terrain. Information on file with state and federal agencies shows the same number of inventoried archaeological sites and a non-substantial difference in the number of inventoried historic buildings and structures (Table 3.9-19). Neither contains identified NRHP-listed or -eligible properties. Land cover appears similar between the two routes (Table 3.9-20).

Given the small difference in length between the two routes and the available information, the potential for HVDC Alternative Route 1-D to contain cultural resources is similar to the estimated low to moderate frequencies of the corresponding links of the Applicant Proposed Route.

3.9.6.3.2.1.2 Region 2

3.9.6.3.2.1.2.1 Alternative Route 2-A

HVDC Alternative Route 2-A parallels the Applicant Proposed Route to the north at a distance of up to approximately 11 miles. HVDC Alternative Route 2-A is longer (by 2.74 miles) than the corresponding link of the Applicant Proposed Route. The alternative route traverses similar terrain to that of the Applicant Proposed Route, but more of the alternative route is in the Cimarron River drainage and close to the river itself. The number of archaeological sites and inventoried historic buildings along HVDC Alternative Route 2-A and the Applicant Proposed Route are not substantially different (Table 3.9-21). Neither contains identified NRHP-listed or -eligible properties. Land cover between the Applicant Proposed Route and the alternative is broadly comparable, although the former appears to have both more cultivated crops and more woodland as compared to the latter (Table 3.9-22); these differences are minor and likely have little difference in terms of potential impacts to cultural resources.

Table 3.9-21:
Frequency of Previously Inventoried Historic and Cultural Resources Per Linear Mile of HVDC Alternative Route in Region 2

Length/Inventory[1]	Region 2 APR	AR 2-A		AR 2-B	
		AR	APR Link 2	AR	APR Link 3
Length (miles)	105.97	57.16	54.42	29.75	31.23

Total Aboveground Historic Properties (n)[2]	0	2	0	0	0
Archaeological Sites per Mile[3]	0	0.03	0.00	0.00	0.00
Historic Properties per Mile[3]	0	0.03	0.00	0.00	0.00

1 The values in the table do not reflect the minor changes that would result from application of route variations and adjustments.
2 ROI for archaeological sites is a 1,000-foot-wide corridor; ROI for aboveground historic properties and historic routes is a 1-mile corridor.
3 Density calculations are based on statewide records available in SHPO and state archaeologist offices.
Source: Clean Line (2013)

Table 3.9-22:
Region 2 HVDC Alternative Routes—Percentage Comparison of Land Cover Groups for Assessment of Potential Project Effects on Historic and Cultural Resources

Land Cover Group[1, 2]	Region 2 APR	AR 2-A		AR 2-B	
		AR	APR Link 2	AR	APR Link 3
A (Manipulated Terrain)	39.7%	29.1%	36.3%	63.7%	63.2%
B (Open Vegetation Patterns)	50.5%	60.5%	46.4%	33.2%	34.4%
C (Closed Vegetation Pattern)	9.6%	9.9%	16.9%	2.2%	2.4%
W (Water)	0.2%	0.4%	0.4%	1.0%	0.0%
Total Acres	2,687	1,480	1,370	759	786

1 The values in the table do not reflect the minor changes that would result from application of route variations and adjustments.
2 Land cover percentages and acreages based on a 200-foot-wide representative ROW and including tensioning work sites, which typically extend outside the transmission line ROW. See Section 3.10 for discussion of source data quality and limitations. Percentages may not sum to 100 due to rounding error.
GIS Data Source: Jin et al. (2013)

The relatively small difference in length between the two routes and the available information suggest that the potential for HVDC Alternative Route 2-A to contain cultural resources is similar to the estimated low frequencies of the Applicant Proposed Route. However, the proximity of the roughly 13.6-mile section of HVDC Alternative Route 2-A, approximately 1.0 to 2.5 miles from the Cimarron River, may slightly increase the overall cultural resources sensitivity or potential of this route as compared to the corresponding link of the Applicant Proposed Route.

3.9.6.3.2.1.2.2 Alternative Route 2-B

HVDC Alternative Route 2-B parallels the Applicant Proposed Route to the north for up to approximately 3.5 miles. HVDC Alternative Route 2-B is shorter (by 1.48 miles) than the corresponding link of the Applicant Proposed Route, but it traverses similar terrain. Information on file with state and federal agencies shows no cultural resources have been recorded along the Applicant Proposed Route or HVDC Alternative Route 2-B (Table 3.9-21). Land cover along the Applicant Proposed Route and along the alternative is highly similar (Table 3.9-22).

Given the small difference in length between the two routes the similarity in land cover, and the available information the potential for HVDC Alternative Route 2-B to contain cultural resources is similar to the estimated low frequencies of the corresponding link of the Applicant Proposed Route.

3.9.6.3.2.1.3 Region 3

3.9.6.3.2.1.3.1 Alternative Route 3-A

HVDC Alternative Route 3-A parallels the Applicant Proposed Route to the northeast for up to approximately 7.5 miles. HVDC Alternative Route 3-A is shorter (by 2.41 miles) than the corresponding link of the Applicant Proposed Route, but it traverses similar terrain. Information on file with state and federal agencies shows no cultural resources have been recorded along the Applicant Proposed Route or HVDC Alternative Route 3-A (Table 3.9-23). There are strong similarities between the land cover of both (Table 3.9-24).

Given the small difference in length between the two routes the similarity in land cover, and the available information, the potential for HVDC Alternative Route 3-A to contain cultural resources is similar to the estimated low frequencies of the corresponding link of the Applicant Proposed Route.

Table 3.9-23:
Frequency of Previously Inventoried Historic and Cultural Resources Per Linear Mile of HVDC Alternative Route in Region 3

		AR 3-A		AR 3-B		AR 3-C		AR 3-D		AR 3-E

Historic Properties per Mile[3]	0.01	0.00	0.00	0.00	0.00	0.02	0.02	0.05	0.00	0.00	0.00

1 The values in the table do not reflect the minor changes that would result from application of route variations and adjustments.
2 ROI for archaeological sites is a 1,000-foot-wide corridor; ROI for aboveground historic properties and historic routes is a 1-mile corridor.
3 Density calculations are based on statewide records available in SHPO and state archaeologist offices.
Source: Clean Line (2013)

As described in Appendix M and summarized in Section 2.4.2.3, a route adjustment was developed for HVDC Alternative Route 3-A to maintain an end-to-end route with Applicant Proposed Route Link 1, Variation 2, and Links 1 and 2, Variation 1. Compared to HVDC Alternative Route 3-A, the route adjustment parallels more parcel boundaries and crosses less pasture/hay and agricultural land, but overall its setting is similar to the original route analyzed in the Draft EIS. There are no recorded historic or cultural resources in the ROI for this route adjustment (Appendix M). The route adjustment is illustrated in Exhibit 1 of Appendix M.

Table 3.9-24:
Region 3 HVDC Alternative Routes—Percentage Comparison of Land Cover Groups for Assessment of Potential Project Effects on Historic and Cultural Resources

1 The values in the table do not reflect the minor changes that would result from application of route variations and adjustments.
2 Land cover percentages and acreages based on a 200-foot-wide representative ROW and including tensioning work sites, which typically extend outside the transmission line ROW. See Section 3.10 for discussion of source data quality and limitations. Percentages may not sum to 100 due to rounding error.
GIS Data Source: Jin et al. (2013)

3.9.6.3.2.1.3.2 Alternative Route 3-B

HVDC Alternative Route 3-B parallels the Applicant Proposed Route to the northeast for up to approximately 7.5 miles. HVDC Alternative Route 3-A is shorter (by 2.19 miles) than the corresponding links of the Applicant Proposed Route, but it traverses similar terrain. Information on file with state and federal agencies shows a non-substantial difference in the number of inventoried archaeological sites. Neither contains any inventoried historic buildings or structures (Table 3.9-23). There are strong similarities between the land cover of the Applicant Proposed Route and that of the alternative (Table 3.9-24).

Given the small difference in length between the two routes the similarity in land cover, and the available information, the potential for HVDC Alternative Route 3-B to contain cultural resources is similar to the estimated low frequencies of the corresponding links of the Applicant Proposed Route.

3.9.6.3.2.1.3.3 Alternative Route 3-C

HVDC Alternative Route 3-C parallels the Applicant Proposed Route to the southwest for up to approximately 9.25 miles. HVDC Alternative Route 3-C is longer (by 3.07 miles) than the corresponding links of the Applicant Proposed Route, but it traverses similar terrain with similar land cover (Table 3.9-24). Information on file with state and federal agencies shows a non-substantial difference in the number of inventoried archaeological sites (Table 3.9-23). Both cross the historic U.S. Route 66 corridor about 5.3 miles west-southwest of Bristow. No inventoried cultural resources are associated with the historic highway in the vicinity of this intersection. HVDC Alternative Route 3-C passes within approximately 0.10 to 0.29 mile of two NRHP-listed properties, one of which is also an NHL:

- Oktaha School, Muskogee County, Oklahoma (NRHP) (within 0.29 mile)
- Honey Springs Battlefield, MacIntosh and Muskogee Counties, Oklahoma (NRHP/NHL) (within 0.10 mile)

Depending on local terrain and vegetation and the size and design of Project structures in the vicinity of these properties, construction of HVDC Alternative Route 3-C could result in visual impacts if it substantially alters the historic setting of one or both of these properties. Therefore, given the available background information, HVDC Alternative Route 3-C has a higher potential to cause construction-related Project impacts than the corresponding links of the Applicant Proposed Route. Aside from potential Project impacts associated with the two NRHP-listed properties, the overall potential for HVDC Alternative Route 3-C to contain historic and cultural resources is similar to the estimated moderate impact potential of the corresponding links of the Applicant Proposed Route, given the modest difference in length between the two routes and the available information.

3.9.6.3.2.1.3.4 Alternative Route 3-D

HVDC Alternative Route 3-D parallels the Applicant Proposed Route to the south for approximately 9 miles. HVDC Alternative Route 3-D is longer (by 4.25 miles) than the corresponding links of the Applicant Proposed Route, but it traverses similar terrain with similar land cover (Table 3.9-24). Information on file with state and federal agencies shows the same number of inventoried archaeological sites. Two historic buildings or structures have been inventoried within the ROI for HVDC Alternative Route 3-D, which is similar to the absence of inventoried historic buildings and structures along the corresponding links of the Applicant Proposed Route (Table 3.9-23). HVDC Alternative Route 3-D passes within approximately 0.10 to 0.29 mile of two NRHP-listed properties, one of which is also an NHL:

- Oktaha School, Muskogee County, Oklahoma (NRHP) (within 0.29 mile)
- Honey Springs Battlefield, MacIntosh and Muskogee Counties, Oklahoma (NRHP/NHL) (within 0.10 mile)

Depending upon local terrain and vegetation and the size and design of Project structures in the vicinity of these properties, construction of HVDC Alternative Route 3-D could result in visual impacts if it substantially alters the historic setting of one or both of these properties. Therefore, given the available information, HVDC Alternative Route 3-D has a higher potential to cause construction-related Project impacts than the corresponding links of the Applicant Proposed Route. Aside from potential Project impacts associated with the two NRHP-listed properties, the overall potential for HVDC Alternative Route 3-D to contain historic and cultural resources is similar to the estimated moderate numbers of historic and cultural resources of the corresponding links of the Applicant Proposed Route given the modest difference in length between the two routes and the available information.

3.9.6.3.2.1.3.5 Alternative Route 3-E

HVDC Alternative Route 3-E parallels the Applicant Proposed Route up to approximately 1 mile to the south at the eastern terminus of this region. HVDC Alternative Route 3-E is longer (by 0.75 mile) than the corresponding link of the Applicant Proposed Route, but it traverses similar terrain. Information on file with state and federal agencies shows that no cultural resources have been recorded along the Applicant Proposed Route or HVDC Alternative Route 3-E (Table 3.9-23). There are strong similarities between the land cover of the Applicant Proposed Route and that of the alternative (Table 3.9-24).

Given the small difference in length between the two routes and the similarity in land cover, the potential for HVDC Alternative Route 3-E to contain historic and cultural resources is similar to that of the corresponding link of the Applicant Proposed Route.

3.9.6.3.2.1.4 Region 4

3.9.6.3.2.1.4.1 Alternative Route 4-A

HVDC Alternative Route 4-A parallels the Applicant Proposed Route to the north for approximately 5.75 miles. HVDC Alternative Route 4-A is shorter (by 1.98 miles) than the corresponding links of the Applicant Proposed Route and traverses somewhat more rugged terrain across the foothills of the Brush Mountains, part of the Boston Mountains region. Information on file with state and federal agencies shows that fewer archaeological sites have been inventoried in the area of HVDC Alternative Route 4-A as compared to the corresponding links of the Applicant Proposed Route, and that an equal number of buildings have been inventoried (Table 3.9-25). The alternative alignment intersects the Bell-Drane Route of the Trail of Tears north of Fort Smith-Van Buren, but no inventoried cultural resources are associated with the trail in the vicinity of this intersection. HVDC Alternative Route 4-A includes no NRHP-listed properties. The alternative route is more wooded than the corresponding links of the Applicant Proposed Route (Table 3.9-26). Wooded terrain may somewhat reduce the potential of visual effects on historic properties through vegetative screening, but also requires more ground disturbance for ROW clearing, road construction, and similar activities, increasing the possibility of effects to archaeological resources.

Table 3.9-25:
Frequency of Previously Inventoried Historic and Cultural Resources Per Linear Mile of HVDC Alternative Route in Region 4

Length/Inventory[1]	Region 4 APR	AR 4-A		AR 4-B		AR 4-C		AR 4-D		AR 4-E

2 Land cover percentages and acreages based on a 200-foot-wide representative ROW and including tensioning work sites, which typically extend outside the transmission line ROW. See Section 3.10 for discussion of source data quality and limitations. Percentages may not sum to 100 due to rounding error.
GIS Data Source: Jin et al. (2013)

Given the rough similarity in length between the two routes and the available information, the potential for HVDC Alternative Route 4-A to contain cultural resources is approximately the same or somewhat higher as compared to the corresponding links of the Applicant Proposed Route.

3.9.6.3.2.1.4.2 Alternative Route 4-B

HVDC Alternative Route 4-B parallels the Applicant Proposed Route to the north by up to approximately 7.5 miles. HVDC Alternative Route 4-B is shorter (by 2.66 miles) than the corresponding links of the Applicant Proposed Route and traverses somewhat more rugged terrain across the foothills of the Brush Mountains, part of the Boston Mountains region. Information on file with state and federal agencies shows that more archaeological sites have been inventoried in the area of proposed HVDC Alternative Route 4-B as compared to the equivalent corresponding links of the Applicant Proposed Route, and roughly equal numbers of buildings have been inventoried (Table 3.9-25). The alternative alignment intersects the Bell-Drane Route of the Trail of Tears north of Fort Smith-Van Buren, but no inventoried cultural resources are associated with the trail in the vicinity of this intersection. HVDC Alternative Route 4-B includes no NRHP-listed properties. The alternative route is more wooded than the corresponding links of the Applicant Proposed Route (Table 3.9-26). HVDC Alternative Route 4-B includes one NRHP-listed property situated in the vicinity of Cedarville, Arkansas:

- Butterfield Overland Mail Route—Lucian Wood Road Segment, Crawford County, Arkansas

HVDC Alternative Route 4-B has the potential to cause adverse visual impacts to this property if its construction substantially alters the historic setting of the road, which is situated within approximately 0.08 mile of the ROI centerline. With effective implementation of plans and measures such as those described in Section 3.9.6.1.1, adverse effects to this property would be resolved through consultation with consulting parties to develop means of avoidance, minimization, or mitigation.

Given the rough similarity in length between the two routes and the available information, the potential for HVDC Alternative Route 4-B to contain cultural resources is approximately the same or somewhat higher as compared to the corresponding links of the Applicant Proposed Route.

3.9.6.3.2.1.4.3 Alternative Route 4-C

HVDC Alternative Route 4-C loops to the south of the Applicant Proposed Route at State Highway 59 north of Fort Smith-Van Buren up to approximately 1 mile away from the Applicant Proposed Route. This route avoids a subdivision now under development. HVDC Alternative Route 4-C is longer (by 1.22 miles) than the corresponding link of the Applicant Proposed Route, but it traverses similar terrain with similar land cover (Table 3.9-26). Information on file with state and federal agencies shows that no cultural resources have been recorded along the Applicant Proposed Route or this alternative (Table 3.9-25). The HVDC Alternative Route 4-C intersects the Bell-Drane Route of the Trail of Tears north of Fort Smith-Van Buren, but no inventoried cultural resources are associated with the trail in the vicinity of this intersection. HVDC Alternative Route 4-C includes no NRHP-listed properties.

Given the small difference in length between the two routes the similarity of land cover, and the available information, the potential for HVDC Alternative Route 4-C to contain cultural resources is similar to the estimated moderate to medium-high numbers of historic and cultural resources of the corresponding link of the Applicant Proposed Route.

3.9.6.3.2.1.4.4 Alternative Route 4-D

HVDC Alternative Route 4-D loops to the north of the Applicant Proposed Route by up to approximately 8.25 miles. HVDC Alternative Route 4-D is the same length as the corresponding links of the Applicant Proposed Route (0.02 mile shorter) but it traverses somewhat more rugged terrain across the foothills of the Brush Mountains, part of the Boston Mountains region. Information on file with state and federal agencies shows that fewer archaeological sites have been inventoried in the area of proposed HVDC Alternative Route 4-D as compared to the equivalent corresponding links of the Applicant Proposed Route, and non-substantially more buildings have been inventoried (Table 3.2-25). The alternative alignment intersects the Bell-Drane Route of the Trail of Tears north of Fort Smith-Van Buren, but no inventoried cultural resources are associated with the trail in the vicinity of this intersection. HVDC Alternative Route 4-D includes no NRHP-listed properties. The alternative route is more wooded than the corresponding links of the Applicant Proposed Route (Table 3.9-26).

Given the rough similarity in length between the two routes and the available information, the potential for HVDC Alternative Route 4-D to contain cultural resources is approximately the same or somewhat higher as compared to the corresponding links of the Applicant Proposed Route.

3.9.6.3.2.1.4.5 Alternative Route 4-E

HVDC Alternative Route 4-E parallels to the south the Applicant Proposed Route at a distance of up to approximately 4 miles. HVDC Alternative Route 4-E is shorter (2.01 miles) than the equivalent section of the Applicant Proposed Route. HVDC Alternative 4-E traverses similar terrain to the Applicant Proposed Route with similar land cover (Table 3.9-26), but is situated closer to the Arkansas River. Information on file with state and federal agencies shows that more archaeological sites have been inventoried in the area of proposed HVDC Alternative Route 4-E as compared to the corresponding links of the Applicant Proposed Route and that the two routes contain equal numbers of inventoried historic buildings and structures (Table 3.9-25). HVDC Alternative Route 4-E intersects the Bell-Drane Route of the Trail of Tears in south-central Johnson County, but no inventoried cultural resources are associated with the trail in the vicinity of this intersection.

HVDC Alternative Route 4-E includes two NRHP-listed properties situated 0.5 to 5 mile southeast of Hagarville, Arkansas:

- Lutherville School, Johnson County, Arkansas
- Munger House, Johnson County, Arkansas

HVDC Alternative Route 4-E has the potential to cause adverse visual impacts to these two properties if its construction substantially alters the historic setting of either, as they are situated within approximately 0.05 to 0.09 mile of the ROI centerline. With effective implementation of plans and measures such as those described in Section 3.9.6.1.1, adverse effects to these properties would be resolved through consultation with consulting parties to develop means of avoidance, minimization, or mitigation.

Given the rough similarity in length between the two routes and the available information, the potential for HVDC Alternative Route 4-E to contain cultural resources may be somewhat greater than that of the corresponding links of the Applicant Proposed Route.

3.9.6.3.2.1.5 Region 5

3.9.6.3.2.1.5.1 Alternative Route 5-A

HVDC Alternative Route 5-A parallels the Applicant Proposed Route to the north for up to just 0.7 mile. HVDC Alternative Route 5-A is approximately the same length (longer by 0.35 mile) as the equivalent section of the Applicant Proposed Route and traverses similar terrain. Information on file with state and federal agencies shows a non-substantial difference in the number of inventoried archaeological. Neither contains inventoried historic buildings or structures (Table 3.9-27). HVDC Alternative Route 5-A contains no identified NRHP-listed or -eligible properties. Land cover is very similar (Table 3.9-28).

Given the small difference in length between the two routes and the available information, the potential for HVDC Alternative Route 5-A to contain cultural resources is similar to that of the corresponding link of the Applicant Proposed Route.

Table 3.9-27:
Frequency of Previously Inventoried Historic and Cultural Resources Per Linear Mile of HVDC Alternative Route in Region 5

Length/Inventory[1]	Region 5 APR	AR 5-A		AR 5-B		AR 5-C		AR 5-D		AR 5-E		AR 5-F	
		AR	APR Link 1	AR	APR Links 3, 4, 5, 6	AR	APR Links 6, 7	AR	APR Link 9	AR	APR Links 4, 5, 6	AR	APR Links 5, 6

1 The values in the table do not reflect the minor changes that would result from application of route variations and adjustments.
2 Land cover percentages and acreages based on a 200-foot-wide representative ROW and including tensioning work sites, which typically extend outside the transmission line ROW. See Section 3.10 for discussion of source data quality and limitations. Percentages may not sum to 100 due to rounding error.
GIS Data Source: Jin et al. (2013)

3.9.6.3.2.1.5.2 Alternative Route 5-B

HVDC Alternative Route 5-B parallels the Applicant Proposed Route to the south by up to approximately 3.5 miles. HVDC Alternative Route 5-B is longer (by 3.89 miles) than the equivalent section of the Applicant Proposed Route, but it traverses similar terrain with generally comparable land cover (Table 3.9-28). Information on file with state and federal agencies shows that substantially more archaeological sites and historic buildings and structures have been inventoried in the area of proposed HVDC Alternative Route 5-B as compared to the equivalent segment of the Applicant Proposed Route (Table 3.9-27). HVDC Alternative Route 5-B includes two NRHP-listed properties:

- Charlie Hall House, Damascus vicinity, Faulkner County, Arkansas
- New Mount Pisgah School, Letona vicinity, White County, Arkansas

Both properties could be subject to visual impacts from Project construction if it substantially alters their historical setting. The Hall House is less than 500 feet south of the ROI centerline for HVDC Alternative Route 5-B, while the New Mount Pisgah School is approximately 0.29 mile north of the ROI centerline for the alternative. The equivalent corresponding links of the Applicant Proposed Route do not contain NRHP-listed properties. With effective implementation of plans and measures such as those described in Section 3.9.6.1.1, adverse effects to this property would be resolved through consultation with consulting parties to develop means of avoidance, minimization, or mitigation.

The available information appears to indicate that construction-related impacts are more likely to occur from HVDC Alternative Route 5-B than from the corresponding links of the Applicant Proposed Route.

As described in Appendix M and summarized in Section 2.4.2.5, a route adjustment was developed for HVDC Alternative Route 5-B to maintain an end-to-end route with Applicant Proposed Route Links 2 and 3, Variation 1. The route adjustment crosses more agricultural land and less forest land, but the setting is similar overall to the original HVDC Alternative Route 5-B analyzed in the Draft EIS. There are no recorded historic or cultural resources in the ROI for this route adjustment (Appendix M). The route adjustment is illustrated in Exhibit 1 of Appendix M.

3.9.6.3.2.1.5.3 Alternative Route 5-C

HVDC Alternative Route 5-C loops to the northwest of the Applicant Proposed Route for up to approximately 1.9 miles. HVDC Alternative Route 5-A is approximately the same length (shorter by 0.2 mile) as the equivalent section of the Applicant Proposed Route and traverses similar terrain, with similar land cover (Table 3.9-28). Information on file with state and federal agencies shows a non-substantial difference in the number of inventoried archaeological sites and inventoried historic buildings and (Table 3.9-27). In addition, one property in the ROI of HVDC Alternative Route 5-C, located in the vicinity of Letona, Arkansas, is listed on the NRHP:

- Wesley Marsh House, White County, Arkansas

The property is located about 0.34 mile from the centerline of the alternative and could be subject to visual impacts from the construction of the proposed HVDC transmission line, if construction substantially alters the property's historic setting. Given the small difference in length between the two routes and available information, the potential for HVDC Alternative Route 5-C to contain cultural resources is similar to that of the corresponding links of the Applicant Proposed Route.

3.9.6.3.2.1.5.4 Alternative Route 5-D

HVDC Alternative Route 5-D parallels the Applicant Proposed Route to the north at a distance of up to approximately 3 miles. HVDC Alternative Route 5-D is longer (by 1.25 miles) than the corresponding link of the Applicant Proposed Route, but it traverses similar terrain. Information on file with state and federal agencies shows a non-substantial difference in the number of inventoried archaeological sites and inventoried historic buildings and structures (Table 3.9-27). HVDC Alternative Route 5-D contains no identified NRHP-listed or -eligible properties. The alternative route is more wooded than the corresponding links of the Applicant Proposed Route (Table 3.9-28).

Given the small difference in length between the two routes and the available information, the potential for HVDC Alternative Route 5-D to contain cultural resources is similar to that of the corresponding link of the Applicant Proposed Route. However, the somewhat more extensive woodland cover of the alternative route possibly indicates an increased potential for construction-related impacts to archaeological resources.

3.9.6.3.2.1.5.5 Alternative Route 5-E

HVDC Alternative Route 5-E parallels the Applicant Proposed Route to the south at a distance of up to approximately 3.5 miles. HVDC Alternative Route 5-E is longer (by 3.15 miles) than the corresponding links of the Applicant Proposed Route, but it traverses similar terrain, with generally similar land cover (Table 3.9-28). Information on file with state and federal agencies shows a non-substantial difference in the number of inventoried archaeological and inventoried historic buildings and structures (Table 3.9-27). HVDC Alternative Route 5-E contains one NRHP-listed property, located in the vicinity of Letona, Arkansas:

- New Mount Pisgah School, White County, Arkansas

The property, situated 0.29 mile from the centerline of the alternative route's ROI could be subject to visual impacts from the proposed HVDC transmission line, if construction substantially alters its historic setting. The corresponding links of the Applicant Proposed Route ROI also includes this NRHP-listed property. With effective implementation of plans and measures such as those described in Section 3.9.6.1.1, adverse effects to this property would be resolved through consultation with consulting parties to develop means of avoidance, minimization, or mitigation.

Given the small difference in length between the two routes and the available information, the potential for HVDC Alternative Route 5-E to cause construction-related adverse effects to cultural resources appears to be similar or somewhat greater than the potential of the corresponding links of the Applicant Proposed Route.

As described in Appendix M and summarized in Section 2.4.2.5, a route variation was developed for HVDC Alternative Route 5-E in response to comments on the Draft EIS to maintain continuity with Applicant Proposed Route Links 3 and 4, Variation 2. The route adjustment crosses more forest land and less pasture/hay and agricultural land, but the setting is similar overall to the original HVDC Alternative Route 5-E analyzed in the Draft EIS. There are no recorded historic or cultural resources in the ROI for this route adjustment (Appendix M). The route adjustment is illustrated in Exhibit 1 of Appendix M.

3.9.6.3.2.1.5.6 Alternative Route 5-F

HVDC Alternative Route 5-F loops south of the Applicant Proposed Route at a distance of up to approximately 3.5 miles. HVDC Alternative Route 5-F is longer (by 3.6 miles) than the corresponding links of the Applicant Proposed Route, but it traverses similar terrain. Information on file with state and federal agencies shows a non-substantial difference in the number of inventoried archaeological sites and inventoried historic buildings and structures (Table 3.9-27). HVDC Alternative Route 5-E contains one NRHP-listed property, located in the vicinity of Letona, Arkansas:

- New Mount Pisgah School, White County, Arkansas

The property, situated 0.29 mile from the centerline of the alternative route's ROI could be subject to visual impacts from the proposed HVDC transmission line if construction substantially alters its historic setting. With effective implementation of plans and measures such as those described in Section 3.9.6.1.1, adverse effects to this property would be resolved through consultation with consulting parties to develop means of avoidance, minimization, or mitigation. The corresponding links of the Applicant Proposed Route ROI also includes this NRHP-listed property. Comparison of land cover groups suggests that the alternative route traverses a somewhat more open landscape than the corresponding links of the Applicant Proposed Route (Table 3.9-28).

On balance, given the modest differences in length and land cover between the two routes and the available information, the potential for HVDC Alternative Route 5-F to contain cultural resources is likely roughly similar to that of the corresponding links of the Applicant Proposed Route.

3.9.6.3.2.1.6 Region 6

3.9.6.3.2.1.6.1 Alternative Route 6-A

HVDC Alternative Route 6-A parallels the Applicant Proposed Route to the south for up to approximately 2.1 miles. HVDC Alternative Route 6-A is shorter (by 1.48 miles) than the corresponding links of the Applicant Proposed Route, but it traverses similar terrain. Information on file with state and federal agencies shows a non-substantial difference in the number of inventoried archaeological sites and the same number of inventoried historic buildings and structures (Table 3.9-29). Like the Applicant Proposed Route, HVDC Alternative Route 6-A contains no identified NRHP-listed or -eligible properties. Both routes almost entirely traverse cultivated crops (Table 3.9-30).

Given the small difference in length between the two routes and the available information, the potential for HVDC Alternative Route 6-A to contain cultural resources is similar to that of the corresponding links of the Applicant Proposed Route.

As described in Appendix M and summarized in Section 2.4.2.6, a route adjustment was developed for HVDC Alternative Route 6-A to maintain an end-to-end route with Applicant Proposed Route Link 2, Variation 1. The route cuts off the western end of HVDC Alternative Route 6-A, which is taken over by Link 2, Variation 1. The route adjustment is reported to contain one cemetery of unknown age and significance (Appendix M). It is otherwise identical to the original Alternative Route 6-A, so adoption of this route adjustment would not alter the Draft EIS analysis of the alternative. The route adjustment is illustrated in Exhibit 1 of Appendix M.

Table 3.9-29:
Frequency of Previously Inventoried Historic and Cultural Resources Per Linear Mile of HVDC Alternative Route in Region 6

Length/Inventory[1]	Region 6 APR	AR 6-A		AR 6-B		AR 6-C		AR 6-D	
		AR	APR Links 2, 3, 4	AR	APR Link 3	AR	APR Links 6, 7	AR	APR Link 7
Length (miles)	54.36	16.18	17.66	14.11	9.61	23.12	24.80	9.15	8.57

1 The values in the table do not reflect the minor changes that would result from application of route variations and adjustments.
2 Land cover percentages and acreages based on a 200-foot-wide representative ROW and including tensioning work sites, which typically extend outside the transmission line ROW. See Section 3.10 for discussion of source data quality and limitations. Percentages may not sum to 100 due to rounding error.

GIS Data Source: Jin et al. (2013)

3.9.6.3.2.1.6.2 Alternative Route 6-B

HVDC Alternative Route 6-B loops north up to approximately 3.5 miles from the Applicant Proposed Route. HVDC Alternative Route 6-B is longer (by 4.5 miles) than the corresponding link of the Applicant Proposed Route, but it traverses similar terrain. Information on file with state and federal agencies shows a non-substantial difference in the number of inventoried archaeological sites and inventoried historic buildings and structures (Table 3.9-29). Neither contains identified NRHP-listed or -eligible properties. Both routes almost entirely traverse cultivated crops (Table 3.9-30).

Given the small difference in length between the two routes and the available information, the potential for HVDC Alternative Route 6-B to contain cultural resources is similar to that of the corresponding link of the Applicant Proposed Route.

3.9.6.3.2.1.6.3 Alternative Route 6-C

HVDC Alternative Route 6-C parallels the Applicant Proposed Route to the south for up to approximately 2.7 miles. HVDC Alternative Route 6-C is shorter (by 1.68 miles) than the corresponding links of the Applicant Proposed Route, but it traverses similar terrain. Information on file with state and federal agencies shows an identical number of inventoried archaeological sites and inventoried historic buildings and structures for HVDC Alternative Route 6-C as compared to the corresponding links of the Applicant Proposed Route (Table 3.9-29). Neither contains identified NRHP-listed or -eligible properties. HVDC Alternative Route 6-C traverses somewhat more open terrain than the Applicant Proposed Route, of which approximately one-quarter is situated in woodland (Table 3.9-30).

Given the small differences in length and land cover between the two routes, the potential for HVDC Alternative Route 6-C to contain cultural resources is similar or less than the potential of the corresponding links of the Applicant Proposed Route.

3.9.6.3.2.1.6.4 Alternative Route 6-D

HVDC Alternative Route 6-D parallels the Applicant Proposed Route approximately 1 mile to the northwest. HVDC Alternative Route 6-C is approximately the same length (longer by 0.58 mile) than the corresponding link of the Applicant Proposed Route, but it traverses similar terrain. Information on file with state and federal agencies shows a non-substantial difference in the number of inventoried archaeological sites and no inventoried historic buildings or structures (Table 3.9-29). Neither contains identified NRHP-listed or -eligible properties. Both routes almost entirely traverse cultivated crops (Table 3.9-30).

Given the small difference in length between the two routes and the available information, the potential for HVDC Alternative Route 6-D to contain cultural resources is similar to that of the corresponding link of the Applicant Proposed Route.

3.9.6.3.2.1.7 Region 7

3.9.6.3.2.1.7.1 Alternative Route 7-A

HVDC Alternative Route 7-A loops north up to approximately 10.5 miles from the Applicant Proposed Route and includes a separate crossing of the Mississippi River, approximately 6.75 miles upriver of the Applicant-proposed crossing. HVDC Alternative Route 7-A is longer (by 14.69 miles) than the corresponding link of the Applicant Proposed Route and traverses a greater section of Mississippi bottomland. Available Information shows a non-substantial difference in the number of inventoried archaeological sites and inventoried historic buildings and structures (Table 3.9-31). HVDC Alternative Route 7-A contains two NRHP- listed properties:

- Highway A-7 Bridges Historic District, Marked Tree vicinity, Poinsett County, Arkansas
- Nodena Site, Wilson vicinity, Mississippi County, Arkansas (NRHP/NHL)

Table 3.9-31:
Frequency of Previously Inventoried Historic and Cultural Resources Per Linear Mile of HVDC Alternative Route in Region 7

Length/Inventory[1]	Region 7 APR	AR 7-A		AR 7-B		AR 7-C		AR 7-D	
		AR	APR Link 1	AR	APR Links 3, 4	AR	APR Links 3, 4, 5	AR	APR Links 4, 5
Length (miles)	42.83	43.24	28.55	8.61	8.38	23.83	13.20	6.54	6.39

Historic Properties per Mile[3]	0.93	0.09	0.00	0.00	0.00	1.64	3.03	0.00	6.26

1 The values in the table do not reflect the minor changes that would result from application of route variations and adjustments.
2 ROI for archaeological sites is a 1,000-foot-wide corridor; ROI for aboveground historic properties and historic routes is a 1-mile corridor.
3 Density calculations are based on statewide records available in SHPO and state archaeologist offices.
Source: Clean Line (2013)

HVDC Alternative Route 7-A intersects the Highway A-7 Bridges Historic District and is believed to pass at least 0.1 mile outside the NRHP/NHL boundaries of the Nodena Site. The HVDC transmission line would be visible from both properties. The line would span the Highway A-7 Bridge. Spanning a historic district could alter the landscape setting.

The line would not cross or span the Nodena Site, so although this route would alter the landscape setting, it would not be expected to alter it substantially.

Comparison of land cover groups suggests that the alternative route traverses a somewhat more open landscape than the corresponding link of the Applicant Proposed Route (Table 3.9-32). Based on the available information, HVDC Alternative Route 7-A appears to have an overall higher potential for impacting cultural resources than the corresponding link of the Applicant Proposed Route.

Table 3.9-32:
Region 7 HVDC Transmission Line Alternative Routes—Percentage Comparison of Land Cover Groups for Assessment of Potential Project Effects on Historic and Cultural Resources

Land Cover Group[1, 2]	Region 7 APR	AR 7-A		AR 7-B		AR 7-C		AR 7-D	
		AR	APR Link 1	AR	APR Links 3, 4	AR	APR Links 3, 4, 5	AR	APR Links 4, 5
A (Manipulated Terrain)	73.8%	88.9%	89.1%	49.6%	39.8%	66.3%	42.8%	53.5%	47.6%
B (Open Vegetation Patterns)	10.4%	0.4%	0.0%	32.4%	33.7%	21.9%	30.8%	32.4%	32.5%
C (Closed Vegetation Pattern)	13.7%	9.5%	7.5%	18.0%	26.5%	11.7%	26.4%	14.0%	19.9%

Total Acres	1,221	1,218	779	264	267	691	411	190	200

1 The values in the table do not reflect the minor changes that would result from application of route variations and adjustments.
2 Land cover percentages and acreages based on a 200-foot-wide representative ROW and including tensioning work sites, which typically extend outside the transmission line ROW. See Section 3.10 for discussion of source data quality and limitations. Percentages may not sum to 100 due to rounding error.
GIS Data Source: Jin et al. (2013)

3.9.6.3.2.1.7.2 Alternative Route 7-B

HVDC Alternative Route 7-B parallels the Applicant Proposed Route to the southwest for up to approximately 1.5 miles. HVDC Alternative Route 7-B is approximately the same length (longer by 0.23 mile) as the corresponding links of the Applicant Proposed Route and traverses similar terrain. The Applicant Proposed Route appears to cross more wooded terrain than the alternative (Table 3.9-32). Information on file with state and federal agencies shows an identical number of inventoried archaeological sites and no inventoried historic buildings and structures for the HVDC Alternative Route 7-B as compared to the corresponding links of the Applicant Proposed Route (Table 3.9-31). Neither contains identified NRHP-listed or -eligible properties.

Given the small difference in length between the two routes and the available information, and the potential for HVDC Alternative Route 7-B to contain cultural resources is similar to that of the corresponding links of the Applicant Proposed Route.

3.9.6.3.2.1.7.3 Alternative Route 7-C

HVDC Alternative Route 7-C includes a portion that parallels the Applicant Proposed Route and portion that loops south of the Applicant Proposed Route by up to 4.75 miles. HVDC Alternative Route 7-C is longer (by 10.63 miles) than the corresponding links of the Applicant Proposed Route, but it traverses similar terrain. The Applicant Proposed Route appears to cross more wooded terrain than the alternative (Table 3.9-32). Information on file with state and federal agencies shows that substantially more archaeological sites have been inventoried in the area of proposed

HVDC Alternative Route 7-C as compared to the corresponding links of the Applicant Proposed Route, but that the number of inventoried historic buildings and structures is not substantially different (Table 3.9-31). Neither contains identified NRHP-listed or -eligible properties.

Given the difference in lengths between the two routes and the available information, the potential for HVDC Alternative Route 7-C to contain cultural resources appears to be somewhat greater overall than that of the corresponding links of the Applicant Proposed Route.

3.9.6.3.2.1.7.4 Alternative Route 7-D

HVDC Alternative Route 7-D loops to the north of the Applicant Proposed Route by approximately 2.7 miles. HVDC Alternative Route 7-D is approximately the same length (longer by 0.15 mile) as corresponding links of the Applicant Proposed Route and traverses similar terrain with similar land cover (Table 3.9-32). Information on file with state and federal agencies shows a non-substantial difference in the number of inventoried archaeological sites, but the number of inventoried historic buildings and structures in the Applicant Proposed Route is greater than the number for the alternative route (Table 3.9-31). Neither contains identified NRHP-listed or -eligible properties.

Given the small difference in length between the two routes and the available information, the potential for HVDC Alternative Route 7-D to contain cultural resources may be similar or somewhat less as compared to the estimated moderate potential of the corresponding links of the Applicant Proposed Route.

3.9.6.3.2.2 Operations and Maintenance Impacts

No impacts would result from the operations and maintenance activities on any of the HVDC alternative routes in Regions 1 through 7 (see Section 3.9.6.1.3).

3.9.6.3.2.3 Decommissioning Impacts

No impacts would result from decommissioning (see Section 3.9.6.1.3).

3.9.6.4 Best Management Practices

Additional BMPs are not recommended, because DOE has developed a draft PA (Appendix P) for the planning and construction phases of the Project that provides a protocol for the identification of historic and cultural resources, evaluation of their possible significance and eligibility to the NRHP, and assessment and resolution of potential Project effects, including, as appropriate and practicable, impact avoidance, minimization, and mitigation. Under the PA, DOE will require the Applicant to develop and implement plans and activities such as those described in Section 3.9.6.1.1 as needed.

3.9.6.5 Unavoidable Adverse Impacts

The Project has the potential to cause adverse impacts to historic and cultural resources in several ways. Construction could result in the loss of archaeological resources as a result of ground disturbances resulting from excavation and related actions that remove or redistribute soils and the contents of soils. The Project could also result in the loss of historic or culturally significant buildings, structures, sites, objects, or other aboveground features and properties if it is necessary to demolish, remove, or relocate them to allow construction of Project elements such as transmission towers, access roads, work and storage yards, and substations and switching stations at their locations. In addition, the Project has the potential to cause adverse impacts by altering the setting of neighboring historical and cultural resources and those spanned by the Project through the introduction of large, modernistic, visually prominent elements, such as transmission towers, and auditory effects such as noise associated with the transmission of high voltage electrical currents and the passage of wind through transmission wires and towers. Such effects would only be adverse if the setting of the resource substantively contributes to its historical or cultural character or significance. In addition, such adverse effects tend to fall off with the distance separating Project elements from the resource and vary with local terrain and vegetation. Project-specific cultural resource surveys, which will be implemented as part of the Section 106 PA, in conjunction with micrositing, would tend to diminish the number and magnitude of such impacts.

3.9.6.6 Irreversible and Irretrievable Commitment of Resources

Historic and cultural resources are nonrenewable, and adverse direct effects to these resources generally constitutes an irreversible and irretrievable commitment of resources. Any Project-related activity that results in the destruction, significant permanent alteration, removal, or relocation of a historic or cultural resource, such as the excavation of soil at an archeological site or the demolition of a building or structure within the Project ROW is irreversible and irretrievable. Some indirect adverse visual effects, such as the removal of large trees within the Project ROW, can be regarded as essentially irreversible, because they would take hundreds of years or more to be fully restored, while other visual and auditory indirect effects, such as those resulting from the presence of transmission towers and lines, persist throughout the lifespan of the Project, i.e., until Project elements are removed during decommissioning.

3.9.6.7 Relationship between Local Short-term Uses and Long-term Productivity

The impacts associated with short-term use of the environment for cultural resources would likely be minor because DOE has developed a PA that provides a protocol for the identification of historic and cultural resources, evaluation of their possible significance and eligibility to the NRHP, and assessment and resolution of potential Project effects, including, as appropriate and practicable, impact avoidance, minimization, where practicable, and mitigation. As part of the PA, DOE will require the Applicant to develop and implement plans and activities such as those described in Section 3.9.6.1.1 as needed. (The draft PA is included in Appendix P.) Long-term productivity would not be affected by short-term use of the environment for cultural resources because impacts from short-term use are expected to be minor.

3.9.6.8 Impacts from Connected Actions

3.9.6.8.1 Wind Energy Generation

The potential impacts common to all Project components (Section 3.9.6.1.1) and impacts common to construction, operations and maintenance, and decommissioning (Sections 3.9.6.1.2 and 3.9.6.1.3) apply to similar activities during wind energy generation.

The WDZs contain low densities of previously recorded prehistoric period and historic period archaeological sites (Table 3.9-12). The numbers of the previously recorded sites may reflect the lack of systematic archaeological survey within the WDZs and the region rather than the actual numbers and densities of prehistoric and historic period sites that are located within them. Most of the recorded sites have not been evaluated for their potential to be eligible to the NRHP.

Impacts to cultural resources that are potentially eligible to or listed in the NRHP could occur as a result of wind energy generation. The level of potential adverse impacts to cultural resources associated with wind energy generation would depend on the level of archaeological surveys conducted and the associated cultural resources BMPs and mitigation plans implemented by wind energy developers.

3.9.6.8.2 Optima Substation

Impacts to historic and cultural resources from construction of the future Optima Substation would be the same as described in Section 3.9.6.2.1 for the Oklahoma Converter Station and AC Interconnection Siting Areas and the common construction impacts described in Sections 3.9.6.1.1.

3.9.6.8.3 TVA Upgrades

Depending on the locations of the required TVA upgrades, ground-disturbing activities associated with upgrades to existing lines and ground-disturbing activities, tree removal, and installation of transmission structures and conductors associated with construction of the new transmission line could affect archaeological sites, historic properties, and tribal resources. The potential for adverse effects to historic properties from upgrades to already existing TVA transmission lines and substations is low. Although TVA would route the new transmission line to minimize effects on historic properties, the potential for these effects from the construction of the proposed new transmission line is greater. TVA is a signatory to the draft PA developed by DOE (Appendix P). In accordance with Section 106 of the NHPA, TVA would consult with the Tennessee SHPO on the potential effects of the new 500kV transmission line and upgrades to existing facilities. Where avoidance of adverse effects to historic properties is not practicable, TVA would, in accordance with Section 106 of the NHPA, take appropriate measures to resolve the adverse effects.

3.9.6.9 Impacts Associated with the No Action Alternative

Under the No Action Alternative, DOE assumes for analytical purposes that the Project would not be constructed. While the No Action Alternative would result in no effects to cultural resources due to Project construction, operations and maintenance, and decommissioning, it is possible that some of the archaeological sites that may be located within the areas that would be affected by the Project would never be evaluated for their potential to be eligible for the NRHP and that some potentially NRHP-eligible and listed sites would suffer degradation due to ongoing neglect, lack of managed attention, and possibly vandalism.

3.10 Land Use

3.10.1 Regulatory Background

Land use laws and regulations relevant to the resources in the ROI are summarized in Table 3.10-1. Permits that may apply to the Project are discussed in further detail in Appendix C. USDA programs are discussed further in Section 3.2.1.

Table 3.10-1:
Land Use Laws and Regulations Applicable to the Project

Statute/Regulation	Agency	Applicability to the Project
Local		
City and county zoning ordinances, development regulations, and general or comprehensive plans under Arkansas Code Annotated Title 14, "Local Government"; Oklahoma Statutes Title 19, "Counties and County Officers," (Section 863.1, "City and County Planning and Zoning," through Section 863.29, "Exclusive Control by Commission"); Tennessee Statute Title 6, "Cities and Towns, Municipal Government Generally," Chapter 54, "Municipal Powers Generally," and Chapter 58, "Comprehensive Growth Plan"	Local governments (cities and counties) in Arkansas, Oklahoma, and Tennessee	May require permits for development in certain areas and determine setbacks and other requirements to protect the health, welfare, and safety of the general public.
State		
Oklahoma Administrative Code Title 385, Chapter 25	Oklahoma Commissioners of the Land Office	Lease and management of school trust lands in Oklahoma, Surface leases and other permits are designed to maximize income for the public school trust (CLO 2014).
Arkansas Code Annotated 15-20-502	Arkansas Natural Heritage Commission (ANHC)	The ANHC is granted the power to choose lands, waters, and interests to be included in the Natural Area System. The Natural Areas System preserves some of the most ecologically important areas in the state. The ANHC co-manages the Singer Forest Natural Area with the AGFC. Hunting is allowed within the Singer Forest Natural Area (ANHC 2014b). Natural areas are lands specifically managed to preserve and restore natural communities that have become rare (ANHC 2014a).
Amendment 35 to the Arkansas Constitution	Arkansas Game and Fish Commission	Approval from the AGFC would be required for construction of a transmission line through a WMA. The AGFC manages WMAs primarily for hunting (AGFC 2014).

Table 3.10-1:
Land Use Laws and Regulations Applicable to the Project

Statute/Regulation	Agency	Applicability to the Project
Federal		
United States Code Title 33, Navigation and Navigable Waters Sec. 408 (33 USC § 408)	U.S. Army Corps of Engineers (USACE)	May grant permission for the alteration or permanent occupation of public works owned by the USACE.
Multiple-Use Sustained-Yield Act of 1960, as amended (16 USC § 528 et seq.) Ozark-St. Francis National Forests' Revised Land and Resource Management Plan (USFS 2005) 36 CFR Part 251, Subpart B—Special Uses	U.S. Forest Service (USFS)	The USFS manages the National Forests for a variety of public benefits, consistent with the Multiple-Use Sustained-Yield Act and the Ozark-St. Francis National Forests' Revised Land and Resources Management Plan. A Special Use Permit would be required for a transmission line through National Forest land.
The Agricultural Act of 2014 (H.R. 2642; Pub.L. 113–79)	U.S. Department of Agriculture (USDA) Natural Resources Conservation Service	Construction of the Project on land enrolled in Wetland Reserve Program easements may require a compatible use authorization or easement modification (NRCS 2011). Refer to Table 3.2-1 for information on the Conservation Reserve Program easements managed by the USDA Farm Service Agency and Commodity Credit Corporation.
National Wildlife Refuge System Administration Act (16 USC §§ 668dd-668ee) Appropriate Refuge Uses—Policy 603 FW 1 Compatibility—Policy 603 FW 2	U.S. Fish and Wildlife Service	This act allows easements or ROWs for powerlines so long as it is determined the powerline is compatible with the purposes for which an NWR was established. This is a two-step process, first to determine compatibility and second that it is an appropriate refuge use.
25 CFR Part 169	Arkansas Riverbed Authority, Bureau of Indian Affairs	A ROW grant or easement across land managed by the Authority may be issued pursuant to regulations governing transmission line ROWs over Indian lands.

3.10.2 Data Sources

Data from the NLCD (GIS Data Source: Jin et al. 2013) were used for the desktop land use analysis. The NLCD is a 16-class categorization of land cover based on satellite imagery and provides a broad description of land cover types. In addition to the NLCD information, existing datasets for existing infrastructure and airports and aerial imagery supplemented with aerial photointerpretation and field verification were used to determine the various land uses within the ROI. GIS sources include data and maps for ArcGIS (a system for working with maps and geographic information) from Environmental Systems Research Institute, Inc. (ESRI). Ground and aerial reconnaissance by the Applicant and comments received during stakeholder outreach and the DOE scoping process supplemented the desktop information. Structure data layers were created based on ESRI 2012 data (GIS Data Source: ESRI 2013) supplemented with aerial photointerpretation and field verification surveys conducted between 2012 and 2015. Structures were categorized as agricultural, church, commercial, industrial, residential, or school (GIS Data Source: Clean Line 2015a). Conservation easement data were found in the National Conservation Easements Database (GIS Data Source: NCED 2014).

3.10.3 Region of Influence

For land use, the ROI for the Project and connected actions is the same as described Section 3.1.1.

3.10.4 Affected Environment

The majority of land in the ROI is privately owned, although some lands managed by state and federal agencies are found throughout the ROI. Table 3.10-2 summarizes the types of public land ownership by region. The ROI with the largest percentage of public land is HVDC Alternative Route 4-B in Region 4, of which 12 percent is the Ozark National Forest. Figure 3.10-1 in Appendix A shows the public land ownership in the ROI.

Several route variations to the Applicant Proposed Route in Regions 2–7 were developed in response to public comments on the Draft EIS and are described in Appendix M and summarized in Sections 2.4.2.1–2.4.2.7. Comparisons in affected environment between the Applicant Proposed Route and the route variations by Project region, including accompanying HVDC alternative route adjustments, are provided below. The variations are presented graphically in Exhibit 1 of Appendix M.

Table 3.10-2:
Public Land Ownership in the ROI

Route[1, 2]	Ownership	Acres	Percent of ROI
Region 1			
APR	State—Oklahoma School Lands	191	1.4
AR 1-A	State—Oklahoma School Lands	780	5.2
AR 1-B	State—Oklahoma School Lands	221	3.5
AR 1-C	State—Oklahoma School Lands	73	1.1
AR 1-D	State—Oklahoma School Lands	264	6.5
AC Collection System Routes			
E-1	Federal—USACE	558	1.4
	Federal—Optima National Wildlife Refuge (and WMA)	176	0.4
	State—Oklahoma School Lands	1,170	3.0
E-2	State—Oklahoma School Lands	509	1.0
	State—Schultz WMA and State Park	93	.17
	State—Shorb WMA	160	0.3
E-3	State—Oklahoma School Lands	2,005	3.7
	State—Schultz WMA and State Park	2005	3.75
NE-1	State—Oklahoma School Lands	1,963	4.9
NE-2	State—Oklahoma School Lands	1,559	4.4
NW-1	State—Oklahoma School Lands	2,591	3.8
NW-2	State—Oklahoma School Lands	1,835	2.5
SE-1	State—Oklahoma School Lands	193	0.4
	State—Schultz WMA and State Park	93	0.17

Table 3.10-2:
Public Land Ownership in the ROI

Route[1, 2]	Ownership	Acres	Percent of ROI
SE-3	State—Oklahoma School Lands	509	0.8
	State—Schultz WMA and State Park	93	0.14
	State—Shorb WMA	160	0.2

Region 4			
Applicant Proposed Route	Federal—U.S. Forest Service (Ozark National Forest, portion managed as a WMA by AGFC)	88	0.6
	Federal—USACE (Webbers Falls Lock, Dam, and Reservoir)	80	0.5
	Federal—USACE (Ozark Lake WMA, managed by AGFC)	12	0.1
	State—AGFC (Frog Bayou WMA)	25	0.2
AR 4-B	Federal—U.S. Forest Service (Ozark National Forest, some land within the boundary is privately owned, a portion managed as a WMA by AGFC)	562	5.8
Region 5			
Region 5 PR	State—AGFC (Cherokee WMA, privately owned but managed by AGFC for hunting)	379	2.8
Arkansas Converter Station Siting Area	State—AGFC (Cherokee WMA, privately owned but managed by AGFC for hunting)	1,589	7.3
	State—AGFC (Rainey WMA)	485	2.2
Representative AR Interconnect	State—AGFC (Cherokee WMA, privately owned but managed by AGFC for hunting)	81	0.8
	State—AGFC (Rainey WMA)	136	1.4
Region 6			
Applicant Proposed Route	State—Arkansas Game and Fish Commission (Singer Forest Natural Area easement, managed by AGFC but owned by the ANHC)	11	0.2

Table 3.10-2:
Public Land Ownership in the ROI

Route[1, 2]	Ownership	Acres	Percent of ROI
	State—AGFC (St. Francis Sunken Lands WMA, primarily owned by AGFC but a portion owned by USACE)	10	0.1
Region 7			
	City of Millington, TN (Aycock Park)	—[3]	—[3]

1 The values in the table do not reflect the minor changes that would result from application of the minor route variations and adjustments.
2 Only regions and alternatives with public land are included in the table.
3 No electronic data were available for the municipally owned Aycock Park in Region 7.
GIS Data Sources: USFWS (2014a), USFS (2014a, 2014b), AHDT (2006c), OSU (2003), TPWD (2012), TWRA (2007)

This section summarizes the existing land uses in the ROI. Land cover is discussed, followed by a qualitative description of the primary land uses found in the ROI including agriculture, transportation/utility, airports, commercial, industrial, public land and easements, parks and recreational/natural areas, residential, tribal land, and planned development. Figure 3.10-2 in Appendix A illustrates the structures and infrastructure in the ROI.

Table 3.10-3 summarizes the percentage of each USGS 2011 NLCD classification within the ROI (GIS Data Source: Jin et al. 2013). Multiple land uses can occur within each land cover type. Grassland/herbaceous is the dominant land cover, constituting almost half of the ROI. Cultivated crops account for approximately 26.9 percent of land cover in the ROI (Table 3.10-2). Figure 3.10-3 in Appendix A illustrates the land cover in the ROI.

Table 3.10-3:
Land Cover in the ROI

Land Cover[1]	Acres	Percent
Barren Land (Rock/Sand/Clay)	549.4	0.1
Cultivated Crops	174,853.8	26.9
Deciduous Forest	37,227.4	5.7
Developed, High Intensity	42.4	0.0
Developed, Low Intensity	1,471.4	0.2
Developed, Medium Intensity	377.6	0.1
Developed, Open Space	28,951.3	4.4
Emergent Herbaceous Wetlands	545.0	0.1
Evergreen Forest	19,108.6	2.9
Grassland/Herbaceous	314,840.4	48.4
Mixed Forest	5,841.6	0.9
Open Water	1,661.5	0.3
Pasture/Hay	37,988.8	5.8
Shrub/Scrub	24,213.4	3.7
Woody Wetlands	2,997.4	0.5
Total	650,670.0	100.0

1 The values in the table do not reflect the minor changes that would result from application of the minor route variations and adjustments.
Source: Jin et al. (2013)

3.10.4.1 Agriculture

Agriculture is the predominant land use in the ROI. In Region 1 (including the AC Collection System Routes) and Region 2, rangeland/pasture is the primary type of agriculture, whereas cultivated crops are more prevalent in Regions 6 and 7 (Figure 3.10-3 in Appendix A). Agricultural structures found in the ROI include concentrated animal feeding operations, barns, and silos, which are distributed throughout the ROI. Center-pivot and mechanically irrigated agricultural fields are predominantly located in western and central Oklahoma and northern Texas. Center-pivot agricultural fields are also dispersed throughout eastern Arkansas. Precision-graded, flood-irrigated agricultural fields, such as those used for rice farming, are predominantly located west and east of the Mississippi River in Arkansas and Tennessee. Agriculture is discussed in greater detail in Section 3.2.

3.10.4.2 Transportation/Utility

Existing infrastructure in the ROI includes roadways, airports, heliports, and airstrips, electrical transmission lines, oil and gas pipelines, railroads, and communication towers. Fifty-two airports, heliports, and airstrips are located throughout the ROI (Figure 3.10-2 in Appendix A). Communication towers are illustrated on Figure 3.10-4 in Appendix A. Subsurface utilities, such as electrical distribution lines, water lines, cables, and telephone lines, are also located throughout the ROI. The linear components of the Project would be located parallel to existing infrastructure such as transmission lines, oil and gas pipelines, and roadways to the extent practicable

The ROI crosses reservoirs that are managed by the USACE along the McClellan-Kerr Arkansas River Navigation System, which provides for barge navigation on the Arkansas River and some of its tributaries. The USACE maintains the locks and navigation system of the Robert S. Kerr Lake and Webbers Falls Reservoir in Regions 3 and 4.

3.10.4.3 Commercial

Commercial land uses are scattered throughout the ROI, but they are generally sparse, given the rural character of the majority of the ROI. Commercial land uses are generally located at intersection of roadways or along major roadways such as Highway 77 near Stillwater, Oklahoma, in Region 3 and in Millington, Tennessee, in Region 7.

3.10.4.4 Industrial

The primary industrial land use in the ROI is oil and gas development and related industries. Oil and gas wells and their appurtenant facilities are very common throughout the ROI in Regions 4 and 5. Three large aboveground compressor stations associated with oil and gas production and distribution are found in the ROI: within the Applicant Proposed Route in Region 5; within the HVDC Alternative Route 1-B in Region 2, and within HVDC Alternative Route 5-B in Region 5. Additionally, there is a large oil storage facility south of Cushing, Oklahoma, crossed by the ROI in Region 3.

3.10.4.5 Public Land and Easements

Publicly owned or managed resources in the ROI include the Ozark National Forest, school trust lands (primarily leased for either oil and gas development or agriculture), WMAs, a state natural area, land and a lake owned by Oklahoma State University, and a NWR, and wetland easements held by the NRCS (NRCS 2014). Additionally, the Arkansas River south of Webbers Falls Lock and Dam 16 in Region 4 is managed by the USACE and is located in the Applicant Proposed Route (Figure 3.10-1 in Appendix A). There is a scenic overlook near the lock, and Webbers

Falls Reservoir is publicly accessible for recreational uses such as boating and fishing. These public lands are discussed in further detail by region in Section 3.10.5.

3.10.4.6 Parks and Recreational/Natural Areas

Recreational resources located in the ROI include WMAs, national forest lands, and local parks. There are no federal or state parks in the ROI. Although there are some municipal parks located near the ROI, they are not very common given the rural character of the majority of the ROI.

Recreational areas and uses are described in greater detail in Section 3.12.

3.10.4.7 Residential

The ROI is predominantly rural and the primary type of residence found in the ROI consists of single-family residences on large lots, generally surrounded by agricultural land uses. These residences are widely dispersed throughout the ROI. Higher density residential developments are found in and around cities and towns. The number of residences found within the ROI by region and alternate route is discussed in Section 3.10.5.

3.10.4.8 Community Resources (Schools and Churches)

Given the primarily rural nature of the ROI, schools and churches are the primary type of land use other than residences where people congregate. Two schools are located within the ROI in the AC Collection System Route E-1, which is located within the town of Hardesty, Oklahoma. Nine churches are within the ROI and are discussed by region in Section 3.10.5.

3.10.4.9 Tribal Land

The Arkansas Riverbed Authority manages the tribal interests of two parcels on the west and east bank of the Arkansas River, south of Webbers Falls Lock and Dam 16 in the ROI in Region 3 and Region 4. Any crossings of tribal lands, as defined by 25 CFR 169.1(d), by the HVDC route and its alternatives would be limited to a width of 400 feet (200 feet either side of the centerline) per 25 CFR 169.27(d). Title 25 CFR Part 169 is the regulation governing ROWs over Indian Lands.

3.10.5 Regional Description

This section summarizes NLCD land cover data for each component of the Project by region and discusses land uses in the ROI for each region in more detail.

3.10.5.1 Region 1

Region 1 is referred to as the Oklahoma Panhandle Region and includes the Applicant Proposed Route and HVDC Alternative Routes I-A through I-D as well as the Oklahoma converter station and AC interconnect and AC collection system routes. The predominant land cover in the ROI for all Project components and alternatives is grassland/herbaceous (Table 3.10-4; Figure 3.10-3 in Appendix A). In the 2-mile-wide ROI for the AC collection routes, grassland/herbaceous is also the primary land cover (Table 3.10-5; Figure 3.10-3 in Appendix A).

AC Collection System Routes NE-1 and SE-2 consist primarily of cultivated crops. Approximately 30 percent of AC Collection System Route E-2 consists of cultivated crops; NE-2, NW-2, NW-1, SE-1, SE-3, and W-1 also have substantial percentages of cultivated crops.

Oklahoma school trust lands are present in the ROI (Figure 3.10-1 in Appendix A). The Optima NWR and Optima Lake (managed by USACE) are located in the ROI of AC Collection System Route E-1. The ROI for Region 1 HVDC, would be located adjacent to and south of the Shorb WMA. The ROI for AC Collection System Routes SE-3 and E-2 would cross the Shorb WMA. The Shorb WMA, located southeast of Hardesty, is managed by the ODWC and offers hunting (GIS Data Source: ODWC 2014). The ROIs associated with AC Collection System Routes E-3, SE-1, SE-3, and E-2 would cross the edges of the Schultz WMA and State Park. The Schultz WMA and State Park, located south of Hardesty, is managed by the ODWC and offers hunting (ODWC 2014b). Recreational opportunities are discussed in Section 3.12.

Communities in the ROI include Goodwell and Hardesty, Oklahoma, and Waka, Texas (Figure 3.10-2 in Appendix A). All of these communities are small agricultural towns along major roadways with a central residential area and limited commercial and industrial development.

Existing infrastructure in the ROI includes roadways, railroad tracks, transmission lines, and pipelines. Three public airports are located in the ROI; airports are discussed further in Section 3.16. Within the ROI for the Applicant Proposed Route and the HVDC alternative routes are 122 agricultural structures, 48 industrial structures, 29 residential structures, 21 commercial structures, 4 abandoned structures, 4 other (unknown) structures, and 1 church. The church is in the ROI for HVDC Alternative Route 1-A. Within the ROI for the Oklahoma Converter Station Siting Area and the representative AC interconnect are 4 industrial structures. Within the 13 AC collection routes are 1,662 agricultural structures, 709 industrial structures, 649 residential structures, 49 other (unknown) structures, 42 commercial structures, 7 abandoned structures, 2 schools, and 1 church. The schools and the church are in the ROI for AC Collection Route E-1.

No route variations were proposed in Region 1.

3.10.5.2 Region 2

Region 2 is referred to as the Oklahoma Central Great Plains Region and includes the Applicant Proposed Route and HVDC Alternative Routes 2-A through 2-B. In Region 2, the primary land cover for the Applicant Proposed Route is grassland/herbaceous (Figure 3.10-3 in Appendix A; 49 percent), followed by cultivated crops (33 percent). Approximately 8 percent of the Applicant Proposed Route ROI is evergreen forest, and almost 6 percent is developed open space. The ROI for HVDC Alternative Route 2-A is primarily composed of grassland/herbaceous (59.8 percent), followed by cultivated crops (23.4 percent) and evergreen forest (6.4 percent). In contrast, 59.6 percent of the ROI for HVDC Alternative Route 2-B is composed of cultivated crops (Table 3.10-6).

State-managed lands in the ROI in Region 2 are limited to one parcel of Oklahoma school trust lands in the Applicant Proposed Route and also in HVDC Alternative Route 2-A. Major County WMA is adjacent to the ROI for HVDC Alternative Route 2-A (Figure 3.10-1 in Appendix A).

There are no communities in the Region 2 ROI. Existing infrastructure in the ROI includes roadways, railroad tracks, transmission lines, and pipelines. One private airport is located in the ROI (Figure 3.10-2 in Appendix A); airports are discussed further in Section 3.16. Within the ROI for the Applicant Proposed Route and HVDC alternative routes are 70 industrial structures, 67 agricultural structures, 26 residential structures, and 16 commercial structures.

1 The values in the table do not reflect the minor changes that would result from application of the minor route variations and adjustments.
Source: Jin et al. (2013)

This page intentionally left blank.

Two route variations to the Applicant Proposed Route were developed in Region 2 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.2. The variations are illustrated in Exhibit 1 of Appendix M. These variations represent minor adjustments to the Applicant Proposed Route and the land uses would remain consistent within the ROI. Land use in Link 1, Variation 1, is similar to the original Applicant Proposed Route Link 1, but it would be closer to more residences and structures. Link 2, Variation 2, generally has the same land use (see Exhibit 1 of Appendix M and Figure 3.10-3b in Appendix A).

3.10.5.3 Region 3

Region 3 is referred to as the Oklahoma Cross Timbers Region and includes the Applicant Proposed Route and HVDC Alternative Routes 3-A through 3-E. In Region 3, the land cover in the ROI of the Applicant Proposed Route is more varied than in Regions 1 and 2. It primarily consists of grassland/herbaceous (Figure 3.10-3 in Appendix A; 34.3 percent), deciduous forest (27.2 percent), and pasture/hay (23.4 percent). The land cover in the ROI for HVDC Alternative Routes 3-B and 3-C is similar. In contrast, half of the ROI for HVDC Alternative Route 3-A has grassland/herbaceous land cover, and approximately half of the land cover in the ROI for HVDC Alternative Routes 3-D and 3-E is pasture/hay (Table 3.10-7).

Federal land in the Region 3 ROI is the Webbers Falls Lock, Dam, and Reservoir. Webbers Falls Reservoir is a 10,900-acre lake on the Arkansas River near Gore, Oklahoma (Figure 3.10-1 in Appendix A). The USACE manages the dam and reservoir, which provides recreational opportunities such as boating and fishing. As discussed in Section 3.10.4.8, the Arkansas Riverbed Authority manages the tribal interests of two parcels on the west and east bank of the Arkansas River, south of Webbers Falls Lock and Dam 16. Any crossings of tribal lands, as defined by 25 CFR 169.1(d), by the HVDC route and its alternatives would be limited to a width of 400 feet (200 feet either side of the centerline) per 25 CFR 169.27(d). State lands in the Region 3 ROI include Oklahoma State University Land Utilization Research Area and Lake Carl Blackwell and school trust lands (Figure 3.10-1 in Appendix A).

Dams constructed by the USDA-NRCS are located in and near the ROI along waterways. These dams were constructed primarily for flood prevention, but also provide irrigation and recreational opportunities. Operations and maintenance of these dams is the responsibility of the local sponsor, typically a drainage district in Oklahoma and a levee district in Arkansas.

Near the Cimarron River, the Applicant Proposed Route travels by oil storage tanks near the city of Cushing and the outer limits of the town of Summit (Figure 3.10-2 in Appendix A). HVDC Alternative Route 3-B traverses a rural commercial/industrial area south of Stillwater, Oklahoma. HVDC Alternative Route 3-C is located along the eastern edge of the city of Perkins. The ROI includes primarily commercial and industrial areas on the outskirts of these communities.

Existing infrastructure in the ROI includes roadways, railroad tracks, transmission lines, and pipelines. Four public airports, four private airports, one public heliport, and three private heliports are located in the ROI; airports and heliports are discussed further in Section 3.16. Within the ROI for the Applicant Proposed Route and the HVDC alternative routes are 281 agricultural structures, 257 residential structures, 33 industrial structures, 28 commercial structures, 17 other (unknown) structures, and 9 abandoned structures.

Five route variations to the Applicant Proposed Route were developed in Region 3 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.3. The variations are illustrated in Exhibit 1 of Appendix M. These variations represent minor adjustments to the Applicant Proposed Route and the land uses would remain consistent within the ROI. Link 1, Variation 2, generally has the same land use as the original Applicant Proposed Route Link 1. Links 1 and 2, Variation 1, generally has the same land use as the original Applicant Proposed Route Link 1. It should be noted that a route adjustment was made for HVDC Alternative Route 3-A to maintain an end-to-end route with the Links 1 and 2 variations. Link 4, Variation 1, is generally undeveloped land, whereas the ROI for the Applicant Proposed Route in this location crosses a quarry operation. Link 4, Variation 2, has the same land use as the original Applicant Proposed Route Link 4. Link 5, Variation 2, has generally the same land use as the original Applicant Proposed Route Link 5 (see Exhibit 1 of Appendix M and Figure 3.10-3c in Appendix A).

3.10.5.4 Region 4

Region 4 is referred to as the Arkansas River Valley Region and includes the Applicant Proposed Route and HVDC Alternative Routes 4-A through 4-E as well as the Lee Creek Variation in Link 3. Link 3 crosses Lee Creek Reservoir in Sequoyah County, Oklahoma and Crawford County, Arkansas, at the upstream end of the reservoir in a buffer zone managed by the city of Fort Smith (Figure 3.10-2 in Appendix A). The Lee Creek Variation is a 3.4-mile variation of the Applicant Proposed Route that was created in response to scoping comments from the city of Fort Smith, Arkansas, expressing concern about the proximity of the proposed route to the Lee Creek Dam and Reservoir.

Land cover in the ROI of the Applicant Proposed Route is predominantly pasture/hay (Figure 3.10-3 in Appendix A; 45.8 percent) and deciduous forest (26.2 percent). There is also a higher percentage of evergreen forest (13.4 percent) than in the western portions (Regions 1, 2, and 3) of the Project. The ROI of HVDC Alternative Routes 4-D and 4-E have similar land cover distributions; in contrast, the ROI for HVDC Alternative Routes 4-A and 4-B is predominantly deciduous forest (Table 3.10-8). The Lee Creek Variation is dominated by forest land (92.6 percent of land cover).

Federally managed lands in the ROI include the USACE-managed Webbers Falls Lock, Dam, and Reservoir, the Ozark National Forest, and approximately 38 acres of land enrolled in the WRP. As discussed in Section 3.10.4.8, the Arkansas Riverbed Authority manages the tribal interests of two parcels on the west and east bank of the Arkansas River, south of Webbers Falls Lock and Dam 16. Any crossings of tribal lands, as defined by 25 CFR 169.1(d), by the HVDC route and its alternatives would be limited to a width of 400 feet (200 feet either side of the centerline) per 25 CFR 169.27(d). State lands in the ROI in Region 4 include Ozark Lake WMA and Frog Bayou WMA.

The ROI for HVDC Alternative Route 4-B and a small portion of the ROI for the Applicant Proposed Route cross portions of the Ozark National Forest and Ozark National Forest WMA (Figure 3.10-1 in Appendix A). These portions are owned by both the federal government (as managed by the USFS) and private citizens. The privately held land within the National Forest lies within the boundary of land approved for acquisition by the federal government for incorporation into the Forest. According to the Revised Land and Resource Management Plan for the Ozark and St. Francis National Forests (USFS 2005), the two forests are managed for multiple uses, including recreation, timber, grazing, minerals extraction, and wildlife habitat. The Arkansas Game and Fish Commission (AGFC) manages hunting in the WMA.

This page intentionally left blank.

The ROI does not traverse any communities. Existing infrastructure in the ROI includes roadways, railroad tracks, transmission lines, and pipelines. Two public airports, two private airports, two public heliports, and one private heliport are located in the ROI (Figure 3.10-2 in Appendix A); airports and heliports are discussed further in Section 3.16. USDA dams are present along waterways such as Sallisaw Creek (Figure 3.10-2 in Appendix A). Within the ROI for the HVDC Applicant Proposed Route, the Lee Creek Variation, and the HVDC alternative routes are 460 residential structures, 436 agricultural structures, 11 commercial structures, 8 industrial structures, 7 abandoned structures, 3 other (unknown) structures, and 2 churches. One church is present in the ROI of the Applicant Proposed Route and another is present in the ROI for HVDC Alternative Route 4-D.

Seven route variations to the Applicant Proposed Route were developed in Region 4 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.4. The variations are illustrated in Exhibit 1 of Appendix M. These variations represent minor adjustments to the Applicant Proposed Route and the land uses would remain consistent within the ROI. Link 3, Variation 1, would parallel parcel boundaries but otherwise generally has the same land use as the original Applicant Proposed Route Link 3. Link 3, Variation 2, generally has the same land use as the original Applicant Proposed Route Link 3. Link 3, Variation 3, generally has the same land use as the original Applicant Proposed Route Link 3, but it has 14 more residences and 7 more structures present within the ROI compared to the original Applicant Proposed Route Link 3. Link 6, Variation 1, generally has the same land uses as the original Applicant Proposed Route Link 6, but it would parallel parcel boundaries. Link 6, Variation 2, would avoid a WRP easement but otherwise generally has the same land use as the original Applicant Proposed Route Link 6. Link 6, Variation 3, and Link 9, Variation 1, generally have the same general land use as the original Applicant Proposed Route Links 6 and 9 (see Exhibit 1 of Appendix M and Figure 3.10-3d in Appendix A).

3.10.5.5 Region 5

Region 5 is referred to as the Central Arkansas Region and includes the Applicant Proposed Route and HVDC Alternative Routes 5-A through 5-F. The primary land cover categories in the Applicant Proposed Route in Region 5 is pasture/hay (29.1 percent), deciduous forest (28.9 percent), and evergreen forest (16.0 percent). Mixed forest makes up a much higher percentage of the Applicant Proposed Route in this region than any other at 10.3 percent (Table 3.10-9; Figure 3.10-3 in Appendix A). Evergreen forest is the primary land cover in the ROI of HVDC Alternative Route 5-A, deciduous forest is the primary land cover in the ROI of HVDC Alternative Routes 5-C and 5-D, and pasture/hay is the primary land cover in the ROI of HVDC Alternative Routes 5-B, 5-E, and 5-F. The land cover in the ROI of the Arkansas Converter Station Alternative Siting Area is deciduous forest (32.8 percent), pasture/hay (26.7 percent), evergreen forest (21.9 percent), and mixed forest (10.0 percent). The land cover in the ROI of the Arkansas AC Interconnection Siting Area is primarily pasture/hay (72.2 percent), followed by evergreen forest (11.5 percent) and deciduous forest (6.3 percent). The area where the new substation would be required adjacent to the existing transmission line is primarily grassland with some forest land.

There are no federal lands in the ROI in Region 5. State-managed lands in the ROI in Region 5 include the state-owned Rainey WMA (in the ROI for the Arkansas converter station) and the state-leased Cherokee WMA (Figure 3.10-1 in Appendix A).

No towns or cities with municipal boundaries are located within the ROI. Existing infrastructure in the ROI includes roadways, railroad tracks, transmission lines, and pipelines. Seven private airports are located in the ROI (Figure 3.10-2 in Appendix A); airports are discussed further in Section 3.16. Within the ROI for the Applicant Proposed

Route, the HVDC alternative routes, the Arkansas Converter Station Siting Area, and the associated AC Interconnection Siting Area, there are 241 residential structures, 218 agricultural structures, 56 industrial structures, 19 commercial structures, 7 abandoned structures, 8 other (unknown) structures, and 2 churches. There are no structures in the area for the new substation associated with the AC interconnection. One church is present in the ROI for HVDC Alternative Routes 5-B and 5-E.

Five route variations to the Applicant Proposed Route were developed in Region 5 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.5. The variations are illustrated in Exhibit 1 of Appendix M. These variations represent minor adjustments to the Applicant Proposed Route and the land uses would remain consistent within the ROI. Link 1, Variation 2, has three more residences and seven more structures in the ROI than does the original Applicant Proposed Route Link 1. Link 2, Variation 2, crosses more forest land and less pasture/hay than the ROI for the original Applicant Proposed Route Link 2. Links 2 and 3, Variation 1, has generally the same land use as the original Applicant Proposed Route Links 2 and 3; it should be noted that a route adjustment was made for HVDC Alternative Route 5-B to maintain an end-to-end route with Links 2 and 3, Variation 1. Links 3 and 4, Variation 2, more closely parallels parcel boundaries than does the original Applicant Proposed Route Links 3 and 4; it should be noted that a route adjustment was made for HVDC Alternative Route 5-E to maintain an end-to-end route with this proposed variation. Link 7, Variation 1, generally has the same land use as the original Applicant Proposed Route Link 7 (see Exhibit 1 of Appendix M and Figure 3.10-3e in Appendix A).

3.10.5.6 Region 6

Region 6 is referred to as the Cache River and Crowley's Ridge Region and includes the Applicant Proposed Route and HVDC Alternative Routes 6-A through 6-D. Land cover in the ROI in Region 6 is more uniform and consists primarily of cultivated crops; this land cover category accounts for approximately 78 percent of the Applicant Proposed Route and at least 73 percent of each HVDC alternative route (Figure 3.10-3 in Appendix A; Table 3.10-10). Open water and woody wetlands are also more prevalent than in western portions of the ROI for the Project, at approximately 4 percent and 6 percent, respectively, of the Applicant Proposed Route. Open water and woody wetlands comprise 2 to 5 percent and 4 to 14 percent, respectively, of the HVDC Alternative Routes in Region 6.

A natural/recreational area found in the ROI is the Singer Forest Natural Area easement, within the St. Francis Sunken Lands WMA (Applicant Proposed Route) (Figure 3.10-1 in Appendix A). Singer Forest Natural Area was Arkansas's first natural area and was donated to ANHC by the Singer Company in 1973 (ANHC 2010a). The Singer Forest Natural Area is currently owned by AGFC but co-managed by both agencies. Although hunting is permitting, travel within the natural area is limited to foot traffic (ANHC 2010b). Recreational opportunities are discussed in Section 3.12.

There are no communities that have towns or cities with municipal boundaries located within the ROI. Existing infrastructure in the ROI includes roadways, railroad tracks, transmission lines, and pipelines. One public airport and 16 private airports are located in the ROI (Figure 3.10-2 in Appendix A); airports are discussed further in Section 3.16. Within the ROI for the Applicant Proposed Route and the HVDC alternative routes there are 43 residential structures, 40 agricultural structures, and 1 other (unknown) structure.

Table 3.10-9:
Land Cover in the Region 5 ROI

Land Cover[1]	Applicant Proposed Route		AR 5-A		AR 5-B		AR 5-C		AR 5-D		AR 5-E		AR 5-F		AR Converter Station Siting Area		AR Interconnect

This page intentionally left blank.

One route variation was developed to the Applicant Proposed Route in Region 6 in response to public comments on the Draft EIS. The route variation is described in Appendix M and summarized in Section 2.4.2.6. The variation is illustrated in Exhibit 1 of Appendix M. This variation represents minor adjustments to the Applicant Proposed Route and the land uses would remain consistent within the ROI. Link 2, Variation 1, generally has the same land uses as the ROI for the original Applicant Proposed Route Link 2 (see Exhibit 1 of Appendix M and Figure 3.10-3f in Appendix A). It should be noted that a route adjustment was made for HVDC Alternative Route 6-A to maintain an end-to-end route with Link 2, Variation 1.

3.10.5.7 Region 7

Region 7 is referred to as the Arkansas Mississippi River Delta and Tennessee Region and includes the Applicant Proposed Route and HVDC Alternative Routes 7-A through 7-D, as well as the Tennessee Converter Station Siting Area. Similar to the ROI in Region 6, the primary land cover in the Applicant Proposed Route in Region 7 is cultivated crops, at approximately 69.1 percent (Figure 3.10-3 in Appendix A; Table 3.10-11). Cultivated crops are also the primary land cover in the ROI for the four HVDC alternative routes in Region 7, whereas the primary land covers in the Tennessee Converter Station Siting Area are deciduous forest and pasture/hay. Pasture/hay accounts for at least 15 percent of the ROI for HVDC Alternative Routes 7-B, 7-C, and 7-D and approximately 30.6 percent of the ROI for the Tennessee Converter Station Siting Area.

Public lands in the ROI in Region 7 include city-owned Aycock Park in the city of Millington, Tennessee (Figure 3.10-1 in Appendix A). There are also approximately 17 acres of WRP land in the ROI.

The ROI does not traverse any communities that have towns or cities with municipal boundaries, although the eastern end of the ROI is near residential developments between the town of Atoka and the city of Millington. There is also a commercial area located near South Millington, Tennessee (i.e., Millington Funeral Home) as well as a number of churches near Alternative Route 7-C (Figure 3.10-2 in Appendix A). Existing infrastructure in the ROI includes roadways, railroad tracks, transmission lines, and pipelines. Three public airports and three private airports are located in the ROI; airports are discussed further in Section 3.16. Within the ROI for the Applicant Proposed Route, the HVDC alternative routes, and the Tennessee Converter Station Siting Area are 125 residential structures, 73 agricultural structures, 5 abandoned structures, 4 commercial structures, 4 other (unknown) structures, and 3 churches. One church is present in the ROI for the Applicant Proposed Route and two churches are present in the ROI for the HVDC Alternative Route 7-C.

Three route variations to the Applicant Proposed Route were developed in Region 7 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.7. The variations are illustrated in Exhibit 1 of Appendix M. Link 1, Variation 1; Link 1, Variation 2; and Link 5, Variation 1, all generally have the same land uses as the ROI for the original Applicant Proposed Route Links 1 and 5 (see Exhibit 1 of Appendix M and Figure 3.10-3f in Appendix A).

3.10.5.8 Connected Actions

3.10.5.8.1 Wind Energy Generation

Land cover in the WDZs is primarily cultivated crops and grassland/herbaceous. The land cover in each WDZ is listed in Table 3.10-12.

This page intentionally left blank

Existing land uses in the WDZs includes agriculture (irrigated and dry crops, feedlots), residences, recreation (municipal parks, hunting areas), wind energy, and oil/gas development. Existing infrastructure includes roadways, railroads, airports, and transmission lines.

State land in the WDZs includes Optima WMA, Schultz WMA, and Oklahoma school trust lands. No federal or tribal lands were identified within the WDZs.

Structures in the WDZs includes residences, agricultural structures such as barns and silos, businesses, oil/gas wells and associated infrastructure, hospitals, churches, and schools, and airports. Residences, businesses, hospitals, and schools are typically concentrated in or near cities and towns. Rural residences are scattered on large parcels of land and generally surrounded by agricultural land uses.

3.10.5.8.1.1 WDZ-A

The land cover in WDZ-A is 60.3 percent cultivated crops, 26.1 percent grassland/herbaceous, 8.3 percent shrub/scrub, and less than 4 percent of all other categories.

Portions of the city of Perryton are within the WDZ, including recreational uses such as Leatherman Park, Murphy Park, Whigham Park, Stark Park, and Whippo Park (all city parks). No state or federal lands are located in the WDZ. Existing uses in the WDZ includes transmission lines north of Perryton and center-pivot irrigation scattered throughout the WDZ. Perryton-Ochiltree County Airport is partially within the WDZ along the eastern border.

3.10.5.8.1.2 WDZ-B

The land cover in WDZ-B is 53.2 percent cultivated crops, 37.8 percent grassland/herbaceous, and less than 5 percent of all other categories.

There are no municipalities or state or federal lands. Recreational uses include Miller’s Lake Public Hunting Area in the central portion of the WDZ. Central-pivot irrigation is found throughout the WDZ. One transmission line crosses the WDZ, and an operating wind energy facility is adjacent to it. Another wind energy facility is present in the northern portion of the WDZ.

3.10.5.8.1.3 WDZ-C

The land cover in WDZ-C is 52.8 percent grassland/herbaceous, 38.8 percent cultivated crops, and less than 5 percent of all other categories.

No municipalities or state or federal lands are present.

Center-pivot irrigation is found throughout the WDZ and a concentrated animal feeding operation is located in the western portion of the WDZ southeast of Stratford, Texas. Transmission lines cross the WDZ. One existing wind energy facility is present in the northeast portion of the WDZ.

3.10.5.8.1.4 WDZ-D

The land cover in WDZ-D is 69.3 percent grassland/herbaceous, 17.8 percent cultivated crops, 7.3 percent shrub/scrub, and less than 6 percent of all other categories.

The town of Hardesty is in the WDZ. No federal lands are present in the WDZ. State lands compose 4.6 percent of the WDZ, including the 256-acre Optima WMA, the 260-acre Schultz WMA, and 2,643 acres of school trust lands. Transmission lines and center-pivot irrigation are present in the northern and southern portions of the WDZ. Two operating wind energy facilities are present in the southwestern portion of the WDZ.

3.10.5.8.1.5 WDZ-E

The land cover in WDZ-E is 57 percent cultivated crops, 31.9 percent grassland/herbaceous, 6.8 percent developed and open space, and less than 4 percent of all other categories.

No municipalities or federal lands are present in the WDZ. There are 404 acres of school trust lands, comprising less than 1 percent of the WDZ. There is an existing wind energy facility in the southwestern portion of the WDZ. Existing uses include transmission lines, wind turbines, center-pivot irrigation, and a concentrated animal feeding operation.

3.10.5.8.1.6 WDZ-F

The land cover in WDZ-F is 67.0 percent grassland/herbaceous, 25.4 percent cultivated crops, and less than 5 percent all other categories.

No federal lands are present in the WDZ. There are 7,263 acres of school trust lands, comprising 6.5 percent of the WDZ. The city of Texhoma and the town of Goodwell are within the WDZ. Center-pivot irrigation is found throughout the WDZ. An existing wind energy facility is present in the southern portion of the WDZ. Existing infrastructure includes transmission lines and a railroad. Texhoma Municipal Airport is located in the southwest corner of the WDZ.

3.10.5.8.1.7 WDZ-G

The land cover in WDZ-G is 53.0 percent grassland/herbaceous, 40.5 percent cultivated crops, and less than 5 percent of all other categories.

No municipalities or federal lands are present in the WDZ. There are 4,886 acres of school trust lands, comprising 2.6 percent of the WDZ. A few parcels with central-pivot irrigation are present in the northern portion of the WDZ. Existing infrastructure includes transmission lines and a railroad.

3.10.5.8.1.8 WDZ-H

The land cover in WDZ-H is 81.5 percent grassland/herbaceous, 12.9 percent cultivated crops, and less than 4 percent of all other categories.

No municipalities or federal lands are present in the WDZ. There are 2,464 acres of school trust lands, or approximately 2 percent of the WDZ. A few parcels have center-pivot irrigation. Existing infrastructure includes a transmission line crossing the central portion of the WDZ.

3.10.5.8.1.9 WDZ-I

The land cover in WDZ-I is 61.1 percent cultivated crops, 23.8 percent grassland/herbaceous, 8.7 percent shrub/scrub, and less than 6 percent of all other categories.

No federal lands are present in the WDZ. There are 975 acres of school trust lands, or approximately 1 percent of the WDZ. The city of Hooker and Hooker Municipal Airport located within the WDZ. Center-pivot irrigation is found primarily in the central portion of the WDZ. Concentrated animal feeding operations are also found in the WDZ. Existing infrastructure includes transmission lines, center-pivot irrigation, and a railroad.

3.10.5.8.1.10 WDZ-J

The land cover in WDZ-J is 73.6 percent grassland/herbaceous, 12.9 percent cultivated crops, 8.7 percent shrub/scrub, and less than 5 percent of all other categories.

No federal lands are present in the WDZ. There are 2,612 acres of school trust lands, or 2.8 percent of the WDZ. Transmission lines cross the WDZ. Center-pivot irrigation structures are present in the central portion of the WDZ. Active oil/gas development is ongoing.

3.10.5.8.1.11 WDZ-K

The land cover in WDZ-K is 46.5 percent cultivated crops, 42.2 percent grassland/herbaceous, 6.5 percent shrub/scrub, and less than 5 percent of all other categories.

No federal lands are present in the WDZ. There are 963 acres of school trust lands, or approximately 1 percent of the WDZ. Existing infrastructure includes transmission lines and some scattered center-pivot irrigation.

3.10.5.8.1.12 WDZ-L

The land cover in WDZ-L is 55.2 percent cultivated crops, 28.4 percent grassland/herbaceous, 10.7 percent shrub/scrub, and less than 4 percent of all other categories.

No state or federal lands are located in the WDZ. The southern portion of the city of Spearman is located within the WDZ, including Spearman Park. Center-pivot irrigation is found throughout the WDZ.

3.10.5.8.2 Optima Substation

The future Optima substation would be constructed on approximately 160 acres partially within the area identified on Figure 2.1-3 in Appendix A as the AC Interconnection Siting Area. The land cover in the future Optima substation location is primarily grassland herbaceous, with some shrub/scrub and developed open space. No structures or existing infrastructure are located on the 160-acre site, although there are roads and an operating wind farm nearby. Irrigated cultivated crops are also in the vicinity.

3.10.5.8.3 TVA Upgrades

The ROI for the direct assignment facilities (which are included in the Applicant Proposed Project) would occur within the Tennessee Converter Station Siting Area and more specifically within the Shelby Substation. The ROI for the network upgrades, and in particular TVA's future 500kV transmission line, cannot be fully determined at this time. The 500kV transmission line would be constructed in western Tennessee, where cultivated crops and grassland/herbaceous are typically the dominant land covers. Its ROW would occupy about 785 acres, assuming a ROW width of 175 feet. The upgrades to existing facilities would mostly be in western and central Tennessee. Upgrades to existing infrastructure would include upgrading terminal equipment at three existing 500kV substations and six existing 161kV substations, making appropriate upgrades to increase heights on 16 existing 161kV transmission lines to increase line ratings, and replacing the conductors on eight existing 161kV transmission lines.

Where possible, general impacts associated with the required TVA upgrades are discussed in the impact sections that follow.

3.10.6 Impacts to Land Use

Comments regarding land use received during the scoping period indicate that the public is concerned about impacts to oil and gas drilling activities and the restrictions the Project would place on future land use and development. The public also expressed concern about impacts to conservation efforts and agreements as well as impacts to public lands.

3.10.6.1 Methodology

To identify potential impacts that may result from construction and operations and maintenance of the Project, the analysis of the HVDC transmission line route alternatives, the Oklahoma and Arkansas AC interconnect lines, and the AC collection system routes in Oklahoma was based on a desktop review of existing land uses within a representative 200-foot-wide ROW (100 feet on either side of a representative centerline). The analysis for other elements of the Project, such as the Oklahoma and Tennessee converter stations, was based on a desktop review of the footprint of the layout dated February 2014 and subsequent revisions provided by the Applicant in their revised Project Description (Appendix F). Quantitative data regarding the resources directly intersected by the 200-foot-wide representative ROW were used to analyze the likely effects of the Project on land use in the context of the EPMs that would be included as part of the Project. Land cover, jurisdictional areas, and structures within the representative ROW were identified through GIS analysis[1]. In the impacts discussion, the number and type of structures within the representative ROW are listed for informational purposes and for comparisons between Project alternatives, although it is likely that the displacement of structures would be avoided in the final engineering and design of the Project. Existing transmission lines, pipelines, and roadways within 50 feet of the representative ROW were also identified through GIS analysis.

Tensioning or pulling sites outside the ROW have been identified, and the land cover and structures within them were identified by GIS analysis. Because the location of other temporary construction areas, such as the 45 multi-use construction yards (approximately 25 acres each) and fly yards, as well as the access roads, have not yet been determined, these impacts were evaluated in a general quantitative way.

With regard to access roads associated with the converter stations, although exact locations have not yet been determined, to quantify impacts, it was assumed each converter station would have an access road 20 feet wide by up to 1 mile long (2.4 acres), with temporary disturbance up to 35 feet wide (1.8 acres temporary, 4.2 acres total).

Most construction impacts would be short term, while the visual impact of the installed transmission structures would be long term until the Project is decommissioned. Cumulative impacts are addressed in Section 4.3.10.

The Applicant has developed a comprehensive list of EPMs that will be implemented with the Project to avoid and minimize impacts to existing land use. Implementation of these EPMs is assumed throughout the impact analysis that follows for both the Applicant Proposed Project and the DOE Alternatives. A complete list of EPMs for the Project is

---

[1] The analysis is based on GIS information available at the time of the analysis in September 2014 and subsequent revisions provided by the Applicant in their revised Project Description (Appendix F).

provided in Appendix F; those EPMs that would specifically avoid or minimize impacts to existing land use are listed below:

- GE-7: Roads not otherwise needed for maintenance and operations will be restored to preconstruction conditions. Restoration practices may include decompacting, recontouring, and re-seeding. Roads needed for maintenance and operations will be retained.
- GE-8: Access controls (e.g., cattle guards, fences, gates) will be installed, maintained, repaired, replaced, or restored as required by regulation, road authority, or as agreed to by landowner.
- GE-9: Clean Line will avoid and/or minimize damage to drainage features and other improvements such as ditches, culverts, levees, tiles, and terraces; however, if these features or improvements are inadvertently damaged, they will be repaired and or restored.
- GE-10: Clean Line will work with landowners to repair damage caused by construction, operation, or maintenance activities of the Project. Repairs will take place in a timely manner, weather and landowner permitting.
- GE-11: Clean Line will conduct construction, operation, and maintenance activities to minimize the creation of dust. This may include measures such as limitations on equipment, speed, and/or travel routes utilized. Water, dust palliative, gravel, combinations of these, or similar control measures may be used. Clean Line will implement measures to minimize the transfer of mud onto public roads.
- GE-20: Clean Line will conduct construction and scheduled maintenance activities on the facilities during daylight hours, except in rare circumstances that may include, for example, to address emergency or unsafe situations, to avoid adverse environmental effects, to minimize traffic disruptions, or to comply with regulatory or permit requirements.
- GE-23: Clean Line will maximize the distance between stationary equipment and sensitive noise receptors consistent with engineering design criteria.
- GE-24: Clean Line will minimize the number and distance of travel routes for construction equipment near sensitive noise receptors.
- GE-27: Clean Line will minimize compaction of soils and rutting through appropriate use of construction equipment (e.g., low ground pressure equipment and temporary equipment mats).
- GE-29: Clean Line will work with landowners and operators of active oil and gas wells, utilities, and other infrastructure to identify and verify the location of facilities and to minimize adverse impacts. Identification may include use of the One Call system (a database that is used to locate underground facilities) and surveying of existing facilities.
- LU-1: Clean Line will work with landowners and operators to ensure that access is maintained as needed to existing operations (e.g., to oil/gas wells, private lands, agricultural areas, pastures, hunting leases).
- LU-2: Clean Line will minimize the frequency and duration of road closures.
- LU-3: Clean Line will work with landowners to avoid and minimize impacts to residential landscaping.
- LU-4: Clean Line will coordinate with landowners to site access roads and temporary construction areas to avoid and/or minimize impacts to existing operations and structures.
- LU-5: Clean Line will make reasonable efforts, consistent with design criteria, to accommodate requests from individual landowners to adjust the siting of the ROW on their properties. These adjustments may include consideration of routes along or parallel to existing divisions of land (e.g., agricultural fields and parcel boundaries) and existing compatible linear infrastructure (e.g., roads, transmission lines, and pipelines), with the intent of reducing the impact of the ROW on private properties.

3.10.6.2 Impacts Associated with the Applicant Proposed Project

This section describes the potential impacts from the Project that would be common to the converter stations, AC interconnection, AC collection system, and Applicant Proposed Route. Impacts from the construction, operations and maintenance, and decommissioning of the Project are discussed separately by Project component.

3.10.6.2.1 Converter Stations and AC Interconnection Siting Areas

This section describes the impacts from the converter stations on either end of the HVDC transmission line and their associated AC interconnection lines.

3.10.6.2.1.1 Construction Impacts

Direct land use impacts during construction would consist of the long-term conversion of land for the converter station and temporary conversion of land within the ROW for the AC interconnection lines. Potential indirect temporary impacts on residences, businesses, schools, and other areas near the construction area would include noise, dust, transportation, health and safety, and visual impacts; all of these are discussed in Sections 3.11, 3.3, 3.16, 3.8, and 3.18, respectively. Utilities such as oil and gas pipelines, water lines, and electrical distribution lines in and near the ROW may be affected for a limited time during construction at a particular location. Construction of a single converter station is estimated to take 32 months.

3.10.6.2.1.1.1 Oklahoma Converter Station Siting Area and AC Interconnection Siting Area

The Oklahoma converter station would be located on undeveloped rangeland; approximately 95 percent of the land cover in the siting area is grassland/herbaceous (Figure 3.10-3 in Appendix A). Construction of this converter station would convert 45 to 60 acres of rangeland to a utility land use. During construction, an additional 5 to 10 acres would be used as laydown areas for equipment. An additional 4.2 acres of rangeland would be converted to access roads (2.4 acres permanent, 1.8 acres temporary).

The Oklahoma AC interconnection would be approximately 3 miles long and would temporarily convert approximately 65.5 acres of primarily undeveloped rangeland to an industrial use. Approximately 0.3 mile, or 12 percent of the route, would be parallel to existing transmission lines (within 50 feet) in an existing ROW and less than 0.1 mile (1.2 percent) of the route would be parallel to existing roads. The land cover in the representative ROW is currently composed of approximately 58 acres of grassland, 5.4 acres of shrub/scrub, and 1.9 acres of developed, open space.

During construction, assembly areas for the pole structures (either lattice or tubular structures) would be required, as well as wire splicing sites and tensioning or pulling sites. Within the 65.5-acre ROW, an assembly area 150 feet wide by 150 feet long would be required for each structure. Assuming five to seven structures per mile would be required, the assembly areas would require up to 10.7 acres within the ROW. Approximately two wire splicing sites, each 100 feet by 100 feet (0.2 acre), would be used within the ROW during construction. Approximately four tensioning or pulling sites, 150 feet wide by 600 feet long, also would be required within the ROW, although it is estimated that 1 acre of the total would be located outside the ROW (2.0 acres each, minus 1 acre, for a total of 7 acres).

Tensioning or pulling sites would be located partially outside the ROW at locations where the line turns more than 8 degrees, estimated at 1 acre.

Approximately 74 acres would be required for the Oklahoma converter station (including access road) and approximately 19 acres would be required for the Oklahoma AC interconnection during construction.

3.10.6.2.1.1.2 Tennessee Converter Station Siting Area and AC Interconnection Tie

The land cover in the Tennessee Converter Station Siting Area is approximately 33 percent deciduous forest, 31 percent pasture/hay, 20 percent cultivated crops, and 12 percent woody wetlands. No existing structures are known to occur. Although the exact location within the 218-acre siting area has not yet been determined, construction of this converter station would convert 45 to 60 acres of currently undeveloped land to a utility land use. During construction, an additional 5 to 10 acres would be required. An additional 4.2 acres of rangeland would be converted to access roads (2.4 acres permanent, 1.8 acres temporary).

Approximately 74 acres would be required for the Tennessee converter station (including access road) during construction; it is anticipated that any temporary construction areas would be contained within the footprint of the Tennessee converter station and the Shelby Substation.

3.10.6.2.1.2 Operations and Maintenance Impacts

Operation and maintenance would result in direct long-term impacts to the land crossed by the ROW because of the vegetation that would be allowed to grow and structures and uses that would be permitted. The presence of the converter stations would remove certain areas from other uses until decommissioning and transmission line structures may interfere with other uses in the ROW, such as farming equipment.

As noted in Section 2.1.5.1, limitations on land uses would be described in individual landowner easement agreements and would be based on site-specific conditions and/or coordination with landowners. Land uses that generally may not be permitted in the ROW include constructing buildings or structures, changing the grading and land contours such that the ground surface elevation within the ROW would change and alter the required electrical clearance, and installing fences or irrigation lines without coordination with the Applicant. Access would be restricted during the performance of maintenance activities.

Maintenance for an individual alternative or Project component would be similar to construction impacts, except maintenance would require shorter work duration and would be at a smaller scale. Maintenance would typically occur on an annual basis and as needed.

Because the locations of access roads to the converter stations are not known at this time, it is possible that the access roads could be located in such a way that small areas of agricultural land would be isolated and no longer practicable to be used for farmland or grazing.

3.10.6.2.1.2.1 Oklahoma Converter Station Siting Area and AC Interconnection Siting Area

Once construction has been completed, only the 45- to 60-acre converter station and 20-foot-wide paved access road totaling 2.4 acres would remain; all other temporary construction areas would be returned to their previous use, primarily rangeland. Approximately 45 acres would be fenced for the Oklahoma converter station.

Within the 3-mile-long Oklahoma AC interconnect ROW, only the pole structures would remain. For lattice structures, the operational footprint would be 5 to 7 structures per mile, or 15 to 21 structures total, each 28 feet by 28 feet (less than 0.1 acre), up to 0.4 acre total. For tubular structures, the operational footprint would be 5 to 7 structures per mile, or 15 to 21 structures total, each 7 feet by 7 feet (less than 0.1 acre), and less than 0.1 acre total. For both lattice and tubular structures, each structure would be 75 to 180 feet tall. All other land in the ROW could return to previous land uses, primarily grazing. Access roads that are not needed for operations and maintenance of the Project would be restored.

3.10.6.2.1.2.2 Tennessee Converter Station Siting Area and AC Interconnection Tie

Once construction has been completed, only the 45- to 60-acre converter station, the AC interconnect facilities, and 20-foot-wide paved access road totaling 2.4 acres would remain; all other temporary construction areas would be returned to their previous use, primarily cultivated crops and pasture/hay. The interconnection facilities are anticipated to be contained within the existing Shelby Substation and the Tennessee converter station. Approximately 45 acres would be fenced for the Tennessee converter station.

3.10.6.2.1.3 Decommissioning Impacts

Potential impacts during decommissioning of the Project would be similar to those of the construction phase for all Project components. Once decommissioning has been completed, all land could return to the preconstruction land uses described in Section 3.10.4 and Section 3.10.5.

3.10.6.2.2 AC Collection System

This section discusses the impacts from the AC collection system. The Applicant Proposed Project would include four to six AC collection lines of up to 345kV from the Oklahoma converter station to points in the Oklahoma and Texas panhandles.

3.10.6.2.2.1 Construction Impacts

The AC collection system would consist of four to six 345kV lines, each extending up to 40 miles from the Oklahoma converter station. Within the 150–200-foot-wide ROW for each transmission line, an assembly area for the pole structures (whether lattice, tubular, or H-frame, the assembly area footprint is the same) would be required. Each assembly area would be 150 feet wide by 150 feet long (0.5 acre) and five to seven assembly areas per mile would be required. Assuming 300 miles of AC collection lines, the total acreage of assembly areas would range between 765 and 1,071 acres. Total disturbance from the construction of access roads (inside and outside the ROW) for the AC collection system would be approximately 301 miles, or 669 acres.

Approximately six fiber optic regeneration sites would be required for the AC collection system. Each fiber optic regeneration site would be approximately 100 feet by 100 feet, with a fenced area of approximately 75 feet by 75 feet. The regeneration equipment would be enclosed in a small control building made of either metal or concrete, approximately 12 feet by 32 feet by 9 feet tall. An access road and power supply to the site would be required, but the same road would be used to access the transmission line, so those access road impacts are included in the impacts for the transmission line. Typically, these sites would be adjacent to or within 750 feet of the ROW. A total of approximately 3 acres of undeveloped land would be converted to a utility use for the six fiber optic regeneration sites anticipated to be required for the entire AC collection system.

Temporary work areas that would be required during construction include wire splicing sites and tensioning or pulling sites. One wire splicing site 100 feet by 100 feet (0.2 acre) would be required every 2 miles; assuming 150 sites, these would total 30 acres. A tensioning or pulling site 150 feet wide by 600 feet long (2 acres) would be required at least every 18,000 feet; assuming a total of 200 sites (400 acres), 64 acres would be located outside the ROW, 336 acres would be located inside the ROW. Additional temporary construction areas that would be required outside the ROW include multi-use construction yards and fly yards. Multi-use construction yards would each be approximately 25 acres in size and would be located approximately 25 miles apart and typically within 10 miles of the ROW. Assuming the AC collection system requires approximately 15 multi-use construction yards, the total footprint would be 375 acres for all 15 yards. Fly yards would each require 10 to 15 acres each and would be located at approximately 5-mile intervals along the ROW and typically within 10 miles of the ROW. Assuming a total of 60 fly yards, 15 of which would be located within multi-use construction yards, 45 fly yards would have a total footprint of 450 to 675 acres. In total, approximately 3,223 acres would be required for the construction of the AC collection system, although construction would only occur in particular construction segments for a limited time.

Potential temporary impacts on residences, businesses, schools, and other areas near the construction area would include noise, dust, transportation, health and safety, and visual impacts; all of these are discussed in Sections 3.11, 3.3, 3.16, 3.8, and 3.18, respectively. Utilities such as oil and gas pipelines, water lines, and electrical distribution lines in and near the ROW may be affected for a limited time during construction at a particular location. The majority of the impacts to agriculture would be temporary. Construction would temporarily prevent the use of rangeland and cultivated crops in the ROW. Impacts to agriculture are addressed in greater detail in Section 3.2.

The duration of construction for the complete AC collection system will be approximately 24 months from mobilization to restoration.

The sections below and Table 3.10-13 describe the land cover that would be affected within each alternative. The sections below also describe the structures that would be affected by each alternative. For each route, it is assumed that the entire acreage within the ROW would be temporarily disturbed during construction, although construction would not occur on the entire length of a route at the same time.

3.10.6.2.2.1.1 Route E-1

AC Collection System Route E-1 would disturb approximately 708 acres. The predominant land cover is grassland herbaceous (574.2 acres, or 81.1 percent of the representative ROW). Less than 0.1 mile (0.1 percent) of the representative ROW is parallel to existing transmission lines and less than 0.1 mile (0.1 percent) is parallel to existing roads. One agricultural structure and one industrial structure are present in the representative ROW.

3.10.6.2.2.1.2 Route E-2

AC Collection System Route E-2 would disturb approximately 974 acres. The land cover is primarily grassland/ herbaceous (572.8 acres, or 58.8 percent of the representative ROW) and cultivated crops (298.6 acres, or 30.6 percent of the ROW). Approximately 18 acres (2 percent of the representative ROW) are Oklahoma school trust lands that would be temporarily unavailable for agriculture and oil/gas development. Approximately 0.1 mile (0.3 percent) of the representative ROW is parallel to existing transmission lines and approximately 1.1 miles (2.8 percent) is parallel to existing roads. No structures are present in the representative ROW.

3.10.6.2.2.1.3 Route E-3

AC Collection System Route E-3 would disturb approximately 978 acres. The land cover is primarily grassland/herbaceous (650.3 acres, or 66.5 percent of the representative ROW). Approximately 50 acres (5 percent of the representative ROW) are Oklahoma school lands that would be temporarily unavailable for agriculture and oil/gas development. Less than 0.1 mile (0.2 percent) of the representative ROW is parallel to existing transmission lines and 1.4 miles (3.6 percent) is parallel to existing roads. Two agricultural structures and one residential structure are present in the representative ROW.

3.10.6.2.2.1.4 Route NE-1

AC Collection System Route NE-1 would disturb approximately 730 acres. The land cover is primarily grassland/herbaceous (291.1 acres, or 39.9 percent of the representative ROW) and cultivated crops (247.2 acres, or 33.9 percent of the ROW). Approximately 27 acres (4 percent of the representative ROW) are Oklahoma school lands that would be temporarily unavailable for agriculture and oil/gas development. Approximately 0.2 mile (0.6 percent) of the representative ROW is parallel to existing transmission lines; none of the route is parallel to existing roads. No structures are present in the representative ROW.

3.10.6.2.2.1.5 Route NE-2

AC Collection System Route NE-2 would disturb approximately 637 acres. The land cover is primarily grassland/herbaceous (450.2 acres, or 70.6 percent of the representative ROW). Approximately 25 acres (4 percent of the representative ROW) are Oklahoma school lands that would be temporarily unavailable for agriculture and oil/gas development. Approximately 0.2 mile (0.8 percent) of the representative ROW is parallel to existing transmission lines; none of the route is parallel to existing roads. One residence and one agricultural structure are present in the representative ROW.

3.10.6.2.2.1.6 Route NW-1

AC Collection System Route NW-1 would disturb approximately 1,265 acres. The land cover is primarily grassland/herbaceous (609.5 acres, or 48.2 percent of the representative ROW) and developed, open space (540.2 acres, or 42.7 percent of the ROW). Approximately 71 acres (6 percent of the representative ROW) are Oklahoma school lands that would be temporarily unavailable for agriculture and oil/gas development. Approximately 12 miles (22.8 percent) of the representative ROW is parallel to existing transmission lines; none of the route is parallel to existing roads. One agricultural structure and one industrial structure are present in the representative ROW.

3.10.6.2.2.1.7 Route NW-2

AC Collection System Route NW-2 would disturb is approximately 1,365 acres. The land cover is primarily grassland/herbaceous (629.3 acres, or 46.1 percent of the representative ROW), cultivated crops (410.9 acres, or 30.1 percent of the ROW), and developed, open space (292.0 acres, or 21.4 percent of the ROW). Approximately 25 acres (2 percent of the representative ROW) are Oklahoma school lands that would be temporarily unavailable for agriculture and oil/gas development. Approximately 0.1 mile (0.2 percent) of the representative ROW is parallel to existing transmission lines; none of the route is parallel to existing roads. No structures are present in the representative ROW.

3.10.6.2.2.1.8 Route SE-1

AC Collection System Route SE-1 would disturb is approximately 979 acres. The land cover is primarily grassland/ herbaceous (513.2 acres, or 52.4 percent of the representative ROW) and cultivated crops (340.0 acres, or 34.7 percent of the ROW). Approximately 0.1 mile (0.3 percent) of the representative ROW is parallel to existing transmission lines and 2.7 miles (6.6 percent) is parallel to existing roads. No structures are present in the representative ROW.

3.10.6.2.2.1.9 Route SE-2

AC Collection System Route SE-2 would disturb is approximately 325.4 acres. The land cover is primarily grassland/ herbaceous (169.9 acres, or 52.2 percent of the representative ROW) and cultivated crops (130.6 acres, or 40.1 percent of the ROW). Approximately 0.3 mile (1.9 percent) of the representative ROW is parallel to existing transmission lines and 0.1 mile (0.8 percent) is parallel to existing roads. No structures are present in the representative ROW.

3.10.6.2.2.1.10 Route SE-3

AC Collection System Route SE-1 would disturb approximately 1,194 acres. The land cover is primarily grassland/ herbaceous (565.7 acres, or 47.4 percent of the representative ROW) and cultivated crops (483.9 acres, or 40.5 percent of the ROW). Approximately 18 acres (2 percent of the representative ROW) are Oklahoma school that would be temporarily unavailable for agriculture and oil/gas development. Approximately 0.1 mile (0.2 percent) of the representative ROW is parallel to existing transmission lines and 11.9 miles (24.2 percent) is parallel to existing roads. No structures are present in the ROW.

3.10.6.2.2.1.11 Route SW-1

AC Collection System Route SW-1 would disturb approximately 326 acres. The land cover is almost entirely grassland/herbaceous (312.8 acres, or 96.1 percent of the representative ROW). Approximately 0.2 mile (1.6 percent) of the representative ROW is parallel to existing transmission lines and 0.2 mile (1.2 percent) is parallel to existing roads. No structures are present in the representative ROW.

3.10.6.2.2.1.12 Route SW-2

AC Collection System Route SW-2 would disturb approximately 901 acres. The predominant land cover is grassland/ herbaceous (733.0 acres, or 81.3 percent of the representative ROW). Less than 0.1 mile (0.1 percent) of the representative ROW is parallel to existing transmission lines and 4.2 miles (11.2 percent) is parallel to existing roads. One industrial structure is present in the ROW.

3.10.6.2.2.1.13 Route W-1

AC Collection System Route W-1 would disturb is approximately 508 acres. The predominant land cover is grassland/herbaceous (377.0 acres, or 74.2 percent of the representative ROW). Less than 0.1 mile (0.4 percent) of the representative ROW is parallel to existing transmission lines; none of the route is parallel to existing roads. One agricultural structure and one industrial structure are present in the ROW.

3.10.6.2.2.2 Operations and Maintenance Impacts

Within the AC collection system ROW (four to six ROWs, each extending up to 40 miles from the converter station), the only Project components that would remain during operations and maintenance would be the pole structures, fiber optic regeneration sites, and most access roads.

Because the type of transmission structure that would be used has not yet been determined, the potential disturbance for each type was estimated. For lattice structures, the operational footprint would be five to seven structures per mile, and each would have 28 feet by 28 feet foundation (less than 0.1 acre). Assuming 300 miles of lattice structures at 7 per mile, the operational footprint would be up to 42 acres. For tubular pole structures, the operational footprint would be five to seven structures per mile, each 49 square feet, up to 2.4 acres total. For H-frame structures, the operational footprint would be two poles spaced 25 feet apart, each with a 7 feet x 7 feet footprint. All of the structures would be 75 to 180 feet tall. Impact calculations assumed lattice structures would be used for a conservative estimate of potential impacts.

A total of approximately 3 acres of undeveloped land would be converted to a utility use for the six fiber optic regeneration sites anticipated to be required for the entire AC collection system.

It is anticipated that all existing roads and existing roads with repairs/improvements would be retained for operations and maintenance of the Project. It is estimated that approximately 75 percent of the new overland roads with no improvements and 90 percent of the new overland roads with clearing and new bladed roads would be retained for operations and maintenance access. These roads would be up to 20 feet wide and would total approximately 489 acres. Access roads that are not needed for operations and maintenance would be restored.

All other land in the ROW could return to most previous land uses if they are compatible with operations and maintenance of the Project. As noted in Section 2.1.5.1, limitations on land uses would be described in individual landowner easement agreements that could be modified in the easement based on site-specific conditions and/or coordination with landowners. Some land uses, such as forest land, would not be permitted due to height restrictions for vegetation below the transmission lines. Some uses may be impeded in the ROW, such as using farming equipment near the pole structures or crop-dusting planes that would not be able to approach the transmission lines. Land uses that generally may not be permitted in the ROW include constructing buildings or structures, changing the grading and land contours such that the ground surface elevation within the ROW would change and alter the required electrical clearance, and installing fences or irrigation lines without coordination with the Applicant. In addition, access would be restricted during the performance of maintenance activities. All of the tensioning or pulling areas and other temporary construction areas could return to existing uses once construction has been completed.

Because the locations of access roads to the AC collection system are not known at this time, it is possible that the access roads could be located in such a way that small areas of agricultural land would be isolated and no longer practicable to be used for farmland or grazing.

The long-term impacts by route are summarized in Table 3.10-14 for structures. No permanent impacts are described for access roads, because the location of access roads has not yet been determined.

Table 3.10-14:
Impacts During the Operational Phase of the AC Collection Lines

AC Collection System Route	Length (miles)	Estimated Footprint of Structures (acres)[1]
E-1	29	4.06
E-2	40	5.6
E-3	40	5.6
NE-1	30	4.2
NE-2	26	3.6
NW-1	52	7.3
NW-2	56	7.8
SE-1	40	5.6
SE-2	13	1.8
SE-3	49	6.9
SW-1	13	1.8
SW-2	37	5.2
W-1	21	2.9

1 For a conservative estimate of impacts, the anticipated footprint of structures assumes seven lattice structures per mile; each would have a 28-foot by 28-foot foundation (less than 0.1 acre).

3.10.6.2.2.3 Decommissioning Impacts

Potential impacts during decommissioning of the Project would be similar to those of the construction phase for all Project components. Once the decommissioning has been completed, all land could return to the pre-construction land uses described in Sections 3.10.4 and 3.10.5.

3.10.6.2.3 HVDC Applicant Proposed Route

This section identifies the potential land use impacts of the approximate 720 mile-long transmission facility during the three phases of the Project: construction, operations and maintenance, and decommissioning. Specific EPMs developed to avoid and minimize land use impacts are described in Section 3.10.6.1 and Section 3.10.6.7 and are referenced in the discussion below in parentheses. Changes to impacts related to the route variations and adjustments developed in response to public comments on the Draft EIS are described at the end of applicable sections.

3.10.6.2.3.1 Construction Impacts

Construction would begin with clearing and grading for access roads, pole structure sites and assembly areas, wire splicing sites, and tensioning or pulling sites. These areas would not be available for agricultural use during construction. Within the ROW, trees would need to be removed. Individual transmission structure sites would be cleared. Hand, mechanized, and chemical clearing may be used. For tensioning or pulling sites, clearing would be limited to the removal of larger woody vegetation or dense brush that may interfere with tensioning equipment; grading would also be limited to what is necessary to provide temporary access for tensioning equipment.

Within or adjacent to the ROW for the transmission line, all trees would be removed. In the border zone adjacent to the ROW, some small trees may remain if they would not pose a risk of falling into the conductors.

The ROW would be 200 feet wide by approximately 720 miles. Within the ROW, assembly areas for the pole structures, tensioning or pulling sites, and wire-splicing sites would be required during construction. The lattice structures would require assembly areas 200 feet wide by 200 feet long for each structure, four to six areas per mile. Monopole structure assembly would also require areas 200 feet wide by 200 feet long for each structure, five to seven structures per mile. Guyed structures (structures that are stabilized by tensioned cables) would require an assembly area 200 feet wide by 300 feet long and would be required in limited situations, such as in turns in the line and deadends. Lattice crossing structures would require an assembly area 200 feet wide by 300 feet long and would be required in limited situations (e.g., Mississippi River and Arkansas River crossings). Assuming six lattice structure assembly areas per mile for 720 miles, assembly areas could require up to 3,888 acres. Tensioning or pulling sites inside the ROW would require areas 200 feet wide by 650 feet long, or 3.0 acres for approximately 755 sites, for a total of 2,265 acres, although only 2,035 acres would be located within the ROW. (It is estimated that 230 acres will be outside the ROW.) Each wire-splicing site would require 100 feet wide by 100 feet long (0.2 acre) and would be spaced 1 to 3 miles apart. Assuming a site every 2 miles or 360 sites, the total footprint of wire-splicing sites for the HVDC transmission line would be 72 acres.

Both inside and outside the ROW, roads to access the transmission line and all temporary construction areas during construction would be required. Total disturbance for all access roads for the transmission lines would be approximately 2,230 acres, 79 percent (1,753 acres) of which would be within the ROW and 21 percent (477 acres) of which would be outside the ROW.

Access roads would include existing roads, existing roads with repairs/improvements, and new roads. New roads would include overland roads with no clearing or grading, overland roads with clearing and minor grading, new bladed roads, and new temporary matted or aggregate roads used to access structures or temporary work areas in soft and wet conditions. Paving of roads would be limited to the approach aprons at intersections with existing paved roads, unless otherwise required by local jurisdictional authorities.

Construction would not impact existing roads that do not need any improvements. For existing roads that would require repairs or improvements, the disturbance areas would include a total width of 35 feet, minus the width of the existing road.

Disturbance areas for new roads would be 35 feet wide for most of the Project, but in areas with steep side slopes (greater than 15 percent), the construction disturbance may be up to 50 feet wide. For new overland roads with no vegetation clearing, vehicular traffic would use an area 14-20 feet wide. For overland roads that require vegetation clearing, up to 20 feet wide would be cleared within a total disturbance corridor 35 feet wide.

Also outside the ROW, additional areas for fiber optic regeneration sites, tensioning or pulling sites, multi-use construction yards, and fly yards would be required. Approximately four fiber optic regeneration sites (one site every 180–200 miles) would be required. Each site would be approximately 100 feet wide by 100 feet long (0.2 acre), with a fenced area of approximately 75 feet by 75 feet. The regeneration equipment would be enclosed in a small control building made of either metal or concrete, approximately 12 feet by 32 feet by 9 feet tall. An access road and power supply to the site would be required. Typically, these sites would be adjacent to or within 750 feet of the ROW. A total of 0.8 acre of undeveloped land would be converted to a utility use for the four fiber optic regeneration sites. Tensioning or pulling sites outside the ROW (or partially outside the ROW) would be required where the line turns more than 8 degrees. Approximately 230 acres of tensioning or pulling sites across the HVDC route would be outside the ROW.

Multi-use construction yards would each be approximately 25 acres in size and would be located approximately 25 miles apart and typically within 10 miles of the ROW. Assuming approximately 29 yards, the total footprint would be approximately 725 acres. Fly yards would each require 10 to 15 acres and would be located at approximate 5-mile intervals along the ROW and typically within 10 miles of the ROW. Of a total of 144 fly yards, 29 of which would be located within multi-use construction yards, 115 would have a total footprint of 1,150 to 1,725 acres. All of these areas would be temporary and would be revegetated once the construction phase has been completed.

In total, approximately 10,906 acres would be required during construction of the HVDC line, although construction would only occur in particular construction segments for a limited time.

Potential temporary impacts on residences, businesses, schools, and other areas near the construction area would include noise, dust, transportation, safety issues, and visual impacts; all of these are discussed in Sections 3.11, 3.3, 3.16, 3.8, and 3.18, respectively. Utilities such as oil and gas pipelines, water lines, and electrical distribution lines in and near the ROW may be affected during construction, although identification and verification of the location of these facilities by the Applicant would minimize impacts.

The majority of the impacts to agriculture would be temporary. Construction would prevent the use of rangeland and cultivated crops in the ROW in a specific location and may change the contour of the land and affect irrigation infrastructure. Impacts to agriculture are addressed in greater detail in Section 3.2.

Potential impacts to oil and gas wells would occur in Regions 1, 2, 3, and 5 of the Project. Construction of the Project could conflict with drilling equipment, but would be minimized by coordination with landowners and/or well operators during construction. Impacts to subsurface collection systems and other infrastructure would be minimized by locating these facilities prior to clearing, grading, and foundation excavation activities were conducted for the Project.

The duration of construction is expected to be approximately 36 to 42 months for the entire Project, although the duration of construction for a single HVDC segment is anticipated to be approximately 24 months from mobilization to restoration.

3.10.6.2.3.1.1 Region 1

The Applicant Proposed Route in Region 1 is approximately 115 miles long. Approximately 2 miles (1.4 percent) is parallel to existing transmission lines and 8 miles (7.0 percent) is parallel to existing roads. The land cover in the 200-foot-wide representative ROW for Region 1, listed in Table 3.10-15, is primarily grassland herbaceous (1,742.3 acres or 61.7 percent) and cultivated crops (748.8 acres or 26.5 percent).

Table 3.10-15:
Land Cover in the Applicant Proposed Route—Region 1

Land Cover	Link 1		Link 2		Link 3		Link 4		Link 5		Total Region 1	
	Acres	%	Acres	%	Acres	%	Acres	%	Acres	%	Acres	%

Source: Jin et al. (2013)

Approximately 18 acres of Oklahoma school trust lands is present in Applicant Proposed Route Link 2, 4 acres in Link 4, and 31 acres in Link 5 that would be temporarily unavailable for other uses, totaling 54 acres (2 percent of the representative ROW). One commercial structure and one agricultural structure (in Link 4) are present in the representative ROW.

Outside the ROW, tensioning or pulling areas totaling approximately 100.8 acres would be required during construction and would be unavailable for other uses. The land cover in these areas is primarily grassland/herbaceous land and cultivated crops. Approximately 0.5 acre is school trust lands. No structures are present in these areas.

No route variations were proposed in Region 1.

3.10.6.2.3.1.2 Region 2

The Applicant Proposed Route in Region 2 is approximately 106 miles long. Approximately 1 mile (1.2 percent) is parallel to existing transmission lines and 12 miles (11.7 percent) is parallel to existing roads. The land cover in the 200-foot-wide representative ROW for Region 2 is listed in Table 3.10-16. The land cover in the ROW is primarily grassland herbaceous (1,299.9 acres or 50.3 percent), cultivated crops (788.0 acres or 30.5 percent), evergreen forest (200.0 acres, or 7.7 percent), and developed, open space (218.0 acres or 8.4 percent).

Table 3.10-16:
Land Cover in the Applicant Proposed Route—Region 2

Land Cover[1]	Link 1		Link 2		Link 3		Total	
	Acres	%	Acres	%	Acres	%	Acres	%

1 The values in the table do not reflect the minor changes that would result from application of the minor route variations and adjustments.
Source: Jin et al. (2013)

Approximately 31 acres of Oklahoma school trust lands are present in Applicant Proposed Route Link 1, 55 acres in Link 2, and 12 acres in Link 3 that would be temporarily unavailable for other uses, totaling 97 acres (4 percent of the representative ROW). Two commercial structures (one each in Link 2 and Link 3), two industrial structures (in Link 2), and two agricultural structures (in Link 3) are present in the representative ROW.

Outside the ROW, tensioning or pulling areas totaling approximately 99.0 acres would be required during construction and would be temporarily unavailable for other uses. The predominant land cover types are grassland/herbaceous and cultivated crops. The 3 acres of school trust lands in Applicant Proposed Route Link 1 and 3 acres in Link 3 would be temporarily unavailable for other uses. No structures are present in these areas.

Two route variations to the Applicant Proposed Route were developed in Region 2 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.2. The variations are illustrated in Exhibit 1 of Appendix M. A description of the impacts of the variations compared to the original Applicant Proposed Route follows. Link 1, Variation 1, has similar land use, but would affect approximately 4 more acres of grassland and approximately 4 acres less of forest land, and would be closer to more residences and structures than the original Applicant Proposed Route Link 1. The variation was developed to reduce impacts to cultivated fields and structures. Link 2, Variation 2, would run closer to the quarter-section line that parallels parcel boundaries than the original Applicant Proposed Route Link 2, and approximately 30 acres more grassland and 24 acres less agricultural land would be impacted compared to the original Applicant Proposed Route Link 2. There is one more residence in the representative ROW of Variation 2.

3.10.6.2.3.1.3 Region 3

The Applicant Proposed Route in Region 3 is approximately 162 miles long. Approximately 3 miles (2 percent) is parallel to existing transmission lines and 8.8 miles (5.4 percent) is parallel to existing roads. The land cover in the 200-foot-wide representative ROW for Region 3 is listed in Table 3.10-17. Land cover in Region 3 is more variable than the two westernmost regions (regions 1 and 2); specifically, there are more forested areas. The land cover in the Applicant Proposed Route is grassland/herbaceous (1,339.5 acres or 33.9 percent), deciduous forest (1,098.2 acres or 27.8 percent), and pasture/hay (941.3 acres or 23.9 percent).

Approximately 48 acres of Oklahoma State University land in Applicant Proposed Route Link 1 is currently used as a research area. Eighty-seven acres of school trust land (33 acres in Link 1, 1 acre in Link 2, 26 acres in Link 3, and 27 acres in Link 4) are present in the representative ROW. Approximately 4 acres in Link 6 are part of the Webbers Falls Lock and Dam and Reservoir and managed by Arkansas Riverbed Authority. All of these areas would be temporarily unavailable during construction in this location. Flood control dams constructed by NRCS would be crossed by and adjacent to Link 4. Two residences (one each in Link 2 and Link 5), two industrial structures (one each in Link 1 and Link 4), and five agricultural structures (one in Link 1, one in Link 2, two in Link 4, and one in Link 6) are present in the representative ROW.

Outside the ROW, tensioning or pulling areas totaling approximately 379 acres would be required during construction and would be temporarily unavailable for other uses. The predominant land cover in these areas is grassland/herbaceous. Approximately 1 acre in Applicant Proposed Route Link 1 is Oklahoma State University land used for research. Sixteen acres of school trust lands are present (9 acres in Link 1, less than 0.1 acre in Link 2, 6 acres in Link 3, and 2 acres in Link 4). Approximately 1 acre of Link 6 is part of the Webbers Falls Lock and Dam and Reservoir. All of these areas would be temporarily unavailable for other uses during construction. No existing structures are present in these areas.

Five route variations to the Applicant Proposed Route were developed in Region 3 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.3. The variations are illustrated in Exhibit 1 of Appendix M. A description of the impacts of the variations compared to the original Applicant Proposed Route follows. The representative ROW for Link 1, Variation 2, would cross approximately 6 acres less of cropland, 11 acres more of forested land, and 5 acres more of grassland. This variation would be farther from a residence and reduce impacts to cultivated cropland compared to the original Applicant Proposed Route Link 1. Links 1 and 2, Variation 1, would cross half as many parcels, has approximately 21 acres more grassland, and, while it would no longer have a residence within 100 feet, it would have six additional residences within 250 feet compared to the original Applicant Proposed Route Links 1 and 2. This variation would parallel parcel boundaries; it should be noted that a route adjustment was made for HVDC Alternative Route 3-A to maintain an end-to-end route with this variation. Link 4, Variation 1, would avoid impacts to a quarry operation and crosses approximately 3 acres more grassland and 1 acre more forest land compared to the original Applicant Proposed Route Link 4. The representative ROW for Link 4, Variation 2, would cross approximately 4 acres more forest land than the original Applicant Proposed Route Link 4 but would avoid a residence. Link 5, Variation 2, avoids a residence, parallels more existing infrastructure, and crosses four fewer parcels than the original Applicant Proposed Route Link 5. The representative ROW of this variation would also cross approximately 9 acres more forest land and 8 acres less pasture/hay.

3.10.6.2.3.1.4 Region 4

The Applicant Proposed Route in Region 4 is approximately 126 miles long. Approximately 2 miles (1.4 percent) is parallel to existing transmission lines and 7 miles (5.5 percent) is parallel to existing roads. The land cover in the 200-foot-wide representative ROW for Region 4 is listed in Table 3.10-18. In contrast to the two westernmost regions (Regions 1 and 2), the land cover in Region 4 is dominated by pasture/hay and forest land. The land cover in the representative ROW is 1,436.1 acres (46.6 percent) pasture/hay, 813.7 acres (26.4 percent) deciduous forest, and 404.7 acres (13.1 percent) evergreen forest.

The Lee Creek Variation is 3.4 miles long. None of the route is parallel to existing infrastructure. The land cover in the 200-foot-wide representative ROW is 94.4 percent forest land. Like all forested areas in the ROW, the height of trees would be restricted within the ROW for the life of the Project if this route is selected.

Approximately 17 acres (8 percent of the Applicant Proposed Route Link 1 representative ROW) includes the USACE-managed Webbers Falls Lock and Dam and Reservoir (managed by Arkansas Riverbed Authority) and 2.5 acres (less than 1 percent of the representative ROW) crosses the edge of the USFS-managed Ozark National Forest.

The representative ROW of Link 6 also crosses through an edge of the Frog Bayou WMA and a thin arm of the Ozark Lake WMA, so disturbance to the primary portions of both WMAs are likely to be minimal. Approximately 2 acres cross the Ozark Lake WMA, and 4 acres cross the Frog Bayou WMA. These areas would be temporarily unavailable for other uses such as hunting during construction.

The representative ROW of Link 6 includes two parcels of land enrolled in the WRP totaling approximately 6 acres. Under these easements, most land use rights are transferred to the USDA, and getting approval for development of the Project on these lands may be difficult because the Project may not be viewed as compatible with the protection and restoration of wetlands. Flood control dams constructed by NRCS are adjacent to Link 3.

One residence (in Link 6) and four agricultural structures (one in Link 6, one in Link 7, and two in Link 9) are present in the representative ROW. There is a hunting cabin immediately adjacent to the representative ROW in Link 9.

Outside the ROW, tensioning or pulling areas totaling approximately 483 acres would be required during construction and would be temporarily unavailable for other uses. The predominant land cover in these areas is pasture/hay followed by deciduous forest. Less than 0.1 acre in Applicant Proposed Link 1 is part of Webbers Falls Lock and Dam and Reservoir, and 4 acres in Link 6 are part of Frog Bayou WMA. These areas would be temporarily unavailable for existing uses during construction. Two residences and one agricultural structure are present in these areas.

This page intentionally left blank.

Seven route variations to the Applicant Proposed Route were developed in Region 4 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.4. The variations are illustrated in Exhibit 1 of Appendix M. A description of the impacts of the variations compared to the original Applicant Proposed Route follows. As compared to the original Links 3, 6, and 9 of the Applicant Proposed Route, Link 3, Variation 1, would parallel parcel boundaries and increase the distance from residences and a cemetery. Link 3, Variation 2, would avoid one airstrips, a residence, and a business while increasing the length parallel to existing infrastructure and following existing parcel boundaries. The representative ROW of this variation would cross approximately 34 acres more forest land and 37 fewer acres of pasture/hay land. Link 3 Variation 2 would cross 17 land parcels, 32 percent fewer land parcels than the Applicant Proposed Route which would cross 25 land parcels. Link 3, Variation 2 parallels 4.4 miles of existing parcel lines and infrastructure including transmission lines and roads, which is more than twice that of the Applicant Proposed Route, which parallels existing parcel lines and infrastructure for 1.9 miles. Link 3, Variation 2 would have 1 residence within 500 feet, while the Applicant Proposed Route would have 9 residences within 500 feet. One private airstrip would be impacted by Link 3, Variation 2 while the Applicant Proposed Route would potentially impact two private airstrips. Link 3, Variation 2 was proposed by landowners, deemed technically feasible by Clean Line, and independently reviewed by DOE.

Link 3, Variation 3, would cross 12 fewer parcels and more closely follow parcel boundaries, although there are seven more residences and four more agricultural structures within 500 feet of the representative ROW. The representative ROW of this variation would cross approximately 13 acres more pasture/hay land and 20 acres less forest land. Link 6, Variation 1, would more closely parallel parcel boundaries and increase the distance from residences. Link 6, Variation 2, would avoid a WRP easement and would cross approximately 4 acres more pasture/hay and 3 acres less crop land. Link 6, Variation 3, would increase the length parallel to existing infrastructure, cross two fewer parcels, and increase the distance from a residence in the representative ROW. The representative ROW of this variation crosses approximately 3 acres less pasture/hay land. Link 9, Variation 1, crosses two more parcels, but would increase the distance from a residence and campground while maintaining the length parallel to existing infrastructure. The representative ROW of this variation would cross approximately 3 acres more pasture/hay land and 5 acres less forest land.

3.10.6.2.3.1.5 Region 5

The Applicant Proposed Route in Region 5 is approximately 113 miles long. Approximately 0.3 mile (0.3 percent) is parallel to existing transmission lines and 7 miles (6.2 percent) is parallel to existing roads. The land cover in the 200-foot-wide representative ROW for Region 5 is listed in Table 3.10-19. The land cover in Region 5 is dominated by forest land. The land cover in the representative ROW is approximately 811 acres (29.4 percent) deciduous forest and 773 acres (28.1 percent) pasture/hay.

Approximately 77 acres of the Cherokee WMA are within the representative ROW for the Applicant Proposed Route 52 acres in Link 2 and 25 acres in Link 5 and would temporarily be unavailable for other uses during construction in this location. WMAs are primarily used for recreation, such as hunting (see Section 3.12). Two abandoned structures (one each in Link 4 and Link 5), one residence (in Link 7), one agricultural structure (in Link 2), and one other structure (in Link 6, use unknown) are present in the representative ROW.

Outside the ROW, tensioning or pulling areas totaling approximately 291 acres would be required during construction. The land cover in these areas is primarily pasture/hay and deciduous forest. Approximately 6 acres of the Cherokee WMA is within the tensioning or pulling area for Link 2 and would be temporarily unavailable during construction at this location. No existing structures are present in these areas.

Five route variations to the Applicant Proposed Route were developed in Region 5 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.5. The variations are illustrated in Exhibit 1 of Appendix M. A description of the impacts of the variations compared to the original Applicant Proposed Route follows. As compared to the original Applicant Proposed Route Links 1, 2, 3, 4, and 7, Link 1, Variation 2, would cross four fewer parcels and would increase the distance from a residence. The representative ROW for this variation crosses approximately 5 acres more pasture/hay land and 3 acres less grassland. Link 2, Variation 2, crosses two more parcels, although it would reduce impacts to a commercial forestry operation and would reduce impacts to the Cherokee WMA by crossing it only one time and doing so along a parcel boundary. The representative ROW for Links 2 and 3, Variation 1, crosses approximately 2 acres more pasture/hay. This variation would increase the distance from a newly identified home and reduce the number of landowners affected; it should be noted that a route adjustment was made for HVDC Alternative Route 5-B to maintain an end-to-end route with this variation. Links 3 and 4, Variation 2, crosses 5 fewer parcels and more closely parallels parcel boundaries while avoiding a homestead site and parcels with conservation easements. The representative ROW for this variation would cross approximately 7 acres less forest land and 4 acres less agricultural land. It should be noted that a route adjustment was made for HVDC Alternative Route 5-E to maintain an end-to-end route with this variation. Link 7, Variation 1, would parallel parcel boundaries and existing infrastructure to avoid a newly identified residence. One less parcel would be crossed, and the representative ROW crosses approximately 3 acres more pasture/hay land and 2 acres more forest land.

3.10.6.2.3.1.6 Region 6
