The NWI database documents approximately 2,896 acres of wetlands within this development zone. This total of 2,896 acres of wetlands includes about 1,119 acres of lake shoreline wetlands and another 1,298 acres of farmed wetlands. As shown in Table 3.15-32, WDZ-A encompasses approximately 4.9 miles of perennial streams, 103.4 miles of intermittent streams, and 1,368 acres of reservoirs, lakes, and ponds, of which 97 percent are identified as only intermittent waterbodies. The acreage of reservoirs, lakes, and ponds, although mostly intermittent, is the second highest of any of the WDZs. There are no 100-year or 500-year floodplains mapped in this WDZ.

3.19.5.8.1.2 WDZ-B

The NWI database documents approximately 1,520 acres of wetlands within this development zone. This total includes 770 acres of lake shoreline wetlands and 202 acres of farmed wetlands. WDZ-B is located in the Palo Duro watershed (Table 3.15-31), but Palo Duro Creek, the watershed's primary drainage feature, runs adjacent to the zone's southeast extent, not through it. As shown in Table 3.15-32, WDZ-B encompasses about 8.0 miles of perennial streams, 124.1 miles of intermittent streams, and 976 acres of reservoirs, lakes, and ponds, of which 83 percent are identified as only intermittent waterbodies. There are no 100-year or 500-year floodplains mapped in this WDZ.

3.19.5.8.1.3 WDZ-C

The NWI database documents approximately 812 acres of wetlands within this development zone. Farmed wetlands account for approximately 131 acres of the total 812 acres of wetlands. There are approximately 226 acres of palustrine emergent wetlands in this zone. WDZ-C is located in the Coldwater watershed (Table 3.15-31), and both Frisco Creek and Coldwater Creek, the watershed's primary drainage features, run through portions of the zone. The north-central portion of WDZ-C includes a small segment of Frisco Creek and Coldwater Creek extends the entire length of the zone, running just inside or outside the southern and southeastern periphery. As shown in Table 3.15-32, WDZ-C encompasses about 6.4 miles of perennial streams, 204.4 miles of intermittent streams, and 323 acres of reservoirs, lakes, and ponds, of which 61 percent are identified as only intermittent waterbodies. There are no 100-year or 500-year floodplains mapped in this WDZ.

3.19.5.8.1.4 WDZ-D

The NWI database documents approximately 382 acres of wetlands within this development zone. There are approximately 121 acres of lake shoreline wetlands within the total of 382 total wetland acres. FEMA has mapped two 100-year floodplains totaling approximately 1,991 acres within this development zone. WDZ-D straddles the Middle Beaver, Coldwater, and Palo Duro watersheds (Table 3.15-31), but the watersheds' primary drainage features (i.e., Beaver River and Coldwater, Frisco, and Palo Duro creeks) do not run through the zone. As shown in Table 3.15-32, WDZ-D encompasses about 12.7 miles of perennial streams, 134.9 miles of intermittent streams, and 166 acres of reservoirs, lakes, and ponds, of which 66 percent are identified as only intermittent waterbodies. There are an estimated 1,991 acres of 100-year floodplains and no acreage of 500-year floodplains mapped in WDZ-D.

3.19.5.8.1.5 WDZ-E

The NWI database documents approximately 430 acres of wetlands within this development zone. There are approximately 121 acres of farmed wetlands and 185 acres if palustrine unconsolidated bottom wetlands in the total of 430 acres. WDZ-E is located primarily within the Middle Beaver watershed (Table 3.15-31), but the Beaver River, the watershed's primary drainage feature, is north of the zone and does not run through it. WDZ-E also extends into the Coldwater watershed, but this watershed's primary drainage features also do not run through the zone. As shown in Table 3.15-32, WDZ-E encompasses about 2.6 miles of perennial streams, 43.6 miles of intermittent streams, and 33 acres of reservoirs, lakes, and ponds, of which 24 percent are identified as only intermittent waterbodies. The miles of perennial and intermittent streams are the second lowest of any of the WDZs and the total acreage of reservoirs, lakes, and ponds is the lowest. There are no 100-year or 500-year floodplains mapped in this WDZ.

3.19.5.8.1.6 WDZ-F

The NWI database documents approximately 507 acres of wetlands within this development zone. These resources are somewhat evenly spread between lake shoreline, palustrine emergent, palustrine forested, and palustrine scrub-shrub wetland types. FEMA has mapped three 100-year floodplains totaling approximately 2,800 acres within this development zone. WDZ-F straddles the Middle Beaver and Coldwater watersheds (Table 3.15-31). The northern and western peripheries of WDZ-F extend over short segments of the Beaver River, a primary drainage feature, but the zone does not extend over either of the Coldwater watershed's primary drainage features. As shown in Table 3.15-32, WDZ-F encompasses about 13.0 miles of perennial streams, 207.1 miles of intermittent streams, and 52 acres of reservoirs, lakes, and ponds, of which 54 percent are identified as only intermittent waterbodies. The total acreage of reservoirs, lakes, and ponds is the second lowest of any of the WDZs. There are an estimated 2,800 acres of 100-year floodplains and no acreage of 500-year floodplains in WDZ-F.

3.19.5.8.1.7 WDZ-G

The NWI database documents approximately 776 acres of wetlands within this development zone. There are approximately 287 acres of farmed wetlands and 261 acres of palustrine emergent wetlands in the total of 776 total acres. WDZ-G is located primarily within the Upper Beaver watershed (Table 3.15-31), but the Beaver River, the watershed's primary drainage feature, does not run through the zone. As shown in Table 3.15-32, WDZ-G encompasses about 6.8 miles of perennial streams, 191.7 miles of intermittent streams, and 281 acres of reservoirs, lakes, and ponds, of which 96 percent are identified as only intermittent waterbodies. The 12 acres of perennial reservoirs, lakes, and ponds is the second lowest of any of the WDZs. There are no 100-year or 500-year floodplains mapped in this WDZ.

3.19.5.8.1.8 WDZ-H

The NWI database documents approximately 819 acres of wetlands within this development zone. This total primarily consists of intermittent riverine wetlands (416 acres), palustrine emergent wetlands (121 acres), and lakeshore emergent wetlands (224 acres). WDZ-H is located within the Upper Beaver watershed (Table 3.15-31) and the Beaver River, the watershed's primary drainage feature, runs adjacent to the zone's southeastern periphery, but does not run through it. As shown in Table 3.15-32, WDZ-H encompasses about 19.9 miles of perennial streams, 205.4 miles of intermittent streams, and 211 acres of reservoirs, lakes, and ponds, of which 96 percent are identified as only intermittent waterbodies. The 8 acres of perennial reservoirs, lakes, and ponds is the lowest acreage of this type of perennial waters from any of the WDZs. There are no 100-year or 500-year floodplains mapped in this WDZ.

3.19.5.8.1.9 WDZ-I

The NWI database documents approximately 1,620 acres of wetlands within this development zone. This total is composed primarily of farmed wetlands (318 acres), palustrine emergent wetlands (688 acres), and lakeshore emergent wetlands (400 acres). WDZ-I is located within the Middle Beaver watershed (Table 3.15-31), but the Beaver River, the watershed's primary drainage feature, does not run through the zone. As shown in Table 3.15-32, WDZ-I encompasses about 1.7 miles of perennial streams, 17.5 miles of intermittent streams, and 705 acres of reservoirs, lakes, and ponds, of which 98 percent are identified as only intermittent waterbodies. The miles of perennial and intermittent streams are the lowest of any of the WDZs. There are no 100-year or 500-year floodplains mapped in this WDZ.

3.19.5.8.1.10 WDZ-J

The NWI database documents approximately 759 acres of wetlands within this development zone. There are approximately 454 acres of palustrine emergent wetlands and 169 acres of palustrine scrub-shrub wetlands within the total of 759 acres. WDZ-J is located primarily within the Middle Beaver watershed, with a portion in the Palo Duro watershed, and an edge crossing into the Lower Beaver watershed (Table 3.15-31). The northernmost point of the zone extends over the Beaver River and the southwest extent of the zone reaches Palo Duro Creek, but these are the only points where the two primary drainage features of the watersheds are at or in the zone. As shown in Table 3.15-32, WDZ-J encompasses about 26.2 miles of perennial streams, 285.0 miles of intermittent streams, and 164 acres of reservoirs, lakes, and ponds, of which 25 percent are identified as only intermittent waterbodies. The miles of perennial streams are the second highest of any of the WDZs and the miles of intermittent streams are the highest. There are no 100-year or 500-year floodplains mapped in this WDZ.

3.19.5.8.1.11 WDZ-K

The NWI database documents approximately 736 acres of wetlands within this development zone. The wetlands within this development zone include 326 acres of farmed wetlands and 251 acres of lake shoreline wetlands. WDZ-K is located primarily within the Lower Beaver watershed, with a small amount of the southwestern periphery extending into the Middle Beaver watershed (Table 3.15-31). The Beaver River, the primary drainage feature for both watersheds, does not run through the zone. As shown in Table 3.15-32, WDZ-K encompasses about 6.3 miles of perennial streams, 220.2 miles of intermittent streams, and 487 acres of reservoirs, lakes, and ponds, of which 88 percent are identified as only intermittent waterbodies. The miles of intermittent streams are the second highest of any of the WDZs. There are no 100-year or 500-year floodplains mapped in this WDZ.

3.19.5.8.1.12 WDZ-L

The NWI database documents approximately 5,214 acres of wetlands within this development zone. This total of approximately 5,200 acres of wetlands includes about 3,135 acres of lake shoreline wetlands, and another 711 acres of farmed wetlands. WDZ-L is located primarily within the Upper Wolf watershed, with a small amount of the western periphery extending into the Palo Duro watershed (Table 3.15-31). Wolf Creek, the primary drainage feature of the Upper Wolf watershed, runs through the northeastern portion of the zone; Palo Duro Creek, the primary drainage feature of the other watershed does not run through the zone. As shown in Table 3.15-32, WDZ-L encompasses about 31.6 miles of perennial streams, 190.6 miles of intermittent streams, and 3,868 acres of reservoirs, lakes, and ponds, of which 83 percent are identified as only intermittent waterbodies. The miles of perennial streams are the highest of any of the WDZs. The acreage of both perennial and intermittent reservoirs, lakes, and ponds are also the highest of any of the WDZs; however, WDZ-L has the largest land area of any of the zones. There are no 100-year or 500-year floodplains mapped in this WDZ.

3.19.5.8.2 Optima Substation

The land cover in the future Optima Substation location is primarily grassland herbaceous, with some shrub/scrub and developed, open space. There are no structures or existing infrastructure on the 160-acre site, although there are roads and an operating wind farm nearby. Irrigated cropland is also in the vicinity. No wetlands, floodplains, or riparian areas are documented for this site.

3.19.5.8.3 TVA Upgrades

The ROI for the direct assignment facilities (which are included in the Applicant Proposed Project) would occur within the Tennessee Converter Station Siting Area and more specifically within the Shelby Substation. The ROI for the network upgrades, and in particular TVA's future 500kV transmission line, cannot be fully determined at this time. The new 500kV transmission line would be constructed in western Tennessee. The upgrades to existing facilities would mostly be in western and central Tennessee. Upgrades to existing infrastructure would include upgrading terminal equipment at three existing 500kV substations and six existing 161kV substations; making appropriate upgrades to increase heights on 16 existing 161kV transmission lines to increase line ratings, and replacing the conductors on eight existing 161kV transmission lines. Where possible, general impacts associated with the required TVA upgrades are discussed in the impact sections that follow.

3.19.6 Impacts to Wetlands, Floodplains, and Riparian Areas

3.19.6.1 Methodology

3.19.6.1.1 Environmental Protection Measures

The Applicant has developed a comprehensive list of EPMs that would avoid and minimize impacts to wetlands, floodplains, and riparian areas. Implementation of these EPMs is assumed throughout the impact analysis that follows for Project. A complete list of EPMs for the Project is provided in Appendix F; those EPMs that would specifically allow for the avoidance and/or minimization of potential adverse impacts in wetlands, floodplains, and riparian areas are listed below:

General EPMs:

- GE-1: Clean Line will train personnel on health, safety, and environmental matters. Training will include practices, techniques, and protocols required by federal and state regulations and applicable permits.
- GE-3: Clean Line will minimize clearing vegetation within the ROW, consistent with a Transmission Vegetation Management Plan (TVMP) filed with NERC, and applicable federal, state, and local regulations. The TVMP may require additional analysis under NEPA depending on whether and under what conditions DOE decides to participate in the Project.
- GE-5: Any herbicides used during construction and operations and maintenance will be applied according to label instructions and any federal, state, and local regulations.
- GE-6: Clean Line will restrict vehicular travel to the ROW and other established areas within the construction, access, or maintenance easement(s).
- GE-7: Roads not otherwise needed for maintenance and operations will be restored to preconstruction conditions. Restoration practices may include decompacting, recontouring, and re-seeding. Roads needed for maintenance and operations will be retained.
- GE-9: Clean Line will avoid and/or minimize damage to drainage features and other improvements such as ditches, culverts, levees, tiles, and terraces; however, if these features or improvements are inadvertently damaged, they will be repaired and or restored.
- GE-13: Emergency and spill response equipment will be kept on hand during construction.
- GE-14: Clean Line will restrict the refueling and maintenance of vehicles and the storage of fuels and hazardous chemicals within at least 100 feet from wetlands, surface waterbodies, and groundwater wells, or as otherwise required by federal, state, or local regulations.
- GE-15: Waste generated during construction or maintenance, including solid waste, petroleum waste, and any potentially hazardous materials will be removed and taken to an authorized disposal facility.
- GE-21: Clean Line will maintain construction equipment in good working order. Equipment and vehicles that show excessive emissions of exhaust gasses and particulates due to poor engine adjustments or other inefficient operating conditions will be repaired or adjusted.
- GE-27: Clean Line will minimize compaction of soils and rutting through appropriate use of construction equipment (e.g., low ground pressure equipment and temporary equipment mats).

Soils and Agriculture EPMs:

- AG-1: Clean Line will avoid or minimize adverse effects to surface and subsurface irrigation and drainage systems (e.g., tiles). Clean Line will work with landowners to minimize the placement of structures in locations that would interfere with the operation of irrigation systems.

- GEO-1: Clean Line will stabilize slopes exposed by its activities to minimize erosion.

Vegetation EPMs:

- FVW-1: Clean Line will identify environmentally sensitive vegetation (e.g., wetlands, protected plant species, riparian areas, large contiguous tracts of native prairie) and avoid and/or minimize impacts to these areas.
- FVW-2: Clean Line will identify and implement measures to control and minimize the spread of non-native invasive species and noxious weeds.
- FVW-3: Clean Line will clearly demarcate boundaries of environmentally sensitive areas during construction to increase visibility to construction crews.

Water EPMs:

- W-1: Clean Line will avoid and/or minimize construction of access roads in special interest waters.
- W-2: Clean Line will identify, avoid, and/or minimize adverse effects to wetlands and waterbodies. Clean Line will not place structure foundations within the Ordinary High Water Mark of Waters of the United States.
- W-3: Clean Line will establish streamside management zones within 50 feet of both sides of intermittent and perennial streams and along margins of bodies of open water where removal of low-lying vegetation is minimized.
- W-4: If used, Clean Line will selectively apply herbicides within streamside management zones.
- W-5: Clean Line will construct access roads to minimize disruption of natural drainage patterns including perennial, intermittent, and ephemeral streams.
- W-6: Clean Line will not construct counterpoise or fiber optic cable trenches across waterbodies.
- W-7: Clean Line will locate spoil piles from foundation excavations and fiber optic cable trenches outside of streamside management zones.
- W-8: Dewatering will be conducted in a manner designed to prevent soil erosion (e.g., through discharge of water to vegetated areas and/or the use of flow control devices).
- W-9: Clean Line will design converter station sites to avoid adverse changes to the base flood elevation within the 100-year floodplain.
- W-10: Clean Line will minimize fill for access roads and structure foundations within 100-year floodplains to avoid adverse changes to the base flood elevation.
- W-11: Clean Line will locate and minimize impacts to groundwater wells and springs within the construction ROW.
- W-14: Clean Line will ensure that there is no off-site discharge of wastewater from batch plant sites.

In addition, Clean Line will prepare the following plans to provide guidance for work activities during the construction and operations and maintenance phases of the proposed Project:

- Transportation and Traffic Management Plan: This plan will describe measures designed to avoid and/or minimize adverse effects associated with the existing transportation system.
- Restoration Plan: This plan will describe post-construction activities to reclaim disturbed areas.
- Spill Prevention, Control and Countermeasures (SPCC) Plan: This plan will describe the measures designed to prevent, control, and clean up spills of hazardous materials.
- Storm Water Pollution Prevention Plan (SWPPP): This plan, consistent with federal and state regulations, will describe the practices, measures, and monitoring programs to control sedimentation, erosion, and runoff from disturbed areas.

- Transmission Vegetation Management Plan (TVMP): This plan, to be filed with the NERC, will describe how Clean Line will conduct work on its right-of-way to prevent outages due to vegetation. The TVMP may require additional analysis under NEPA depending on whether and under what conditions DOE decides to participate in the Project.

Finally, DOE will prepare a Statement of Findings as required by 10 CFR 1022.14 and Executive Orders 11988 and 11990. The Project, through appropriate use of EPMs and BMPs would avoid and/or minimize impacts to wetlands, floodplains, and riparian areas.

3.19.6.1.2 Construction Impacts Common to All Alternatives

3.19.6.1.2.1 Wetlands

The potential impacts to wetland resources were calculated using the NWI database (GIS Data Source: USFWS 2014g). The 200-foot-wide representative ROWs for Project elements (e.g., AC collection system, the Applicant Proposed Route, and the HVDC alternative routes) were evaluated according to their respective widths and lengths as they intersected specific NWI-mapped wetland features. These intersections of ROW with wetland resources yielded an acreage estimate for potential impacts. It should be noted that these impact estimates do not account for implementation of the EPM's listed in Section 3.19.6.1.1. In many cases, the use of EPMs would greatly diminish or, in some cases, eliminate the potential for impact altogether. In the case of the converter stations and AC interconnection siting areas, GIS was used to determine the acreage of intersection between siting area footprints and NWI-mapped wetland resources to yield acreage of potential impact to wetland resources. All estimated impact numbers have been rounded to the nearest acre. Impact estimates for acreage and mileage have been rounded to the tenths place (e.g., 0.1 mile, 2.5 acres, etc.).

The potential short-term impacts to wetlands from construction activities could include:

- Mechanical damage/crushing of wetland vegetation from use of heavy machinery
- Compaction of wetland soils, which could reduce the soil's water-holding capacity
- Sedimentation and turbidity from construction activities adjacent to wetlands
- Alteration of hydrology from access road construction, excavations for structure foundations, dewatering activities, or blasting
- Contamination from herbicide runoff and from accidental spills of hazardous substances, such as fuels, lubricants, and that may be accidentally released into wetlands or which could reach wetlands through overland runoff paths

The potential long-term impacts to wetlands from Project construction may include:

- Placement of fill into wetlands at foundation footprint locations or for permanent access roads
- Long-term conversion of forested wetlands to shrubby or herbaceous cover type within the ROW
- Changes to wetland hydrology from any permanent access roads constructed through wetlands
- Introduction of invasive species from construction equipment (Clean Line 2013)

The potential impacts to wetlands from specific construction activities and proposed avoidance and minimization measures are discussed in the following sections.

Clearing and Grading

Construction of the Project would require the removal of some wetland vegetation for the purposes of equipment access, safe construction processes, and for long-term electrical safety clearances. The removal of wetland vegetation may reduce water retention capacity of affected wetland ecosystems. Vegetation removal may also impair individual wetlands' ability to filter sediments. Soil and water temperatures in wetland ecosystems could increase where shading is diminished by vegetation removal. Wetland habitat suitability would be altered where forested wetland vegetation or scrub-shrub wetland vegetation types are removed during construction and are replaced with palustrine emergent wetland vegetation (wetlands typically dominated by grasses, sedges, and rushes).

The grading of soils in wetlands has the potential to change existing topographic contours. This alteration may change flow regimes through these ecosystems, resulting in increased erosion, additional loss of vegetation, and potential for sedimentation downstream/downgradient of the affected wetlands.

To address the short-term and potentially long-term direct and indirect impacts of the clearing of wetland vegetation, clearing of vegetation would be minimized during construction within the representative 200-foot-wide ROW, consistent with a TVMP (EPM GE-3). Vegetation removed during clearing would be disposed of according to federal, state, and local regulations (EPM GE-4).

Herbicide Use

Herbicides would be used selectively to minimize regrowth of certain trees and woody species in the ROW as needed during construction activities. Herbicides may have adverse impacts on wetland vegetation, potentially causing both short-term and long-term loss of living tissue as well as changes in growth and reproduction. Use of herbicides also carries the threat of harm to non-target organisms if the active ingredient is mobilized in semi-aquatic or aquatic ecosystem such as wetlands. All herbicides used during construction would be applied according to labeled instructions and any federal, state, and local regulations (EPM GE-5).

Structure Placement within Wetlands

If structural foundations were placed in wetlands, that action could constitute fill under the CWA, and as such, would require permitting through the appropriate regulatory office of the USACE. If realized, this type of impact would constitute a long-term loss of wetland acreage because the structures would remain for the life of the Project. The Applicant would avoid or minimize foundations and foundation spoil piles in wetlands (EPM W-2 and EPM W-7). If final siting of structures is determined to be planned for areas identified as potential wetlands or other waters of the United States, then these resources should be formally delineated prior to construction to establish true wetland/upland boundaries and to determine acreage of potential impact.

Construction Equipment Usage in Wetland Areas

The Applicant would use low ground-pressure equipment and temporary equipment mats and mat boards when activity is required within the boundaries of wetland ecosystems (EPM GE-27). If construction equipment is driven through wetlands, it can result in mechanical damage to or loss of vegetation and it may lead to compacted wetland soils. Soil compaction reduces the ability of a wetland to retain water. When temporary crossings (e.g., matting) of wetlands is necessary and unavoidable, these crossing materials would be removed following construction activities. The use of construction equipment in wetlands and use of construction matting would require permit verification with the USACE. The Applicant would restrict vehicular travel to the ROW and other established areas within the construction, access, or maintenance easements (EPM GE-6). Roads traversing wetland areas not otherwise needed for maintenance and operations would be restored to preconstruction contours and reseeded (EPM GE-7). The Applicant would prepare and implement a Restoration Plan that would describe post-construction activities to reclaim disturbed areas, including wetlands.

Excavation and Dewatering

Construction of AC and HVDC transmission structure foundations, trenches for buried counterpoise wire and fiber optic cables, and any excavation needed at converter station locations (i.e., for structural foundation installation and for installation of electrical raceways and grounds) may temporarily accumulate water either from groundwater intrusion or from precipitation. The excavations and trenches may need to be dewatered periodically to allow for proper and safe construction. In areas where the Applicant encounters groundwater during excavation, impacts to the water table may occur if excavations require dewatering, which could affect hydrology of adjacent wetlands. These indirect impacts would be temporary and localized. The Applicant would minimize the amount of time that any excavations remain open (EPM GE-30) to minimize the amount of dewatering required. Dewatering would be conducted in a manner designed to prevent soil erosion (e.g., through discharge of water to vegetated areas and/or the use of flow control devices) (EPM W-8). The implementation of the SWPPP would control erosion, sedimentation, and runoff in areas affected by dewatering. The Applicant would not construct counterpoise or fiber optic cable trenches across waterbodies (EPM W-6). It is anticipated that excavation and dewatering impacts would be minor in intensity and short-term in duration.

Blasting

The use of blasting techniques may be required in some locations, such as transmission line structure foundations. The Applicant would not place structure foundations within the Ordinary High Water Mark of waters of the United States (EPM W-2). Blasting in or adjacent to Waters of the United States, including wetlands, is not anticipated. The Applicant would avoid such blasting; however, if blasting is required within 150 feet of a spring or groundwater well, the Applicant would conduct preconstruction monitoring of yield and water quality in cooperation with the landowner (EPM W-12). The Applicant would develop and implement a Blasting Plan in the unlikely event blasting is required. This plan would describe measures designed to minimize adverse effects due to blasting. No impact to wetlands from blasting is anticipated.

Hazardous Materials Handling

Accidental spills of fluids used during construction, such as fuel, insulating oil, lubricants, antifreeze, detergents, paints, solvents, and herbicides, could contaminate wetland vegetation, waters, and soils. To minimize the potential for these short-term and long-term direct and indirect impacts, the Applicant would restrict the refueling and maintenance of vehicles and the storage of fuels and hazardous chemicals to areas outside of a 100-foot buffer from wetlands, or as otherwise required by federal, state, or local regulations (EPM GE-14). The Applicant would maintain construction equipment in good working order (EPM GE-21). Emergency and spill response equipment would be kept on hand during construction (EPM GE-13). It is anticipated that these impacts would be generally minor and temporary, or short term.

Wastewater Discharge from Concrete Batch Plants

Temporary concrete batch plants may be required at multi-use construction yards. If left uncontrolled, process wastewater and contaminated stormwater runoff from the temporary concrete batch plants could potentially wash into wetlands, resulting in short-term direct and indirect impacts. To minimize the potential for these impacts, the Applicant would ensure that there is no off-site discharge of wastewater from temporary batch plant sites (EPM

W-14). Waste generated during construction, including solid waste, petroleum waste, and any potentially hazardous materials, would be removed and taken to an authorized disposal facility (EPM GE-15).

3.19.6.1.2.2 Floodplains

The potential impacts to floodplain resources were calculated using FEMA floodplain data for 100-year floodplains (GIS Data Source: FEMA 2014). No 500-year floodplain data were available in this most recent FEMA national flood hazard layer for any portion of the planned Project ROWs. FEMA has not delineated 500-yeard floodplains in the most current data set and these areas are thus considered non-special flood hazard areas. The planned ROWs for Project elements (e.g., AC collection system, the Applicant Proposed Route, and the HVDC alternative routes) were evaluated according to their respective widths and lengths as they intersected specific FEMA-mapped floodplain features. These intersections of ROW with floodplain resources yielded an acreage estimate for potential impacts. In the case of the converter station and AC interconnection siting areas, GIS was used to determine the acreage of intersection between siting area footprints and FEMA-mapped floodplain resources to yield acreage of potential impact to floodplain resources. All impact values have been rounded to the nearest acre. For those floodplain impact estimates where the value derived from GIS data was less than 0.5 acre, values in the impact tables have been reported as <1 acre. Values between 0.5 and 0.9 acre are reported as 1 acre in the impact tables.

The construction activities that could affect floodplains include placing long-term structures such as AC and HVDC transmission structures, converter station foundations, and permanent above-grade access roads within a floodplain and driving heavy equipment within a floodplain resulting in soil compaction. The quantity of impact from construction related activities on floodplains was calculated using GIS and has been rounded to the nearest tenth of an acre.

Structure Placement within Floodplains

The placement of structure foundations within 100-year floodplains would be avoided; however, placement of some structures in 100-year floodplains would be necessary in some areas (e.g., the Mississippi River floodplain) (EPM W-10). Transmission line structures would not prohibit the flow of water within floodplains, because water can flow around structure foundations.

Placing converter stations within a floodplain would increase impermeable surfaces within the floodplain and reduce water absorption, and could change the grade of the floodplain, limiting the ability of water to spread during high-flow events. The Applicant would not construct a converter station within 100-year floodplains, if practicable. If impacts to a floodplain are unavoidable, the design of the converter station sites would seek to avoid adverse changes to the base flood elevation (EPM W-9). Impacts are anticipated to be minor in intensity, and temporary in duration.

Driving Heavy Equipment within a Floodplain

The addition of new access roads within a floodplain can result in soil compaction, an increase in impervious surfaces, and reduction in water absorption. Access roads can also change the gradient of the floodplain, limiting the ability of water to spread during high-flow events. To address these potential long-term impacts, the Applicant would limit building new access roads within 100-year floodplains to the extent practicable (EPM W-10). The Applicant would utilize low ground-pressure equipment and temporary equipment mats (EPM GE-27) as practicable. A Restoration Plan would detail measures the Applicant would implement to minimize long-term impact from compaction.

3.19.6.1.2.3 Riparian Areas

Riparian systems may be broadly defined as transitional areas between surface water systems and purely upland areas. Riparian areas share some of the same characteristics of hydrology, hydric soils, and hydrophytic vegetation with wetlands and surface water resources, but they also may feature more mesic soils and vegetation. Given this diversity, riparian areas are ecologically significant in any landscape where they occur and they tend to provide important ecosystem services, such as wildlife habitat, flood flow attenuation, and sediment retention. The impacts that take place in wetlands and floodplains may impact riparian areas, especially those wetlands and floodplains associated with perennial creeks and rivers that are intersected by the ROW.

Riparian areas have not been specifically mapped, nor field verified for environmental impacts. No specific database concerning riparian resources was identified during desktop analysis. In order to provide an assessment of potential impacts for riparian areas, data developed for perennial streams, intermittent streams, and other surface waterbodies (ponds, lakes, reservoirs, etc.) have been reproduced from Section 3.15. These data come from the National Hydrography Dataset. These data, while not definitive in identifying riparian areas specifically, do provide a measure of understanding concerning their potential to exist and to be impacted within a given Project component ROW or siting area footprint. The data were obtained using GIS and include estimates of the mileage that national hydrography dataset-mapped perennial and intermittent streams cross ROWs or siting areas, as well as estimates of the acreage for ponds, lakes, and reservoirs that are intersected by ROWs or siting areas.

The construction activities that could affect riparian areas includes short–term loss of vegetation due construction vehicle access through riparian corridors, plus long-term loss of vegetation due to placement of structures such as AC and HVDC support structures, converter station foundations, and permanent above-grade access roads. Riparian areas may also incur soil compaction from the use of heavy construction equipment in more hydric areas.

3.19.6.1.3 Operations and Maintenance Impacts Common to All Alternatives

This section details potential impacts to wetlands, floodplains and riparian areas from the operation and maintenance of the converter stations and interconnections, the HVDC and AC transmission lines, access roads, and fiber optic regeneration stations.

3.19.6.1.3.1 Wetlands

Wetland ecosystems may be impacted by the operations and maintenance activities associated with vegetation maintenance, herbicide use, driving vehicles within wetlands, and hazardous materials handling during inspections and maintenance work. Impacts are expected to be minor and short-term.

Vegetation Maintenance

The Applicant would maintain a 150- to 200-foot-wide ROW (typical) during operation in accordance with a TVMP. Maintenance may include the long-term direct impact of vegetation removal as well as the short-term impact of trimming or pruning of vegetation in wetland areas. Vegetation maintenance (i.e., trimming of woody vegetation) within wetlands could potentially decrease evapotranspiration rates and increase soil and water temperatures due to lack of shading. To minimize these potential impacts, the Applicant would minimize clearing of vegetation within the ROW, consistent with the TVMP and applicable federal, state, and local regulations (EPM GE-3). Vegetation impacts are projected to be long-term in some portions of the Project, especially the areas of forested and scrub-shrub wetlands cover types. Vegetation impacts in palustrine emergent wetlands would likely be minor and short-term. The Applicant would restrict vehicular travel to the ROW and other established areas within the access or maintenance easement(s) to avoid or minimize impacts to wetland resources (EPM GE-6).

Herbicide Use

The Applicant may selectively apply herbicides to minimize regrowth of certain trees and woody species in forested and scrub-shrub wetlands. Herbicides may be toxic to aquatic organisms depending on the type used and the concentration. Any herbicides used during operations and maintenance would be applied according to labeled instructions and any federal, state, and local regulations (EPM GE-5). To minimize potential short-term and direct impacts, the Applicant would selectively apply herbicides to protect wetland and other water resources.

Equipment Usage in Wetland Areas

It may be necessary to drive operations and maintenance equipment across wetlands when dry, or to establish temporary crossings using mat boards when soils are saturated. Driving equipment across wetlands could compact or rut wetland soils as well as cause sedimentation in wetlands and increased turbidity in surface waters. The Applicant would minimize compaction of soils and rutting through appropriate use of equipment (e.g., low ground-pressure equipment and temporary equipment mats) (EPM GE-27). Following removal of the temporary crossings, wetlands would be restored to pre-disturbance conditions. Any impacts associated with driving construction vehicles in wetlands would be minor and temporary. Dredge or fill of wetlands may occur during the operations and maintenance phase of the Project; however, any impacts would be subject to permit requirements at the time.

During operations and maintenance, the Applicant would restrict vehicular travel to the ROW and other established areas within the access or maintenance easement(s) (EPM GE-6).

Hazardous Materials Handling

Inadvertent spills of fluids, such as fuel, insulating oil, lubricants, antifreeze, detergents, paints, solvents, and herbicides used during operations and maintenance along the HVDC or AC transmission line ROWs, or at the converter stations, could contaminate wetland soils and vegetation. While spills of insulating fluid at converter stations could potentially contaminate wetlands, standard design of the facilities would include secondary containment to minimize potential impact. Industry-standard equipment and vehicles used by employees and used for operations and maintenance activities also could be a source of inadvertent minor spills. The Applicant would implement EPMs GE-13, GE-14, GE-15, and GE-21 to minimize potential impacts and would implement an SPCCP. Impacts to wetlands from hazardous materials handling should be minor in intensity and temporary in duration.

3.19.6.1.3.2 Floodplains

It is anticipated that unpaved roads or two-track access would be used for maintenance. This usage would result in long-term but low intensity impact in the form of soil compaction in floodplains. Vehicular travel would be restricted to the ROW and other established areas within the access and maintenance easement where operations and maintenance are necessary (EPM GE-6). No additions of impervious surfaces or changes to grade within the ROW would be made during operations and maintenance. The Applicant would not conduct operations and maintenance activity during flooding conditions in any floodplain unless emergency conditions warrant.

3.19.6.1.3.3 Riparian Areas

Riparian areas are predicted to experience only minor, short-term impacts during the operations and maintenance phase of the Project. The impact types are likely to include minor clearing of wetland and floodplain vegetation to satisfy line safety considerations or to keep access roads passable. The occasional use of access roads may result in minor soil compaction where they cross riparian zones. There is a potential for drift or runoff of selective herbicide applications in riparian areas that could cause damage or loss of riparian vegetation and for accidental spills of small quantities of hazardous materials, such as fuels and lubricants. Such spills could cause damage to or loss of riparian area vegetation.

3.19.6.1.4 Decommissioning Impacts Common to All Alternatives

Transmission line and converter station decommissioning could occur at the end of the useful life of the facilities. Decommissioning for the Project would include the dismantling and removal of conductors, insulators, and support structures as well as removal of the converter and regeneration stations. The Applicant would decommission access roads that were solely designed and built to provide maintenance crews with access to the Project infrastructure. The Applicant may decommission access roads before the end of the transmission line's useful life if it determined the roads were no longer necessary. The Applicant would consult with landowners to assess whether landowners wish to keep the access roads.

Decommissioning of the Project could result in impacts to wetlands, floodplains, and riparian vegetation very similar to those incurred during construction (e.g., mechanical damage or loss of wetland and riparian vegetation, increased sedimentation and turbidity, erosion, soil compaction, damage or loss of wetland and riparian vegetation from drift or runoff of herbicides, and damage or loss of wetland and riparian vegetation from spills of hazardous materials.

Assuming that the ROW is allowed to revert to preconstruction conditions and unnecessary access roads are removed, many of the long-term impacts resulting from construction (e.g. loss of forested and scrub-shrub wetlands, establishment of permanent access roads in through floodplains and wetlands) could be reversed, resulting in beneficial impacts.

A Decommissioning Plan would be developed prior to decommissioning, but given the uncertainty of future technology and unknown future environmental requirements, the contents and requirements of such a plan cannot be known at this time. Any plan document would follow appropriate governing requirements in place at the time the plan is drafted.

3.19.6.2 Impacts Associated with the Applicant Proposed Project

3.19.6.2.1 Construction Impacts

Impacts to wetlands, floodplains, and riparian areas during construction of the converter stations may vary from minor and short term to long term and potentially permanent loss of wetland, floodplain, and riparian acreage. Impacts to wetlands and other waters of the United States would need to be permitted under Section 404 of the CWA. Typically those impacts totaling more than one-tenth of an acre would require a preconstruction notification to the appropriate regulatory office of the USACE. In Arkansas, the counties crossed by the Project are all within the so-called Fayetteville shale play area. Any level of impacts to wetlands and other waters of the United States in the Fayetteville shale play require permit verification to be evaluated by the USACE. Verification could be accomplished through the nationwide permits, but also with other types of permits, as required. Additional permitting may be required from local jurisdictions for changes or adverse impacts to floodplains. Construction of a single converter station is estimated to take 32 months.

3.19.6.2.1.1.1 Oklahoma Converter Station Siting Area and AC Interconnection Siting Area

The Oklahoma Converter Station and AC Interconnection Siting Areas are dominated by grassland/herbaceous vegetation (605 acres). Desktop analysis, including a review of NWI data and NLCD data, has not identified wetland resources within the estimated siting areas. Based on the desktop analysis, it is not anticipated that there would be adverse impacts to wetland ecosystems from construction of the converter station or the AC interconnection.

No 100-year floodplains are mapped for the Oklahoma Converter Station and AC Interconnection Siting Areas, and thus no impacts to mapped floodplain resources are estimated.

Potential impacts to riparian areas associated with construction of the converter station and AC interconnections are unlikely. Limited surface water features consisting of less than 2 miles of intermittent stream beds, no perennial streams, and no major waterbodies are present within the Oklahoma Converter Station Siting Area. Similarly, surface water features are limited in the AC Interconnection Siting Area. The Applicant would adhere to EPM FVW-1 to avoid and/or minimize impacts to areas with sensitive vegetation resources such as wetlands and riparian areas. The Applicant would also avoid open water ecosystems such as intermittent and perennial streams, and other open water bodies such as ponds, lakes, and reservoirs (EPM W-3).

3.19.6.2.1.1.2 Tennessee Converter Station Siting Area and AC Interconnection Tie

The Tennessee Converter Station Siting Area and AC Interconnection Tie include approximately 2.7 acres of palustrine forested wetlands according to the NWI database.

Construction that causes dredge or fill impacts in wetlands and other waters of the United States would require permitting under the CWA Section 404 program. The construction effort would avoid wetlands and waters of the United States to the extent practicable. Where impacts appear unavoidable, those wetland sites would receive a formal wetland delineation and appropriate consultation with the USACE.

Approximately 38.6 acres of floodplains are mapped for the Tennessee Converter Station Siting Area and AC Interconnection Tie. There are 1.5 miles of intermittent and 0.2 mile of perennial streams within the converter station siting area. No other surface waterbodies are present within the Tennessee Converter Station Siting Area and AC Interconnection Tie. Potential impacts to riparian areas associated with construction of the converter station and AC interconnection tie are unlikely.

3.19.6.2.1.2 Operations and Maintenance Impacts

3.19.6.2.1.2.1 Oklahoma Converter Station Siting Area and AC Interconnection Siting Area

The Oklahoma Converter Station and AC Interconnection Siting Areas have been determined not to contain wetlands based on desktop analysis, including a review of NWI data. For this reason, it is not anticipated that there would be adverse impacts to wetland ecosystems from operation and maintenance of the Oklahoma Converter Station. In addition, no data exist to identify 100-year floodplains in the siting areas. Riparian areas are likely very limited in the siting area and unlikely to be impacted by operations and maintenance.

3.19.6.2.1.2.2 Tennessee Converter Station Siting Area and AC Interconnection Tie

As stated in the construction impacts section for the Tennessee converter station, the siting area may contain 2.7 acres of wetlands and/or waters of the United States. If these areas can be avoided during construction activity, then they should also be avoided during all operation and maintenance activities. Field reconnaissance and potentially wetland delineation should be conducted prior to construction to identify exact locations and sizes of wetlands in the siting area. Potential impacts that result in fill of a wetland would be permitted under Section 404 of the CWA prior to construction. Operations and maintenance activities would adhere to all restrictions and conditions that are established as part of the permitting process.

3.19.6.2.1.3 Decommissioning Impacts

The decommissioning impacts related to the Project would be similar in nature to the set of temporary impacts resulting from initial construction. These temporary impacts would involve use of construction machinery at each of the two converter stations (i.e., Oklahoma and Tennessee), as well as the ROW areas that would have been used for AC interconnection. The specific acreages for the footprints of the two converter stations total a projected maximum of 120 acres that would be reclaimed and revegetated according to the details that would be written into the Decommissioning Plan.

3.19.6.2.2 AC Collection System

3.19.6.2.2.1 Construction Impacts

Impacts to wetlands, floodplains, and riparian areas during construction of the AC collection system routes may vary from minor and short term to long term and potentially permanent loss of wetland acreage. The duration of construction for the complete AC collection system will be approximately 24 months from mobilization to restoration.

The following discussion of potential impacts is specific to the 200-foot-wide representative ROW within the overall 2-mile-wide ROI.

3.19.6.2.2.1.1 Route E-1

The construction of AC Collection System Route E-1 has been estimated to potentially result in as much as 8.4 acres of impacts to wetlands. Wetland impacts are predicted for a total of seven wetlands from five different wetland types (Table 3.19-45).

Table 3.19-45:
Potential Construction Impacts to Wetlands in AC Collection System Route E-1

Wetland Type	Number of Wetlands	Acreage of Potential Impact
PEM	2	2.8
PFO	1	2.9
PSS	2	2.1
R2UB	1	0.5
R2US	1	0.1
Totals	7	8.4

GIS Data Source: USFWS (2014g)

One 100-year floodplain totaling 1.0 acre exists within the ROW for AC Collection System Route E-1 and could be impacted.

As shown in Table 3.15-5, AC Collection System Route E-1 encompasses about 0.2 mile of perennial streams, 1.6 miles of intermittent streams, no major waterbodies, and 0.5 acre of reservoirs, lakes, and ponds. Riparian areas may be associated with many, if not all, of these surface water features.

3.19.6.2.2.1.2 Route E-2

Construction of AC Collection System Route E-2 could result in a total of up to 7.8 acres of impacts to wetlands. The representative ROW for AC Collection System Route E-2 features nine wetlands in five different types (Table 3.19-46).

Table 3.19-46:
Potential Construction Impacts to Wetlands in AC Collection System Route E-2

Wetland Type	Number of Wetlands	Acreage of Potential Impact
PEM	4	1.6
PFO/PSS	1	0.8
PSS	2	4.2
R2UB	1	0.3
R2US	1	0.9
Totals	9	7.8

GIS Data Source: USFWS (2014g)

Two 100-year floodplains totaling 54.6 acres are present in the ROW that could be impacted by construction along AC Collection System Route E-2.

As shown in Table 3.15-5, the AC Collection System Route E-2 includes approximately 0.4 mile of perennial streams, 2.2 miles of intermittent streams, 0.1 mile of major waterbodies, and 1.0 acres of reservoirs, lakes, and ponds. Riparian areas may be associated with many, if not all, of these surface water features.

3.19.6.2.2.1.3 Route E-3

Construction of AC Collection System Route E-3 could result in a total of up to 2.8 acres of impacts to wetlands in the ROW. Route E-3 features a total of three wetlands representing three different wetland types (Table 3.19-47).

Table 3.19-47:
Potential Construction Impacts to Wetlands in AC Collection System Route E-3

Wetland Type	Number of Wetlands	Acreage of Potential Impact
PSS	1	0.8
R2UB	1	0.3
R2US	1	1.7
Totals	3	2.8

GIS Data Source: USFWS (2014g)

Two 100-year floodplains totaling 6.8 acres may be impacted by construction along AC Collection System Route E-3.

The AC Collection System Route E-3 includes approximately 0.1 mile of perennial streams, 2.4 miles of intermittent streams, less than 0.1 mile of major waterbodies, and 0.3 acre of reservoirs, lakes, and ponds (Table 3.15-5). The length of intermittent streams is the highest of any of the AC collection system routes. Riparian areas may be associated with many, if not all, of these surface water features.

3.19.6.2.2.1.4 Route NE-1

Construction of AC Collection System Route NE-1 could potentially result in a total of 3.4 acres of impacts to wetlands within the ROW. Wetland impacts could occur in five wetlands representing four types (Table 3.19-48).

Table 3.19-48:
Potential Construction Impacts to Wetlands in AC Collection System Route NE-1

Wetland Type	Number of Wetlands	Acreage of Potential Impact
PEM/PSS	1	0.6
Pf	1	1.3
R2UB	1	0.7
R4SB	2	0.8
Totals	5	3.4

GIS Data Source: USFWS (2014g)

Two 100-year floodplains totaling 19.1 acres could potentially be impacted by construction along AC Collection System Route NE-1.

The AC Collection System Route NE-1 includes approximately 0.4 mile of perennial streams, 0.3 mile of intermittent streams, 0.1 mile of major waterbodies, and no acreage of reservoirs, lakes, and ponds (Table 3.15-5). The length of perennial streams is the second highest of any of the AC collection system routes. Riparian areas may be associated with many, if not all, of these surface water features.

3.19.6.2.2.1.5 Route NE-2

Construction of AC Collection System Route NE-2 could potentially result in a total of approximately 20.1 acres of impacts to wetlands in the representative ROW. AC Collection System Route NE-2 ROW contains 14 wetlands representing seven wetland types (Table 3.19-49).

Table 3.19-49:
Potential Construction Impacts to Wetlands in AC Collection System Route NE-2

Wetland Type	Number of Wetlands	Acreage of Potential Impact
L2EM	1	9.3
PEM/PSS	2	1.1
PEM	6	8.1
PSS	1	0.8
R2UB	1	0.4
R2US	2	0.1
R4SB	1	0.3
Totals	14	20.1

GIS Data Source: USFWS (2014g)

One 100-year floodplain totaling approximately 24.3 acres within the ROW may be impacted by construction of AC Collection System Route NE-2.

The AC Collection System Route NE-2 includes approximately 0.2 mile of perennial streams, 1.3 miles of intermittent streams, 0.1 mile of major waterbodies, and 2.0 acres of reservoirs, lakes, and ponds (Table 3.15-5).Riparian areas may be associated with many, if not all, of these surface water features.

3.19.6.2.2.1.6 Route NW-1

Construction of AC Collection System Route NW-1 could potentially result in a total of 1.0 acre of total impact to a set of two wetlands in the ROW (Table 3.19-50).

Table 3.19-50:
Potential Construction Impacts to Wetlands in AC Collection System Route NW-1

Wetland Type	Number of Wetlands	Acreage of Potential Impact
PEM	1	0.7
R4SB	1	0.3
Totals	2	1.0

GIS Data Source: USFWS (2014g)

Two 100-year floodplains totaling 32.8 acres within the ROW could be impacted by construction for AC Collection System Route NW-1.

The AC Collection System Route NW-1 includes approximately 0.2 mile of perennial streams, 2.0 miles of intermittent streams 0.1 mile of major waterbodies, and no acreage of reservoirs, lakes, and ponds (Table 3.15-5). Riparian areas may be associated with many, if not all, of these surface water features.

3.19.6.2.2.1.7 Route NW-2

The construction of AC Collection System Route NW-2 could result in a total of approximately 4.1 acres of impacts to wetlands in the ROW. A total of nine wetlands distributed through four types are represented in the ROW (Table 3.19-51).

Table 3.19-51:
Potential Construction Impacts to Wetlands in AC Collection System Route NW-2

Wetland Type	Number of Wetlands	Acreage of Potential Impact
PEM/PSS	1	0.6
PEM	1	0.2
R2UB	1	0.7
R4SB	6	2.6
Totals	9	4.1

GIS Data Source: USFWS (2014g)

One floodplain totaling 19.1 acres could be impacted by construction along AC Collection System Route NW-2.

The AC Collection System Route NW-2 includes approximately 0.5 mile of perennial streams, 1.0 mile of intermittent streams, 0.2 mile of major waterbodies, and less than 0.1 mile of reservoirs, lakes, and ponds (Table 3.15-5). Riparian areas may be associated with many, if not all, of these surface water features.

3.19.6.2.2.1.8 Route SE-1

The ROW for AC Collection System Route SE-1 contains eight wetlands from four wetland types (Table 3.19-52). The construction of AC Collection System Route SE-1 could potentially result in a total of approximately 4.9 acres of impacts to these wetlands.

Table 3.19-52:
Potential Construction Impacts to Wetlands in AC Collection System Route SE-1

Wetland Type	Number of Wetlands	Acreage of Potential Impact
L2EM	1	0.2
PEM	3	2.8
Pf	1	0.1
PSS	3	1.8
Totals	8	4.9

GIS Data Source: USFWS (2014g)

Two floodplains totaling 54.6 acres could be impacted by construction along AC Collection System Route SE-1.

The AC Collection System Route SE-1 includes approximately 0.4 mile of perennial streams, 2.1 miles of intermittent streams, less than 0.1 mile of major waterbodies, and 2.6 acres of reservoirs, lakes, and ponds (Table 3.15-5). The area of reservoirs, lakes, and ponds is the second highest of any of the AC collection system routes. Riparian areas may be associated with many, if not all, of these surface water features.

3.19.6.2.2.1.9 Route SE-2

No wetlands are documented by NWI mapping in the representative ROW for AC Collection System Route SE-2. Based on the NWI data there would be no expected impacts to wetlands within the representative ROW. However, the data should be verified in the field prior to construction to avoid potential impacts if wetlands are present that were not included in the NWI mapping.

No mapped 100-year floodplains are present within this ROW.

The AC Collection System Route SE-2 encompasses no perennial streams, 0.3 mile of intermittent streams, no major waterbodies, and 0.4 acre of reservoirs, lakes, and ponds (Table 3.15-5). Riparian areas may be associated with many, if not all, of these surface water features.

3.19.6.2.2.1.10 Route SE-3

Construction of AC Collection System Route SE-3 could affect 13 total wetlands representing six wetland types for a combined potential acreage of impact of approximately 14.3 acres within the ROW (Table 3.19-53).

Table 3.19-53:
Potential Construction Impacts to Wetlands in AC Collection System Route SE-3

Wetland Type	Number of Wetlands	Acreage of Potential Impact
PEM	4	2.6
Pf	4	5.5
PFO/PSS	1	0.8
PSS	2	4.2
R2UB	1	0.3
R2US	1	0.9
Totals	13	14.3

GIS Data Source: USFWS (2014g)

Two floodplains are predicted to be impacted within the ROW by construction of AC Collection System Route SE-3 for a total of 54.6 acres.

The AC Collection System Route SE-3 includes approximately 0.4 mile of perennial streams, 2.1 miles of intermittent streams, 0.1 mile of major waterbodies, and 1.0 acre of reservoirs, lakes, and ponds (Table 3.15-5). The area of reservoirs, lakes, and ponds is the highest of any of the AC collection system routes. Riparian areas may be associated with many, if not all, of these surface water features.

3.19.6.2.2.1.11 Route SW-1

Desktop analysis, including a review of NWI data and NLCD data, has not identified wetland resources within the ROW for AC Collection System Route SW-1. Based on this level of analysis, it is not anticipated that there would be adverse impacts to wetland ecosystems from construction of SW-1.

No 100-year floodplains are mapped within this alternative's ROW.

The AC Collection System Route SW-1 includes no perennial streams, 0.9 mile of intermittent streams, no major waterbodies, and no reservoirs, lakes, or ponds (Table 3.15-5). Riparian areas may be associated with many, if not all, of these surface water features.

3.19.6.2.2.1.12 Route SW-2

Construction of AC Collection System Route SW-2 is predicted to impact less than 1 acre of a single palustrine emergent wetland that would be crossed.

Two floodplains are predicted to be impacted within the ROW by construction of AC Collection System Route SW-2 for a total of 16.6 acres.

The AC Collection System Route SW-2 includes approximately 0.1 mile of perennial streams, 2.9 miles of intermittent streams, 0.1 mile of major waterbodies, and 0.2 acre of reservoirs, lakes, and ponds (Table 3.15-5). Riparian areas may be associated with many, if not all, of these surface water features.

3.19.6.2.2.1.13 Route W-1

No wetlands are documented in the representative ROW for AC Collection System Route W-1, so no impacts are anticipated to wetlands from construction.

Two floodplains could be impacted by construction along the representative ROW for AC Collection System Route W-1 for a total of 15.2 acres.

The AC Collection System Route W-1 includes approximately 0.2 mile of perennial streams, 1.1 miles of intermittent streams, 0.1 mile of major waterbodies, and 0.5 acre of reservoirs, lakes, and ponds (Table 3.15-5). The area of reservoirs, lakes, and ponds is the lowest of any of the AC collection system routes. Riparian areas may be associated with many, if not all, of these surface water features.

3.19.6.2.2.2 Operations and Maintenance Impacts

Impacts related to operations and maintenance may result from use of heavy machinery through wetlands, floodplains, and riparian areas. These impacts can cause soil compaction and mechanical damage or removal of vegetation. These operations and maintenance impacts are anticipated to cover a range from temporary and minor to potentially more severe and long-term/permanent. The estimated acreage of each resource type (wetlands, floodplains, and riparian areas) by alternative, are provided in the previous subsections of 3.19.6.2.2.1.

The use of vegetation management would be necessary to protect the Project infrastructure and enhance safety. However, the trimming, mowing, or removal of vegetation can cause changes to plant diversity and function in all three ecosystem types (i.e., wetlands, floodplains, and riparian areas). Vegetation maintenance in wetlands and riparian areas should be kept to a minimum. Additionally, the use of herbicides can cause minor to severe impacts to vegetation in areas where they are applied. If used, the Applicant would selectively apply herbicides within streamside management zones.

3.19.6.2.2.3 Decommissioning Impacts

The decommissioning impacts related to the Project would be similar in nature to the set of temporary impacts resulting from initial construction. These temporary impacts would involve use of construction machinery at the various locations where there is AC collection system infrastructure, (e.g., the lattice structures, tubular structures, H-frame structures, fiber optic infrastructure, etc.) which would involve removal of aboveground material, and foundation material where required. Use of construction machinery would have the potential to crush or remove vegetation (primarily in grasslands or croplands), but these areas would be reseeded following removal of infrastructure. No long-term effects are judged to be likely from the decommissioning phase of the Project. Revegetation for wetlands, floodplains, and riparian areas would be guided by the Project’s Decommissioning Plan and by the conditions set forth in any CWA permitting that would be required.

3.19.6.2.3 HVDC Applicant Proposed Route

3.19.6.2.3.1 Construction Impacts

Impacts to wetlands, floodplains, and riparian areas during construction of the Applicant Proposed Route may vary from minor and short term to long term and potentially permanent loss of acreage. In Arkansas, the counties crossed by the Project are all within the Fayetteville Shale Play area. Any level of impacts to wetlands and other waters of the United States in the Fayetteville Shale Play are required to be reported to the USACE under regional conditions for nationwide permitting. Additional permitting may be required from local jurisdictions for changes or adverse impacts to floodplains.

Impacts presented for the Applicant Proposed Route represent impacts to the amount of wetlands, floodplains, and riparian areas estimated to exist within the 200-foot-wide representative ROW.

Changes to impacts due to route variations and adjustments developed in response to public comments on the Draft EIS are described at the end of applicable sections.

3.19.6.2.3.1.1 Region 1

Construction of the Applicant Proposed Route in Region 1 could cause impacts to six wetland types totaling approximately 22.1 acres within the ROW. Table 3.19-54 provides the number of wetlands by type with the associated prediction of impact acreage. No route variations were proposed in Region 1.

Table 3.19-54:
Potential Construction Impacts to Wetlands within the ROW of the Applicant Proposed Route—Region 1

Wetland Type	Number of Wetlands	Acreage of Potential Impact
PEM	11	3.1
Pf	3	9.4
PFO	2	0.6
PSS	5	5.4
PUS	5	2.3
R2UB	1	1.3
Totals	27	22.1

GIS Data Source: USFWS (2014g)

Two 100-year floodplains within Region 1 would be crossed by the construction of the Applicant Proposed Route in its representative ROW. These crossings may result in the potential for 52.4 acres of impact. No floodplains are anticipated to be crossed by the Applicant Proposed Route in this region.

As shown in Table 3.15-4, the 200-foot-wide corridor of the Applicant Proposed Route in Region 1 includes approximately 0.9 mile of perennial streams, 5.9 miles of intermittent streams, less than 0.1 mile of major waterbodies and 9.9 acres of reservoirs, lakes, and ponds. Riparian areas may be associated with many, if not all, of these surface water features.

3.19.6.2.3.1.2 Region 2

The Applicant Proposed Route in Region 2 could result in construction impacts to eight wetland types and approximately 14 total acres within the ROW. Table 3.19-55 provides the number of wetlands by type, and the associated estimate for potential impact acreage.

Two route variations to the Applicant Proposed Route were developed in Region 2 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.2. The variations are illustrated in Exhibit 1 of Appendix M. These variations represent minor adjustments to the Applicant Proposed Route. Link 1, Variation 1, would have no predicted impacts to wetland, floodplain, or riparian area resources. Link 2, Variation 2, would add 1 acre of non-forested wetland in the ROW involving one crossing of more than 1,000 feet through this feature as compared to the original Applicant Proposed Route.

Table 3.19-55:
Potential Construction Impacts to Wetlands within the ROW for the Applicant Proposed Route—Region 2

Wetland Type	Number of Wetlands	Acreage of Potential Impact
PEM/PSS	2	0.8
PEM	8	2.5
PFO	4	2.6
PSS	1	0.2
PUB	6	2.3
PUS	8	1.0
R2UB	1	0.6
R2US	2	3.6
Totals	32	13.6

GIS Data Source: USFWS (2014g)

Five 100-year floodplains within Region 2 would be crossed by the construction of the Applicant Proposed Route. These crossings could account for a potential of 157.0 acres of impact.

The 200-foot-wide corridor of the Applicant Proposed Route in Region 2 includes approximately 1.4 miles of perennial streams, 3.8 miles of intermittent streams, less than 0.1 mile of major waterbodies, and 1.9 acres of reservoirs, lakes, and ponds (Table 3.15-8). Riparian areas may be associated with many, if not all, of these surface water features.

3.19.6.2.3.1.3 Region 3

Construction of the Applicant Proposed Route in Region 3 could result in as much as 61 acres of impacts to wetlands within the representative ROW. Table 3.19-56 provides the number of wetlands by type and the associated estimate of potential impact acreage within the ROW.

Table 3.19-56:
Potential Construction Impacts to Wetlands within the ROW of the Applicant Proposed Route—Region 3

Wetland Type	Number of Wetlands	Acreage of Potential Impact
L1UB	1	0.6

R2UB	3	3.4
Totals	151	60.8

GIS Data Source: USFWS (2014g)

Twenty 100-year floodplains within Region 3 would be crossed by the construction of the Applicant Proposed Route. These crossings could account for as much as 293.8 acres of impact to floodplains in the ROW.

The 200-foot-wide corridor of the Applicant Proposed Route in Region 3 includes approximately 10.5 miles of perennial streams, 7.8 miles of intermittent streams, 0.2 mile of major waterbodies, and 39.5 acres of reservoirs, lakes, and ponds (Table 3.15-12). Riparian areas may be associated with many, if not all, of these surface water features.

Five route variations to the Applicant Proposed Route were developed in Region 3 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.3. The variations are illustrated in Exhibit 1 of Appendix M. These variations represent minor adjustments to the original Applicant Proposed Route Links 1, 2, 4, and 5 as follows. Link 1, Variation 2, would have fewer miles of streams. Links 1 and 2, Variation 1, differs from the Applicant Proposed Route Link 1 in having approximately one-half the mileage of streams within the ROW, a decrease in floodplains encountered and floodplain acreage that would be crossed, and a decrease in the total number of waterbodies encountered. It should be noted that a route adjustment was made for HVDC Alternative Route 3-A to maintain an end-to-end route with the Links 1 and 2 variations. The route adjustment for HVDC Alternative Route 3-A would not result in additional numbers of, or acreages for, wetlands, floodplains, or riparian areas impacted compared with the original HVDC Alternative Route 3-A. Link 4, Variation 1, would have a very slight increase in stream mileage, and an increase in the number of total waterbodies encountered by the variation. Link 4, Variation 2, would not result in additional numbers of, or acreages for, wetlands, floodplains, or riparian areas impacted. Link 5, Variation 2, would result in a very slight increase of stream mileage and a small increase in the number of surface waterbodies impacted.

3.19.6.2.3.1.4 Region 4

Construction of the Applicant Proposed Route in Region 4 could cause impacts to as many as seven wetland types totaling 22.8 acres of wetlands within the representative ROW. Table 3.19-57 provides the number of wetlands by type and the associated potential impact acreage.

Table 3.19-57:
Potential Construction Impacts to Wetlands within the ROW for the Applicant Proposed Route—Region 4

Wetland Type	Number of Wetlands	Acreage of Potential Impact
L1UB	1	5.3
PEM	3	1.8
PFO	8	8.6
PSS	1	0.0
PUB	19	4.6
R2UB	4	2.1
R2US	2	0.4
Totals	38	22.8

GIS Data Source: USFWS (2014g)

Thirty-two 100-year floodplains within Region 4 would be crossed by construction of the Applicant Proposed Route. These crossings could account for a potential of up to 545.7 acres of impact to floodplains in the ROW.

As shown in Table 3.15-16, the 200-foot-wide corridor of the Applicant Proposed Route in Region 4 includes approximately 3.5 miles of perennial streams, 9.0 miles of intermittent streams, 0.2 mile of major waterbodies, and 16.1 acres of reservoirs, lakes, and ponds. Riparian areas may be associated with many, if not all, of these surface water features.

A 100-foot buffer was applied to each side of the centerline of the Lee Creek Variation in order to calculate potential impacts to wetland and floodplain resources in a 200-foot-wide ROW. Results of potential impacts to NWI wetland resources include 0.44 acres of riverine, unconsolidated bottom (R2UB) wetlands and less than 0.1 acre of riverine, unconsolidated shore (R2US) wetlands. There is a potential for riparian area impacts associated with these riverine wetland types. 100-year floodplains impacts for the Lee Creek Variation were calculated at 7.7 acres within the 200-foot-wide ROW. As noted in Section 3.15.5.4.2, the Lee Creek Variation within the Applicant Proposed Route avoids the 300-foot buffer zone established around Lee Creek Reservoir by the city of Fort Smith, Arkansas.

Seven route variations to the Applicant Proposed Route were developed in Region 4 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.4. The variations are illustrated in Exhibit 1 of Appendix M. These variations represent minor adjustments to the original Applicant Proposed Route Links 3, 6, and 9 as follows. Link 3, Variation 1, would involve a very small increase in stream mileage crossed. It would result in decreases in the number of, and acreage for, forested wetlands. There would also be a decrease in floodplain acreage. Link 3, Variation 2, would avoid wetland resources. Variation 2 would also result in decreases in stream mileage crossed, the number and acreage of floodplains crossed, and the number of designated waterbodies crossed. Link 3, Variation 3, has the same wetland, floodplain, and riparian area resources. Link 6, Variation 1, has the same wetland, floodplain, and riparian area resources. Link 6, Variation 2, would have a decrease in stream mileage and floodplain acreage. Link 6, Variation 3, would result in a decrease in the number of crossings of surface waterbodies. Link 9, Variation 1, would have a decrease in stream mileage and floodplain acreage crossed and would avoid surface waterbodies.

3.19.6.2.3.1.5 Region 5

Construction of the Applicant Proposed Route in Region 5 could result in impacts to four wetland types and totaling approximately 12 total acres within the ROW. Table 3.19-58 provides the number of wetlands by type and the associated potential impact acreage.

Table 3.19-58:
Potential Construction Impacts to Wetlands within the ROW of the Applicant Proposed Route—Region 5

Wetland Type	Number of Wetlands	Acreage of Potential Impact
PEM	3	1.3
PFO	5	4.8
PUB	7	1.7
L2UB	2	3.8
Totals	17	11.6

GIS Data Source: USFWS (2014g)

Fourteen 100-year floodplains within Region 5 could be impacted by construction of the Applicant Proposed Route. The floodplain crossings could account for a potential of up to 111.1 acres of impact.

The 200-foot-wide corridor of the Applicant Proposed Route in Region 5 includes approximately 2.2 miles of perennial streams, 9.3 miles of intermittent streams, 0.2 mile of major waterbodies, and 17.3 acres of reservoirs, lakes, and ponds (Table 3.15-20). Riparian areas may be associated with many, if not all, of these surface water features.

Five route variations to the Applicant Proposed Route were developed in Region 5 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.5. The variations are illustrated in Exhibit 1 of Appendix M. These variations represent minor adjustments to the original Applicant Proposed Route Links 1, 2, 3, 4, and 7 as follows. Link 1, Variation 2, would have increases in stream mileage crossed as well as increases in mileage and acreage of forested wetland crossed. Link 1, Variation 2, would have decreases in the number of non-forested wetlands crossed and the number of waterbodies crossed. Link 2, Variation 2, would have a small increase in stream mileage. Links 2 and 3, Variation 1, would result in a decrease in stream mileage and floodplain acreage crossed. It should be noted that a route adjustment was made for HVDC Alternative Route 5-B to maintain an end-to-end route with Links 2 and 3, Variation 1. HVDC Alternative Route 5-B would result in a very slight increase in floodplain acreage. Links 3 and 4, Variation 2, would result in a small decrease in stream mileage crossed. A route adjustment was made for HVDC Alternative Route 5-E to maintain an end-to-end route with Links 3 and 4, Variation 2. This route adjustment would cross one fewer floodplain than the original HVDC Alternative Route 5-E. Link 7, Variation 1, would cross one additional waterbody.

3.19.6.2.3.1.6 Region 6

Construction of the Applicant Proposed Route in Region 6 could cause impacts to five wetland types totaling approximately 13.5 acres within the representative ROW. Table 3.19-59 provides the number of wetlands by type and the associated potential impact acreage.

Table 3.19-59:
Potential Construction Impacts to Wetlands within the ROW of the Applicant Proposed Route—Region 6

Wetland Type	Number of Wetlands	Acreage of Potential Impact
PEM	12	3.2
PFO	4	5.1
PSS	1	0.1
PUB	2	2.8
R2UB	2	2.3
Totals	21	13.5

GIS Data Source: USFWS (2014g)

Five 100-year floodplains within Region 6 could be impacted by construction of the Applicant Proposed Route. The floodplain crossings could account for a potential of up to 335.5 acres of impact in the representative ROW.

The 200-foot-wide corridor of the Applicant Proposed Route in Region 6 includes approximately 0.8 mile of perennial streams, 3.5 miles of intermittent streams, 0.2 mile of major waterbodies, and 5.2 acres of reservoirs, lakes, and ponds (Table 3.15-24). Riparian areas may be associated with many, if not all, of these surface water features.

One route variation was developed in Region 6 in response to public comments on the Draft EIS to parallel more parcel boundaries to minimize impacts to agricultural operations and is shown in Exhibit 1 of Appendix M. This variation represents a minor adjustment to the original Applicant Proposed Route Link 2. Link 2, Variation 1, would produce small increases in stream mileage and forested wetland acreage crossed and would add one crossing of a >1,000-foot forested wetland. This variation would also have a small decrease in non-forested wetland acreage to be crossed. It should be noted that a route adjustment was made for HVDC Alternative Route 6-A to maintain an end-to-end route with Link 2, Variation 1. The route adjustment for HVDC Alternative Route 6-A would cross fewer non-forested and forested wetland acres compared with the original alternative route.

3.19.6.2.3.1.7 Region 7

Construction of the Applicant Proposed Route in Region 7 could cause impacts to five wetland types and 42 total acres within the ROW. Table 3.19-60 provides the number of wetlands by type with the associated predicted impact acreage.

Table 3.19-60:
Potential Construction Impacts to Wetlands within the ROW of the Applicant Proposed Route–Region 7

Wetland Type	Number of Wetlands	Acreage of Potential Impact
PEM	3	1.8
PFO	14	17.7
PSS	1	2.6
PUB	3	2.8
R2UB	2	16.9
Totals	23	41.8

GIS Data Source: USFWS (2014g)

Twenty-five 100-year floodplains within Region 7 could be impacted by construction of the Applicant Proposed Route. These floodplain crossings account for a potential of 344.6 acres of impact within the ROW.

The 200-foot-wide corridor of the Applicant Proposed Route in Region 7 includes approximately 0.5 mile of perennial streams, 4.3 miles of intermittent streams, 0.6 mile of major waterbodies, and 2.4 acres of reservoirs, lakes, and ponds (Table 3.15-28). Riparian areas may be associated with many, if not all, of these surface water features.

Three route variations to the Applicant Proposed Route were developed in Region 7 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.7. The variations are illustrated in Exhibit 1 of Appendix M. These variations represent minor adjustments to the original Applicant Proposed Route Links 1 and 5 as follows. Link 1, Variation 1, would result in an increase in stream mileage. Link 1, Variation 2, would cross fewer miles of streams, fewer acres of floodplain, and fewer surface waterbodies. This variation would cross more acreage of forested wetland, a larger number of non-forested wetlands, and a larger number of wetland crossings that are greater than 1,000 feet in width. Link 5, Variation 1, would have no predicted impacts to wetlands, floodplains, or riparian areas.

3.19.6.2.3.2 Operations and Maintenance Impacts

The operation and maintenance for the Applicant Proposed Route would involve routine and periodic vegetation management according to the TVMP. Impacts related to operations and maintenance may result from use of heavy machinery through wetlands, floodplains, and riparian areas. These impacts can cause soil compaction and mechanical damage or removal of vegetation. These operations and maintenance impacts are anticipated to cover a range from temporary and minor to potentially more severe and long term/permanent. The estimated acreage of each resource type (wetlands, floodplains, and riparian areas) by region is provided in the previous subsections of Section 3.19.6.2.3.1.

The use of vegetation management would be necessary to protect the Project infrastructure and enhance safety. However, the trimming, mowing, or removal of vegetation can cause changes to plant diversity and function in all three ecosystem types (i.e., wetlands, floodplains, and riparian areas). Vegetation maintenance in wetlands and riparian areas should be kept to a minimum to the extent practicable. Additionally, the use of herbicides can cause minor to severe impacts to vegetation in areas where they are applied. Great care would need to be used when applying herbicides in close proximity to wetlands and riparian areas. Herbicides may drift in windy conditions and cause impacts to non-target plants, so application should be avoided in these conditions. Label directions for herbicides typically advise the applicator as to whether a specific herbicide can be used in or near wetlands and waterways.

3.19.6.2.3.3 Decommissioning Impacts

The decommissioning impacts related to Project would be similar in nature to the set of temporary impacts resulting from initial construction. These temporary impacts would involve use of construction machinery at the various sites of infrastructure (e.g., the lattice structures, lattice crossing structures, monopole structures, guyed structures, fiber optic infrastructure, etc.) to remove aboveground material, and foundation material where required. Use of construction machinery would have the potential to crush or remove vegetation, but no long-term effects are anticipated to be likely from the decommissioning phase of the Project. Revegetation for wetlands, floodplains, and riparian areas would be guided by the Project's Decommissioning Plan and by the conditions set forth in any CWA permitting that would be required.

3.19.6.3 Impacts Associated with the DOE Alternatives

3.19.6.3.1 Arkansas Converter Station Alternative Siting Area and AC Interconnection Siting Area

3.19.6.3.1.1 Construction Impacts

Although the exact location of the Arkansas converter station within the siting area has not yet been determined, construction of this converter station would convert 20 to 35 acres of undeveloped land to a utility land use. An additional 5 to 10 acres would be required for construction only. These areas would be used as laydown areas for equipment during construction. An additional 4.2 acres of undeveloped land would be converted to access roads (2.4 acres permanent, 1.8 acres temporary). The converter station siting area ROW includes 0.6 mile of intermittent streams, 43.8 acres of floodplains, and 2.6 acres of surface waterbodies (ponds/lakes). Construction that causes dredge or fill impacts in wetlands and waters of the United States would require permitting under the CWA Section 404 program. Wetland impacts would typically require a preconstruction notification filed with the applicable regulatory office of the USACE. In Arkansas, the counties crossed by the Project are all within the so-called Fayetteville Shale Play area. Any level of impacts to wetlands and other waters of the United States in the Fayetteville Shale Play are required to be reported to the USACE under regional conditions for nationwide permitting. The construction effort should avoid wetlands and waters of the United States to the extent practicable.

The Arkansas AC interconnect siting area is approximately 1,000 feet wide and the permanent ROW would be 150 to 200 feet wide and approximately 5 miles long with a total acreage of approximately 661.6 acres. The interconnection siting area ROW includes 1.5 miles of intermittent streams, 0.2 mile of perennial streams, 463.8 acres of floodplains, and 1.7 acres of other surface waterbodies (ponds/lakes). A new substation would be constructed to interconnect the AC interconnection transmission line with an existing 500 kV line. The site is adjacent to the existing transmission line and is primarily grassland with some wooded areas. The site contains two freshwater ponds and approximately 0.1 miles of streams. The substation would occupy 25 to 35 acres and would also temporarily disturb an additional 5 acres during construction. Any surface water features would be avoided.

3.19.6.3.1.2 Operations and Maintenance Impacts

The operation and maintenance of the Arkansas converter station would involve routine and periodic vegetation management according to the TVMP. Wetlands, floodplains and riparian areas associated with perennial streams have all been documented within the siting area, but ultimately only 25–45 acres of land would be disturbed. These resources should be avoided during siting so that no impacts would be incurred during operations and routine maintenance.

3.19.6.3.1.3 Decommissioning Impacts

The decommissioning impacts related to the Project would be similar in nature to the set of temporary impacts resulting from initial construction. These temporary impacts would involve use of construction machinery at the Arkansas converter station, as well as the ROW areas that would have been used for the AC interconnection. The specific acreage for the footprint of the converter station would total a projected maximum of 60 acres that would be reclaimed and revegetated according to the details that would be written into the Decommissioning Plan.

3.19.6.3.2 HVDC Alternative Routes

3.19.6.3.2.1 Construction Impacts

Impacts to wetlands during construction of the HVDC alternative routes would vary depending upon alternative chosen. Impacts may vary from no impact, to minor and short term to long term, and, potentially, permanent loss of wetland acreage. Impacts presented below represent the amount of wetlands, floodplains, and riparian areas estimated to exist within the 200-foot-wide representative ROW for the HVDC alternative routes. Riparian areas may be associated with many, if not all, of these surface water features listed for each alternative.

3.19.6.3.2.1.1 Region 1

3.19.6.3.2.1.1.1 Alternative Route 1-A

HVDC Alternative Route 1-A is 123.0 miles in length and corresponds to Applicant Proposed Route Links 2, 3, 4, and 5, which are a combined 113.6 miles in length.

HVDC Alternative Route 1-A could cause up to 15.1 acres of impacts in 30 wetlands within the representative ROW. Table 3.19-61 provides the number of wetlands by type with the associated estimate of potential impact acreage for HVDC Alternative Route 1-A. By comparison, Applicant Proposed Route Links 2, 3, 4, and 5 are predicted to potentially cause as much as 22 acres of impacts to wetlands.

Table 3.19-61:
Potential Construction Impacts to Wetlands within the ROW of HVDC Alternative Route 1-A

Wetland Type	Number of Wetlands	Acreage of Potential Impact
PEM	10	8.6
PFO	2	1.3
PSS	5	2.1
PUS	10	2.6
R2UB	2	0.4
R2US	1	0.1
Totals	30	15.1

GIS Data Source: USFWS (2014g)

One 100-year floodplain could be impacted by construction in the 200-foot-wide ROW of HVDC Alternative Route 1-A. The estimated potential impact for this floodplain crossing is 5.3 acres. Floodplain impacts for Applicant Proposed Route Links 2, 3, 4, and 5 include the crossing of two 100-year floodplains; the potential impact acreage for those crossings equals 52 acres.

As shown in Table 3.15-4, the 200-foot-wide ROW of HVDC Alternative Route 1-A includes approximately 0.8 mile of perennial streams, 8.6 miles of intermittent streams, less than 0.1 mile of major waterbodies, and 6.8 acres of reservoirs, lakes, and ponds. In comparison, the Applicant Proposed Route Links 2, 3, 4, and 5 feature approximately 0.9 mile of perennial streams, 5.9 miles of intermittent streams, less than 0.1 mile of major waterbodies, and 9.9 acres of reservoirs, lakes, and ponds.

3.19.6.3.2.1.1.2 Alternative Route 1-B

HVDC Alternative Route 1-B is 51.8 miles in length and corresponds to Applicant Proposed Route Links 2 and 3 which are a combined 53.8 miles in length.

HVDC Alternative Route 1-B could cause impacts to four wetland types that would equal as much as 2.8 total acres within the ROW. Table 3.19-62 provides the number of wetlands by type with the associated potential impact acreage for HVDC Alternative Route 1-B. The potential acreage of wetland impact for Applicant Proposed Route Links 2 and 3 is 14.9 acres located within 17 NWI-mapped wetlands.

Table 3.19-62:
Potential Construction Impacts to Wetlands within the ROW of HVDC Alternative Route 1-B

Wetland Type	Number of Wetlands	Acreage of Potential Impact
PEM/PSS	1	0.4
PSS	2	1.1
R2UB	1	0.3
R2US	1	1.0
Totals	5	2.8

GIS Data Source: USFWS (2014g)

Two 100-year floodplains could be impacted by construction in the 200-foot-wide ROW of HVDC Alternative Route 1-B. The estimated potential acreage of impact for these floodplain crossings is 6.0 acres. Floodplain impacts for

Applicant Proposed Route Links 2 and 3 include the crossing of two 100-year floodplains; the acreage for those crossings equals approximately 52.4 acres.

The 200-foot-wide ROW of HVDC Alternative Route 1-B includes approximately 0.1 mile of perennial streams, 3.0 miles of intermittent streams, less than 0.1 mile of major waterbodies, and 1.1 acres of reservoirs, lakes, and ponds (Table 3.15-4). In comparison, the corresponding Applicant Proposed Route Links 2 and 3 feature approximately 0.3 mile of perennial streams, 2.4 miles of intermittent streams, less than 0.1 mile of major waterbodies, and 1.1 acres of reservoirs, lakes, and ponds.

3.19.6.3.2.1.1.3 Alternative Route 1-C

HVDC Alternative Route 1-C is 52.0 miles in length. It corresponds to Applicant Proposed Route Links 2 and 3, which are a combined 53.8 miles in length.

HVDC Alternative Route 1-C could cause impacts to five wetland types and up to a total of 4.9 acres within the representative ROW. Table 3.19-63 provides the number of wetlands by type with the associated potential impact acreage for HVDC Alternative Route 1-C. The Applicant Proposed Route Links 2 and 3 could impact up to 14.9 acres within 17 NWI-mapped wetlands in the ROW.

Table 3.19-63:
Potential Construction Impacts to Wetlands within the ROW of HVDC Alternative Route 1-C

Wetland Type	Number of Wetlands	Acreage of Potential Impact
PEM	3	1.4
PFO	1	0.9

PUS	1	0.1
R2UB	2	0.4
Totals	13	4.9

GIS Data Source: USFWS (2014g)

One 100-year floodplain could be impacted by construction in the 200-foot-wide ROW of HVDC Alternative Route 1-C. The estimated acreage of impact for this floodplain crossing is 5.3 acres. Floodplain impacts for Applicant Proposed Route Links 2 and 3 include the crossing of two 100-year floodplains; the acreage for those crossings equals 52.4 acres.

The 200-foot-wide ROW of HVDC Alternative Route 1-C includes approximately 0.2 mile of perennial streams, 2.6 miles of intermittent streams, less than 0.1 mile of major waterbodies, and 1.2 acres of reservoirs, lakes, and ponds (Table 3.15-4). In comparison, the corresponding Applicant Proposed Route Links 2 and 3 feature approximately 0.3 mile of perennial streams, 2.4 miles of intermittent streams, less than 0.1 mile of major waterbodies, and 7.2 acres of reservoirs, lakes, and ponds.

3.19.6.3.2.1.1.4 Alternative Route 1-D

HVDC Alternative Route 1-D is 33.5 miles in length. It corresponds to Applicant Proposed Route Links 3 and 4, which are a combined 33.6 miles in length.

HVDC Alternative Route 1-D could impact up to three wetland types and a total of 1.7 acres within the ROW. Table 3.19-64 provides the number of wetlands by type with the associated prediction of impact acreage for HVDC Alternative Route 1-D. In comparison, there is 0.9 acre of potential impact to wetlands in the Applicant Proposed Route Links 3 and 4.

Table 3.19-64:
Potential Construction Impacts to Wetlands within the ROW of HVDC Alternative Route 1-D

Wetland Type	Number of Wetlands	Acreage of Potential Impact
PEM	1	0.1
PSS	1	1.4
PUS	1	0.2
Totals	3	1.7

GIS Data Source: USFWS (2014g)

No FEMA 100-year floodplains are mapped within the ROW for HVDC Alternative Route 1-D. The 200-foot-wide ROW of HVDC Alternative Route 1-D includes approximately 0.1 mile of perennial streams, 2.2 miles of intermittent streams, no major waterbodies, and 0.2 acre of reservoirs, lakes, and ponds (Table 3.15-4). In comparison, the corresponding Applicant Proposed Route Links 3 and 4 feature approximately 0.1 mile of perennial streams, 2.6 miles of intermittent streams, no major waterbodies, and 1.0 acre of reservoirs, lakes, and ponds.

3.19.6.3.2.1.2 Region 2

3.19.6.3.2.1.2.1 Alternative Route 2-A

HVDC Alternative Route 2-A is 57.2 miles in length. It corresponds to Applicant Proposed Route Link 2, which is 54.4 miles in length. HVDC Alternative Route 2-A features 11 land cover types.

HVDC Alternative Route 2-A could cause as many as 10.4 acres of impacts in 26 wetlands that NWI has mapped in the ROW of the alternative. Table 3.19-65 provides the number of wetlands by type with the associated potential impact acreage for HVDC Alternative Route 2-A. By comparison, there are predicted to be as many as 9.1 acres of wetlands that could be impacted within the ROW for Applicant Proposed Route Link 2.

Table 3.19-65:
Potential Construction Impacts to Wetlands within the ROW of HVDC Alternative Route 2-A

Wetland Type	Number of Wetlands	Acreage of Potential Impact
PEM	4	0.6

PUS	8	1.4
R2UB	1	0.8
R2US	3	2.8
Totals	26	10.4

GIS Data Source: USFWS (2014g)

One 100-year floodplain is predicted to be impacted by construction in the 200-foot-wide ROW along HVDC Alternative Route 2-A. The estimated acreage of impact for this floodplain crossing is 4.5 acres. Applicant Proposed Route Link 2 is not projected to cross floodplains within its ROW.

As shown in Table 3.15-8, the 200-foot-wide ROW of HVDC Alternative 2-A includes approximately 3.4 miles of perennial streams, 0.6 mile of intermittent streams, 0.1 mile of major waterbodies, and 6.5 acres of reservoirs, lakes, and ponds. In comparison, the corresponding Applicant Proposed Route Link 2 features approximately 1.3 miles of perennial streams, 1.8 miles of intermittent streams, less than 0.1 mile of major waterbodies, and 0.8 acre of reservoirs, lakes, and ponds.

3.19.6.3.2.1.2.2 Alternative Route 2-B

HVDC Alternative Route 2-B is 29.8 miles in length. It corresponds to Region 2, Applicant Proposed Route Link 3, which is 31.2 miles in length.

Three 100-year floodplains are predicted to be impacted by construction in the 200-foot-wide ROW along HVDC Alternative Route 2-B. The estimated total acreage of impact for these floodplain crossings is 83.0 acres. Applicant Proposed Route Link 3 would cross four 100-year floodplains, with an estimated total of 64.5 acres of impact within the 200-foot-wide ROW.

HVDC Alternative Route 2-B could cause impacts to five wetland types and 9.3 total acres within the ROW. Table 3.19-66 provides the number of wetlands by type with the associated potential impact acreage for HVDC Alternative Route 2-B. Twelve NWI wetlands (4.5 acres within the ROW) are present in Applicant Proposed Route Link 3.

The 200-foot-wide ROW of HVDC Alternative Route 2-B includes approximately 0.5 mile of perennial streams, 1.3 miles of intermittent streams, no major waterbodies, and 1.6 acres of reservoirs, lakes, and ponds (Table 3.15-8). In comparison, the corresponding Applicant Proposed Route Link 3 features approximately 0.1 mile of perennial streams, 1.9 miles of intermittent streams, no major waterbodies, and 1.1 acres of reservoirs, lakes, and ponds.

Table 3.19-66:
Potential Construction Impacts to Wetlands within the ROW of HVDC Alternative Route 2-B

3.19.6.3.2.1.3 Region 3

3.19.6.3.2.1.3.1 Alternative Route 3-A

HVDC Alternative Route 3-A is 37.6 miles in length. It corresponds to Applicant Proposed Route Link 1, which is 40.0 miles in length.

HVDC Alternative Route 3-A could cause impacts to four wetland types and up to 11.3 total acres within the ROW. Table 3.19-67 provides the number of wetlands by type with the associated potential impact acreage for HVDC Alternative Route 3-A. Applicant Proposed Route Link 1 features 14 NWI-mapped wetlands in its ROW. Impact for Region 3, Applicant Proposed Route Link 1 could be as many as 6.8 acres.

Table 3.19-67:
Potential Construction Impacts to Wetlands within the ROW of HVDC Alternative Route 3-A

Totals	35	11.3

GIS Data Source: USFWS (2014g)

Nine 100-year floodplains are predicted to be impacted by construction along the HVDC Alternative Route 3-A 200-foot-wide ROW. The estimated acreage of impact for these floodplain crossings equal 43.6 acres. Applicant Proposed Route Link 1 is predicted to cross six 100-year floodplains, with a total potential impact of 95 acres.

The 200-foot-wide ROW of HVDC Alternative Route 3-A includes approximately 3.6 miles of perennial streams, 1.3 miles of intermittent streams, no major waterbodies, and 9.6 acres of reservoirs, lakes, and ponds (Table 3.15-12). In comparison, the corresponding Applicant Proposed Route Link 1 features approximately 2.7 miles of perennial streams, 2.1 miles of intermittent streams, less than 0.1 mile of major waterbodies, and 4.0 acres of reservoirs, lakes, and ponds.

As described in Appendix M and summarized in Section 2.4.2.3, a route adjustment was developed for HVDC Alternative Route 3-A to maintain an end-to-end route with Applicant Proposed Route Link 1, Variation 2, and Links 1 and 2, Variation 1. The route adjustment would not include any perennial streams or intermittent streams, wetlands, floodplains, or other surface water bodies.

3.19.6.3.2.1.3.2 Alternative Route 3-B

HVDC Alternative Route 3-B is 47.7 miles in length. It corresponds to Applicant Proposed Route Links 1, 2, and 3, which are a combined 49.9 miles in length.

HVDC Alternative Route 3-B could cause impacts to as many as 49 wetlands totaling 16.8 acres within the representative ROW. Table 3.19-68 provides the number of wetlands by type with the associated potential impact acreage for HVDC Alternative Route 3-B. Applicant Proposed Route Links 1, 2, and 3 could cause as much as 9 total acres of impact in a set of 25 wetlands.

Table 3.19-68:
Potential Construction Impacts to Wetlands within the ROW of HVDC Alternative Route 3-B

Wetland Type	Number of Wetlands	Acreage of Potential Impact
PEM	1	0.4
PFO	7	4.1
PUB	19	7.7
PUS	22	4.6
Totals	49	16.8

GIS Data Source: USFWS (2014g)

Eleven 100-year floodplains are predicted to be impacted by construction in the 200-foot-wide ROW along HVDC Alternative Route 3-B. The estimated acreage of impact for these floodplain crossings equal 60.5 acres. Applicant Proposed Route Links 1, 2, and 3 are predicted to impact eight 100-year floodplains, totaling 123.5 acres in the ROW.

The 200-foot-wide ROW of HVDC Alternative Route 3-B includes approximately 4.7 miles of perennial streams, 1.3 miles of intermittent streams, less than 0.1 mile of major waterbodies, and 13.2 acres of reservoirs, lakes, and ponds (Table 3.15-12). In comparison, the corresponding Applicant Proposed Route Links 1, 2 and 3 feature approximately 4.1 miles of perennial streams, 2.1 miles of intermittent streams, less than 0.1 mile of major waterbodies, and 7.2 acres of reservoirs, lakes, and ponds.

3.19.6.3.2.1.3.3 Alternative Route 3-C

HVDC Alternative Route 3-C is 121.6 miles in length. It corresponds to Applicant Proposed Route Links 3, 4, 5, and 6, which are a combined 118.6 miles in length.

HVDC Alternative Route 3-C could cause 90.3 acres of impact to as many as 127 wetlands within the ROW. Table 3.19-69 provides the number of wetlands by type with the associated potential impact acreage for HVDC Alternative Route 3-C. Corresponding Applicant Proposed Route Links 3, 4, 5, and 6 could cause a total of 52.6 acres of impact to a group of approximately 130 wetlands within the representative ROW.

Table 3.19-69:
Potential Construction Impacts to Wetlands within the ROW of HVDC Alternative Route 3-C

Wetland Type	Number of Wetlands	Acreage of Potential Impact
L1UB	1	0.0
PEM	14	6.2
PFO/PSS	3	5.6
PFO	26	55.3
PEM/PSS	2	1.3
PUB	76	17.3
PUS	2	0.3
R2UB	1	1.3
R2US	2	3.0
Totals	127	90.3

GIS Data Source: USFWS (2014g)

Seventeen 100-year floodplains are predicted to be impacted by construction in the 200-foot-wide ROW along HVDC Alternative Route 3-C; the estimated acreage of impact equals 305.6 acres. Applicant Proposed Route Links 3, 4, 5, and 6 are predicted to cross 13 100-year floodplains, with a predicted impact total of 198.2 acres.

The 200-foot-wide ROW of HVDC Alternative Route 3-C includes approximately 5.6 miles of perennial streams, 8.8 miles of intermittent streams, 0.1 mile of major waterbodies, and 20.4 acres of reservoirs, lakes, and ponds (Table 3.15-12). In comparison, the corresponding Applicant Proposed Route Links 3, 4, 5 and 6 feature approximately 7.2 miles of perennial streams, 5.7 miles of intermittent streams, 0.1 mile of major waterbodies, and 32.3 acres of reservoirs, lakes, and ponds.

3.19.6.3.2.1.3.4 Alternative Route 3-D

HVDC Alternative Route 3-D is 39.3 miles in length. It corresponds to Applicant Proposed Route Links 5 and 6, which are a combined 35.1 miles in length.

HVDC Alternative Route 3-D could cause impacts to 66 wetlands totaling up to 37.9 acres within the representative ROW. Table 3.19-70 provides the number of wetlands by type and the associated potential impact acreage for HVDC Alternative Route 3-D. The corresponding Applicant Proposed Route Links 5 and 6 could cause 14.7 acres of impact in 39 NWI-mapped wetlands within the ROW.

Table 3.19-70:
Potential Construction Impacts to Wetlands within the ROW of HVDC Alternative Route 3-D

Wetland Type	Number of Wetlands	Acreage of Potential Impact
PEM	10	5.1
PFO/PSS	3	5.6
PFO	14	19.3
PEM/PSS	2	1.3
PUB	37	6.6
Totals	66	37.9

GIS Data Source: USFWS (2014g)

Seven 100-year floodplains are predicted to be impacted by construction in the 200-foot-wide ROW along HVDC Alternative Route 3-D; the estimated acreage of impact equals 91.5 acres. Applicant Proposed Route Links 5 and 6 are predicted to total approximately 41.6 acres of impact from the crossing of three 100-year floodplains.

The 200-foot-wide ROW of HVDC Alternative Route 3-D includes approximately 0.8 mile of perennial streams, 4.2 miles of intermittent streams, no major waterbodies, and 9.1 acres of reservoirs, lakes, and ponds (Table 3.15-12). In comparison, the corresponding Applicant Proposed Route Links 5 and 6 feature approximately 2.0 miles of perennial streams, 1.9 miles of intermittent streams, less than 0.1 mile of major waterbodies, and 7.1 acres of reservoirs, lakes, and ponds.

3.19.6.3.2.1.3.5 Alternative Route 3-E

HVDC Alternative Route 3-E is 8.5 miles in length. It corresponds to Applicant Proposed Route Link 6, which is 7.7 miles in length.

HVDC Alternative Route 3-E could cause impacts to 12 wetlands totaling 10.9 acres within the representative ROW. Table 3.19-71 provides the number of wetlands by type with the associated potential impact acreage for HVDC Alternative Route 3-E. The corresponding Applicant Proposed Route Link 6 could cause 1.8 acres of impact within seven NWI-mapped wetlands in its representative ROW.

Table 3.19-71:
Potential Construction Impacts to Wetlands within the ROW of HVDC Alternative Route 3-E

Wetland Type	Number of Wetlands	Acreage of Potential Impact
PFO/PSS	3	7.2
PFO	2	2.1
PUB	7	1.6
Totals	12	10.9

GIS Data Source: USFWS (2014g)

Two 100-year floodplains are predicted to be impacted by construction in the 200-foot-wide ROW along HVDC Alternative Route 3-E. The estimated acreage of impact for these 100-year floodplain crossings is predicted to be 21.2 acres.

The 200-foot-wide ROW of HVDC Alternative Route 3-E includes approximately 0.1 mile of perennial streams, 1.5 miles of intermittent streams, no major waterbodies, and 1.3 acres of reservoirs, lakes, and ponds (Table 3.15-12). In comparison, the corresponding Applicant Proposed Route Link 6 features no perennial streams, 0.8 mile of intermittent streams, no major waterbodies, and 1.5 acres of reservoirs, lakes, and ponds.

3.19.6.3.2.1.4 Region 4

3.19.6.3.2.1.4.1 Alternative Route 4-A

HVDC Alternative Route 4-A is 58.4 miles in length. It corresponds to Applicant Proposed Route Links 3, 4, 5, and 6, which are a combined 60.4 miles in length.

HVDC Alternative Route 4-A could cause impacts in as many as 27 NWI-mapped wetlands for a total of 11.3 acres within the representative ROW. Table 3.19-72 provides the number of wetlands by type with the associated potential impact acreage HVDC Alternative Route 4-A. Applicant Proposed Route Links 3, 4, 5, and 6 could have a total of approximately 13.6 acres of impact to wetlands in its representative ROW.

Table 3.19-72:
Potential Construction Impacts to Wetlands within the ROW of HVDC Alternative Route 4-A

Wetland Type	Number of Wetlands	Acreage of Potential Impact
PFO	2	1.8
PEM/PSS	1	1.3
PUB	22	6.8
L2US	2	1.4
Totals	27	11.3

GIS Data Source: USFWS (2014g)

Thirteen 100-year floodplains are predicted to be impacted by construction in the 200-foot-wide ROW along HVDC Alternative Route 4-A. The estimated acreage of impact for these floodplain crossings equals 130.2 acres. Applicant

Proposed Route Links 3, 4, 5, and 6 are predicted to total approximately 409.2 acres of temporary impact to 23 100-year floodplains within the ROW.

The 200-foot-wide ROW of HVDC Alternative Route 4-A includes approximately 1.4 miles of perennial streams, 4.3 miles of intermittent streams, 0.1 mile of major waterbodies, and 5.5 acres of reservoirs, lakes, and ponds (Table 3.15-16). In comparison, the corresponding Applicant Proposed Route Links 3, 4, 5, and 6 feature approximately 1.7 miles of perennial streams, 3.9 miles of intermittent streams, 0.2 mile of major waterbodies, and 4.4 acres of reservoirs, lakes, and ponds.

3.19.6.3.2.1.4.2 Alternative Route 4-B

HVDC Alternative Route 4-B is 78.6 miles in length. It corresponds to Region 4, Applicant Proposed Route Links 2–8, which are a combined 81.3 miles in length.

HVDC Alternative Route 4-B could cause impacts to 18 wetlands and 9.0 total acres within the representative ROW. Table 3.19-73 provides the number of wetlands by type with the associated potential impact acreage for HVDC Alternative Route 4-B. By comparison, construction of the Applicant Proposed Route Links 2–8 could result in approximately 13.7 acres of impact to 29 NWI-mapped wetlands in its ROW.

Table 3.19-73:
Potential Construction Impacts to Wetlands within the ROW of HVDC Alternative Route 4-B

Wetland Type	Number of Wetlands	Acreage of Potential Impact
PFO/PSS	1	0.7
PFO	1	2.0
PEM/PSS	1	1.3
PSS	1	0.1
PUB	12	4.1
L2UB	1	0.5
L2US	1	0.3
Totals	18	9

GIS Data Source: USFWS (2014g)

Twelve 100-year floodplains may be impacted by construction in the 200-foot-wide ROW along HVDC Alternative Route 4-B. These impacts are predicted to equal 104.4 acres. Applicant Proposed Route Links 2–8 are predicted to cross approximately 25 100-year floodplains, resulting in the potential for 413.4 acres of impact within the ROW.

The 200-foot-wide ROW would of HVDC Alternative Route 4-B encompasses includes approximately 1.6 miles of perennial streams, 5.9 miles of intermittent streams, 0.1 mile of major waterbodies, and 5.0 acres of reservoirs, lakes, and ponds (Table 3.15-16). In comparison, the corresponding Applicant Proposed Route Links 2, 3, 4, 5, 6, 7 and 8 feature approximately 2.5 miles of perennial streams, 4.8 miles of intermittent streams, 0.2 mile of major waterbodies, and 7.6 acres of reservoirs, lakes, and ponds.

3.19.6.3.2.1.4.3 Alternative Route 4-C

HVDC Alternative Route 4-C is 3 miles in length. It corresponds to Applicant Proposed Route Link 5, which is 2 miles in length.

No NWI-mapped wetlands are documented for the ROW in Alternative Route 4-C. Because NWI data is lacking for this alternative route, NLCD was also queried to estimate wetland acreage within this ROW. NLCD data also documented no wetlands in the ROW.

No 100-year floodplains are mapped in the 200-foot-wide ROW for HVDC Alternative Route 4-C.

The 200-foot-wide corridor of HVDC Alternative Route 4-C includes approximately 0.2 mile of perennial streams, 0.1 mile of intermittent streams, no major waterbodies, and 0.8 acre of reservoirs, lakes, and ponds (Table 3.15-16). In comparison, the corresponding Applicant Proposed Route Link 5 features approximately less than 0.1 mile of perennial streams, 0.2 mile of intermittent streams, no major waterbodies, and 0.3 acre of reservoirs, lakes, and ponds.

3.19.6.3.2.1.4.4 Alternative Route 4-D

HVDC Alternative Route 4-D is 25.3 miles in length. It corresponds to Applicant Proposed Route Links 4, 5 and 6, which are a combined 25.4 miles in length.

HVDC Alternative Route 4-D could cause impacts in two wetlands with a total of 0.3 acre of impacts within the ROW. In comparison, the Applicant Proposed Route Links 4, 5, and 6 could impact 0.1 acre of wetland in a single wetland that is crossed by its representative ROW.

Seven 100-year floodplains are predicted to be impacted by construction in the 200-foot-wide ROW along HVDC Alternative Route 4-D. The estimated acreage of impact for these floodplain crossings equal 47.9 acres. Applicant Proposed Route Links 4, 5 and 6 are predicted to total approximately 409.2 acres of impact from the crossing of 23 100-year floodplains.

The 200-foot-wide ROW of HVDC Alternative Route 4-D includes approximately 0.7 mile of perennial streams, 2.1-miles of intermittent streams, less than 0.1 mile of major waterbodies, and 3.1 acres of reservoirs, lakes, and ponds (Table 3.15-16). In comparison, the corresponding Applicant Proposed Route Links 4, 5, and 6 feature approximately 1.3 miles of perennial streams, 1.3 miles of intermittent streams, 0.1 mile of major waterbodies, 2.9 acres of reservoirs, lakes, and ponds.

3.19.6.3.2.1.4.5 Alternative Route 4-E

HVDC Alternative Route 4-E is 36.7 miles in length. It corresponds to Applicant Proposed Route Links 8 and 9, which are a combined 38.7 miles in length.

There are no documented NWI wetlands in the 200-foot-wide ROW along the route of HVDC Alternative 4-E or along the corresponding Applicant Proposed Route Links 8 and 9 in Region 4. Because NWI data is lacking for this alternative route, NLCD land cover data were also evaluated. That data set documented 0.09 acres of woody wetlands in the ROW. The corresponding Applicant Proposed Route Links 8 and 9 did not have documented wetland land cover within the representative ROW.

Nine 100-year floodplains are predicted to be impacted by construction in the 200-foot-wide ROW along HVDC Alternative Route 4-E for a total of 67.4 acres. Applicant Proposed Route Links 8 and 9 are predicted to total approximately 95.2 acres of impact in existing floodplains.

The 200-foot-wide corridor of HVDC Alternative Route 4-E includes approximately 0.6 mile of perennial streams, 3.8 miles of intermittent streams, 0.1 mile of major waterbodies, and 7.5 acres of reservoirs, lakes, and ponds (Table 3.15-16). In comparison, the corresponding Applicant Proposed Route Links 8 and 9 feature approximately 0.9 mile of perennial streams, 2.9 miles of intermittent streams, less than 0.1 mile of major waterbodies, and 3.2 acres of reservoirs, lakes, and ponds.

3.19.6.3.2.1.5 Region 5

3.19.6.3.2.1.5.1 Alternative Route 5-A

HVDC Alternative Route 5-A is 12.6 miles in length. It corresponds to Region 5, Applicant Proposed Route Link 1, which is 12.3 miles in length.

There are no NWI wetlands mapped in the representative ROW along the route of HVDC Alternative Route 5-A, nor is there NLCD wetland land cover documented in ROW. There are no predicted impacts to NWI wetlands documented within the representative ROW corresponding to Applicant Proposed Route Link 1.

Two 100-year floodplains are predicted to be impacted by construction in the 200-foot-wide ROW along HVDC Alternative Route 5-A for a total of 13.7 acres. Applicant Proposed Route Link 1 is predicted to total approximately 24.6 acres of impact to a single 100-year floodplain within its ROW.

The 200-foot-wide ROW of HVDC Alternative Route 5-A includes approximately 0.1 mile of perennial streams, 0.9 mile of intermittent streams, less than 0.1 mile of major waterbodies, and 0.5 acre of reservoirs, lakes, and ponds (Table 3.15-20). In comparison, the corresponding Applicant Proposed Route Link 1 features approximately 0.3 mile of perennial streams, 0.6 mile of intermittent streams, less than 0.1 mile of major waterbodies, and 0.9 acre of reservoirs, lakes, and ponds.

3.19.6.3.2.1.5.2 Alternative Route 5-B

HVDC Alternative Route 5-B is 71.0 miles in length. It corresponds to Applicant Proposed Route Links 3, 4, 5, and 6, which are a combined 67.1 miles in length. There are no NWI wetlands documented in the representative ROW along the route of Alternative Route 5-B; however, there are 4.3 acres of NLCD wetland land cover (woody wetlands) present in the ROW that could be impacted. Construction of Applicant Proposed Route Links 3, 4, 5, and 6 is not predicted to cause adverse impacts to wetland resources within the representative ROWs based on NWI data. However, NLCD data document a total of 9.3 acres of woody wetland land cover.

Eight 100-year floodplains are predicted to be impacted by construction in the 200-foot-wide ROW along HVDC Alternative Route 5-B for a total of 159.5 acres. Applicant Proposed Route Links 3, 4, 5, and 6 are predicted to impact a total of approximately 64.6 acres within nine 100-year floodplains in the ROW.

The 200-foot-wide ROW of HVDC Alternative Route 5-B includes approximately 1.2 miles of perennial streams, 8.6 miles of intermittent streams, 0.1 mile of major waterbodies, and 10.4 acres of reservoirs, lakes, and ponds (Table 3.15-20). In comparison, the corresponding Applicant Proposed Route Links 3, 4, 5 and 6 feature approximately 1.0 miles of perennial streams, 6.6 miles of intermittent streams, 0.1 mile of major waterbodies, and 13.8 acres of reservoirs, lakes, and ponds.

As described in Appendix M and summarized in Section 2.4.2.5, a route adjustment was developed for HVDC Alternative Route 5-B to maintain an end-to-end route with Applicant Proposed Route Links 2 and 3, Variation 1. The route adjustment would include no perennial or intermittent streams, no wetlands, two floodplains totaling approximately 4.9 acres, and no other surface waterbodies.

3.19.6.3.2.1.5.3 Alternative Route 5-C

HVDC Alternative Route 5-C is 9.2 miles in length. It corresponds to Applicant Proposed Route Link 6, which is approximately 9.4 miles in length.

There are no NWI wetlands mapped in the 200-foot-wide ROW along HVDC Alternative Route 5-C; however, there is 0.3 acre of NLCD wetland land cover (woody wetlands) documented in the ROW. There are no NWI wetlands documented within the representative ROW corresponding to Applicant Proposed Route Link 6; however, there are 8.2 acres of woody wetland land cover documented for the 200-foot-wide ROW for this link.

One 100-year floodplain is predicted to be impacted by construction in the 200-foot-wide ROW along HVDC Alternative Route 5-C for a total of 19.2 acres. Construction of Applicant Proposed Route Link 6 is predicted to cross one 100-year floodplain and total approximately 19.3 acres of temporary impacts in the ROW.

The 200-foot-wide ROW of HVDC Alternative Route 5-C includes under 0.4 mile of perennial streams, approximately 0.5 mile of intermittent streams, less than 0.1 mile of major waterbodies, and 0.4 acre of reservoirs, lakes, and ponds (Table 3.15-20). In comparison, the corresponding Applicant Proposed Route Link 6 features approximately 0.2 mile of perennial streams, 0.4 mile of intermittent streams, less than 0.1 mile of major waterbodies, and 1.3 acres of reservoirs, lakes, and ponds.

3.19.6.3.2.1.5.4 Alternative Route 5-D

HVDC Alternative Route 5-D is 21.7 miles in length. It corresponds to Applicant Proposed Route Link 9, which is 20.5 miles in length. HVDC Alternative Route 5-D could cause impacts to 15 wetlands totaling 12.4 total acres within the representative ROW. Table 3.19-74 provides the number of wetlands by type with the associated potential impact acreage for HVDC Alternative Route 5-D. Construction of Applicant Proposed Route Link 9 may result in impacts totaling 11.5 acres in 17 wetlands within its representative ROW.

Table 3.19-74:
Potential Construction Impacts to Wetlands within the ROW of HVDC Alternative Route 5-D

Wetland Type	Number of Wetlands	Acreage of Potential Impact
PEM	2	1.0
PFO	2	4.7
PUB	9	3.0
R2UB	2	3.7
Totals	15	12.4

GIS Data Source: USFWS (2014g)

One 100-year floodplain is predicted to be impacted by construction in the 200-foot-wide ROW along HVDC Alternative Route 5-D for a total of 4.1 acres. Construction of Applicant Proposed Route Link 9 is predicted to result in 1.3 acres of impact within one mapped floodplain.

The 200-foot-wide ROW of HVDC Alternative Route 5-D includes approximately 0.4 mile of perennial streams, 1.7 miles of intermittent streams, 0.1 mile of major waterbodies, and 1.6 acres of reservoirs, lakes, and ponds (Table 3.15-20). In comparison, the corresponding Applicant Proposed Route Link 9 features approximately 0.3 mile of perennial streams, 1.4 miles of intermittent streams, 0.1 mile of major waterbodies, and 2 acres of reservoirs, lakes, and ponds.

3.19.6.3.2.1.5.5 Alternative Route 5-E

HVDC Alternative Route 5-E is 36.3 miles in length. It corresponds to Applicant Proposed Route Links 4, 5, and 6, which are a combined 33.1 miles in length.

There are no predicted impacts to NWI wetlands in the representative ROW along HVDC Alternative Route 5-E. NLCD wetland land cover does document 0.1 acre of woody wetlands within the 200-foot-wide ROW. No NWI wetlands were documented for the representative ROW for the corresponding Applicant Proposed Route Links 4, 5, and 6. However, the NLCD database does document 8.2 acres of woody wetlands within Link 6.

Five 100-year floodplains are predicted to be impacted by construction in the 200-foot-wide ROW along HVDC Alternative Route 5-E for a total of 93.1 acres. Construction of Applicant Proposed Route Links 4, 5, and 6 are predicted to result in the crossing of six 100-year floodplains, with a predicted total of 42.6 acres of impacts.

The 200-foot-wide corridor of HVDC Alternative Route 5-E includes approximately 0.5 mile of perennial streams, 4.3 miles of intermittent streams, less than 0.1 mile of major waterbodies, and 3.2 acres of reservoirs, lakes, and ponds (Table 3.15-20). In comparison, the corresponding Applicant Proposed Route Links 4, 5 and 6 feature approximately 0.4 mile of perennial streams, 3.3 miles of intermittent streams, less than 0.1 mile of major waterbodies, and 7.0 acres of reservoirs, lakes, and ponds.

As described in Appendix M and summarized in Section 2.4.2.5, a route variation was developed for HVDC Alternative Route 5-E in response to public comments on the Draft EIS to maintain continuity with Applicant Proposed Route Links 3 and 4, Variation 2. The route adjustment would include no perennial or intermittent streams, no wetlands, one floodplain totaling approximately 0.3 acre, and one surface waterbody (pond or lake).

3.19.6.3.2.1.5.6 Alternative Route 5-F

HVDC Alternative Route 5-F is 22.3 miles in length. It corresponds to Applicant Proposed Route Links 5 and 6, which are a combined 18.7 miles in length.

There are no mapped wetland resources within the representative ROW for either HVDC Alternative Route 5-F or Applicant Proposed Route Links 5 and 6. NLCD data reveal 0.1 acre of woody wetland land cover within the 200-foot-wide ROW for Alternative Route 5-F, and also document 8.2 acres of woody wetland land cover for the ROW for Link 6 of the Applicant Proposed Route.

Three 100-year floodplains are predicted to be impacted by construction along HVDC Alternative Route 5-F for a total impact acreage of 74.7 acres. Construction of Applicant Proposed Route Links 5 and 6 are predicted to result in 38.1 acres of impacts four 100-year floodplains crossed by this ROW.

The 200-foot-wide ROW of HVDC Alternative Route 5-F includes under 0.3 mile of perennial streams, approximately 2.6 miles of intermittent streams, less than 0.1 mile of major waterbodies, and 0.7 acre of reservoirs, lakes, and ponds (Table 3.15-20). In comparison, the corresponding Applicant Proposed Route Links 5 and 6 feature approximately 0.3 mile of perennial streams, 2.1 miles of intermittent streams, less than 0.1 mile of major waterbodies, and 3.4 acres of reservoirs, lakes, and ponds.

3.19.6.3.2.1.6 Region 6

3.19.6.3.2.1.6.1 Alternative Route 6-A

HVDC Alternative Route 6-A is 16.2 miles in length. It corresponds to Region 6, Applicant Proposed Route Links 2, 3, and 4, which are a combined 17.7 miles in length.

HVDC Alternative Route 6-A could cause impacts to 18 wetlands and 25.9 total acres within the representative ROW. Table 3.19-75 provides the number of wetlands by type with the associated potential impact acreage for HVDC Alternative Route 6-A. In comparison, construction of Applicant Proposed Route Links 2, 3 and 4 could result in as much as 3.4 acres of impacts to a set of eight wetlands.

Table 3.19-75:
Potential Construction Impacts to Wetlands within the ROW of HVDC Alternative Route 6-A

Wetland Type	Number of Wetlands	Acreage of Potential Impact
PEM	2	0.4
PFO	11	19.7
PSS	1	1.6
PUB	2	3.2
R2UB	2	1.0
Totals	18	25.9

GIS Data Source: USFWS (2014g)

One 100-year floodplain is predicted to be impacted by construction in the 200-foot-wide ROW along HVDC Alternative Route 6-A for a total of 232.5 acres. Applicant Proposed Route Links 2, 3, and 4 are predicted to cross one 100-year floodplain with a potential to cause 103.2 acres of impacts.

The 200-foot-wide ROW of HVDC Alternative Route 6-A includes approximately 0.3 mile of perennial streams, 2.2 miles of intermittent streams, less than 0.1 mile of major waterbodies, and 0.4 acre of reservoirs, lakes, and ponds (Table 3.15-24). In comparison, the corresponding Applicant Proposed Route Links 2, 3 and 4 feature approximately 0.3 mile of perennial streams, 2.2 miles of intermittent streams, less than 0.1 mile of major waterbodies, and 1.9 acres of reservoirs, lakes, and ponds.

As described in Appendix M and summarized in Section 2.4.2.6, a route adjustment was developed for HVDC Alternative Route 6-A to maintain an end-to-end route with Applicant Proposed Route Link 2, Variation 1. The route adjustment would include no perennial or intermittent stream mileage, 21.2 acres of forested wetlands, 0.2 acre of non-forested wetlands, one floodplain totaling approximately 129.4 acres, and six other surface waterbodies.

3.19.6.3.2.1.6.2 Alternative Route 6-B

HVDC Alternative Route 6-B is 14.1 miles in length. It corresponds to Region 6, Applicant Proposed Route Link 3, which is 9.6 miles in length.

HVDC Alternative Route 6-B could cause impacts to 10 wetlands and 15.8 total acres within the ROW. Table 3.19-76 provides the number of wetlands by type with the associated potential impact acreage for HVDC Alternative Route 6-B. In comparison, construction of Applicant Proposed Route Link 3 is predicted to result in 3.1 acres of impacts in four wetlands within its representative ROW.

Table 3.19-76:
Potential Construction Impacts to Wetlands within the ROW of HVDC Alternative Route 6-B

Wetland Type	Number of Wetlands	Acreage of Potential Impact
PFO	6	13.2
PSS	1	1.0
PUB	3	1.6
Totals	10	15.8

GIS Data Source: USFWS (2014g)

No 100-year floodplains are predicted to be crossed by HVDC Alternative Route 6-B in its 200-foot-wide ROW.

The 200-foot-wide ROW of HVDC Alternative Route 6-B includes approximately 0.2 mile of perennial streams, 1.5 miles of intermittent streams, no major waterbodies, and 2.4 acres of reservoirs, lakes, and ponds (Table 3.15-24). In comparison, the corresponding Applicant Proposed Route Link 3 features less than 0.1 mile of perennial streams, 1.9 miles of intermittent streams, less than 0.1 mile of major waterbodies, and 0.9 acre of reservoirs, lakes, and ponds.

3.19.6.3.2.1.6.3 Alternative Route 6-C

HVDC Alternative Route 6-C is 23.1 miles in length. It corresponds to Applicant Proposed Route Links 6 and 7, which are a combined 24.8 miles in length.

There are no NWI-mapped wetlands in the representative ROW for either HVDC Alternative Route 6-C, or for Applicant Proposed Route Links 6 and 7. However, NLCD data show that there are 9.4 acres of woody wetland land cover in HVDC Alternative Route 6-D, and Applicant Proposed Route Links 6 and 7 have a combined total of 45.9 acres of woody wetland and emergent herbaceous wetland land cover.

Four 100-year floodplains are predicted to be impacted by construction in the 200-foot-wide ROW along HVDC Alternative Route 6-C for a total of 94.6 acres. Applicant Proposed Route Links 6 and 7 are predicted to cross two 100-year floodplains with a resultant potential for 170.2 acres of wetland impacts in the ROW.

The 200-foot-wide ROW of HVDC Alternative Route 6-C includes approximately 0.4 mile of perennial streams, 1.1 miles of intermittent streams, 0.1 mile of major waterbodies, and 1.6 acres of reservoirs, lakes, and ponds (Table 3.15-24). In comparison, the corresponding Applicant Proposed Route Links 6 and 7 feature approximately 0.3 mile of perennial streams, 1.0 miles of intermittent streams, 0.1 mile of major waterbodies, and 0.1 acre of reservoirs, lakes, and ponds.

3.19.6.3.2.1.6.4 Alternative Route 6-D

HVDC Alternative Route 6-D is 9.2 miles in length. It corresponds to Region 6, Applicant Proposed Route Link 7, which is 8.6 miles in length.

There are no NWI-mapped wetlands in the representative ROW for either HVDC Alternative Route 6-D or for Applicant Proposed Route Link 7. However, NLCD data show that there are 22.1 acres of woody wetland land cover in HVDC Alternative Route 6-C, and Applicant Proposed Route Links 6 and 7 have a combined total of 45.9 acres of woody wetland and emergent herbaceous wetland land cover.

Two 100-year floodplains are predicted to be impacted by construction in the 200-foot-wide ROW along HVDC Alternative Route 6-D for a total of 108.8 acres. In contrast, Applicant Proposed Route Link 7 is predicted to cross one 100-year floodplain, resulting in the potential for 151.0 acres of impact.

The 200-foot-wide ROW of HVDC Alternative Route 6-D includes approximately 0.3 mile of perennial streams, 0.3 mile of intermittent streams, 0.1 mile of major waterbodies, and no acreage of reservoirs, lakes, and ponds (Table 3.15-24). Riparian areas may be associated with many, if not all, of these surface water features. In comparison, the corresponding Applicant Proposed Route Link 7 features approximately 0.1 mile of perennial streams, 0.2 mile of intermittent streams, 0.1 mile of major waterbodies, and no acreage of reservoirs, lakes or ponds.

3.19.6.3.2.1.7 Region 7

3.19.6.3.2.1.7.1 Alternative Route 7-A

HVDC Alternative Route 7-A is 43.2 miles in length. It corresponds to Region 7, Applicant Proposed Route Link 1, which is 28.6 miles in length.

HVDC Alternative Route 7-A could cause impacts in 10 wetlands totaling 26.6 acres within the representative ROW. Table 3.19-77 provides the number of wetlands by type with the associated potential impact acreage for HVDC Alternative Route 7-A. Construction of Applicant Proposed Route Link 1 could result in up to 38.3 acres of impacts to 19 wetlands.

Table 3.19-77:
Potential Construction Impacts to Wetlands within the ROW of HVDC Alternative Route 7-A

Wetland Type	Number of Wetlands	Acreage of Potential Impact
PEM	1	1.9
PFO	7	10.0
L2UB	2	14.7
Totals	10	26.6

GIS Data Source: USFWS (2014g)

Eight 100-year floodplains are predicted to be impacted by construction in the 200-foot-wide ROW along HVDC Alternative Route 7-A for a total of 314.4 acres. Applicant Proposed Route Link 1 is predicted would cross 10 mapped 100-year floodplains resulting in an estimated 247.9 acres of impacts.

As shown in Table 3.15-28, the 200-foot-wide ROW of HVDC Alternative Route 7-A includes approximately 1.8 miles of perennial streams, 4.7 miles of intermittent streams, 0.9 mile of major waterbodies, and 2.4 acres of reservoirs, lakes, and ponds. In comparison, the corresponding Applicant Proposed Route Link 1 features approximately 0.3 mile of perennial streams, 2.7 miles of intermittent streams, 0.6 mile of major waterbodies, and 1.5 acres of reservoirs, lakes or ponds.

3.19.6.3.2.1.7.2 Alternative Route 7-B

HVDC Alternative Route 7-B is 8.6 miles in length. It corresponds to Applicant Proposed Route Links 3 and 4, which are a combined 8.4 miles in length.

HVDC Alternative Route 7-B could cause impacts to five wetland types and 2.6 acres within the ROW. Table 3.19-78 provides the number of wetlands by type with the associated potential impact acreage. In comparison, construction of Applicant Proposed Route Links 3 and 4 could result in approximately 1.4 acre of impacts in a set of two wetlands.

Table 3.19-78:
Potential Construction Impacts to Wetlands within the ROW of HVDC Alternative Route 7-B

Wetland Type	Number of Wetlands	Acreage of Potential Impact
PFO	3	2.0
PSS	1	0.5
PUB	1	0.1
Totals	5	2.6

GIS Data Source: USFWS (2014g)

Three 100-year floodplains are predicted to be impacted by construction in the 200-foot-wide ROW along HVDC Alternative Route 7-B for a total of 50.4 acres. Applicant Proposed Route Links 3 and 4 would cross nine 100-year floodplains with a resultant potential for 47.9 acres of impact.

The 200-foot-wide ROW of HVDC Alternative Route 7-B includes approximately 0.1 mile of perennial streams, 0.6 mile of intermittent streams, no major waterbodies, and no acreage of reservoirs, lakes, and ponds (Table 3.15-28). In comparison, the corresponding Applicant Proposed Route Links 3 and 4 feature approximately 0.1 mile of perennial streams, 0.8 mile of intermittent streams, no major waterbodies, and 0.1 acre of reservoirs, lakes, or ponds.

3.19.6.3.2.1.7.3 Alternative Route 7-C

HVDC Alternative Route 7-C is 23.8 miles in length. It corresponds to Region 7, Applicant Proposed Route Links 3, 4 and 5, which are a combined 13.2 miles in length.

HVDC Alternative Route 7-C could cause impacts to as many as 22 wetlands totaling 16.9 total acres within the ROW. Table 3.19-79 provides the number of wetlands by type with the associated potential impact acreage. Construction of Applicant Proposed Route Links 3, 4, and 5 could result in approximately 3.5 acres of impacts in four wetlands within its ROW.

Table 3.19-79:
Potential Construction Impacts to Wetlands within the ROW of HVDC Alternative Route 7-C

Wetland Type	Number of Wetlands	Acreage of Potential Impact
PEM	2	0.5
PFO	11	12.9
PSS	3	0.5
PUB	6	3.0
Totals	22	16.9

GIS Data Source: USFWS (2014g)

Fifteen 100-year floodplains are predicted to be impacted by construction in the 200-foot-wide ROW along HVDC Alternative Route 7-C for a total impact acreage of 160.2 acres. Applicant Proposed Route Links 3, 4, and 5 would cross 13 100-year floodplains with a potential for 69.9 acres of total impact.

The 200-foot-wide ROW of HVDC Alternative Route 7-C includes approximately 0.4 mile of perennial streams, 1.9 miles of intermittent streams, less than 0.1 mile of major waterbodies, and 0.9 acre of reservoirs, lakes, and ponds (Table 3.15-28). In comparison, the corresponding Applicant Proposed Route Links 3, 4 and 5 feature approximately 0.2 mile of perennial streams, 1.6 miles of intermittent streams, no major waterbodies, and 0.9 acre of reservoirs, lakes or ponds.

3.19.6.3.2.1.7.4 Alternative Route 7-D

HVDC Alternative Route 7-D is 6.5 miles in length. It corresponds to Applicant Proposed Route Links 4 and 5, which are a combined 6.4 miles in length.

HVDC Alternative Route 7-D could cause impacts to four wetlands and 7.3 total acres within the representative ROW. Table 3.19-80 provides the number of wetlands by type with the associated potential impact acreage. Construction of Applicant Proposed Route Links 4 and 5 could result in approximately 2.3 acres of impacts in a total of three wetlands within its representative ROW.

Table 3.19-80:
Potential Construction Impacts to Wetlands within the ROW of HVDC Alternative Route 7-D

Wetland Type	Number of Wetlands	Acreage of Potential Impact
PFO	3	7.3
PUB	1	0.1
Totals	4	7.4

GIS Data Source: USFWS (2014g)

Nine 100-year floodplains are predicted to be impacted by construction in the 200-foot-wide ROW along HVDC Alternative Route 7-D for a total of 56.2 acres. Applicant Proposed Route Links 4 and 5 would cross seven 100-year floodplains and could potentially impact 43.2 acres within the ROW.

The 200-foot-wide ROW of HVDC Alternative Route 7-D includes approximately 0.3 mile of perennial streams, 0.9 mile of intermittent streams, no major waterbodies, and no acreage of reservoirs, lakes, and ponds (Table 3.15-28). In comparison, the corresponding Applicant Proposed Route Links 4 and 5 feature approximately

0.1 mile of perennial streams, 1.0 mile of intermittent streams, no major waterbodies, and 0.8 acre of reservoirs, lakes, or ponds.

3.19.6.3.2.2 Operations and Maintenance Impacts

The operation and maintenance of the HVDC transmission line in the alternative routes would involve routine and periodic vegetation management according to the TVMP. Impacts related to operations and maintenance may result from use of heavy machinery through wetlands, floodplains, and riparian areas. These impacts can cause soil compaction and mechanical damage or removal of vegetation. These operations and maintenance impacts are anticipated to cover a range from temporary and minor to potentially more severe and long-term/permanent. The estimated acreage of each resource type (wetlands, floodplains, and riparian areas) for each route, is provided in the previous subsections of 3.19.6.3.2.1.

The use of vegetation management would be necessary to protect the Project infrastructure and enhance safety. However, the trimming, mowing, or removal of vegetation can cause changes to plant diversity and function in all three ecosystem types (i.e., wetlands, floodplains, and riparian areas). Vegetation maintenance in wetlands and riparian areas should be kept to a minimum to the extent practicable. Additionally, the use of herbicides can cause minor to severe impacts to vegetation in areas where they are applied. If used, the Applicant would selectively apply herbicides within streamside management zones.

3.19.6.3.2.3 Decommissioning Impacts

The decommissioning impacts relative to the alternative routes would be similar in nature to the set of temporary impacts resulting from initial construction. These temporary impacts would involve use of construction machinery at the various sites of infrastructure (e.g., the lattice structures, lattice crossing structures, monopole structures, guyed structures, fiber optic infrastructure, etc.) to remove aboveground material, and foundation material where required. Use of construction machinery would have the potential to crush or remove vegetation, but no long-term effects are judged to be likely from the decommissioning phase of the Project. Revegetation would be guided by the Project’s Decommissioning Plan and by any conditions of a CWA permit, where applicable.

3.19.6.4 Best Management Practices

The Applicant has developed a comprehensive list of EPMs that avoid and minimize impacts to wetlands, floodplains, and riparian areas. A complete list of EPMs for the Project is provided in Appendix F; those EPMs that would specifically minimize the potential for an impact on wetlands, floodplains, and riparian areas are summarized in Section 3.19.6.1. DOE, in consultation with the USACE, has identified the following BMPs to avoid or minimize impacts on wetlands, floodplains, and riparian areas:

- In addition to protection of intermittent and perennial streams, ephemeral streams would also be included in the Applicant’s streamside management zones. This BMP would add to EPM W-3.
- In addition to minimization of clearing vegetation within the ROW (GE-3), it is recommended that where tree removal is necessary in the ROW, this removal should be accomplished at ground level leaving root wads in place to aid in the stabilization of soils.
- Limit, to the extent practicable, the amount of vegetation removed along streambanks and minimizing the disruption of natural drainage patterns.

- All permanent and temporary crossings of waterbodies would be suitably culverted, bridged, or otherwise designed and constructed to maintain low flows to sustain the movement of aquatic species. The crossings would also be constructed to withstand expected high flows. The crossings would not restrict or impede the passage of normal or high flows.
- Excavated trenches that are to be backfilled should separate the upper 12 inches of topsoil from the rest of the excavated material. The topsoil should be used as the final backfill.

3.19.6.5 Unavoidable Adverse Impacts

Unavoidable adverse impacts to wetlands, floodplains, and riparian areas from the Project may include, but are not necessarily limited to, the following elements:

- Removal of vegetation in the footprints of new transmission line support structures, access roads, converter stations, and other associated infrastructure, some of which may be wetland vegetation, or vegetation present in floodplains or riparian zones
- Conversion of vegetation structure (e.g., floodplain/riparian forest conversion to grassland/herbaceous or shrub/scrub land cover)
- Changes to species diversity within wetlands, floodplains, and/or riparian areas
- Changes in total cover percentage in wetland, floodplain, and riparian zone vegetation

3.19.6.6 Irreversible and Irretrievable Commitment of Resources

The potential permanent loss or alteration of wetlands, floodplains, and riparian areas would last throughout the life of the Project; however, gradual recovery of these resources is expected after decommissioning. It is reasonable to assume that some wetlands, floodplains, and riparian areas may be irreversibly and irretrievably impacted.

3.19.6.7 Relationship between Local Short-term Uses and Long-term Productivity

The Project would result in a short-term disturbance to wetlands, floodplains, and riparian areas; however, these impacts should not affect the long-term productivity of these resources.

3.19.6.8 Impacts from Connected Actions

3.19.6.8.1 Wind Energy Generation

3.19.6.8.1.1 Construction Impacts

Construction of wind farms in the Oklahoma and Texas Panhandle regions would be expected to involve potential impacts to wetlands, floodplains, and riparian areas similar to those described in Section 3.19.6.1 for common construction activities. The potential short-term impacts from construction activities for wind energy generation could include mechanical damage/crushing of vegetation from use of heavy machinery, compaction of soils, sedimentation and turbidity from construction activities adjacent to these resources, alteration of hydrology from access road construction, dewatering activities, and contamination from accidental spills of hazardous substances such as fuels and lubricants. The potential long-term impacts to wetlands, floodplains, and riparian resources from construction in wind development zones could include removal of vegetation during excavations for structure foundations, electrical collection lines, or during permanent access road construction, conversion of forested wetlands and riparian areas to shrubby or herbaceous cover types within the ROW, changes to hydrology from permanent access roads construction, and the introduction of invasive species from construction equipment.

Section 3.19.5.8.1 provides an estimate of the wetlands and floodplains that could potentially be affected in each of the twelve WDZs. Based on the maximum capacity of the Project and information from wind energy developers, it is estimated that 20–30 percent of the potentially suitable land, as identified in Section 2.5.1, would actually be developed for wind energy facilities using transmission capacity from the Project. It is further estimated that during the construction phase, approximately 2 percent of land within a wind energy facility, would be affected (Denholm et al. 2009). That would reduce to 1 percent of the land that would remain disturbed during operations and maintenance of the wind energy facilities.

Wind turbines and associated facilities are typically located outside of wetlands, floodplains, and riparian areas to the extent practicable. Wind lease agreements typically include provisions to minimize the impacts to wetlands, floodplains and riparian areas, including minimizing soil compaction and revegetating temporary work areas.

3.19.6.8.2 Optima Substation

No wetlands, floodplains, or riparian areas are documented for this site. No impacts to wetlands, floodplains, or riparian areas would be expected.

3.19.6.8.3 TVA Upgrades

Much of the following discussion is relevant for the new 500kV transmission line, or for certain upgrades associated with the 161kV transmission lines. The required TVA upgrades to existing facilities (including existing transmission lines and existing substations) would likely have no impact to wetlands, floodplains or riparian areas. The construction, operation, and maintenance of the new 500kV transmission line, would have impacts similar to the Project although on a smaller scale. These impacts to wetlands, floodplains, and riparian areas may be largely avoided or minimized by spanning these resource areas. On average, the construction of new TVA transmission lines during the last decade has affected 0.7 acre of wetlands per mile of new line, including 0.4 acre of forested wetlands per mile. Potential impacts from constructing the new transmission line through or adjacent to wetlands, floodplains and riparian areas may include sedimentation and turbidity, placement of fill or dredging, alteration of hydrology, contamination from herbicide runoff or accidental, long-term conversion of forested vegetation types to shrubby or herbaceous cover types within the ROW, changes in flood grade or elevation, mechanical damage/crushing of vegetation, compaction of soils potentially reducing soil’s water-holding capacity, and introduction of invasive species from construction equipment.

3.19.6.9 Impacts Associated with the No Action Alternative

Under the No Action Alternative, DOE assumes for analytical purposes that the Project would not be constructed. No impacts on wetlands, floodplains, or riparian areas would occur. The existing diversity, structure, and function of these areas within the ROW would be expected to remain consistent within their current parameters.

3.20 Wildlife, Fish, and Aquatic Invertebrates

3.20.1 Wildlife

3.20.1.1 Regulatory Background

In general, statutes and regulations that influence the evaluation of wildlife resources in the areas crossed by the Project are implemented by the USFWS and state wildlife agencies. The state agencies applicable to this Project include the ODWC, AGFC, TWRA, and TPWD. The wildlife regulations relevant to this Project are presented in Table 3.20.1-1.

Table 3.20.1-1:
Relevant Regulations for Wildlife Species

Regulation	Regulatory Agency	Summary
Endangered Species Act (ESA), (16 USC § 1531 *et seq.*; 50 CFR Part 402)	USFWS	Establishes lists of threatened or endangered species and their designated critical habitats; requires federal agencies to ensure that actions they authorize, fund, or carry out are not likely to jeopardize the continued existence of listed species or result in adverse modification to designated critical habitat.
Migratory Bird Treaty Act (MBTA) (16 USC §§ 703–712)	USFWS	Prohibits take, possess, import, export, transport, sell, purchase, barter, or offer for sale, purchase, or barter, any migratory bird, or the parts, nests, or eggs of such a bird unless expressly permitted by federal regulations or authorized under a MBTA permit.
Executive Order 13186, “Responsibilities of Federal Agencies to Protect Migratory Birds”	USFWS	Directs executive departments and agencies to take certain actions to protect and conserve migratory birds. It provides broad guidelines on conservation responsibilities and requires the development of more detailed guidance in Memoranda of Understanding (MOU).
Bald and Golden Eagle Protection Act (BGEPA), (16 USC §§ 668–668d; 50 CFR Part 22)	USFWS	Prohibits the “take” of bald and golden eagles as defined: pursue, shoot, shoot at, poison, wound, kill, capture, trap, collect, molest, or disturb without a BGEPA Permit.
Oklahoma Statutes 29-5-412.1 Oklahoma Administrative Code Title 800, “Department of Wildlife Conservation”	ODWC	Establishes list of threatened or endangered species within Oklahoma. Describes the function, organization, powers and duties of the Oklahoma Department of Wildlife Conservation with respect to managing fish and wildlife resources.
Texas Administrative Code 31-65.171–65.177	TPWD	Establishes list of threatened or endangered wildlife within Texas; prohibits the taking, possession, transportation, or sale of threatened or endangered species within the issuance of a permit.
Arkansas Code Annotated 15-45-301–306	AGFC[1]	Prohibits imports, transportation, sale, purchase, hunting, harassment, or possession of threatened or endangered wildlife or their parts.
Tennessee Administrative Code 70-1-101 *et seq*.	TWRA	Establishes a list of threatened or endangered wildlife within Tennessee; prohibits the take, attempt to take, possession, transportation, export, processing, selling, offering to sell, shipment of, or knowing receipt of shipment of threatened or endangered wildlife.

1 Arkansas does not have an endangered species law, but does maintain a list of Species of Special Concern.

3.20.1.2 Data Sources

Data sources included a desktop analysis of relevant information; research findings; reports available to the public; a database that includes GIS data from government agencies as well as non-governmental organizations; and information received from both regulatory agencies and stakeholders during the DOE scoping process. All data sources used for this analysis were limited to those that were open source and readily available to the public (i.e., the public may assess them without restrictions). As a result, comprehensive state wildlife agency databases regarding designated habitats types (e.g., extent of big game ranges), species presence, or wildlife use of habitats (e.g., raptor nest or bat hibernacula locations) were not used in this assessment due to data sharing restrictions (i.e., DOE could not ensure the state agencies that these data would not be released to the public without the DOE's consent). The lack of comprehensive state wildlife data used in this assessment would constitute "incomplete or unavailable" data per CEQ regulations at 40 CFR 1502.22. Because comprehensive state wildlife data were not used in this assessment, it was assumed that wildlife were present or used habitats if their range overlapped an area and suitable habitats were present (i.e., due to the lack or more robust data, a conservative estimate of species use was used for this assessment). The data sources available to DOE during this analysis are summarized in Table 3.20.1-2.

Table 3.20.1-2:
Summary of Data Sources Wildlife

Resource	Data Source
Representative common wildlife species within each vegetative cover type in the ROI	NatureServe Explorer (http://explorer.natureserve.org/) ODWC WMA Fact Sheets (http://www.wildlifedepartment.com/facts_maps/wmastate.htm) ANHC (http://www.naturalheritage.com/) TDEC Division of Natural Areas (http://www.state.tn.us/environment/natural-areas/natural-areas/) TPWD (http://www.tpwd.state.tx.us/)
Important commercial or recreation species in the ROI	Stakeholder Outreach
Migratory birds	National Audubon Society Important Bird Areas (IBAs) Interactive Map (NAS 2013) USFWS Migratory Bird Program (http://www.fws.gov/migratorybirds/dmbmdbhc.html) Oklahoma Breeding Bird Atlas (http://suttoncenter.org/pages/oklahoma_breeding_bird_atlas) Arkansas Breeding Bird Atlas (http://birdatlas.cast.uark.edu) Tennessee Breeding Bird Atlas (http://www.tnbirds.org/birdatlas.htm) Texas Breeding Bird Atlas (http://txtbba.tamu.edu/)

3.20.1.3 Region of Influence

The ROIs used for the evaluation of potential impacts to wildlife from the Project and connected actions are identical to the ROIs described in Section 3.1.1.

3.20.1.4 Affected Environment

As discussed in Section 3.18, the Project would cross multiple ecoregions that individually support diverse vegetation communities. Overall, the Project is within the Great Plains and Eastern Temperate Forests Level I Ecoregions (EPA 2012). From the western end of the Project (in the Oklahoma Panhandle) moving eastward (across Oklahoma, Arkansas, and western Tennessee), the vegetation changes from arid and semi-arid grasslands to forests, river valleys, and coastal plains. This change in vegetation type results as precipitation and elevation change from west to east. Because of this variation in vegetation type across the seven regions, a variety of wildlife species (both terrestrial and aquatic) are expected to occur within the habitats found within the ROI. The highest species diversity can be expected to occur in areas of greater habitat diversity (Recher 1969; MacArthur and Wilson 1967), such as transitional zones between one habitat type and another (the highest diversity in habitats mostly occurs within Regions 3, 4, and 5). The following sub-sections provide regional descriptions of common resident and migratory species including important recreation species, migratory birds, reptiles, amphibians, and mammals known to occur or that have the potential to occur within the ROI based on habitat associations and known range information. It should be noted that the following is not a comprehensive list of every wildlife species that could occur in the region, but rather it is only a list of the more common species typically found in the region.

It should be noted that several route variations to the Applicant Proposed Route in Regions 2–7 were developed in response to public comments on the Draft EIS; they are described in detail within Appendix M and summarized in Sections 2.4.2.1–2.4.2.7. These variations are presented graphically in Exhibit 1 of Appendix M, and are included in the affected environment discussion.

3.20.1.4.1 Important Recreation Species

Areas managed either wholly or in part for recreational opportunities, such as hunting and fishing, include public and private lands such as WMAs, Public Hunting Areas, Game Management Areas, Wildlife Management Units, various USACE lands, conservation easements, National Recreational Areas, and NWRs. Recreational areas within the ROI are described in detail within Section 3.12.

Texas

Big game species potentially within the ROI for the AC collection system in Texas include white-tailed deer (*Odocoileus virginianus*), mule deer (*Odocoileus hemionus*), and pronghorn (*Antilocapra americana*) (TPWD 2013).

Small game species potentially within the ROI for the AC collection system in Texas include cottontail (*Sylvilagus* spp.) and jackrabbits (*Lepus* spp.).

Bird species that are hunted within the state (and potentially within the ROI for the AC collection system in Texas) include the white-winged dove (*Zenaida asiatica*), mourning dove (*Zenaida macroura*), as well as various species of duck, pheasant, and quail (TPWD 2013).

Oklahoma

Big game species potentially within the Project's ROI in Oklahoma include white-tailed deer, elk *(Cervus elaphus),* and pronghorn. White-tailed deer hunting occurs statewide. Within the ROI, elk hunting occurs in Sequoyah and Muskogee counties. Pronghorn hunting (referred to as "antelope" by ODWC) occurs in Texas County, west of State Highway 136 (ODWC 2013).

Small game species potentially within the Project's ROI in Oklahoma include squirrels *(Sciurus* spp. *and Tamiasciurus* spp.), cottontail, and jackrabbits. Furbearers hunted in Oklahoma include bobcat *(Lynx rufus),* raccoon *(Procyon lotor),* river otter *(Lontra canadensis),* gray fox *(Urocyon cinereoargenteus),* and red fox

(Vulpes vulpes). Additionally, year-round seasons are open statewide for coyote *(Canis latrans),* beaver *(Castor canadensis),* nutria *(Myocastor coypus*), and striped skunk *(Mephitis mephitis*) (ODWC 2013).

Bird species that are hunted within the state (and potentially within the Project's ROI in Oklahoma) include the ring-necked pheasant *(Phasianus colchicus),* wild turkey *(Meleagris gallopavo),* northern bobwhite *(Colinus virginianus),* scaled quail *(Callipepla squamata),* sora *(Porzana carolina),* Virginia rail *(Rallus limicola),* common snipe *(Gallinago gallinago),* mourning dove *(Zenaida macroura),* Canada goose *(Branta canadensis),* American woodcock *(Scolopax minor),* common gallinule *(Gallinula galeata)* (previously "moorhen"), and 16 waterfowl species (ODWC 2013).

Arkansas

Big game species potentially within the Project's ROI in Arkansas include white-tailed deer, elk, American alligator (*Alligator mississippiensis),* and American black bear (*Ursus americanus*) (AGFC 2013c).

Small game species that potentially occur within the Project's ROI in Arkansas include squirrels (red and fox) and rabbits (eastern cottontail [*Sylvilagus floridanus*] and swamp rabbit [*Sylvilagus aquaticus*]*)* (AGFC 2013c). Furbearers harvested within the state include beaver, bobcat, coyote, gray fox, mink *(Neovison vison),* muskrat *(Ondatra zibethicus),* nutria, opossum *(Didelphis virginiana),* raccoon, red fox, river otter and striped skunk (AGFC 2013c).

Bird species that are hunted within the state (and potentially within the Project's ROI in Arkansas) include the common gallinule, common snipe, Virginia rail, purple gallinule (*Porphyrio martinica*), mallards (*Anas platyrhynchos*), American woodcock, Eurasian collared-dove (*Streptopelia decaocto),* mourning dove, northern bobwhite, sora, wild turkey, blue-winged teal *(Anas discors),* green-winged teal *(Anas crecca),* cinnamon teal *(Anas cyanoptera),* Canada goose, snow goose *(Chen caerulescens;* also referred to as blue goose depending on the color morph), Ross's goose *(Chen rossii),* greater white-fronted goose *(Anser albifrons),* American coot *(Fulica americana),* and 21 other species of duck (AGFC 2013a, 2013b).

Tennessee

Big game species potentially within the Project's ROI in Tennessee include white-tailed deer, wild turkey, and American black bear.

Small game species that potentially occur within the Project's ROI in Tennessee include nine-banded armadillo (*Dasypus novemcinctus*), bullfrog, Eurasian collared-dove, ruffed grouse (*Bonasa umbellus*), quail, rabbit, squirrel, beaver, bobcat, coyote, fox, groundhog (*Marmota monax*), mink, muskrat, opossum, river otter, raccoon, skunk, and various weasel species (TWRA 2013a, 2013b).

Bird species that are hunted within the state (and potentially within the Project's ROI in Tennessee) include the American coots, common crow (*Corvus brachyrhynchos*), purple gallinules, Virginia rail, mourning dove, Wilson snipe, American woodcock, Canada goose, greater white-fronted goose, Ross's goose, snow goose, and thirteen species of duck (TWRA 2013a).

3.20.1.4.2 Migratory Birds

The regulatory use of the term "migratory bird" refers to any bird native to the United States that is protected by the MBTA (USFWS 2011), but does not typically include upland game birds (e.g., pheasants), because they are typically managed at the state level. Section 3.20.1.1 defines the MBTA. As of November 2013, the MBTA protects more than 1,000 species of native birds, hundreds of which have the potential to be present in the Project's ROI (78 FR 65843, November 1, 2013). Species composition and abundance vary by geography, habitat, and time of year; but migratory birds may occur in the ROI either during their migration or throughout the year (Table 3-10 in the Applicant's *Fish, Wildlife, and Vegetation Technical Report* [Clean Line 2013] lists the migratory birds that could potentially occur in the area).

Migratory birds use general north-south flyways, which are main transit corridors between southern wintering grounds and northern breeding areas (USFWS 2009). The Project's ROI crosses both the Central and the Mississippi Flyways. The Central Flyway encompasses the Great Plains west of the Mississippi River Valley as well as the Rocky Mountains of the central United States (Regions 1 through 3 of the Project) (USFWS 2009). The Mississippi Flyway reflects a general path of migration along the Mississippi River and extends across Arkansas and Tennessee (Regions 4 through 7 of the Project).

Along these flyways, the National Audubon Society has identified specific Important Bird Areas (IBAs), which are considered "vital to birds and other biodiversity" (NAS 2013). Two Audubon-designated IBAs are in the ROI for the Project: the Ozark National Forest Global IBA (which is located within the ROI for the Applicant Proposed Route in Region 4) and the Cache-Lower White Rivers Global IBA (which is located in the ROI for the Project in Region 6). The extreme southern edge of the Ozark National Forest IBA intersects the northern extent of the ROI for the Applicant Proposed Route, east of Hagerville (Region 4). The ROI traverses the northernmost extension of the Cache-Lower White Rivers IBA in Region 6, in conjunction with the crossing of the Cache River and associated riparian forest. A third Audubon-designated IBA, the Selman Ranch IBA, occurs 10 miles north of the ROI for HVDC Alternative Route 1-A in Harper County, Oklahoma in Region 1 (NAS 2013). No other IBAs occur within 15 miles of the ROI for the Project.

3.20.1.4.3 Reptiles and Amphibians

Two hundred nineteen common reptile and amphibian species are known to occur or have the potential to occur within the ROI. Species composition and abundance of reptile and amphibian species vary by geography, habitat, and time of year, but reptiles and amphibians may occur in all habitat types found within the Project's ROI throughout the year. The common reptiles and amphibian species are identified by state in Appendix L.

3.20.1.4.4 Mammals

Because the Project is centrally located in the United States, species from the Rocky Mountains, the Great Plains, the eastern deciduous forests, the Southeastern and Gulf Coastal Plain, and the arid Southwest compose the mammalian fauna potentially present within the Project's ROI in Regions 1 through 7 (Caire et al. 1989; Sealander and Heidt 1990). Within the jurisdictional counties of the four states crossed, 81 common mammal species are known to occur or have the potential to occur within the ROI. Species composition and abundance of mammal species varies by geography, habitat, and time of year, but mammals may occur in the Project's ROI throughout the year. The common mammal species, by state, are summarized in Appendix L.

3.20.1.5 Regional Description

As described in Section 3.20.1.4 above, numerous terrestrial wildlife species are known to occur or have the potential to occur within the ROI. A summary of the terrestrial wildlife species and habitat occurrence by Project region is provided in the sections below.

3.20.1.5.1 Region 1

Region 1 is referred to as the Oklahoma Panhandle Region and includes the Oklahoma Converter Station and AC Interconnection Siting Area, AC collection system routes, the Applicant Proposed Route, and the HVDC Alternative Routes I-A through I-D.

The wildlife species that occur in the Project's ROI are adapted to dry or seasonally dry habitat conditions of the semi-arid eastern Oklahoma Panhandle. As described in Section 3.10, the dominant land cover in the ROI of Region 1 is grasslands (i.e., grassland/herbaceous). Other less dominant land cover types in this region include croplands (i.e., cultivated crops; primarily center-pivot irrigated with some dryland areas), and shrub/scrub. Wetland areas that may be used by wildlife in this region are described in detail in Section 3.19.

As discussed in Section 3.12, wildlife areas that are managed for recreation within Region 1 include the Optima NWR, Optima WMA, and the Schultz WMA.

- Optima NWR is managed as a woody wetland and mixed-grass prairie, containing cottonwoods, big bluestem (*Andropogon gerardii*), little bluestem (*Schizachyrium scoparium*), and indiangrass (*Sorghastrum nutans*). Wildlife species known to occur at Optima NWR include white-tailed deer, coyotes, Rio Grande wild turkeys (*M.g.intermedia*), quail species, and numerous migratory birds that use the NWR as a stopover location during migration. Optima NWR is located within the ROI for the AC Collection System Route E-1.
- The Optima WMA contains similar habitats as the Optima NWR, and is managed for recreational hunting (see Section 3.12). The following wildlife species are hunted at Optima WMA: pheasant, quail species, white-tailed and mule deer, Rio Grande wild turkey, rabbit species, coyote, bobcat, raccoon, dove species, and numerous waterfowl species. The Optima WMA is not in the ROI for the Project, but is located 3 miles east of the AC Collection System Route NE-2 centerline.
- The Schultz WMA and State Park is managed by the Oklahoma Department of Wildlife Conservation (ODWC 2014). Game species include various species of pheasant, quail, deer, rabbit, and coyote. Habitat at this WMA consists of a mixture of uplands and floodplain habitats, with side oats and buffalo grass common on upland areas and salt cedar and cottonwood dominating the lowlands. The ROIs associated with AC Collection System Routes E-3, SE-1, SE-3, and E-2 would cross the edges of the Schultz WMA and State Park.

Major rivers often serve as stopover habitats or migratory corridors for migrating birds. As discussed in Section 3.15, portions of the Beaver River and its tributaries are located within the ROI for Region 1. This river and its tributaries are within the ROI associated with the HVDC transmission line routes, as well as the ROI for the AC collection system routes.

No route variations were proposed in Region 1.

3.20.1.5.2 Region 2

Region 2 is referred to as the Oklahoma Central Great Plains Region and includes the Applicant Proposed Route as well as Alternative Routes 2-A and 2-B.

The wildlife species that occur in the Project's ROI in Region 2 are adapted to dry or seasonally dry habitat conditions of the semi-arid eastern Oklahoma Panhandle. As described in Section 3.10, the dominant land cover in the ROI of Region 2 is grasslands. Other less dominant land cover types in this region include croplands (primarily center-pivot irrigated with some dryland areas). Wetland areas that may be used by wildlife in this region are described in detail in Section 3.19.

As discussed in Section 3.12, wildlife areas that are managed for recreation within Region 2 include the Major County WMA (which is located within the ROI associated with the HVDC Alternative Route 2-A). Habitat in this WMA consists of mixed grass uplands dissected by deep canyons that support several hardwood tree species including American elm, bur oak, chinquapin oak, Eastern red cedar. Game species known to occur at Major County WMA include northern bobwhite, white-tailed deer, Rio Grande wild turkey, rabbit species, coyote, bobcat, and raccoon.

Major rivers often serve as stopover habitats or migratory corridors for migrating birds. As discussed in Section 3.15, portions of the Cimarron River are located within the ROI for Region 2 (as well as other various creeks/waterbodies). The Cimarron River would be crossed by the Applicant Proposed Route as well as Alternative Route 2-A.

Two route variations to the Applicant Proposed Route were developed in Region 2 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.2. The variations are illustrated in Exhibit 1 of Appendix M. These variations represent minor adjustments to the Applicant Proposed Route. Link 1, Variation 1, as well as Link 2, Variation 2, would cross through similar types of vegetation and habitat compared to the original Applicant Proposed Route.

3.20.1.5.3 Region 3

Region 3 is referred to as the Oklahoma Cross Timbers Region and includes the Applicant Proposed Route and Alternative Routes 3-A through 3-E.

The wildlife species that occur in the ROI in Region 3 are adapted to the semi-arid conditions of northwestern Oklahoma and the mesic conditions of north-central Oklahoma. As described in Section 3.10, the dominant land cover in the ROI is grasslands. Other less dominant land cover types in this region include deciduous forests and pasture/hay. Wetland areas that may potentially be used by wildlife in this region are described in detail in Section 3.19.

As discussed in Section 3.15, portions of the Cimarron River are located within the ROI for Region 3 (as well as various creeks/waterbodies). The Cimarron River would be crossed by the Applicant Proposed Route in Payne County, Oklahoma; the route would also occur close to the Arkansas River (the river is located approximately 0.5 mile north of the Applicant Proposed Route in Muskogee County, Oklahoma, at its nearest point).

Five route variations to the Applicant Proposed Route were developed in Region 3 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.3. The variations are illustrated in Exhibit 1 of Appendix M. These variations represent minor adjustments to the Applicant

Proposed Route. Links 1 and 2, Variation 1; Link 1, Variation 2; Link 4, Variation 1; and Link 5, Variation 2, would cross through similar types of vegetation and habitats compared to the original Applicant Proposed Route. Although forests are found in the ROI for all of these routes (both the route variations and applicable portion of the Applicant Proposed Routes), forested habitats are more common along the following route variations compared to the ROI for the Applicant Proposed Route: Link 1, Variation 2; Link 4, Variation 2; and Link 5, Variation 2. Also, Link 4, Variation 1, would cross through some undeveloped land (which include forested habitats), while the ROI for the original Applicant Proposed Route in this location crosses a quarry operation and would entirely avoid forested habitats.

3.20.1.5.4 Region 4

Region 4 is referred to as the Arkansas River Valley Region and includes the Applicant Proposed Route, including the Lee Creek Variation, and Alternative Routes 4-A through 4-E.

The wildlife species that occur in the ROI of Region 4 are adapted to the mesic conditions of north-central Oklahoma and north-central Arkansas. As described in Section 3.10, the dominant land cover in the ROI is pasture/hay. Other less dominant land cover types in this region include deciduous forest and evergreen forest. As the ROI moves west to east, the percentage of evergreen forests within the ROI increases. Wetland areas that may be used by wildlife in this region are described in detail in Section 3.19.

As discussed in Section 3.12, wildlife areas that are managed for recreation within Region 4 include the Ozark National Forest WMA, Ozark Lake WMA, and Frog Bayou WMA:

- The Ozark National Forest WMA would be crossed by the ROI associated with HVDC Alternative Route 4-B and Applicant Proposed Route Link 9. Habitat within this WMA consists of upland hardwood of oak-hickory with scattered pine and a brushy undergrowth, dominated by such various species of dogwood, maple, redbud, and serviceberry. Game species known to occur at this WMA include white-tailed deer, black bear, quail species, rabbit, squirrel, and crow.
- The Ozark Lake WMA would be crossed by the ROI associated with the Applicant Proposed Route Link 6. The majority of this WMA area consists of moist soil lowlands with a small amount of vegetated uplands. Much of the area is within levees, containing old fields. Game species known to occur at this WMA include white-tailed deer, quail species, rabbit, squirrel, and crow.
- The Frog Bayou WMA would be crossed by the ROI associated with the Applicant Proposed Route Link 6. This WMA was a former farm that has been restored to a wetland habitat. Game species known to occur at this WMA include white-tailed deer, quail species, rabbit, squirrel, and crow.

As discussed in Section 3.15, portions of the Arkansas River and Lower Illinois River are located within the ROI for Region 4 (as well as various creeks/waterbodies).

The ROI associated with the HVDC Alternative Route 4-B crosses the Ozark-St. Francis National Forests. The ROI for the Applicant Proposed Route also crosses the Ozark National Forest Global IBA (as discussed in Section 3.20.1.4.2).

It should be noted that Region 4 also contains the “Lee Creek Variation,” which is a variation of the Applicant Proposed Route. The Lee Creek Variation is 3.4 miles long and none of the route is parallel to existing infrastructure. The land cover in the 200-foot-wide representative ROW is 94.4 percent forest land.

Seven route variations to the Applicant Proposed Route were developed in Region 4 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.4. The variations are illustrated in Exhibit 1 of Appendix M. These variations represent minor adjustments to the Applicant Proposed Route. Link 3, Variation 1; Link 3, Variation 3; Link 6, Variation 1; Link 6, Variation 2; Link 6, Variation 3; and Link 9, Variation 1, would cross through similar types of vegetation and habitats compared to the original Applicant Proposed Route. Applicant Proposed Route Link 3, Variation 2, would parallel almost four times the length of existing infrastructure compared to the original Applicant Proposed Route, and would cross through areas that contain fewer wetland and waterbody features compared to the original Applicant Proposed Route.

3.20.1.5.5 Region 5

Region 5 is referred to as the Central Arkansas Region and includes the Applicant Proposed Route and Alternative Routes 5-A through 5-F.

The wildlife species that occur in the ROI are adapted to the mesic conditions of north-central Arkansas. As described in Section 3.10, the dominant land cover in the ROI is deciduous forest. Other less dominant land cover types in this region include pasture/hay and evergreen forest. As the ROI moves west to east, the percentage of evergreen forests within the ROI increases. Wetland areas that may be used by wildlife are described in detail in Section 3.19.

The Cherokee WMA is located in the ROI associated with the Applicant Proposed Route, Links 2 and 5. Habitat within this WMA varies from upland hardwood, mixed pine/hardwood, to pine habitats. Game species found within this WMA include various species of turkey, deer, bear, quail, rabbit, squirrel, and crow.

Five route variations to the Applicant Proposed Route were developed in Region 5 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.5. The variations are illustrated in Exhibit 1 of Appendix M. These variations represent minor adjustments to the Applicant Proposed Route. Link 1, Variation 2; Link 2, Variation 2; Links 2 and 3, Variation 1; Links 3 and 4, Variation 2; and Link 7, Variation 1, would cross through similar types of vegetation and habitats compared to the original Applicant Proposed Route.

3.20.1.5.6 Region 6

Region 6 is referred to as the Cache River and Crowley’s Ridge Region and includes the Applicant Proposed Route and Alternative Routes 6-A through 6-D.

The wildlife species that occur in the ROI of Region 6 are adapted to the mesic conditions of northeastern Arkansas. As described in Section 3.10, the dominant land cover in the ROI of Region 6 is croplands. Other less dominant land cover types in this region include deciduous forest. Wetland areas that may be used by wildlife are described in detail in Section 3.19.

As discussed in Sections 3.12, wildlife areas that are managed for recreation within Region 5 include the Singer Forest Natural Area/St. Francis Sunken Lands WMA and portions of USFWS acquisition areas associated with the Cache River NWR.

- The Singer Forest Natural Area/St. Francis Sunken Lands WMA is within the ROI associated with the Applicant Proposed Route Link 7. Habitats within this WMA include upland forest and forested wetland habitat. This area is managed for recreationally hunted wildlife species, such as waterfowl, wild turkey, white-tailed deer, quail, rabbit, and squirrel.
- A section of approved acquisition area for the Cache River NWR occurs within the ROI associated with HVDC Alternative Route 6-B near Amagon, Arkansas, and by the ROIs associated with the Applicant Proposed Route Links 3 and 4, and HVDC Alternative Route 6-A north and west of Fisher, Arkansas. The Cache River NWR was specifically designated to provide protection for wetland habitats used by migratory birds as foraging and roosting areas during migration (USFWS 2014). This area contains a large amount of bottomland hardwood forests along the Cache River, White River, and Bayou Deview.

As discussed in Section 3.15, habitats used by wildlife species in Region 6 include sections of the White, Cache, L'Anguille, and St. Francis rivers. The ROI for the HVDC transmission line routes also cross the Cache-Lower White Rivers Global IBA (as discussed in Section 3.20.1.4.2).

One route variation to the Applicant Proposed Route in Region 6 (i.e., Applicant Proposed Route Link 2, Variation 1) was developed in response to public comments on the Draft EIS. This route variation is described in Appendix M and summarized in Section 2.4.2.6. The variation is illustrated in Exhibit 1 of Appendix M. This variation represents a minor adjustment to the Applicant Proposed Route. Link 2, Variation 1, would cross through similar types of vegetation and habitats compared to the original Applicant Proposed Route.

3.20.1.5.7 Region 7

Region 7 is referred to as the Arkansas Mississippi River Delta and Tennessee Region and includes the Applicant Proposed Route and Alternative Routes 7-A through 7-D.

The wildlife species that occur in the ROI are adapted to the mesic conditions of northeastern Arkansas and southwestern Tennessee. As described in Section 3.10, the dominant land cover in the ROI of Region 7 is croplands. Other less dominant land cover types in the region include deciduous forest, scrub/shrub, and pasture/hay. Wetland areas that may be used by wildlife are described in detail in Section 3.19.

As discussed in Section 3.15, portions of the St. Francis, Mississippi, and Loosahatchie rivers are located within the ROI for Region 7 associated with the HVDC transmission line routes.

Three route variations to the Applicant Proposed Route were developed in Region 7 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.7. The variations are illustrated in Exhibit 1 of Appendix M. Link 1, Variation 1; Link 1, Variation 2; and Link 5, Variation 1, would cross through similar types of vegetation and habitats compared to the original Applicant Proposed Route.

3.20.1.6 Connected Actions

3.20.1.6.1 Wind Energy Generation

Wind energy generation would likely occur within WDZs. The wildlife species that occur in WDZ-A, WDZ-B, WDZ-C, and WDZ-L are adapted to dry or seasonally dry habitat conditions of the semi-arid eastern Texas Panhandle. The wildlife species that occur in WDZ–D, WDZ-E, WDZ-F, WDZ-G, WDZ-H, WDZ-I, WDZ-J, and WDZ-K are adapted to dry or seasonally dry habitat conditions of the semi-arid eastern Oklahoma Panhandle. As described in Section 3.10, the dominant land cover in WDZ-A, WDZ–B, WDZ–E, WDZ–I, WDZ–K, and WDZ–L is croplands (primarily center-pivot irrigated with some dryland areas), while the dominant land cover in WDZ-C, WDZ-D, WDZ-F, WDZ-G, WDZ-H, and WDZ-J is grasslands. Other less dominant land cover types in WDZ-A, WDZ-B, WDZ-E, WDZ-I, WDZ-K, and WDZ-L include grasslands, and shrub/scrub, while less dominant land cover types in WDZ-C, WDZ-D, WDZ-F, WDZ-G, WDZ-H, and WDZ-J include croplands (primarily center-pivot irrigated with some dryland areas) and shrub/scrub habitats. Wetland habitats that may be used by wildlife in these areas are described in detail in Section 3.19.

3.20.1.6.2 Optima Substation

As discussed in Section 3.1, the future Optima Substation may be constructed just east of the Oklahoma Converter Station Siting Area and partially within the AC Interconnection Siting Area in Region 1. The location for the substation occurs on grassland habitats adjacent to croplands. The wildlife species that occur in this area are adapted to dry or seasonally dry habitat conditions of the semi-arid eastern Texas/Oklahoma Panhandle.

3.20.1.6.3 TVA Upgrades

The ROI for the direct assignment facilities (which are included in the Applicant Proposed Project) would occur within the Tennessee Converter Station Siting Area and more specifically within the Shelby Substation. The ROI for the network upgrades, and in particular TVA's future 500kV transmission line, cannot be fully determined at this time. The new transmission line would be constructed in western Tennessee. The upgrades to existing facilities would mostly be in western and central Tennessee. Upgrades to existing infrastructure would include upgrading terminal equipment at three existing 500kV substations and six existing 161kV substations; making appropriate upgrades to increase heights on 16 existing 161kV transmission lines to increase line ratings, and replacing the conductors on eight existing 161kV transmission lines. Where possible, general impacts associated with the required TVA upgrades are discussed in the impact sections that follow.

3.20.1.7 Impacts to Wildlife

3.20.1.7.1 Methodology

Within the ROI, Project activities were assessed that could potentially impact wildlife or their habitats. This wildlife assessment references the quantitative assessment of habitat impacts presented in Sections 3.10 and 3.17 (i.e., acres of disturbance listed in the Land Use and Vegetation sections, respectively), as well as the quantitative assessment of potential impacts to waterbodies as presented in Section 3.15 (i.e., waterbody crossings and impacts listed in the Surface Water section).

Wildlife resources that were evaluated in this assessment included important recreational species, migratory birds, reptiles, amphibians, and mammal species that are known to occur or have the potential to occur within the applicable ROI. The impact assessment addressed the following:

- Potential impacts from temporary or long-term displacement of wildlife species
- Potential impacts from fragmentation of wildlife habitat
- Potential disturbance to known populations and/or suitable habitat for wildlife species
- Potential impacts to wildlife movement, migratory birds and flyways (including the Mississippi Flyway, Audubon-designated IBAs, or other federal or state designated bird areas)
- Potential for avian collisions and/or electrocution
- Potential impacts of invasive plant species on wildlife habitats

The Applicant has developed EPMs that would be implemented during design/engineering, construction, and operations and maintenance. The complete list of EPMs is provided in Appendix F. Implementation of these EPMs is assumed throughout the impact analysis for the Project. During the initial construction phase of the Project, both general EPMs and those specific to wildlife resources would be implemented to avoid or minimize impacts to wildlife resources (as described below).

General EPMs for the Project that relate to wildlife resources include the following:

- GE-1: Clean Line will train personnel on health, safety, and environmental matters. Training will include practices, techniques, and protocols required by federal and state regulations and applicable permits.
- GE-2: Clean Line will design, construct, maintain, and operate the Project following current Avian and Power Line Interaction Committee guidelines to minimize risk of avian mortality.
- GE-3: Clean Line will minimize clearing vegetation within the ROW, consistent with a Transmission Vegetation Management Plan (TVMP) filed with NERC, and applicable federal, state, and local regulations. The TVMP may require additional analysis under NEPA depending on whether and under what conditions DOE decides to participate in the Project.
- GE-4: Vegetation removed during clearing will be disposed of according to federal, state, and local regulations.
- GE-5: Any herbicides used during construction and operations and maintenance will be applied according to label instructions and any federal, state, and local regulations.
- GE-6: Clean Line will restrict vehicular travel to the ROW and other established areas within the construction, access, or maintenance easement(s).
- GE-7: Roads not otherwise needed for maintenance and operations will be restored to preconstruction conditions. Restoration practices may include decompacting, recontouring, and re-seeding. Roads needed for maintenance and operations will be retained.
- GE-9: Clean Line will avoid and/or minimize damage to drainage features and other improvements such as ditches, culverts, levees, tiles, and terraces; however, if these features or improvements are inadvertently damaged, they will be repaired and or restored.
- GE-10: Clean Line will work with landowners to repair damage caused by construction, operation, or maintenance activities of the Project. Repairs will take place in a timely manner, weather and landowner permitting.
- GE-11: Clean Line will conduct construction, operation, and maintenance activities to minimize the creation of dust. This may include measures such as limitations on equipment, speed, and/or travel routes utilized. Water, dust palliative, gravel, combinations of these, or similar control measures may be used. Clean Line will implement measures to minimize the transfer of mud onto public roads.
- GE-13: Emergency and spill response equipment will be kept on hand during construction.

- GE-14: Clean Line will restrict the refueling and maintenance of vehicles and the storage of fuels and hazardous chemicals within at least 100 feet from wetlands, surface waterbodies, and groundwater wells, or as otherwise required by federal, state, or local regulations.
- GE-15: Waste generated during construction or maintenance, including solid waste, petroleum waste, and any potentially hazardous materials will be removed and taken to an authorized disposal facility.
- GE-20: Clean Line will conduct construction and scheduled maintenance activities on the facilities during daylight hours, except in rare circumstances that may include, for example, to address emergency or unsafe situations, to avoid adverse environmental effects, to minimize traffic disruptions, or to comply with regulatory or permit requirements.
- GE-21: Clean Line will maintain construction equipment in good working order. Equipment and vehicles that show excessive emissions of exhaust gases and particulates due to poor engine adjustments or other inefficient operating conditions will be repaired or adjusted.
- GE-22: Clean Line will impose speed limits during construction for access roads (e.g., to reduce dust emissions, for safety reasons, and for protection of wildlife).
- GE-25: Clean Line will turn off idling equipment when not in use.
- GE-27: Clean Line will minimize compaction of soils and rutting through appropriate use of construction equipment (e.g., low ground pressure equipment and temporary equipment mats).
- GE-28: Hazardous materials and chemicals will be transported, stored, and disposed of according to federal, state, or local regulations or permit requirements.
- GE-30: Clean Line will minimize the amount of time that any excavations remain open.

Fish, vegetation, and wildlife specific EPMs, or other EPMs that may aid to minimize or avoid impacts to fish and wildlife species, include the following:

- FVW-1: Clean Line will identify environmentally sensitive vegetation (e.g., wetlands, protected plant species, riparian areas, large contiguous tracts of native prairie) and avoid and/or minimize impacts to these areas.
- FVW-2: Clean Line will identify and implement measures to control and minimize the spread of non-native invasive species and noxious weeds.
- FVW-3: Clean Line will clearly demarcate boundaries of environmentally sensitive areas during construction to increase visibility to construction crews.
- FVW-4: If construction- and/or decommissioning-related activities occur during the migratory bird breeding season, Clean Line will work with USFWS to identify migratory species of concern and conduct pre-construction surveys for active nests for such species. Clean Line will consult with USFWS and/or other resource agencies for guidance on seasonal and/or spatial restrictions designed to avoid and/or minimize adverse effects.
- FVW-5: If construction occurs during important time periods (e.g., breeding, migration, etc.) or at close distances to environmentally sensitive areas with vegetation, wildlife, or aquatic resources, Clean Line will consult with USFWS and/or other resource agencies for guidance on seasonal and/or spatial restrictions designed to avoid and/or minimize adverse effects.
- FVW-6: Clean Line will avoid and/or minimize construction within 300 feet of caves known to be occupied by threatened or endangered species.
- W-2: Clean Line will identify, avoid, and/or minimize adverse effects to wetlands and waterbodies. Clean Line will not place structure foundations within the Ordinary High Water Mark of Waters of the United States.

- W-3: Clean Line will establish streamside management zones within 50 feet of both sides of intermittent and perennial streams and along margins of bodies of open water where removal of low-lying vegetation is minimized.
- W-4: If used, Clean Line will selectively apply herbicides within streamside management zones.
- W-5: Clean Line will construct access roads to minimize disruption of natural drainage patterns including perennial, intermittent, and ephemeral streams.
- W-6: Clean Line will not construct counterpoise or fiber optic cable trenches across waterbodies.
- W-7: Clean Line will locate spoil piles from foundation excavations and fiber optic cable trenches outside of streamside management zones.
- W-8: Dewatering will be conducted in a manner designed to prevent soil erosion (e.g., through discharge of water to vegetated areas and/or the use of flow control devices).
- W-9: Clean Line will design converter station sites to avoid adverse changes to the base flood elevation within the 100-year floodplain.
- W-10: Clean Line will minimize fill for access roads and structure foundations within 100-year floodplains to avoid adverse changes to the base flood elevation.

Additional site-specific EPMs may be developed as part of the ongoing consultation process between the Applicant and federal and state agencies.

The following plans would be developed and implemented by the Applicant to avoid or minimize impacts:

- Blasting Plan: This plan will contain measures designed to minimize adverse effects due to blasting.
- Restoration Plan: This plan will describe post-construction activities that would be implemented to reclaim disturbed areas.
- Spill Prevention, Control and Countermeasures (SPCC) Plan: This plan will contain the measures designed to prevent, control, and clean up spills of hazardous materials.
- Storm Water Pollution Prevention Plan (SWPPP): This plan, consistent with federal and state regulations, will describe the practices, measures, and monitoring programs to control sedimentation, erosion, and runoff from disturbed areas.
- Transmission Vegetation Management Plan (TVMP): This plan, to be filed with NERC, will describe how the Applicant will conduct work on its right-of-way to prevent outages due to vegetation. The TVMP may require additional analysis under NEPA depending on whether and under what conditions DOE decides to participate in the Project.
- Avian Protection Plan (APP): This plan, consistent with APLIC guidelines, will describe a program of specific and comprehensive actions that, when implemented, reduce risk of avian mortality. The Applicant would develop the APP in coordination with the USFWS and other applicable agencies.

3.20.1.7.2 Impacts Associated with the Applicant Proposed Project

This section identifies the potential impacts on wildlife and their habitat that could occur as a result of the Project. The discussion of potential impacts is broken out into the three phases of the Project: (1) construction; (2) operations and maintenance; and (3) decommissioning. The Applicant would conduct each phase of the Project in compliance with applicable state and federal laws, regulations, and permits related to environmental protection. Specific EPMs developed to avoid or minimize impacts are described in Section 3.20.1.7.1.

The impacts discussed in the subsections below are common to all aspects of the Project, while the impacts associated with specific portions of the Project (e.g., converter stations, AC collection system, HVDC routes, as well as their alternatives) are discussed separately following this general impact discussion. Both direct (i.e., impacts that result from the action and occur at the same time and place as the action) and indirect impacts (i.e., impacts that result from the action, but which occur later in time or farther in distance) are addressed. The impacts that could result from activities related to the Project would vary in duration. Some impacts would be temporary, with the resource returning to pre-disturbance conditions after the Project-related disturbance has ceased. Temporary impacts can be further defined as either short-term or long-term impacts. Short-term impacts could continue beyond the completion of construction and could last up to 5 years. Long-term impacts would last beyond 5 years (e.g., these impacts often relate to affected resources such as forests that require long recovery periods to return to pre-disturbance conditions), and may last for the duration of the Project life (i.e., 80 years). Permanent impacts result from activities that modify a resource to such an extent that it cannot return to pre-disturbance conditions even after the Project-related disturbance has ceased.

Construction Impacts

Mortality and Injury. Mortality, by definition, would constitute a permanent impact to an individual (i.e., the individual no longer exists); however, the magnitude of effect related to a single mortality on an entire wildlife population (i.e., the effects that a single mortality has to the entire group) can vary depending on the dynamics of the population. Small populations or those that have a low fecundity can be sensitive to individual mortalities (e.g., the death of a single Florida panther can have a major impact to the success rate of the entire population due to the low population number and slow reproduction rate of this species as described in Section 3.14). However, large and/or healthy populations are often less sensitive to the loss of an individual. In general, many small mammals, small birds, and amphibians (i.e., species that typically have a high birth rate and large population sizes) are less sensitive to individual mortality events compared to large mammals and large birds (e.g., raptors). Bats are an exception to this generality though, because although bats are small mammals, they typically bear only a single litter per year, produce one young at a time, and do not breed until their second year (Nagorsen and Brigham 1993).

Construction of the Project could result in the direct mortality or injury of wildlife species. Of the construction activities proposed, the clearing of vegetation and preparation of work sites would pose the greatest risk of injuring or killing wildlife. Although some individuals would move away from construction activities given the disruptive nature of these activities (see further discussion of wildlife disturbances in the "Disturbance" subsection below), some individuals would either attempt to hide within the path of disturbance (e.g., small mammals or reptiles may attempt to burrow underground or remain motionless within the vegetation during clearing) or would be unable to relocate away from the disturbed area (e.g., eggs and some juvenile birds would be killed if clearing was conducted during the breeding season). These mortalities/injuries can be minimized by timing the construction activities to avoid sensitive periods (e.g., the breeding seasons), and the Applicant has agreed to consult with the USFWS regarding the appropriate seasonal and/or spatial restrictions that should be applied (see EPM FVW-5); however, some mortality events would still occur even with the implementation of seasonal and spatial restrictions. Based on their life-histories, avian species and small mammals would likely constitute a large component of wildlife injuries and/or mortalities if construction was conducted during the breeding season. Large mammals would likely constitute a low component of wildlife injuries and/or mortalities that are a direct result of vegetation clearing, regardless of the timing of construction (e.g., Project-related large mammal injuries/mortalities would likely result from factors not directly related to vegetation clearing; see further discussion below).

Use of heavy equipment and vehicles during construction of the Project could result in additional wildlife injuries or mortalities (beyond those resulting from vegetation clearing) as wildlife can be struck or run over by vehicles. The likelihood of striking or running over wildlife increases if construction occurs during the night when visibility is limited, or if vehicles are operated at high speeds. In order to minimize this risk, the applicant would implement EPMs GE-6, GE-20, and GE-22.

Wildlife species can become sick or die if they are exposed to hazardous chemicals such as those that would be used during construction of the Project (e.g., oils and fuels that would be used while operating machinery, or herbicides that would be used to control vegetation and invasive species). Illness and/or mortality can result from direct contact with the toxin, or if the species is indirectly exposed through the food web. Improper use of these chemicals as well as accidental spills can expose wildlife to these chemicals; however, the Applicant would implement EPMs GE-1, GE-5, GE-13, GE-21, and GE-28, as well as the measures that would be outlined in the required SPCCP and SWPPP to minimize these risks. These EPMs include measures that would reduce the risks of accidental spills (e.g., GE-13, GE-21, GE-28), as well as measures that would ensure that the use of herbicides is conducted in accordance with labeled instructions and any federal, state, and local regulations (i.e., GE-5). In addition, a TVMP would be prepared and would address situations where herbicide use is necessary (e.g., the Applicant would evaluate herbicidal treatment options in consideration of site-specific ecological conditions, surrounding and underlying land uses, and any environmental sensitivities before selecting and applying a control). The Vegetation Program and TVMP would be developed to comply with federal, state, and local regulations and standards for reliability and ROW vegetation clearing and maintenance, including NERC Reliability Standard FAC-003 (NERC 2011). The Vegetation Program and TVMP would also comply with relevant regulations applicable to all lands, including, but not limited to the Clean Water Act (CWA) Sections 303(d) and 404 and the Endangered Species Act (ESA) of 1973 as amended in Section 7(a)(2). See Section 3.17 for a detailed discussion of the Vegetation Program and use of herbicides. The TVMP may require additional analysis under NEPA depending on whether and under what conditions DOE decides to participate in the Project.

Construction of the Project could result in the ignition of wildfires. For example, the hot undercarriage of construction vehicles can ignite the grasses found along access roads (see Section 3.8 for more details regarding fire risk). Although many wildlife species are adapted to dealing with fire to some degree (e.g., small mammals and reptiles may burrow underground, while birds and large mammals would move away from the affected area), wildfires could still result in some wildlife mortalities (especially for less mobile species or individuals or in habitats and regions not typically exposed to fire) (Smith 2000).

The Project's construction has the potential to increase the numbers of predators in the immediate area, due to the presence of trash in the work area. Trash created by construction personnel can attract predators like crows and raccoons (*Procyon lotor*). This would be a short-term impact that would end with the removal of the trash source. The Applicant would minimize the risk of attracting predators to the area through the implementation of EPM GE-15.

Concern has been expressed by the public that bats may collide with construction equipment during construction of the Project. This sort of collision is unlikely to occur as construction equipment would typically be present in the construction area during daylight hours when bats are not active (however, see further discussion below regarding the possibility of construction occurring at night). Furthermore, bats are capable of avoiding stationary structures via the use of echolocation, so they would likely be able to avoid any Project-related stationary structures that may be present at night; however, bats may collide with and be killed by the turbines found at the associated wind-farms during operation of the Project (see further discussion in the “Impacts from Connected Actions” section below). The greatest risk to bat species during construction of the Project is the potential clearing of trees that are used by bats for roosting habitats (resulting in direct mortality), or the potential disturbance of bats in hibernacula (see the discussion below in the “Disturbance” subsection).

Disturbance. The increased presence of humans as well as the noise and vibrations associated with construction activities could disturb wildlife in the vicinity of the Project. Disturbances associated with elevated noise levels would likely have a farther reaching affect compared to visual disturbances (i.e., depending on limited sight lines due to topography and/or visual screening, noise can potentially affect areas beyond the visual range of an individual). As discussed in Section 3.11, construction noise is typically made up of intermittent peaks and continuous lower levels of noise from equipment cycling through use. Noise levels associated with individual pieces of equipment would generally range between 55 and 85 dBA L_{max} (see Section 3.11). Maximum instantaneous construction noise levels could be as high as 95 dBA L_{eq} at 50 feet from any work site. Table 3.11-4 in Section 3.11 provides noise level data for Project-related construction activities.

The responses of wildlife to disturbances may include temporary habitat displacement or avoidance of the area, stress, and disorientation. This could have negative impacts by causing animals to move to less suitable areas, which could result in less available or lower quality forage, loss of access to preferred nesting/breeding sites, increased exposure to predation, and increased energy expenditure. Individual stress, habitat displacement, and avoidance association with disturbance can take time away from life history activities, including feeding, reproduction, and parental care resulting in a reduction of overall fitness. The resulting adverse impacts to adults would be expected to be temporary and short-term, occurring during active construction hours and ceasing after construction activities have moved from a given area (unless the habitat is degraded below its ability to support the species; see further discussion below). However, if adults abandon their young due to these disturbances (e.g., if the adult birds abandoned their nests), these disturbances could result in the death of young (see the “Mortality and Injury” subsection above).

The Applicant has indicated that they would conduct all construction activities during daylight hours to the extent practical (see EPM GE-20); however, EPM GE-20 indicates that nighttime construction may be required under certain conditions (e.g., to address emergency or unsafe situations). Wildlife would likely be more sensitive to disturbance during nighttime hours because natural background noise levels are typically lower at night compared to daylight hours (i.e., there would be a larger difference between background noise levels and construction noise at night, resulting in a greater disturbance affect to wildlife if work occurs at night). Furthermore, artificial lighting would be required to safely work at night. Migrating avian species could be attracted to the work areas during the night due to this artificial lighting, thereby exposing these species to increased risks of disturbance or injury. The artificial lighting could also attract insects to the area resulting in exposure of bat species (which feed on insects) to increased risks of disturbance or injury. Artificial lighting could also disrupt natural wildlife processes such as foraging, reproduction, and communication within areas that are artificially lit during nighttime construction.

All wildlife taxa have the potential for habitat displacement and avoidance due to Project-related disturbance. Many bat and bird species are highly sensitivity to disturbances, because disturbed birds may abandon their young (resulting in the death of the young), while roosting bats that are disturbed during the day may abandon hibernaculum thereby expending critical and limited energy resources (potentially resulting in the death of the bat). Big game species (i.e., large mammals) can also be sensitive to disturbance. For example, displacement of big game from both winter and parturition (birthing) areas could affect over-winter survival by causing animals to mobilize stored bodily energy reserves that are needed to survive seasons when food is scarce. This could also impact reproductive success on parturition ranges if females are sufficiently disturbed so as to not provide adequate care for their young.

Habitat Loss and Modification. Construction of the Project would result in the loss or modification of wildlife habitat. Affected habitats may be temporarily lost to wildlife during the construction phase of the Project (e.g., wildlife may not use these habitats during construction due to disturbance from construction activities), but use of the habitat could be restored once construction disturbances cease in the area and the habitat is restored. However, areas that are occupied by permanent Project features (e.g., towers, substations, etc.) would be permanently lost to wildlife. The Project would also convert some habitats from one type to another. For example, trees and tall shrubs would be cleared within the Project's ROW to prevent this tall vegetation from interfering with or damaging the Project's transmission line (see Section 3.17). Clearing the ROW would convert forested and riparian areas to a grassland and low shrub habitat type; subsequent vegetation management, as described below, would maintain these grassland and low shrub habitat types, resulting in a long-term impact. Conversion of habitats from one type to another could alter the composition of wildlife found within the affected habitat (e.g., shifting from an interior forested wildlife community to a grassland or forest-edge community within the affected area). It should be noted that the entire ROW would be cleared in forested habitats, but not in low vegetation types such as grasslands or croplands (where only areas needed for construction would be cleared as described in Section 3.17). As a result, the acreage of cleared land per mile of Project would be greatest in forested habitats compared to other habitats that contain only low vegetation types.

The amount of time necessary for temporarily impacted habitats to restore to pre-construction conditions would depend on the type and structure of the affected habitat. Grasslands and croplands would be capable of restoring to pre-disturbance levels in a short timeframe (defined as less than 5 years). As a result, impacts could be short-term within the grasslands and croplands habitats that are allowed to restore to pre-construction conditions following completion of construction (i.e., areas not encompassed by the footprint of the converter station, transmission line structures, access roads, etc.). However, forested and riparian areas can take many decades to restore to pre-disturbance conditions; as a result, habitat loss would have a long-term impact in forested and riparian areas (even for those forested and riparian areas that are allowed to restore to pre-construction conditions).

The Project could indirectly impact wildlife by decreasing habitat quality through habitat fragmentation. Although fragmentation of habitats would begin during construction, the majority of fragmentation related impacts would occur after construction; therefore, fragmentation is discussed below, under the "Operations and Maintenance Impacts" subheading.

The clearing of vegetation and disturbance to soils could promote the spread and or establishment of invasive plant species. Invasive plant species can reduce the quality of habitats for wildlife by competing with native plants for resources such as water and light, changing the community composition, eliminating or reducing native plants, or changing the vegetation structure. All habitat types are susceptible to establishment or invasion by invasive plant species. The Applicant would implement EPM FVW-2 to minimize the risk of spreading or creating new infestations of invasive plant species. Section 3.17 discusses in detail the potential effects of invasive plants species on native habitats, as well as the measures that would be taken to minimize the risk of these effects. The subsection "Mortality and Injury" above and Section 3.17 discuss the use of herbicides to control invasive plant species as well as the potential effects of this herbicide use on wildlife.

Operations and Maintenance Impacts

The direct and indirect effects on wildlife resources (e.g., mortality and/or injury, disturbance, habitat loss and/or modification) that would occur during the operations and maintenance phase of the Project would generally result from the presence of permanent Project structures, the presence of maintenance personnel and equipment in the area, and vegetation reclamation and maintenance activities that would be conducted. However, the magnitude of these effects would generally be less than what was described above for construction related impacts due to the periodic nature of the required maintenance and reclamation work (see Section 2.1.5 for a detailed description of the estimated operations and maintenance schedule).

Fragmentation refers to the breaking up of contiguous areas of vegetation or habitat into smaller patches. Many wildlife species require contiguous patches of suitable habitat of certain size and connectivity to carry out life functions such as foraging, finding a mate, and the dispersal of young to adjacent suitable habitat areas. For some species, the generally 14 to 16-foot-wide access roads associated with the Project (as well as the cleared ROW in forested and riparian areas) could serve as a barrier to movement, thereby isolating subpopulations and increasing the risk of local extirpation (this would be predominantly experienced by smaller species or those less likely to move through open areas that are either devoid of vegetation or contain modified vegetation). Although the Project may not serve as a barrier to movement for all species (e.g., the presence of access roads, the ROW, or the transmission line itself would not likely limit the movement of large mammals), roads can reduce habitat quality by promoting the spread or establishment of invasive plant species (discussed in detail above).

In addition, the presence of the transmission line itself could exclude some species from areas adjacent to the line or increase predation rates near the line, thereby contributing to the effect and magnitude of habitat fragmentation for some prey species. This is because the presence of the suspended powerline could become an attractant to raptors and ravens/crows for nesting and perching habitats. The numbers of ravens and crows that use existing transmission lines for perching habitat can become quite substantial (Engel et al. 1992), and the potential increase in raptor and raven/crows numbers along the Project could result in an increase in harassment and predation rates on prey species (e.g., small mammals or prey bird species) that are present at or adjacent to the Project (Stahlecker 1978; Steenhof et al. 1993; Manzer and Hannon 2005; Coates and Delehanty 2010). The effect of increased raptor and raven/crow predation rates on prey species would be most prominent where the Project is located in areas that do not contain other tall structures, such as existing transmission lines or trees. Fragmentation and the creation of a cleared ROW in forested and woodland habitats could also facilitate the movement and improve hunting efficiency for some mammalian predators. In forests, for example, coyotes are most abundant in areas of disturbance (Kays et al. 2008). They are also known to travel extensive distances on linear pathways, including transmission line ROWs (Way and Eatough 2006).

In addition to the general effects of fragmentation discussed above, forested and riparian habitats could experience a substantial edge effect. Edge effects result when two different types of habitat are adjacent to each other. Edge effects tend to be more pronounced with increasing differences in the structure, height, density, or complexity of the two adjacent habitat types (e.g., a mature forest adjacent to a grassland). A variety of impacts are associated with edge effects. For example, edge effects can affect wildlife and habitat quality by altering nutrient flows/cycling; increasing the rate of invasion by noxious weeds, invasive wildlife species, and pathogens; lowering the carrying capacity of a habitat/patch; and disrupting meta-population dynamics[1] (Saunders and Hobbs 1991). The creation of habitat edges within forests can impact microclimatic factors such as wind, humidity, and light, and can lead to a change in plant or animal species composition within the adjacent habitat (Murcia 1995). Compared to the interior of a forest, areas near edges receive more direct solar radiation during the day, lose more long-wave radiation at night, have lower humidity, and receive less short-wave radiation. Increased solar radiation and wind can desiccate vegetation by increasing evapotranspiration, can affect which plant species survive along the edge (typically favoring shade-intolerant species), and can impact soil characteristics; all of these factors can alter the composition of wildlife habitats and the species that inhabit them.

The impacts of fragmentation and edge effects do not affect all habitats, taxa, and species equally. Some species will avoid edge habitats, while others species preferentially select edge habitats. For example, crows, blue jays, raccoons, and brown-headed cowbirds are often associated with edge habitats (Masters et al. 2002). Edge habitats provide these species with a diversity of cover types and foraging/feeding opportunities. The creation of edge habitats by the Project in forested areas (primarily in Regions 4 and 5; as well as Regions 3 and 7 to a lesser extent) could result in the numbers of species that prefer edge habitats to increase along the ROW, while decreasing the number of species that prefer dense, continuous, unfragmented habitats. Also, the potential increase in brown-headed cowbirds could adversely affect other avian species in the areas, because this species parasitizes the nests of other birds (Lowther 1993). Fragmentation and edge effects can also affect grassland and other non-forested habitats as well. For example, the increased predation rates experienced along the Project (due to the consolidation of raptors and ravens/crows along the lines) could result in the fragmentation of grassland and other low-vegetation habitats crossed by the Project (see discussion above).

Some avian mortality may occur as a result of collisions with the transmission lines and Project features during operations (CEC 2005). A variety of factors influence the rate of avian collisions with powerlines or other anthropogenic features, including: configuration and location of powerlines; the tendency of certain species to collide with structures; and environmental factors such as weather, topography, and habitat (APLIC and USFWS 2005). Line placement with respect to other structures and topography can influence the collision rate of avian species at a given powerline. Collisions usually occur near water or migration corridors, and occur more often during inclement weather. Less agile birds, such as heavy-bodied birds or birds that travel in flocks, are more likely to collide with overhead lines because they lack the ability to quickly negotiate obstacles. As discussed in Section 3.20.1.5, rivers/waterbodies often serve as stopover habitats or migratory corridors for migrating birds. As a result, the highest rate of Project-related avian species mortalities due to collisions are likely to occur in areas where the transmission line spans waterbodies (Tables 3.15-4, 3.15-5, 3.15-8, 3.15-12, 3.15-16, 3.15-20, 3.15-24, and 3.15-28 provide a list the waterbodies that could potentially be crossed by the Project). As a result, points where the Project spans major rivers (such as the Mississippi or Cache rivers) could become areas along the line where increased rates of collisions and mortality occur (compared to other areas along the line). Furthermore, structures that use guys (i.e., thin wires that hold tall towers stable) have been found to be associated with higher avian mortality than un-guyed structures. The Applicant has proposed to use guyed structures in some circumstances (see Chapter 2). As a result, the guyed structures used for this Project would likely have higher rates of associated avian mortality compared to the un-guyed structures. To minimize the risk of avian collisions and mortalities, the Applicant would develop and implement an

[1] Meta-population dynamics refers to the interplay between source and sink populations. Meta-population dynamics are an important factor in gene flow between populations, and disruptions to this dynamic can alter or disconnect sub-populations.

APP (as described in Section 3.20.1.7.1) consistent with APLIC guidelines. The APP would be developed in coordination with the USFWS and other applicable agencies.

Avian species are also susceptible to electrocutions as a result of powerlines. In order for a bird to become electrocuted it needs to come into contact with two energized conductors at the same time. As a result, multiple factors influence the risk of avian electrocutions including: the spacing between energized conductors, the tendency of a species to perch along powerlines or fly near conductors, as well as the avian species body-size and wing-length. Of the avian species in the area, raptors have the highest likelihood of becoming electrocuted because raptors commonly perch along transmission lines and have relatively large bodies compared to other taxa of birds. Ravens/crows (which also perch on powerlines) and waterbirds (which do not typically perch on powerlines, but can have large wingspans and can potentially come into contact with two energized conductors if they fly close to the power-lines) are also at risk of electrocutions. As described in Appendix F, the spacing for the conductors as currently proposed would minimize the risk of avian species coming into contact with two energized conductors and/or becoming electrocuted. To further minimize the risk of avian electrocutions, the Applicant would develop and implement an APP (as described in Section 3.20.1.7.1) consistent with APLIC guidelines (see the APP discussion above).

Decommissioning Impacts

Decommissioning of the Project would involve methods similar to those that would be required to construct the Project. As a result, the impacts of decommissioning would be similar to those previously described for construction. The Applicant would follow the same general and resource-specific EPMs during decommissioning that would be implemented during construction. In addition, the Applicant would develop a Decommissioning Plan prior to any decommissioning actions for review and approval by the appropriate state and federal agencies.

Although decommissioning would have short-term adverse impacts to wildlife (similar to what was discussed for construction related impacts), it is assumed that decommissioning of the Project would generally have long-term beneficial impacts to wildlife species and their habitats because it would remove the Project and its related impacts from the environment. However, areas disturbed by the decommissioning activities would still take time to recover from this disturbance (with disturbances in grasslands and croplands likely recovering within 5 years or less, and recovery in forests taking many decades). Also, any wildlife that used the Project features during its operation (e.g., raptors that may perch along the line) may experience an adverse impact when the Project is decommissioned (e.g., loss of perching habitat for raptors).

3.20.1.7.2.1 Converter Stations and AC Interconnection Siting Areas

3.20.1.7.2.1.1 Construction Impacts

3.20.1.7.2.1.1.1 Oklahoma Converter Station Siting Area and AC Interconnection Siting Area

The Oklahoma Converter Station and AC Interconnection Sitting Areas are located within Region 1. As discussed in Sections 3.10 and 3.17, grasslands and croplands are the dominant habitat types found at the proposed site for the Oklahoma converter station and AC interconnection. As a result, the wildlife species that would be exposed to Project-related mortality or injury in this area would be those species that inhabit these types of habitats, i.e., those adapted to dry or seasonally dry habitat conditions of the semi-arid eastern Oklahoma Panhandle. Appendix L lists the wildlife species that inhabit this area and could be impacted by the Project.

Grasslands and croplands are capable of restoring to pre-disturbance levels in a short timeframe (defined as less than 5 years). As a result, the majority of Project-related impacts to grasslands and croplands habitats in Region 1 would be short term in nature (i.e., these areas would likely restore to pre-construction conditions within 5 years or less). However, some permanent loss of grassland and croplands habitats would also occur as a result of the Project's permanent footprint (i.e., some areas would be encompassed permanently by Project structures such as the converter station, transmission line structures, access roads, etc.). Sections 3.10 and 3.17 list the types of habitats that could be affected and the acres that could be impacted by the Oklahoma converter station and AC interconnection.

As currently proposed, the Oklahoma converter station and AC interconnection would be sited within and impact grassland and croplands habitats. Furthermore, the habitats found within Region 1 are relatively common throughout the ROI (i.e., grasslands and croplands dominate the entire area with very few other habitat types present); therefore, potential modifications to the location of the converter station or the route of the AC interconnection within the ROI in Region 1 would not likely substantially alter the types or magnitude of impacts that would occur to wildlife species or their habitats in this area.

3.20.1.7.2.1.1.2 Tennessee Converter Station Siting Area and AC Interconnection Tie

The Tennessee Converter Station Siting Area and AC Interconnection Tie are located within Region 7. The AC Transmission Interconnection Tie would occur entirely within the existing Shelby substation. As discussed in Sections 3.10 and 3.17, croplands and pasture lands are the dominant habitat types found at the proposed site for the Tennessee Converter Station Siting Area; however, hardwood forests and riparian areas are also present within the ROI for the Tennessee Converter Station Siting Area. As a result, the wildlife species that would be exposed to Project-related mortality or injury in this area would be those species that inhabit these types of habitats. This includes those adapted to the mesic conditions of northeastern Arkansas and southwestern Tennessee. Tables in Appendix L list the wildlife species that inhabit this area and could be impacted by the Project.

Croplands and pasture lands are capable of restoring to pre-disturbance levels in a short timeframe (defined as less than 5 years). As a result, the majority of Project-related impacts to these areas in Region 7 would be short-term in nature (i.e., these areas would likely restore to pre-construction conditions within 5 years or less). However, some permanent loss of habitats would still occur as a result of the Project's permanent footprint (i.e., some areas would be encompassed permanently by Project structures such as the converter station, access roads, etc.). Furthermore, because forests and riparian areas are also present with the ROI for the Tennessee Converter Station Siting Area, these types of habitats could also be potentially impacted as well. As previously discussed, forested and riparian areas could take decades to restore to pre-construction conditions if they are disturbed or cleared (i.e., impacts would be long-term in these habitat types). Sections 3.10 and 3.17 list the types of habitats that could be affected and the acres that could be impacted by construction of the Tennessee converter station.

As discussed above, impacts to wildlife would likely be less if the converter station were located within the crop and pasture lands, and would be greater if they were located in forested areas due to the effects of long-term habitat loss, the extensive time necessary for forests to regenerate to pre-disturbance conditions, and the impacts associated with edge effects in forested habitats.

3.20.1.7.2.1.2 Operations and Maintenance Impacts

3.20.1.7.2.1.2.1 Oklahoma Converter Station Siting Area and AC Interconnection Siting Area

Operation and maintenance activities would result in long-term impacts to the habitats around the converter station and AC Interconnection siting area (see Section 3.20.1.7.2 for a detailed discussion of potential impacts related to wildlife disturbance and habitat disruption). Furthermore, as discussed above, some permanent loss of habitat would occur as a result of the Project's permanent footprint (i.e., some areas would be encompassed permanently by Project structures such as the converter station, transmission line structures, access roads, etc.). Sections 3.10 and 3.17 list the types of habitats that could be affected and the acres that would be permanently impacted by the Oklahoma converter station and AC interconnection during operations and maintenance.

The permanent loss of habitat related to the Oklahoma converter station and AC interconnection (see Sections 3.10 and 3.17), is unlikely to have substantial long-term impacts to wildlife populations in the area because the type of habitats affected are common in the region and found elsewhere in the vicinity of the Project ROI (i.e., the affected grasslands and croplands are not limited on the landscape).

3.20.1.7.2.1.2.2 Tennessee Converter Station Siting Area and AC Interconnection Tie

Operation and maintenance activities would result in long-term impacts to the habitats around the converter station siting area (see Section 3.20.1.7.2 for a detailed discussion of potential impacts related to wildlife disturbance and habitat disruption). Furthermore, some permanent loss of habitat would occur as a result of the Project's permanent footprint (i.e., some areas would be encompassed permanently by Project structures such as the converter station, access roads, etc.). Sections 3.10 and 3.17 list the types of habitats that could be affected and the acres that would be permanently impacted by the Tennessee Converter Station Siting Area during operations and maintenance.

The permanent loss of habitat related to the converter station (see Sections 3.10 and 3.17), is unlikely to have substantial long-term impacts to wildlife populations in the area because the type of habitats affected are common in the region and found elsewhere in the vicinity of the Project ROI (i.e., the affected pasture and croplands are not limited on the landscape) unless forested habitats are impacted. As discussed above, forested areas are less common in this area, and impacts to these areas could have greater impacts to forested species compared to the more common pasture and cropland habitats).

3.20.1.7.2.1.3 Decommissioning Impacts

Impacts related to the decommissioning of the converter stations and AC interconnections would not substantially differ from the general discussion of decommissioning related to the Project in general (see Section 3.20.1.7.2).

3.20.1.7.2.2 AC Collection System

3.20.1.7.2.2.1 Construction Impacts

The AC collection system would be located entirely within Region 1. As discussed above, the habitat types found within Region 1 are relatively common throughout the ROI (e.g., grasslands and croplands dominate the entire area with very few other habitat types present); therefore, potential modifications to the routes of the AC collection system would not likely substantially alter the types of habitats that could be impacted. The species composition found along the AC collection system routes would be similar to what was discussed above for the Oklahoma Converter Station and the AC Interconnection Sitting Areas (as both of these Project components occur within the same region).

Table 3.20.1-3 lists the length of the various AC collection system routes, the total acreage within the AC collection system ROW (see Table 3.10-13 in Section 3.10 for more details), the predominant land cover found along each route, and any substantial differences regarding the impacts that would occur under any particular route compared to the other routes. As shown in Table 3.20.1-5, AC Collection System Routes E-1 and NE-2 would have a potentially greater risk of impacting wildlife compared to the other routes, due to these routes' position near important wildlife areas (i.e., both routes are located in close proximity to Optima NWR and Optima WMA[2]), which would elevated the risk of avian collision during the migration seasons (if birds use areas near the Project for stopover habitats). Although AC Collection System Routes NW-1, NW-2, and SE-3 would not have a differential impact to wildlife based on their position (i.e., the types of habitats that could be impacted), they could have a potentially greater impact to wildlife compared to the other routes due to their longer length compared to the other routes (e.g., more habitat would be impacted by these three routes compared to the other routes). It should be noted that these AC collection system routes are not Project alternatives (i.e., one route would not be selected over another as described in Section 2.1.2.3) and the comparison of impacts between these routes is only presented here for impact disclosure purposes.

Table 3.20.1-3:
Summary Information related to Wildlife Resources for the AC Collection System Routes during Construction

AC Collection System Alternatives	Length (miles)	Total Area within the AC ROW (acres)	Predominant Land Cover[1]	Impacts to Wildlife that would be Unique to this Route
E-1	29	708.0	Grasslands (574.2 acres, or 81.1 percent of the ROW)	E-1 would have an elevated risk of avian collision during the migration seasons compared to the other routes, as well as a higher potential for disturbances to important wildlife areas due to this route's proximity to important wildlife areas (i.e., Optima NWR and Optima WMA).
E-2	40	974.4	Grasslands (572.8 acres, or 58.8 percent of the ROW) and croplands (298.6 acres, or 30.6 percent of the ROW)	No substantial difference between this route and the other routes in regards to the types of wildlife impacts that would likely occur as a result of the route's location and position.
E-3	40	977.5	Grasslands (650.3 acres, or 66.5 percent of the ROW)	No substantial difference between this route and the other routes in regards to the types of wildlife impacts that would likely occur as a result of the route's location and position.
NE-1	30	729.8	Grasslands (291.1 acres, or 39.9 percent of the ROI) and croplands (247.2 acres, or 33.9 percent of the ROW)	No substantial difference between this route and the other routes in regards to the types of wildlife impacts that would likely occur as a result of the route's location and position.
NE-2	26	637.4	Grasslands (450.2 acres, or 70.6 percent of the ROW)	NE-2 would have an elevated risk of avian collision during the migration seasons compared to the other routes, as well as a higher potential for disturbances to important wildlife areas due to this route's proximity to important wildlife areas (i.e., Optima NWR and Optima WMA).

2 These areas are managed for wildlife species, including numerous migratory birds that may use the areas as potential stopover locations during migration

Table 3.20.1-3:
Summary Information related to Wildlife Resources for the AC Collection System Routes during Construction

AC Collection System Alternatives	Length (miles)	Total Area within the AC ROW (acres)	Predominant Land Cover[1]	Impacts to Wildlife that would be Unique to this Route
NW-1	52	1,265.4	Grasslands (609.5 acres, or 48.2 percent of the ROW) and developed, open space (540.2 acres, or 42.7 percent of the ROW)	No substantial difference between this route and the other routes in regards to the types of wildlife impacts that would likely occur as a result of the route's location and position; however, longer routes would likely have a greater impact due to the greater length and extent of areas impacted.
NW-2	56	1,365.0	Grasslands (629.3 acres, or 46.1 percent of the ROW), croplands (410.9 acres, or 30.1 percent of the ROW), and developed/open space (292.0 acres, or 21.4 percent of the ROW)	No substantial difference between this route and the other routes in regards to the types of wildlife impacts that would likely occur as a result of the route's location and position; however, longer routes would likely have a greater impact due to the greater length and extent of areas impacted.
SE-1	40	979.4	Grasslands (513.2 acres, or 52.4 percent of the ROI) and croplands (340 acres, or 34.7 percent of the ROI)	No substantial difference between this route and the other routes in regards to the types of wildlife impacts that would likely occur as a result of the route's location and position.
SE-2	13	325.4	Grasslands (169.9 acres, or 52.2 percent of the ROW) and croplands (130.6 acres, or 40.1percent of the ROW)	No substantial difference between this route and the other routes in regards to the types of wildlife impacts that would likely occur as a result of the route's location and position.
SE-3	49	1,193.6	Grasslands (565.7 acres, or 47.4 percent of the ROW) and croplands (483.9 acres, or 40.5 percent of the ROW)	No substantial difference between this route and the other routes in regards to the types of wildlife impacts that would likely occur as a result of the route's location and position; however, longer routes would likely have a greater impact due to the greater length and extent of areas impacted.
SW-1	13	325.6	Grasslands (312.8 acres, or 96.1 percent of the ROW)	No substantial difference between this route and the other routes in regards to the types of wildlife impacts that would likely occur as a result of the route's location and position.
SW-2	37	901.4	Grasslands (733.0 acres, or 81.3 percent of the ROW)	No substantial difference between this route and the other routes in regards to the types of wildlife impacts that would likely occur as a result of the route's location and position.
W-1	21	507.8	Grasslands (377 acres, or 74.2 percent of the ROW)	No substantial difference between this route and the other routes in regards to the types of wildlife impacts that would likely occur as a result of the route's location and position.

3.20.1.7.2.2.2 Operations and Maintenance Impacts

Table 3.20.1-4 lists the acreage of permanent habitat loss that would be experienced during operation of the AC collection system.

As discussed above, AC Collection System Routes E-1 and NE-2 would have a greater risk of directly impacting wildlife resources compared to the other routes. The elevated risk of avian collisions along these two routes would be experienced throughout the operational phase of the Project.

Table 3.20.1-4:
Summary Information related to Wildlife Resources for the AC Collection System Routes during Operation

AC Collection System Route	Estimated Footprint of Structures (acres)[1]
E-1	4.1
E-2	5.6
E-3	5.6
NE-1	4.2
NE-2	3.6
NW-1	7.3
NW-2	7.8
SE-1	5.6
SE-2	1.8
SE-3	6.9
SW-1	1.8
SW-2	5.2
W-1	2.9

1 The anticipated footprint of structures assumes seven lattice structures per mile, each of which would have a 28-foot by 28-foot foundation.

3.20.1.7.2.2.3 Decommissioning Impacts

Impacts related to the decommissioning of the AC collection system routes would not substantially differ from the general discussion of decommissioning related to the Project in general (see Section 3.20.1.7.2).

3.20.1.7.2.3 HVDC Applicant Proposed Route

3.20.1.7.2.3.1 Construction Impacts

The Applicant Proposed Route would pass through a variety of habitat types, ranging from grassland and cropland habitats to forested and riparian areas. The Applicant Proposed Route within Regions 1, 2, and 6 would cross predominantly through grassland and cropland habitats. Forested and riparian habitats become more prevalent within Regions 4 and 5 (as well as within Region 3 and 7 to a lesser extent). As discussed above, habitat-related impacts within grassland and croplands would be primarily short-term in nature (with the exception of areas encompassed by permanent Project features); however, habitat-related impacts would be long-term in nature within forested and riparian habitats. These long-term impacts in forested and riparian areas would be related to (1) the long timeframes necessary for forested and riparian areas to restore to pre-construction conditions; (2) the effects of fragmentation and edge effects experienced in dense habitat types; (3) the permanent habitat type conversion resulting from vegetation maintenance conducted within previously forested portions of the ROW; and (4) the elevated risk of wildlife mortalities that would be experienced during the extensive vegetation clearing necessary in forested and riparian areas[3] (see Section 3.20.1.7.2 for more details). As a result, the effects of potential impacts to wildlife related

[3] As discussed previously, the entire ROW would be cleared in forested habitats, but not in low vegetation types such as grasslands or croplands (where only areas needed for construction would be cleared; see Section 3.17). As a result, the acreage of cleared land per mile of Project would be greatest in forested habitats compared to other habitats that contain only low vegetation types.

to the construction of the Applicant Proposed Route would be greatest within Regions 4 and 5 (and to a lesser extent within Regions 3 and 7) compared to Regions 1, 2, and 6.

To minimize impacts to wildlife, the Applicant attempted to route the Project parallel to existing infrastructure when possible. By routing the Project parallel to existing infrastructure, the Project's impacts would be consolidated within areas that have already been impacted by existing infrastructure to some degree, as opposed to routing the Project though previously "un-impacted" areas.

Table 3.20.1-5 lists the approximate length of the Applicant Proposed Route in each region, the total acreage within the HVDC ROW, the predominant habitat type that could be impacted, and how much of the route is parallel to existing infrastructure; however, see Sections 3.10 for a more detailed description regarding the breakdown of vegetation types by acreage (i.e., Tables 3.10-15 through 3.10-21). A description of the dominant wildlife species that are likely to occur within each area is found in Section 3.20.1.4.

Table 3.20.1-5:
Summary Information related to Wildlife Resources for the Applicant Proposed Route

Region	Total Length of HVDC (miles)	Total Area within the HVDC ROW (acres)	Predominant Land Cover found along the HVDC[1]	Length of Route Parallel to Existing Infrastructure (miles)
1	115	2,822.3	Grasslands (1,742.3 acres) and croplands (748.8 acres)	Approximately 20 miles, or 18 percent of the route
2	106	2,586.7	Grasslands (1,299.9 acres) and croplands (788 acres)	Approximately 27 miles, or 25 percent of the route
3	162	3,945.5	Grasslands (1,339.5 acres), deciduous forest (1,098.2 acres), and pasture/hay (941.3 acres)	Approximately 21 miles, or 13 percent of the route
4	126	3,081.8	Pasture/hay (1,436.1 acres), deciduous forest (813.7 acres), and evergreen forest (404.7 acres)	Approximately 11 miles, or 9 percent of the route
5	113	2,753.8	Deciduous forest (810.8 acres), pasture/hay (773.4 acres), and evergreen forest (444.3 acres)	Approximately 15 miles, or 13 percent of the route
6	54	1,326.9	Croplands (1,056.5 acres)	Approximately 11 miles, or 20 percent of the route
7	43	1,045	Croplands (691.8) and deciduous forest (79.1 acres)	Approximately 7 miles, or 17 percent of the route

1 Source: Jin et al. (2013)

As noted above, several route variations to the Applicant Proposed Route in Regions 2–7 were developed in response to public comments on the Draft EIS; they are described in detail within Appendix M and summarized in Sections 2.4.2.1–2.4.2.7. Because these route variations mostly cross through similar types of vegetation and habitats compared to the original Applicant Proposed Route, impacts from most of these route variations on wildlife would be similar compared to what would occur as a result of the original Applicant Proposed Route. However, a few of the route variations could result in more long-term impacts to habitats given the extent of forested habitats or other sensitive areas that would be impacted.

- The following route variations would result in at least twice the acreage of impact to forested habitats (see Section 3.17), thereby potentially resulting in a larger extent of long-term impacts to wildlife and their habitats:

Link 1, Variation 2, for Region 3; Link 4, Variation 1, for Region 3; Link 4, Variation 2, for Region 3; and Link 5, Variation 2, for Region 3.

- The following route variations would result in at least half the acreage of impact to forested habitats compared to the original Applicant Proposed Route (see Section 3.17), thereby potentially resulting in fewer long-term impacts to wildlife and their habitats: Link 1, Variation 1, for Region 2; and Links 1 and 2, Variation 1, for Region 3.
- Link 4, Variation 1, for Region 3 could potentially cross more waterbodies compared to the original Applicant Proposed Route, thereby increasing the scope of potential impacts to avian species (e.g., as a result of collisions with wires that span waterbodies), riparian areas, and aquatic species.
- Link 3, Variation 2, in Region 4 would parallel almost four times the length of existing infrastructure compared to the original Applicant Proposed Route, thereby reducing the impacts to areas that have not already been impacted by existing infrastructure, and would cross through areas that contain fewer wetland and waterbody features compared to the original Applicant Proposed Route; however, both the original Applicant Proposed Route and the Applicant Proposed Route Link 3, Variation 2, in Region 4 are part of the current proposal.

3.20.1.7.2.3.2 Operations and Maintenance Impacts

The impacts of the HVDC portion of the Project's operations and maintenance on wildlife and their habitats would be similar to what was described in Section 3.20.1.7.2. As described above, the ongoing impacts related to permanent vegetation maintenance in the ROW, as well as the effects of fragmentation and edge effects, would be greatest in Regions 3, 4, 5, and 7 (due to the presence of forested and riparian areas within the ROW within these regions; see Section 3.20.1.7.2 for more details regarding these effects).

Although the exact placement of the Applicant Proposed Route in relation to waterbodies is unknown at this time, the Applicant Proposed Route in Regions 3, 4, and 5 would likely have a substantial number of waterbody crossings due to the extent of waterbodies in these regions (see Tables 3.15-12, 3.15-16, and 3.15-20). The extent of waterbodies near the HVDC portion of the Project is lower within the remaining regions (see Section 3.15; Tables 3.15-4, 3.15-5, 3.15-8, 3.15-12, 3.15-16, 3.15-20, 3.15-24, and 3.15-28), however, crossings are also likely to occur in these regions as well. As discussed in Section 3.20.1.7.2, there is an elevated risk for avian collisions and mortalities where the Project would span waterbodies.

As described in Section 3.20.1.4.2 above, Regions 1, 2, and 3 of the Applicant Proposed Route occur within the Central Flyway, while Regions 4 through 7 occurs within the Mississippi Flyway. The presence of the transmission structures and line within areas crossed by these flyways increases the risk that the Project would have an impact to migrating avian species. Migrating flocks could potentially occur within the area on an annual basis due to the Applicant Proposed Route's proximity to the:

- Optima NWR, Optima WMA, and Lake Schultz State Park in Region 1
- Major County WMA in Region 2
- Cimarron and Arkansas rivers in Region 3
- Ozark National Forest IBA in Regions 4 and 5
- Cache-Lower White rivers IBA in Region 6
- Various rivers and creeks found within each region (see Section 3.20.1.5 and Section 3.15)

No field studies have been conducted to identify the occurrence and avian use of the ROI; however, the presence of these IBAs implies that resident and migrating birds may use these areas, thereby increasing the risk of impacts to avian species (e.g., habitat disturbance, habitat loss, and risk of collisions with Project structures). The Applicant would develop and implement an APP, consistent with APLIC guidelines, that describes a program of specific and comprehensive actions that when implemented, would reduce risk of avian mortality. EPMs would also be implemented (FVW-2, GE-2, GE-20) as described in Section 3.20.1.7.1, to avoid or minimize impacts to wildlife resources (including avian species).

3.20.1.7.2.3.3 Decommissioning Impacts

Impacts related to the decommissioning of the HVDC portion of the Project would not substantially differ from the general discussion of decommissioning related to the Project in general (see Section 3.20.1.7.2).

3.20.1.7.3 Impacts Associated with the DOE Alternatives

3.20.1.7.3.1 Arkansas Converter Station Alternative Siting Area and AC Interconnection Siting Area

3.20.1.7.3.1.1 Construction Impacts

The Arkansas Converter Station Alternative and AC Interconnection Siting Area are located within Region 5. As discussed in Section 3.10, the general area being considered for placement of the Arkansas converter station and AC interconnection is dominated by evergreen and deciduous forests as well as pasture/hay fields. In addition, the interconnection would also require a 25- to 35-acre substation near the tap with the existing Arkansas Nuclear One-Pleasant Hill 500kV line, with another 5 acres for material staging and equipment storage. The substation would be within the AC Interconnection Siting Area and contains the same types of habitat as the Arkansas Converter Station Alternative Siting Area (i.e., an area dominated by evergreen and deciduous forests as well as pasture/hay fields). As a result, the wildlife species that would potentially be exposed to Project-related mortality or injury in this area would be those species that inhabit these types of habitats. Tables provided in Appendix L list the wildlife species that inhabit the area and could be impacted by the Project in this area.

Given the potential for clearing forested habitats during the construction of this converter station, substation, and AC interconnection, the Project could result in long-term impacts to wildlife habitats (due to the timeframes necessary for these forests areas to restore to pre-construction conditions; see previous discussions above). Because the pasture/hay fields that could potentially be impacted are capable of restoring to pre-disturbance levels in a short timeframe (defined as less than 5 years), most impacts to these types of habitats would likely be short-term in nature (i.e., these areas could restore to pre-construction conditions within 5 years or less). However, some permanent loss of pasture/hay field habitats would still occur as a result of the Project's permanent footprint (i.e., some areas would be encompassed permanently by Project structures such as the converter station, transmission line structures, access roads, etc.). Sections 3.10 and 3.17 list the types of habitats that could be affected and the acres that could be impacted by the Arkansas converter station, substation, and AC interconnection.

The area considered for the Arkansas converter station, substation, and AC interconnection contains a variety of habitats that range from forested areas to pasture lands. As discussed above, impacts to wildlife would likely be less if the converter station, substation, and AC Interconnection were located within the pasture lands, and would be greater if they were located in forested areas (due to the effects of long-term habitat loss, the extensive time necessary for forests to regenerate to pre-disturbance conditions, and the impacts associated with edge effects in forested habitats).

3.20.1.7.3.1.2 Operations and Maintenance Impacts

Operation and maintenance activities would result in long-term impacts to the habitats around the converter station, substation, and AC interconnection (see Section 3.20.1.7.2 for a detailed discussion of potential impacts related to wildlife disturbance and habitat disruption). Furthermore, some permanent loss of habitat would occur as a result of the Project's permanent footprint (i.e., some areas would be encompassed permanently by Project structures such as the converter station, substation, transmission line structures, access roads, etc.). Sections 3.10 and 3.17 list the types of habitats that could be affected and the acres that would be permanently impacted by the Arkansas converter station, substation, and AC interconnection during operations and maintenance.

The permanent loss of habitat related to the Arkansas converter station, substation, and AC interconnection (see Sections 3.10 and 3.17) is unlikely to have substantial long-term impacts to wildlife populations in the area because the type of habitats affected are common in the region and found elsewhere in the vicinity of the Project ROI.

3.20.1.7.3.1.3 Decommissioning Impacts

Impacts related to decommissioning of the Arkansas converter station and AC interconnection would not substantially differ from the general discussion of decommissioning related to the Project in general (see Section 3.20.1.7.2).

3.20.1.7.3.2 HVDC Alternative Routes

3.20.1.7.3.2.1 Construction Impacts

Table 3.20.1-6 lists the approximate length of the HVDC alternative routes by region, the total acreage within the HVDC alternative route's ROW, the predominant habitat type that could be impacted (see Sections 3.10 and 3.17 for more details regarding the acres of impact that could occur), and any substantial impacts that would differ by alternative compared to the Applicant Proposed Route. A description of the dominant and/or common wildlife species that are likely to occur within each area is found in Section 3.20.1.4.

As described in Appendix M, route adjustments were developed for HVDC Alternative Route 3-A, Alternative Route 5-B, Alternative Route 5-E, and Alternative Route 6-A to maintain an end-to-end route with the Applicant Proposed Route and the new route variations. These route adjustments would cross through similar types of vegetation and habitats compared to the original alternative routes, with the exception of the route adjustment for HVDC Alternative Route 3-A, which would impact some forested habitats. This route adjustment would result in more long-term impacts to wildlife habitats (e.g.,, see previous discussions regarding the time necessary for forested habitats to restore to pre-disturbance conditions).

Table 3.20.1-6:
Summary Information Related to Wildlife Resources for the HVDC Alternative Routes

Region	Alternative Route	Total Length of Route (miles)	Total Area within the HVDC ROW (acre)[1]	Predominant Land Cover[2]	Impacts to Wildlife that would Differ Compared to the Proposed Route
1	1-A	123	3,003.1	Grasslands (2,265.4 acres)	This alternative compares to the Applicant Proposed Route Links 2, 3, 4, and 5. No substantial difference between the Applicant Proposed Route and this alternative because similar habitats would be impacted.
	1-B	52	1,268.4	Grassland (886.6 acres)	This alternative compares to the Applicant Proposed Route Links 2 and 3. No substantial difference between the Applicant Proposed Route and this alternative because similar habitats would be impacted.
	1-C	52	1,272.5	Grasslands (892.3 acres)	This alternative compares to the Applicant Proposed Route Links 2 and 3. No substantial difference between the Applicant Proposed Route and this alternative because similar habitats would be impacted.
	1-D	33.5	819.2	Grasslands (568.9 acres)	This alternative compares to the Applicant Proposed Route Links 3 and 4. No substantial difference between the Applicant Proposed Route and this alternative because similar habitats would be impacted.
2	2-A	57	1,396.3	Grasslands (833.5 acres)	This alternative compares to the Applicant Proposed Route Link 2. No substantial difference between the Applicant Proposed Route and this alternative because similar habitats would be impacted.
	2-B	30	727.7	Croplands (440.3 acres), grasslands (240.0 acres)	This alternative compares to the Applicant Proposed Route Link 3. No substantial difference between the Applicant Proposed Route and this alternative because similar habitats would be impacted.
3	3-A	38	919.1	Grasslands (497.3 acres) and deciduous forest (187.7 acres)	This alternative compares to the Applicant Proposed Route Link 1. No substantial difference between the Applicant Proposed Route and this alternative because similar habitats would be impacted.
	3-B	48	1,166.6	Grasslands (645.2 acres) and deciduous forest (219.0 acres)	This alternative compares to the Applicant Proposed Route Links 1, 2, and 3. No substantial difference between the Applicant Proposed Route and this alternative because similar habitats would be impacted.
	3-C	122	2,967.5	Grasslands (1,061.2 acres), deciduous forest (869.2 acres), and pasture/hay (773.4 acres)	This alternative compares to the Applicant Proposed Route Links 3, 4, 5, and 6. This route alternative would impact slightly more forested areas compared to the Applicant Proposed Route.
	3-D	39	958.8	Primarily pasture/hay (491.8 acres), grasslands (188.9 acres) and deciduous forest (184.3 acres) grasslands	This alternative compares to the Applicant Proposed Route Links 5 and 6. No substantial difference between the Applicant Proposed Route and this alternative because similar habitats would be impacted.

Table 3.20.1-6:
Summary Information Related to Wildlife Resources for the HVDC Alternative Routes

Region	Alternative Route	Total Length of Route (miles)	Total Area within the HVDC ROW (acre)[1]	Predominant Land Cover[2]	Impacts to Wildlife that would Differ Compared to the Proposed Route
	3-E	8.5	207.8	Pasture/hay (98.3 acres) and deciduous forest (74.1 acres)	This alternative compares to the Applicant Proposed Route Link 6. No substantial difference between the Applicant Proposed Route and this alternative because similar habitats would be impacted; however, Link 6 would have slightly more deciduous forest and pasture/hay.
4	4-A	58	1,426.0	Deciduous forest (624.0 acres) and pasture/hay (497.4 acres)	This alternative compares to the Applicant Proposed Route Links 3, 4, 5, and 6. No substantial difference between the Applicant Proposed Route and this alternative because similar habitats would be impacted.
	4-B	79	1,919.9	Deciduous forest (873.2 acres) and pasture/hay (459.6 acres)	This alternative compares to the Applicant Proposed Route Links 2–8. Approximately 102 acres of the federally owned land in the Ozark National Forest and an additional 157 acres of private land within the Ozark National Forest boundary (use unknown) are within the ROI for HVDC Alternative Route 4-B, compared to no federal land present in Links 2–8, although approximately 6 acres of state land are present in Link 6. The interspersed land ownership suggests that a variety of land uses may occur along the ROI, and a variety of wildlife species, common to both deciduous forests and pasture/hay land covers may occur. HVDC Alternative Route 4-B would cross into the Ozark National Forest IBA, potentially indirectly impacting wildlife species during construction, as a result of mortality and/or injury, sensory disturbance, and habitat loss or modification.
	4-C	3	82.6	Deciduous forest (32.4 acres) and pasture/hay (19.0 acres)	This alternative compares to the Applicant Proposed Route Link 5. No substantial difference between the Applicant Proposed Route and this alternative because similar habitats would be impacted.
	4-D	25	617.6	Pasture/hay (299.9 acres) and deciduous forest (179.6 acres)	This alternative compares to the Applicant Proposed Route Link 4. This route alternative would impact slightly more forested areas compared to the Applicant Proposed Route.
	4-E	37	897.2	Pasture/hay (395.5 acres) and evergreen forest (218.7 acres)	This alternative compares to the Applicant Proposed Route Links 8 and 9. No substantial difference between the Applicant Proposed Route and this alternative because similar habitats would be impacted.
5	5-A	13	308.5	Evergreen forest (130.4 acres) and deciduous forest (78.8 acres)	This alternative compares to the Applicant Proposed Route Link 1. No substantial difference between the Applicant Proposed Route and this alternative because similar habitats would be impacted.
	5-B	71	1,732.3	Pasture/hay (740.3 acres) and deciduous forest (479.5 acres)	This alternative compares to the Applicant Proposed Route Links 3, 4, 5, and 6. No substantial difference between the Applicant Proposed Route and this alternative because similar habitats would be impacted.

Table 3.20.1-6:
Summary Information Related to Wildlife Resources for the HVDC Alternative Routes

Region	Alternative Route	Total Length of Route (miles)	Total Area within the HVDC ROW (acre)[1]	Predominant Land Cover[2]	Impacts to Wildlife that would Differ Compared to the Proposed Route
	5-C	9	224.6	Deciduous forest (99.9 acres) and pasture/hay (70.9 acres)	This alternative compares to the Applicant Proposed Route Links 6 and 7. No substantial difference between the Applicant Proposed Route and this alternative because similar habitats would be impacted; however, Link 6 would have slightly more forested habitats.
	5-D	22	529.6	Deciduous forest (246.5 acres) and croplands (92.0 acres)	This alternative compares to the Applicant Proposed Route Link 9. No substantial difference between the Applicant Proposed Route and this alternative because similar habitats would be impacted; however, Link 9 would have more croplands.
	5-E	36	885.1	Pasture/hay (383.5 acres) and deciduous forest (249.3 acres)	This alternative compares to the Applicant Proposed Route Links 4, 5, and 6. No substantial difference between the Applicant Proposed Route and this alternative because similar habitats would be impacted.
	5-F	22	544.5	Pasture /hay (209.9 acres) and deciduous forest (153.2 acres)	This alternative compares to the Applicant Proposed Route Links 5 and 6. No substantial difference between the Applicant Proposed Route and this alternative because similar habitats would be impacted.
6	6-A	16	395.7	Croplands (328.6 acres)	This alternative compares to the Applicant Proposed Route Links 2, 3, and 4. No substantial difference between the Applicant Proposed Route and this alternative because similar habitats would be impacted.
	6-B	14	343.7	Croplands (272.1 acres) and woody wetlands (44.6 acres)	This alternative compares to the Applicant Proposed Route Link 3. No substantial difference between the Applicant Proposed Route and this alternative because similar habitats would be impacted.
	6-C	23	565.6	Croplands (410.6 acres)	This alternative compares to the Applicant Proposed Route Links 6 and 7. No substantial difference between the Applicant Proposed Route and this alternative because similar habitats would be impacted.
	6-D	9	223.6	Croplands (205.3 acres)	This alternative compares to the Applicant Proposed Route Link 7. No substantial difference between the Applicant Proposed Route and this alternative because similar habitats would be impacted.
7	7-A	43	1,052.0	Croplands (827.8 acres) and woody wetlands (110.5 acres)	This alternative compares to the Applicant Proposed Route Link 1. No substantial difference between the Applicant Proposed Route and this alternative because similar habitats would be impacted.
	7-B	9	209.9	Croplands (86.4 acres), deciduous forest (42.7 acres), pasture/hay (34 acres) and shrub/scrub (32.7 acres)	This alternative compares to the Applicant Proposed Route Links 3 and 4. No substantial difference between the Applicant Proposed Route and this alternative because similar habitats would be impacted; however, Link 4 would have no forests and more pasture/hay.

Table 3.20.1-6:
Summary Information Related to Wildlife Resources for the HVDC Alternative Routes

Region	Alternative Route	Total Length of Route (miles)	Total Area within the HVDC ROW (acre)[1]	Predominant Land Cover[2]	Impacts to Wildlife that would Differ Compared to the Proposed Route
	7-C	24	578.6	Croplands (350.6 acres), deciduous forest (58.4 acres), and pasture/hay (72.2 acres), and	This alternative compares to the Applicant Proposed Route Links 3, 4, and 5. No substantial difference between the Applicant Proposed Route and this alternative because similar habitats would be impacted; however, Links 3, 4, and 5 would have slightly more deciduous forest and shrub/scrub.
	7-D		159.5	Croplands (76.8 acres), pasture/hay (32.2 acres), and shrub/scrub (20.6 acres)	This alternative compares to the Applicant Proposed Route Links and 5. No substantial difference between the Applicant Proposed Route and this alternative because similar habitats would be impacted.

1 A more detailed breakdown of vegetation types that could be impacted by the HVDC Alternative Routes, by region, can be found in Tables 3.10-22 through 3.10-30 in Section 3.10. A more detailed description of the acreage of vegetation types that could be impacted along each of the Applicant Proposed Route's various links, by region, can be found in Tables 3.10-15 through 3.10-21 in Section 3.10.

2 Source: Jin et al. (2013)

3.20.1.7.3.2.2 Operations and Maintenance Impacts

Direct and indirect impacts to wildlife and their habitat from operations and maintenance of all of the HVDC Alternative Routes (except for 3-C, 4-B, and 4-D; which are discussed below) are anticipated to be similar to the operations and maintenance of the Applicant Proposed Route because the habitat composition is similar between the HVDC alternative routes and the Applicant Proposed Route. As a result, wildlife species occurrence and use of the ROWs along these route alternatives would likely also be similar.

HVDC Alternative Routes 3-C, 4-B, and 4-D would have a differential effect to wildlife and their habitats compared to the Applicant Proposed Route. As shown in Table 3.20.1-6, HVDC Alternative Route 4-B would cross into the Ozark National Forest IBA, potentially indirectly impacting wildlife species to a greater extent than the Applicant Proposed Route due to this route's proximity to an IBA. The interspersed land cover and land ownership along HVDC Alternative Route 4-B suggest that a variety of land uses may occur along the ROW, and a variety of wildlife species common to both deciduous forests and pasture/hay land covers may occur in this area (thereby potentially exposing more wildlife species to project related impacts compared to the Applicant Proposed Route). Furthermore, HVDC Alternative Routes 3-C and 4-D would impact slightly more forested areas compared to the Applicant Proposed Route, thereby increasing the extent of long-term impacts to forested habitat.

3.20.1.7.3.2.3 Decommissioning Impacts

Impacts related to the decommissioning of the HVDC portion of the Project would not substantially differ from the general discussion of decommissioning related to the Project in general (see Section 3.20.1.7.2).

3.20.1.7.4 Best Management Practices

The Applicant has developed a list of EPMs intended to avoid or minimize impacts to wildlife resources. A complete list of EPMs for the Project is provided in Appendix F. Those EPMs that would specifically minimize the potential for impacts to wildlife resources are summarized in Section 3.20.1.7.1. In addition to these EPMs, the following BMP could also be implemented to further minimize impacts to wildlife:

- All vegetation clearing should comply with both state and federal spatial and timing windows, and should not occur during the avian breeding season applicable to each respective Region.

The implementation of this BMP is suggested because without proper implementation of seasonal and spatial restrictions on construction activities (e.g., if vegetation clearing was conducted during sensitive breeding seasons), avian mortalities would be more likely to occur during construction.

3.20.1.7.5 Unavoidable Adverse Impacts

The Applicant would implement EPMs to avoid or minimize impacts. A BMP has been identified that could be implemented to further reduce impacts (see Section 3.20.1.7.4). However, some adverse impacts would occur even with the implementation of these measures. Construction and operations and maintenance of the Project would result in the death of some wildlife species. Mortalities could result from the vegetation clearing activities as well as avian collisions with Project structures during operation. These mortality events would likely be higher if vegetation clearing is conducted during the breeding season (see previous discussion above), as well as in areas where the Project spans waterbodies. Construction-related disturbances to habitats would also result in temporary loss of some wildlife habitats through noise and visual disturbances. Wildlife habitat also could be lost during operation and maintenance from the effects of fragmentation, edge effects, and invasive plant species. ROW maintenance in forested habitats as well as the footprint of Project structures would result in a permanent loss of habitats.

3.20.1.7.6 Irreversible and Irretrievable Commitment of Resources

The potential permanent loss or alteration of established trees in mature forests in the eastern Project area (in Regions 3, 4, 5, and 7) would last throughout the life of the Project; however, gradual recovery of habitat may occur once the Project has been decommissioned. Because the exact state of this recovery is not known (e.g., substantial changes related to climate, land-use, and/or weeds or pathogens may occur during the 80-year lifespan of the project), and mature forests are subject to long-term climatic regimes, it is reasonable to assume that some portions of the wildlife habitat in these forests would be irreversibly and irretrievably impacted.

3.20.1.7.7 Relationship between Local Short-term Uses and Long-term Productivity

Both the Applicant Proposed Route and the HVDC alternative routes may result in a short-term disturbance to wildlife resources; however, these impacts should not affect the long-term productivity of populations of wildlife resources.

3.20.1.7.8 Impacts from Connected Actions

3.20.1.7.8.1 Wind Energy Generation

Section 3.1 contains a detailed discussion of how the general WDZs were developed as well as how the estimate of potential wind development related impacts was determined. It should be noted that the exact location of potential wind-farms is not known at this time. The assessment of wind energy generation found in this EIS does not constitute approval or official designation of any area for wind development (i.e., there is no assurance that these areas would be developed); nor does this EIS exert authority over the potential development of these areas.

This EIS assumes the development of multiple commercial-scale wind energy projects in the area, which are considered as connected actions. Although the exact placement or location of potential future wind-farms is unknown, for this assessment, it is assumed that these wind energy projects may be developed somewhere within the WDZs. It is assumed that each phase of a commercial-scale wind energy development in the WDZs would be conducted in such a way as to protect the quality of the environment. It is general industry standard for wind developers to comply with applicable state and federal wildlife regulations (see Table 3.20.1-1 above), implement worker safety policies, practice good housekeeping, manage waste properly, and maintain equipment in good working order, thereby minimizing and/or avoiding impacts on wildlife resources and their habitats.

Areas deemed generally unsuitable for commercial-scale wind energy development, including cities, open water, cemeteries, parks, federal lands, recreational areas, state wildlife management areas, lands within 2.5 miles of public use airports, and areas with sensitive environmental resources (such as native prairie, water bodies, and potential habitat for the lesser prairie-chicken) were excluded from the analysis of the WDZs, resulting in 1,082,000 acres of the 1,385,069 total acres in the 12 WDZs that could be considered potentially suitable for wind energy development. Based on the maximum capacity of the Project and information from wind energy developers, it is estimated that 20–30 percent of the potentially suitable land, or between 216,400 and 324,600 acres, could be developed for wind energy facilities using transmission capacity from the Project; however, it should be noted that this is just an estimate, and the exact locations of these wind projects' potential footprints are not known.

The impacts discussed below are common to the majority of wind energy development; however, it is unknown what wildlife species would occur within a given wind energy development zone without coordination and consultation with the future wind energy developer. Wind energy developers are expected to develop and construct wind energy projects based on guidance outlined by the USFWS Land-Based Wind Energy Guidance (USFWS 2012) and the APLIC guidelines (APLIC 2012), which may include the development of conservation strategies and which describe a program of specific and comprehensive actions that, when implemented, could reduce the risk of wildlife species and their habitats.

Short-term, impacts to wildlife resources during construction may include disturbance due to increased noise, dust, and traffic. Additionally, there is the potential for short-term indirect impacts to wildlife habitats as a result of the clearing of vegetation and soil disruption during construction. There is the potential for long-term, direct habitat loss related to construction of a wind energy development; however, the extent of that impact is unknown and dependent upon the competing land uses within a specific WDZ.

During the operations and maintenance phase of wind energy developments, approximately 1 percent or less of the land may be affected. For the 12 WDZs, assuming 20 to 30 percent build-out, between 2,164 and 3,246 acres may be temporarily impacted. Once construction has been completed, temporary construction areas would revert to their previous use over a period of time, depending on the habitat type impacted. Only turbine footprints, access roads, generation tie-lines (if necessary), substations, and operations and maintenance buildings would remain. Existing land uses, primarily agriculture and grazing, would be expected to return to almost all areas of the facilities, unless deemed incompatible with the operation of a wind energy development.

Operations and maintenance of wind energy developments are known to have direct impacts on some wildlife species, specifically avian and bat species, due to collisions with wind turbine blades, collisions and electrocutions associated with generation tie-lines, and barotrauma of bat species. Historically, the average number of avian and bat fatalities associated within operations and maintenance of a wind energy development has varied between developments and was considered a function of a number of factors, including the proximity to known maternity colonies, hibernacula, staging areas, winter ranges, nesting sites, migration stopovers or corridors, leks, or other areas of seasonal importance (USFWS 2012). Occurrence of avian and bat species within the WDZ and potential for direct impacts due to the operations and maintenance of the wind energy development would be documented by wind energy developers under the Land-Based Wind Energy Guidelines, and would be in accordance with appropriate state and federal regulations (including the USFWS BMPs, as provided in the Guidelines).

Limited publicly available post-construction mortality studies have been completed in Texas and Oklahoma, and no publicly available studies have been completed within or in the vicinity of the various WDZs. Therefore, conclusions of the direct impacts to avian and bat species related to operations and maintenance of wind energy developments are determined based on publicly available information for the southern Great Plains. A single study completed in Oklahoma at the Oklahoma Wind Energy Center, located approximately 60 miles east of WDZ-K, reports bat fatality estimates of 1.2 bat fatalities per turbine for the brief three-month study period (Piorkowski and O'Connell 2010). During the summer breeding season at the Oklahoma Wind Energy Center, Piorkowski (2006) reported an avian fatality rate of 0.04 to 0.12 birds per turbine.

Avian and bat mortality rates that occur at various wind energy developments, however, are dependent on multiple factors such as the position of the facility in related to the landscape (e.g., whether landscape features could funnel flight paths into the facility); the size of the facility (i.e., megawatts produced); the number and placement of the turbines; the height or the roto-sweep area; the season and timing of the facility's typical operation (generally, turbines are not continuously run at wind farms); the migratory paths of avian or bat species through the area; and the composition of avian and bat species in the area (not all species have the same tendencies to collide with wind energy facilities). Because no wind development facilities are currently planned in the WDZs, the average avian or bat mortality rates that could occur cannot be accurately calculated or estimated at this time. In other words, the factors listed above are not knowable at this time).

Table 3.20.1-7 lists the size of each of the 12 WDZs, the primary land cover type, and the estimated acres of impact assuming a 30 percent build-out with 5 percent of the land affected during construction and 1 percent affected during operation. Each of the WDZs is likely to have occurrence and use of bat and avian species potentially susceptible to direct impacts related to the operations and maintenance of wind energy developments; however, the occurrence and use of bat and avian in the area is not known (as the precise location of these potential wind facilities has not been determined).

Table 3.20.1-7:
Summary of the 12 WDZ in Regards to Wildlife Resources

WDZ	Total Size (acres)	Estimated Acres of Impact during Construction	Estimated Acres of Impact during Operation[1]
WDZ-A	109,747	659 acres of primarily croplands and grasslands	329 acres
WDZ-B	125,479	752 acres of primarily croplands and grassland	376 acres
WDZ-C	161,048	966 acres of primarily croplands and grasslands	483 acres
WDZ-D	69,189	415 acres of primarily grassland	204 acres
WDZ-E	47,092	282 acres of primarily croplands and grasslands	141 acres
WDZ-F	112,461	675 acres of primarily grasslands and croplands	337 acres
WDZ-G	187,315	1,124 acres of primarily grasslands and croplands	562 acres
WDZ-H	116,226	697 acres of primarily grasslands and croplands	349 acres
WDZ-I	105,203	631 acres of primarily grasslands and croplands	316 acres
WDZ-J	92,568	555 acres of primarily grasslands	278 acres
WDZ-K	92,893.9	557 acres of primarily grasslands and croplands	279 acres
WDZ-L	165,848	995 acres of primarily grasslands and croplands	498 acres

1 The estimated acres of impact assuming a 30 percent build-out with 2 percent of the land affected during construction and 1 percent affected during operation.

Once the decommissioning phase has concluded, wind energy developments would be restored to their pre-construction conditions. Permanent structures, including wind turbines and generation tie-lines, would be dismantled. Impacts associated with the construction, operations and maintenance of wind turbines, generation tie lines, and other permanent structures would be eliminated as these areas are restored to pre-construction conditions.

3.20.1.7.8.2 Optima Substation

As discussed above, the future Optima Substation may be constructed just east of the Oklahoma Converter Station Siting Area and partially within the AC Interconnection Siting Area in Region 1. The location for the substation occurs on grassland habitats adjacent to croplands. Approximately 160 acres would be disturbed as a result of this substation. Potential impacts to wildlife that would occur if this station were constructed would be similar to those that were discussed above for the Oklahoma Converter Station (see Section 3.20.1.7.2.1) and include habitat loss, disturbance, and mortality.

3.20.1.7.8.3 TVA Upgrades

The required TVA upgrades related to the construction of new electric transmission line could involve temporary or long-term displacement of wildlife species; fragmentation of wildlife habitat; potential disturbance to wildlife species and habitats as well as populations and/or habitats for species designated as candidate, threatened and endangered under the ESA; potential impacts to wildlife movement; and potential mortality events related to avian collisions and/or electrocution. The required TVA upgrades that would involve upgrades of existing facilities (i.e., project components where impacts from initial construction as well as operation of the facilities have already occurred or are ongoing) could result in temporary displacement of wildlife species, potential disturbance to wildlife species and habitats as well as populations and/or habitats for species designated as candidate, threatened and endangered under the ESA; and potential impacts to wildlife movement. Because the specific locations of the required TVA upgrades (including the new electric transmission line) are unknown at this time, the spatial and temporal (i.e., seasonal presence) distributions of wildlife populations and suitable habitats also are unknown at this time.

Existing TVA facilities would require fewer construction activities to complete upgrades than the new transmission line and would occur to existing facilities (where previous construction related impacts have already occurred). Existing TVA facilities have also already experienced operations and maintenance activities. As a result, potential impacts are expected to be less substantial in areas affected by upgrades to existing TVA facilities than in areas where the new electric transmission line could be constructed. Impacts to wildlife from the construction and operation of the new transmission line would be similar to those described in Section 3.20.1.7.2.

3.20.1.7.9 Impacts Associated with the No Action Alternative

Under the No Action Alternative, the Project would not be constructed or operated, and impacts to wildlife species and their habitats would be consistent with current levels of disturbance related to natural conditions in the environment, such as annual changes in climates, land use changes, and wildfires. No Project-related disturbances or impacts would occur to wildlife or their habitats under the No Action Alternative.

3.20.2 Fish and Aquatic Invertebrates

3.20.2.1 Regulatory Background

In general, statutes and regulations that influence the evaluation of fish and aquatic invertebrate species in the areas crossed by the Project are primarily implemented by the USFWS and state agencies. The state agencies applicable to the Project include the ODWC, AGFC, TWRA, and TPWD. The fish and aquatic invertebrate species laws and regulations relevant to the Project are discussed further in Section 3.14.2.

3.20.2.2 Data Sources

Data sources included a desktop analysis of relevant information; research findings; reports available to the public; a database that includes GIS data from government agencies as well as non-governmental organizations, and information received from both regulatory agencies and stakeholders during the DOE scoping process. All data sources used for this analysis were limited to those that were open source and readily available to the public (i.e., the public may assess them without restrictions). For general fish classifications within the ROI, the following data sources were reviewed:

- EPA National Rivers and Streams Assessment (http://water.epa.gov/type/rsl/monitoring/riverssurvey/index.cfm)
- USGS National Hydrography Dataset (GIS Data Source: USGS 2014a)
- NPS NRI (GIS Data Source: USGS 1996)

3.20.2.3 Region of Influence

The ROIs used for the evaluation of potential impacts to fish and aquatic invertebrate species from the Project and connected actions are identical to the ROIs described in Section 3.1.1.

3.20.2.4 Affected Environment

As discussed in Section 3.15, the Project would cross multiple watersheds that individually contain varying surface water features. Overall, the Project is within the Arkansas-White-Red and Lower Mississippi drainage systems. From the western end of the Project (in the Oklahoma Panhandle) moving eastward (across Oklahoma and into central Arkansas), the local streams may flow in different directions, but as they join larger streams, their overall progression is to the southeast. In the eastern portion of Arkansas, within the Lower Mississippi drainage system, drainage systems still flow east and southeast toward the Mississippi River, but the flow routes can be different. Throughout the drainage systems, the highest fish and aquatic invertebrate species diversity mostly occurs within Regions 4, 5, 6, and 7.

The following sections provide regional descriptions of common fish and aquatic invertebrate species, including important recreational species, known to occur or that have the potential to occur within the ROI based on habitat associations or documented presence information from the data sources identified in Section 3.20.2.2. It should be noted that the following is not a comprehensive list of every fish and aquatic invertebrate species that could occur in a given region, but rather only a list of the more common species typically found in a given region.

3.20.2.4.1 Oklahoma

There are multiple recreational fishing areas within the Oklahoma portion of the ROI, including the Cimarron River, the Arkansas River, Webbers Fall Reservoir, and the Illinois River. Other important recreational fishing areas located within 10 miles of the Oklahoma Converter Station include Frisco Creek, North Fork Frisco Creek, and Steji Lake (HookandBullet 2014a). Within the ROI for the AC collection system, important recreational fishing areas include Optima Lake, Sunset Lake, Schultz Lake, multiple creeks in Texas County, as well as Webb Lake (HookandBullet 2014a). In addition, although multiple creeks in Beaver County are within the ROI for the AC collection system, very few of them are used in a recreational capacity in this county.

Important recreational fish species potentially occurring in the ROI in Oklahoma include largemouth bass (*Micropterus salmoides*), smallmouth bass (*Micropterus dolomieu*), spotted bass (*Micropterus punctulatus*), striped bass (*Morone saxatilis*), white bass (*Morone chrysops*), channel catfish (*Ictalurus punctatus*), blue catfish (*Ictalurus furcatus*), flathead catfish (*Pylodictis olivaris*), white crappie (*Pomoxis annularis*), black crappie (*Pomoxis nigromaculatus*), bluegill (*Lepomis macrochirus*), rainbow trout (*Oncorhynchus mykiss*), brown trout (*Salmo trutta*), walleye (*Stizostedion vitreum*), sauger (*Sander canadensis*), saugeye (hatchery-produced hybrid cross between walleye and sauger), paddlefish (*Polyodon spathula*), and alligator gar (*Atractosteus spatula*) (ODWC 2014).

There are approximately 57 species of native freshwater mussels in the state of Oklahoma, with the species richness declining from the eastern to the western part of the state. Species with ranges that potentially overlap the ROI include, but are not limited to threeridge (*Amblema plicata*), flat floater (*Anodonta suborbiculata*), Wabash pigtoe or lake pigtoe (*Fusconaia flava*), Plain pocketbook (*Lampsilis cardium*), and yellow sandshell (*Lampsilis teres*) (Mather 2005). Other aquatic invertebrates with a range within the ROI include, but are not limited to, the White River crawfish (*Procambarus acutus acutus*) and the Ohio shrimp (*Macrobrachium ohione*) (USGS 2014).

Appendix L contains a representative listing of fish and aquatic invertebrate species potentially occurring in each state.

3.20.2.4.2 Arkansas

Important recreational fishing areas occur within the ROI in Arkansas, including multiple perennial creeks, the St. Francis River, the White River, and the Mississippi River. There is a reach of the Little Red River crossed in Region 5 in White County, which is officially designated “Trout Waters” from below Greers Ferry Dam to Searcy (Clean Line 2013b).

Important recreational fish species in Arkansas potentially occurring in the ROI include largemouth bass, smallmouth bass, spotted bass, striped bass, white bass, yellow bass (*Morone mississippiensis*), Ozark bass (*Ambloplites constellatus*), yellow bullhead catfish (*Ictalurus natalis*), channel catfish, blue catfish, flathead catfish, white crappie, black crappie, rainbow trout, brown trout, brook trout (*Salvenius fontinalis*), cutthroat trout (*Oncorhynchus clarkii*), walleye, bluegill, longear sunfish (*Lepomis megalotis*), redear sunfish (*Lepomis microlophus*), green sunfish (*Lepomis cyanellus*), warmouth (*Lepomis gulosus*), paddlefish, shovelnose sturgeon (*Scaphirhynchus platorynchus*), and alligator gar (AGFC 2011).

There are approximately 75 native mussel species in Arkansas, with many of these potentially found within the ROI (Harris et al. 2009). Recreational and commercial mussel species that potentially overlap the ROI include ebony (*Fusconaia ebena*), lake pigtoe or Wabash pigtoe, washboard (*Megalonaias nervosa*), river pigtoe or Ohio pigtoe (*Pleurobema cordatum*), and mapleleaf (*Quadrula quadrula*) (Anderson 2006; Harris et al. 2009). Other aquatic invertebrates with a range within the ROI include, but are not limited to, Cajun dwarf crayfish (*Cambarellus shufeldtii*), White River crawfish, red swamp crayfish, Mississippi grass shrimp (*Palaemonetes kadiakensis*), and Ohio shrimp (USGS 2014).

3.20.2.4.3 Tennessee

Within the Tennessee portion of the ROI, the Mississippi River is both the largest and most important recreational fishing area. Other important recreational fishing areas located within 10 miles of the Tennessee Converter Station Siting Area include multiple lakes, reservoirs, and creeks (HookandBullet 2014b).

Important recreational fish species potentially occurring in Tipton and Shelby counties include largemouth bass, smallmouth bass, channel catfish, bluegill, crappie, bullhead catfish (*Ameiurus* spp.), yellow perch (*Perca flavescens*), rainbow trout, and walleye (HookandBullet 2014b).

Recreational and commercial mussel species that potentially overlap the ROI include threeridge, elephant ear (*Elliptio crassidens*), ebony, lake pigtoe or Wabash pigtoe, washboard, river pigtoe or Ohio pigtoe, and mapleleaf (TWRA 2011; Clean Line 2013a). Other aquatic invertebrates with a range within the ROI include Cajun dwarf crayfish, White River crawfish, red swamp crayfish (*Procambarus clarkii*), Mississippi grass shrimp, and Ohio shrimp (USGS 2014).

3.20.2.4.4 Texas

Important recreational fishing areas are located within the ROI for the AC collection system, including in Sherman County (Steji Lake, Bryson Lake, Runyun Lake, Kenson Lake), in Hansford County (Palo Duro Reservoir, Venneman Lake, Miller's Lake), and in Ochiltree County (Middle Prong Wolf Creek, Deer Lake, Peckenpaugh Lake) (HookandBullet 2014c).

Important recreational fish species in Texas potentially occurring in the ROI include largemouth bass, smallmouth bass, spotted bass, white bass, yellow bass, striped bass, channel catfish, bluegill, crappie, gar, black bullhead catfish (*Ameiurus melas*) and yellow bullhead catfish (TPWD 2014a).

Recreational and commercial mussel species that potentially overlap the ROI include, but are not limited to threeridge, mapleleaf, pimpleback (*Quadrula* spp.), and bleufer (*Potamilus purpuratus*) (TPWD 2014a).

3.20.2.5 Regional Description

As described in Section 3.20.2.4 above, numerous fish and aquatic invertebrate species are known to occur or have the potential to occur within the ROI. A summary of the fish and aquatic invertebrate species and potential habitat occurrence by Project region is provided in the sections below. Information from ANHC Natural Areas and Focal Areas and state natural heritage program species occurrence records, including related waterbodies found by Project region, are included in Table 3.20.2-1. Federally designated candidate, threatened, and endangered fish, aquatic invertebrate, and amphibian species potentially occurring in the ROI by state, are included in Table 3.14.2-3. State designated threatened and endangered aquatic wildlife species by state, county, and region are included in Table 3.14.2-4.

Table 3.20.2-1:
State Natural Heritage Occurrences within the ROI or Waterbodies Crossed by the ROI

Common Name	Scientific Name	State Rank[1] or Status[2]	Waterbody	Project Region
Oklahoma				
Fish				
Pallid shiner	*Notropis amnis*	S1S2	Lee Creek	4
Red River shiner	*Notropis bairdi*	S3	Cimarron River	2, 3
Aquatic Invertebrates				
Crawfish species	*Orconectes palmeri longimanus*	S5	Ross Branch of Little Sallisaw Creek	4
Southern plains crayfish	*Procambarus simulans*	S5	Beaver River	1
White River crawfish	*Procambarus acutus*	S5	Beaver River	1
Arkansas				
Fish				
Autumn darter	*Etheostoma autumnale*	S2 / INV	Ten Mile Creek[4]	5
Sunburst darter	*Etheostoma mihileze*	S3 / INV	Mill Creek[4]	4
Aquatic Invertebrates				
A crayfish (no common name)	*Cambarus causeyi*	S1 / INV	Big Piney Creek[4]	4
Black sandshell	*Ligumia recta*	S2 / INV	Big Piney Creek[4], White River,[3,4] and Tyronza River[4]	4, 5, 7
Elktoe	*Alasmidonta marginata*	S3 / INV	Big Piney Creek[4]	4

Table 3.20.2-1:
State Natural Heritage Occurrences within the ROI or Waterbodies Crossed by the ROI

Common Name	Scientific Name	State Rank[1] or Status[2]	Waterbody	Project Region
Fat mucket	*Lampsilis siliquoidea*	S3 / INV	North Fork Cadron Creek[4]	5
Flutedshell	*Lasmigona costata*	S3 / INV	Frog Bayou[4], Big Piney Creek[4], and West Fork Point Remove Creek[4]	4
Isopod (no common name)	*Lirceus bicuspidatus*	S2 / INV	Unamed Spring[3] and Departee Creek[4]	4
Little spectaclecase	*Villosa lienosa*	S3 / INV	Big Piney Creek[4], West Fork Point Remove Creek[4] and St. Francis floodway ditch[5]	4, 6
Monkeyface	*Quadrula metanevra*	S3S4 / INV	White River[3] and St. Francis River[4]	5, 7
Ohio pigtoe	*Pleurobema cordatum*	S1 / INV	White River[3]	5
Ouachita kidneyshell	*Ptychobranchus occidentalis*	S3 / INV	White River[3]	5
Pondhorn	*Uniomerus tetralasmus*	S2 / INV	St. Francis floodway ditch[4]	6
Purple lilliput	*Toxolasma lividum*	S2 / INV	Frog Bayou[4], Illinois Bayou[4], West Fork Point Remove Creek[4], Jones Creek[3], and Tyronza River[3]	4, 5, 7
Pyramid pigtoe	*Pleurobema rubrum*	S2 / INV	White River[4], and St. Francis River[4], Tyronza River[4]	5, 7
Southern mapleleaf	*Quadrula apiculata*	S2 / INV	Bayou DeView[4]	6
Western fanshell	*Cyprogenia aberti*	S2 / INV	White River[3] and St. Francis River[4]	5, 7
Tennessee				
Fish				
Bigmouth shiner	*Notropis dorsalis*	S1 / D[5]	Bear Creek	7
Texas				
None				

1 State rank is a conservation rank used by State Heritage Programs and The Nature Conservancy that indicates the relative rarity of an element throughout the state. S1 = Critically imperiled; S2 = Imperiled; S3 = Vulnerable; S4 = Apparently secure; S5 = Secure in the state
2 State status: INV = Inventory Element.
3 Occurrence element located within the ROI.
4 Occurrence element located outside the ROI, but within a waterbody that is crossed by the Project.
5 D = Deemed in Need of Management
Sources: ODWC (2014, 2015), ANHC (2014), TDEC (2014), TPWD (2014a, 2014b)

3.20.2.5.1 Region 1

Region 1 is referred to as the Oklahoma Panhandle Region and includes the Oklahoma Converter Station Siting Area, AC collection system, the Applicant Proposed Route and the HVDC Alternative Routes I-A through I-D. This region includes Texas, Beaver, Harper, and Woodward counties in Oklahoma. The Cimarron River crosses Beaver, Harper, and Woodward counties in this region. Forested wetland areas crossed by the ROI in Region 1 include Palo Duro Creek, Clear Creek, Beaver River, and Skeleton Creek (Clean Line 2013b). There are many fish and aquatic species that potentially occur in these waterbodies that cross the ROI; fish and aquatic invertebrate species are listed in Appendix L. Although crossing locations within a given drainage vary between the Applicant Proposed Route and the HVDC Alternative Routes I-A through I-D, the potential occurrence of fish and aquatic species within the ROI would generally be similar.

No route variations were proposed in Region 1.

3.20.2.5.1.1 AC Collection System

A description of the AC collection system is provided in Section 2.1.2.3. The AC collection system routes are represented by a 2-mile-wide corridor for analysis purposes. The miles of perennial and intermittent streams, major waterbodies, and the acres of reservoirs, lakes, and ponds reported for each of the AC collection system routes are described in detail in Section 3.15. Wetland areas that may be used by aquatic species in this region are described in Section 3.19. In addition to reporting miles of perennial and intermittent streams, major waterbodies, acres of reservoirs, lakes, and ponds, and wetland areas for the 2-mile-wide corridor, Sections 3.15 and 3.19 also report values for the 200-foot-wide representative ROW because the ROWs for the AC collection system transmission lines would typically be 200 feet wide. Although the ROW is more typical, the 2-mile-wide corridor was used for fish and aquatic invertebrate analysis purposes to account for the various ranges of aquatic species, including the unique and varied habitat that each species potentially occupies, as well as the potential downstream transport of sediment and hazardous materials. NWI-mapped wetlands occur within the ROI, including both forested and non-forested wetlands (Clean Line 2013a). Riparian corridors may also exist along the Beaver River and Coldwater and Palo Duro creeks (Clean Line 2013a). Lake Schultz State Park in Oklahoma is within the 2-mile-wide corridor and is a part of the Schultz WMA (Clean Line 2013a). Forested wetland areas crossed by the AC collection system routes are mostly associated with Palo Duro Creek (Clean Line 2013b). Of the AC collection system routes, E-1, E-2, E-3, SE-1, SE-3, NE-1, NE-2, NW-1, and NW-2 may provide aquatic habitat to fish and aquatic invertebrate species.

AC Collection System Route SE-3 crosses Wolf Creek in Ochiltree County, Texas, a waterbody that has been designated as a high water quality, exceptional aquatic life, and high aesthetic value waterbody. It has diverse benthic macroinvertebrate and fish communities (Clean Line 2013b).

3.20.2.5.2 Region 2

Region 2 is referred to as the Oklahoma Central Great Plains Region and includes the Applicant Proposed Route and HVDC Alternative Routes 2-A and 2-B. This region includes Woodward, Major, and Garfield counties in Oklahoma. The Cimarron River crosses Woodward and Major counties in this region. Link 2 of the Applicant Proposed Route and HVDC Alternative Route 2-A cross the Cimarron River in Major County). Many fish and aquatic invertebrate species potentially occur in these waterbodies that cross the ROI; fish and aquatic species are listed in Appendix L. Although crossing locations on the Cimarron River vary between the Applicant Proposed Route and the HVDC Alternative Routes 2-A and 2-B, the potential occurrence of fish and aquatic species within the ROI would generally be similar.

Two route variations to the Applicant Proposed Route were developed in Region 2 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.2. The variations are illustrated in Exhibit 1 of Appendix M. These variations represent minor adjustments to the Applicant Proposed Route. Link 1, Variation 1, as well as Link 2, Variation 2, would cross through similar types of wetlands and habitat compared to the original Applicant Proposed Route.

3.20.2.5.3 Region 3

Region 3 is referred to as the Oklahoma Cross Timbers Region and includes the Applicant Proposed Route and HVDC Alternative Routes 3-A through 3-E. This region includes Garfield, Kingfisher, Logan, Payne, Lincoln, Creek, Okmulgee, and Muskogee counties in Oklahoma. The Cimarron River crosses Logan, Payne, and Creek counties in this region. Link 4 of the Applicant Proposed Route and HVDC Alternative Route 3-C cross the Cimarron River in Payne County. Forested wetland areas crossed by the ROI in Region 3 include Stillwater Creek, the Cimarron River, Browns Creek, Snake Creek, Little Deep Fork Creek, Salt Creek, Pecan Creek, Beaver River, Anderson Creek, Butler Creek, and tributaries to both Cane Creek and Dirty Creek (Clean Line 2013b). Many fish and aquatic invertebrate species potentially occur in these waterbodies; fish and aquatic species are listed in Appendix L. Although crossing locations within a given drainage vary between the Applicant Proposed Route and the HVDC Alternative Routes 3-A through 3-E, the potential occurrence of fish and aquatic species within the ROI would generally be similar.

Five route variations to the Applicant Proposed Route were developed in Region 3 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.3. The variations are illustrated in Exhibit 1 of Appendix M. These variations represent minor adjustments to the Applicant Proposed Route. Links 1 and 2, Variation 1; Link 1, Variation 2; Link 4, Variation 1; and Link 5, Variation 2, would cross through similar types of wetlands and habitats compared to the original Applicant Proposed Route. The number of waterbodies crossed decreases from three to zero in Links 1 and 2, Variation 1, while the number of waterbodies crossed increases from one to two in Applicant Proposed Route Link 1, Variation 2.

3.20.2.5.4 Region 4

Region 4 is referred to as the Arkansas River Valley Region and includes the Applicant Proposed Route, including the Lee Creek Variation, and Alternative Routes 4-A through 4-E. This region includes Muskogee and Sequoyah counties in Oklahoma, and Crawford, Franklin, Johnson, and Pope counties in Arkansas. The Applicant Proposed Route Link I crosses the Arkansas River in Muskogee County and the Illinois River in Sequoyah County (Clean Link 2013b). The Applicant Proposed Route Link 6 crosses the Mulberry River downstream of I-40 bridge at the Crawford-Franklin County line (Clean Link 2013b). HVDC Alternative Routes 4-A and 4-B, Applicant Proposed Route Link 3, and the Lee Creek Variation cross Lee Creek in Sequoyah County (Clean Line 2013b). HVDC Alternative Route 4-E and Applicant Proposed Route Link 9 cross Big Piney Creek in Pope County; however, the Applicant Proposed Route Link 9 parallels the Big Piney Creek in Pope County, while HVDC Alternative Route 4-E only crosses Big Piney Creek (Clean Line 2013b). The Mulberry River overlaps with HVDC Alternative Routes 4-A, 4-B, 4-D, and Applicant Proposed Route Link 6 near the Crawford-Franklin County line in Arkansas (Clean Line 2013b). In Oklahoma, one forested wetland area (Sallisaw Creek) is crossed by the ROI in Region 4 (Clean Line 2013b). In Arkansas, forested wetland areas crossed by the ROI in Region 4 include Short Branch, Cottonwood Slough, Spadra Creek, and Big Piney Creek (Clean Line 2013b). Many fish and aquatic invertebrate species potentially occur in these waterbodies that cross the ROI; lists of fish and aquatic species are provided in Appendix L. Although crossing locations within a given drainage vary between the Applicant Proposed Route and HVDC Alternative Routes 4-A through 4-E, the potential occurrence of fish and aquatic species within the ROI would generally be similar.

Seven route variations to the Applicant Proposed Route were developed in Region 4 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.4. The variations are illustrated in Exhibit 1 of Appendix M. These variations represent minor adjustments to the Applicant Proposed Route. Link 3, Variation 1; Link 3, Variation 3; Link 6, Variation 1; Link 6, Variation 2; Link 6, Variation 3; and Link 9, Variation 1, would cross through similar types of wetlands and habitats compared to the original Applicant Proposed Route. Link 3, Variation 2, would parallel almost four times the length of existing infrastructure compared to the original Applicant Proposed Route and would cross through areas that contain fewer wetland and waterbody features compared to the original Applicant Proposed Route.

3.20.2.5.5 Region 5

Region 5 is referred to as the Central Arkansas Region and includes the Applicant Proposed Route and HVDC Alternative Routes 5-A through 5-F. This region includes Pope, Conway, Van Buren, Faulkner, Cleburne, White, and Jackson counties in Arkansas. The Applicant Proposed Route Link 9 and HVDC Alternative Route 5-D cross the White River in Jackson County (Clean Line 2013b). The Applicant Proposed Route Link 4 and HVDC Alternative Route 5-E cross Cadron Creek in Van Buren County, while HVDC Alternative Route 5-B crosses Cadron Creek in Faulkner County (Clean Line 2013b). HVDC Alternative Routes 5-B, 5-E, and 5-F cross East Fork Cadron Creek in Faulkner County (Clean Line 2013b). HVDC Alternative Route 5-D crosses a reach of the Departee Creek in Arkansas that is considered an Ecologically Sensitive Waterbody because of the presence of the flat floater mussel (*Anodonta suborbiculata*) (Clean Line 2013b). Applicant Proposed Route Link 7 and HVDC Alternative Route 5-C cross the Little Red River in White County, which is designated as "Trout Waters" from below the Greers Ferry Dam to Searcy (Clean Line 2013b). In Arkansas, forested wetland areas crossed by the ROI in Region 5 include West Fork Point Remove Creek, Briar Creek, Oats Creek, and tributaries to both Departee Creek and Mill Creek (Clean Line 2013b). Many fish and aquatic invertebrate species potentially occur in these waterbodies that cross the ROI; fish and aquatic species are listed in Appendix L. Although crossing locations within a given drainage vary between the Applicant Proposed Route and the HVDC Alternative Routes 5-A through 5-F, the potential occurrence of fish and aquatic species within the ROI would generally be similar.

Five route variations to the Applicant Proposed Route were developed in Region 5 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.5. The variations are illustrated in Exhibit 1 of Appendix M. These variations represent minor adjustments to the Applicant Proposed Route. Link 1, Variation 2; Link 2, Variation 2; Links 2 and 3, Variation 1; Links 3 and 4, Variation 2; and Link 7, Variation 1, would cross through similar types of wetlands and habitats compared to the original Applicant Proposed Route.

3.20.2.5.6 Region 6

Region 6 is referred to as the Cache River and Crowley's Ridge Region and includes the Applicant Proposed Route and HVDC Alternative Routes 6-A through 6-D. This region includes Jackson, Cross, and Poinsett counties in Arkansas. The Applicant Proposed Route Link 6 crosses a reach of the L'Anguille River in Cross County, while HVDC Alternative Route 6-C crosses the L'Anguille River in Poinsett County (Clean Line 2013b). HVDC Alternative Route 6-D runs parallel to the Straight Slough in Cross and Poinsett counties, then crosses Straight Slough in Poinsett County; the lower 10 miles of this waterbody is designated as an Ecologically Sensitive Waterbody because of the presence of the fat pocketbook mussel (Clean Line 2013b); which is a special status aquatic invertebrate species and discussed further in Section 3.14.2. Forested wetland areas crossed by the ROI in Region 6 include Bayou DeView, Caney Creek, L'Anguille River, and Ditches No. 10, 123, and 61 (Clean Line 2013b). Many fish and aquatic invertebrate species potentially occur in these waterbodies that cross the ROI; fish and aquatic species are listed in Appendix L. Although crossing locations within a given drainage vary between the Applicant Proposed Route and HVDC Alternative Routes 6-A through 6-D, the potential occurrence of fish and aquatic species within the ROI would generally be similar.

One route variation to the Applicant Proposed Route in Region 6 (i.e., Applicant Proposed Route Link 2, Variation 1) was developed in response to public comments on the Draft EIS. This route variation is described in Appendix M and summarized in Section 2.4.2.6. The variation is illustrated in Exhibit 1 of Appendix M. This variation represents a minor adjustment to the Applicant Proposed Route. Link 2, Variation 1, would cross through similar types of wetlands and habitats compared to the original Applicant Proposed Route and includes increased acreage of forested wetland habitat.

3.20.2.5.7 Region 7

Region 7 is referred to as the Arkansas Mississippi River Delta and Tennessee Region and includes the Applicant Proposed Route and HVDC Alternative Routes 7-A through 7-D. This region includes Poinsett and Mississippi counties in Arkansas and Tipton and Shelby counties in Tennessee. The Applicant Proposed Route Link 1 and HVDC Alternative Route 7-A cross the St. Francis River in Poinsett County, Arkansas, and the Mississippi River at the Arkansas-Tennessee state line (Clean Line 2013b). Applicant Proposed Route Link 1 and HVDC Alternative Route 7-A cross the Mississippi River in Tipton County; this waterbody is designated as an Exceptional Tennessee Water because of the presence of the pallid sturgeon and the blue sucker (Clean Line 2013b), both of which are special status fish species and discussed further in Section 3.14.2. In Arkansas, forested wetland areas crossed by the ROI in Region 7 include the Cache River and Ditches No. 1 and 47 (Clean Line 2013b). In Tennessee, forested wetland areas crossed by the ROI in Region 7 include the Mississippi River, Sullivan Lake and Big Slough, Dead Timber, Ditch No. 1, a tributary to Cole Creek, and tributaries to Big Creek (Clean Line 2013b). Many fish and aquatic invertebrate species potentially occur in these waterbodies that cross the ROI; fish and aquatic species are listed in Appendix L. Although crossing locations within a given drainage vary between the Applicant Proposed Route and HVDC Alternative Routes 7-A through 7-D, the potential occurrence of fish and aquatic species within the ROI would generally be similar.

Three route variations to the Applicant Proposed Route were developed in Region 7 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.7. The variations are illustrated in Exhibit 1 of Appendix M. Link 1, Variation 1; Link 1, Variation 2; and Link 5, Variation 1, would cross through similar types of wetlands and habitats compared to the original Applicant Proposed Route. The number of waterbodies crossed potentially decreased by half in Link 1, Variation 2.

3.20.2.6 Connected Actions

3.20.2.6.1 Wind Energy Generation

Acres of woody wetland and emergent herbaceous wetlands that are provided below are from Section 3.10. The land cover in each WDZ is summarized in Section 3.10. Miles of perennial streams and acres of perennial reservoirs, lakes, and ponds are from Section 3.15. A summary of the fish and aquatic species and habitat occurrence by WDZ is provided in the sections below.

3.20.2.6.1.1 WDZ-A

The dominant land cover in WDZ-A is croplands and grasslands, with 19.1 acres of woody wetlands and 79.0 acres of emergent herbaceous wetlands (GIS Data Source: Jin et al. 2013). There are approximately 4.9 miles of perennial streams and 38 acres of perennial reservoirs, lakes, and ponds. WDZ-A intersects the Middle Beaver, Lower Beaver, Palo Duro, and Upper Wolf watersheds. Deer Lake and Peckenpaugh Lake both fall within WDZ-A and are important recreational fishing areas (HookandBullet 2014c). Important recreational fish species in the Texas Panhandle include largemouth bass, smallmouth bass, spotted bass, white bass, yellow bass, striped bass, channel catfish, bluegill, white crappie, and black crappie (TPWD 2014a). Recreational and commercial freshwater mussel species in Texas include threeridge, mapleleaf, pimpleback, and bleufer, among others (TPWD 2014a).

3.20.2.6.1.2 WDZ-B

The dominant land cover in WDZ-B is croplands and grasslands areas, with 15 acres of woody wetlands and 60 acres of emergent herbaceous wetlands. There are approximately 8 miles of perennial streams and 164 acres of perennial reservoirs, lakes, and ponds. WDZ-B intersects the Palo Duro watershed. A portion of the Palo Duro Reservoir, where recreational fishing occurs, is within WDZ-B. In addition, Venneman Lake and Miller's Lake are both within WDZ-B, and are also important recreational fishing areas (HookandBullet 2014c). Important recreational fish species in the Texas Panhandle include largemouth bass, smallmouth bass, spotted bass, white bass, yellow bass, striped bass, channel catfish, bluegill, white crappie, and black crappie (TPWD 2014a). Recreational and commercial freshwater mussel species in Texas include threeridge, mapleleaf, pimpleback, and bleufer, among others (TPWD 2014a).

3.20.2.6.1.3 WDZ-C

The dominant land cover in WDZ-C is grasslands areas and croplands, with 2 acres of woody wetlands and 4 acres of emergent herbaceous wetlands. There are approximately 6.4 miles of perennial streams and 125 acres of perennial reservoirs, lakes, and ponds. WDZ-C intersects the Coldwater watershed. WDZ-C includes Steji Lake and Bryson Lake, both important recreational fishing areas (HookandBullet 2014c). Important recreational fish species in the Texas Panhandle include largemouth bass, smallmouth bass, spotted bass, white bass, yellow bass, striped bass, channel catfish, bluegill, white crappie, and black crappie (TPWD 2014a). Recreational and commercial freshwater mussel species in Texas include threeridge, mapleleaf, pimpleback, and bleufer, among others (TPWD 2014a).

3.20.2.6.1.4 WDZ-D

The dominant land cover in WDZ-D is grasslands areas and croplands, with 52 acres of woody wetlands (occurring along Hackberry Creek within Lake Schultz Wildlife Management Area). There are approximately 12.7 miles of perennial streams and 57 acres of perennial reservoirs, lakes, and ponds. WDZ-D intersects the Coldwater, Middle Beaver, and Palo Duro watersheds. WDZ-D contains 313.6 acres of Oklahoma Waters of Recreational and/or Ecological Significance. Schultz Lake and Webb Lake both occur within WDZ-D and are important recreational fishing areas. Recreational fish species found in this area of the Oklahoma Panhandle include striped bass, smallmouth bass, largemouth bass, walleye, bluegill, brown trout, and rainbow trout (HookandBullet 2014d).

3.20.2.6.1.5 WDZ-E

The dominant land cover in WDZ-E is croplands and grasslands areas with 9 acres of woody wetlands. There are approximately 2.6 miles of perennial streams and 25 acres of perennial reservoirs, lakes, and ponds. WDZ-E intersects the Coldwater and Middle Beaver watersheds. Recreational fish species found in this area of the Oklahoma Panhandle include striped bass, smallmouth bass, largemouth bass, walleye, bluegill, brown trout, and rainbow trout (HookandBullet 2014d).

3.20.2.6.1.6 WDZ-F

The dominant land cover in WDZ-F is grasslands areas and croplands, with 21 acres of woody wetlands (occurring along the Beaver [North Canadian] River) and 18 acres of emergent herbaceous wetlands. There are approximately 13 miles of perennial streams and 24 acres of perennial reservoirs, lakes, and ponds. WDZ-F intersects the Coldwater and Upper Beaver watersheds. WDZ-F contains 5.8 miles of waters which have been designated by the state of Oklahoma as impaired pursuant to Section 303(d). Recreational fish species found in this area of the Oklahoma Panhandle include striped bass, smallmouth bass, largemouth bass, walleye, bluegill, brown trout, and rainbow trout (HookandBullet 2014d).

3.20.2.6.1.7 WDZ-G

The dominant land cover in WDZ-G is grasslands areas and croplands, with 146 acres of emergent herbaceous wetlands and 2 acres of woody wetlands. There are approximately 6.8 miles of perennial streams and 12 acres of perennial reservoirs, lakes, and ponds. WDZ-G intersects the Upper Beaver watershed. Recreational fish species found in this area of the Oklahoma Panhandle include striped bass, smallmouth bass, largemouth bass, walleye, bluegill, brown trout, and rainbow trout (HookandBullet 2014d).

3.20.2.6.1.8 WDZ-H

The dominant land cover in WDZ-H is grasslands areas and croplands, with 4 acres of woody wetlands and 2 acres of emergent herbaceous wetlands. There are approximately 19.9 miles of perennial streams and 8 acres of perennial reservoirs, lakes, and ponds. WDZ-H intersects the Upper Beaver watershed. Recreational fish species found in this area of the Oklahoma Panhandle include striped bass, smallmouth bass, largemouth bass, walleye, bluegill, brown trout, and rainbow trout (HookandBullet 2014d).

3.20.2.6.1.9 WDZ-I

The dominant land cover in WDZ-I is croplands and grasslands areas, with 49 acres of woody wetlands and 93 acres of emergent herbaceous wetlands. There are approximately 1.7 miles of perennial streams and 17 acres of perennial reservoirs, lakes, and ponds. WDZ-I intersects the Middle Beaver watershed. Recreational fish species found in this area of the Oklahoma Panhandle include striped bass, smallmouth bass, largemouth bass, walleye, bluegill, brown trout, and rainbow trout (HookandBullet 2014d).

3.20.2.6.1.10 WDZ-J

The dominant land cover in WDZ-J is grasslands areas and croplands, with 83 acres of woody wetlands (occurring along the Beaver [North Canadian] River and Fulton Creek). There are approximately 26.2 miles of perennial streams and 123 acres of perennial reservoirs, lakes, and ponds. WDZ-J intersects the Middle Beaver and Palo Duro watersheds. WDZ-J contains 2.3 miles of waters which have been designated by Oklahoma State as impaired pursuant to Section 303(d). Recreational fish species found in this area of the Oklahoma Panhandle include striped bass, smallmouth bass, largemouth bass, walleye, bluegill, brown trout, and rainbow trout (HookandBullet 2014d).

3.20.2.6.1.11 WDZ-K

The dominant land cover in WDZ-K is croplands and grasslands areas, with 50 acres of woody wetlands and 1 acre of emergent herbaceous wetlands. There are approximately 6.3 miles of perennial streams and 60 acres of perennial reservoirs, lakes, and ponds. WDZ-K intersects the Lower Beaver watershed. WDZ-K contains 9.2 miles of waters which have been designated by the state of Oklahoma as impaired pursuant to Section 303(d). Recreational fish species found in this area of the Oklahoma Panhandle include striped bass, smallmouth bass, largemouth bass, walleye, bluegill, brown trout, and rainbow trout (HookandBullet 2014d).

3.20.2.6.1.12 WDZ-L

The dominant land cover in WDZ-L is croplands, grasslands, and shrub/scrub areas, with 19 acres of woody wetlands (occurring along Wolf Creek within Wolf Creek County Park) and 2,286 acres of emergent herbaceous wetlands. There are approximately 31.6 miles of perennial streams and 650 acres of perennial reservoirs, lakes, and ponds. WDZ-L intersects the Upper Wolf watershed. WDZ-L contains 15.6 miles of Wolf Creek; a state of Texas designated Ecologically Unique River and Stream Segment. Wolf Creek is designated as a high quality/exceptional aquatic life/high aesthetic value waterbody. It is also used as a reference stream to develop the regionalized index of biotic integrity for Texas, with diverse benthic macroinvertebrate and fish communities. Fish species found within Wolf Creek include red shiner, sand shiner (*Notropis stramineus*), suckermouth minnow, plains killifish, western mosquitofish, green sunfish, longear sunfish, and largemouth bass (Linam et al. 2002). Wolf Creek and Deer Lake are both important recreational fishing areas within WDZ-L (HookandBullet 2014c). Important recreational fish species in the Texas Panhandle and potentially found in Deer Lake include largemouth bass, smallmouth bass, spotted bass, white bass, yellow bass, striped bass, channel catfish, bluegill, white crappie, and black crappie (TPWD 2014a). Recreational and commercial freshwater mussel species in Texas include threeridge, mapleleaf, pimpleback, and bleufer, among others (TPWD 2014a).

3.20.2.6.2 Optima Substation

As discussed in Section 3.1, the future Optima Substation may be constructed just east of the Oklahoma Converter Station and partially within the AC Interconnection Siting Area in Region 1. The location for the substation occurs on grassland habitats adjacent to croplands. Because there are no likely waterbodies within the future Optima Substation, no occurrences of fish and aquatic invertebrate species are likely.

3.20.2.6.3 TVA Upgrades

The ROI for the direct assignment facilities (which are included in the Applicant Proposed Project) would occur within the Tennessee Converter Station Siting Area and more specifically within the Shelby Substation. The ROI for the network upgrades, and in particular TVA's future 500kV transmission line, cannot be fully determined at this time. The new 500kV transmission line would be constructed in western Tennessee. The upgrades to existing facilities would mostly be in western and central Tennessee. Upgrades to existing infrastructure would include upgrading terminal equipment at three existing 500kV substations and six existing 161kV substations, making appropriate upgrades to increase heights on 16 existing 161kV transmission lines to increase line ratings, and replacing the conductors on eight existing 161kV transmission lines. Where possible, general impacts associated with the required TVA upgrades are discussed in the impact sections that follow.

3.20.2.7 Impacts to Fish and Aquatic Invertebrates

3.20.2.7.1 Methodology

The methodology for evaluating impacts on fish and aquatic resources included comparisons of impacts of the Applicant Proposed Route to impacts of the HVDC alternative routes. Within the applicable ROI, the analysis assessed Project activities that could potentially impact aquatic species and their habitats. Potential impacts to aquatic resources that were evaluated included stream crossings that fall within the ROI and soil disturbance with the potential to increase erosion and sedimentation into nearby waterbodies. The Project crosses or runs parallel to multiple surface water features (e.g., perennial and intermittent streams, major waterbodies, and reservoirs, lakes, and ponds), including special interest waterbodies, within each region. Because the Project crosses or runs parallel to multiple surface water features that may provide suitable aquatic habitat, the potential occurrence of fish and aquatic invertebrate species varies greatly across the Project. To assess potential occurrences of fish and aquatic invertebrate species and to evaluate potential downstream impacts from Project activities thoroughly and adequately, the 1,000-foot-wide ROI was used to identify potential occurrences of fish and aquatic invertebrate species. Considering the mobility of fish and larval mussels, and the potential transport of sediment and hazardous materials, the 1,000-foot-wide ROI was used for comparisons of impacts of the Applicant Proposed Route to impacts of the HVDC alternative routes. The ROI is extensive enough to account for the various ranges of fish and aquatic invertebrates, including the unique and varied habitat that each species potentially occupies, as well as the potential transport of sediment and hazardous materials. The final alignment within the ROI may have different overall effects depending on location as to the number and types of streams actually crossed or paralleled by Project access roads and transmission line clearings, as well as Project activities that could impact nearby waterbodies (within or outside of the ROI). Potential impacts on aquatic resources include the following and are further discussed for each phase of the Project:

- Potential impacts on aquatic species and their habitats from construction activities, vehicles, equipment, and access roads, including road crossings such as culverts, fords, and bridges, as well increased runoff and sedimentation
- Potential impacts from permanent and temporary removal of terrestrial vegetation or temporary mechanical damage to terrestrial vegetation
- Possible spread and/or introduction of invasive plants or animals or listed noxious weed species from the use of construction equipment at waterbody crossings
- Potential impacts associated with ROW terrestrial vegetation maintenance, including the use of herbicides on terrestrial vegetation during operation of the Project
- Potential for sediment loading and introduction of chemicals from spills into aquatic habitats, causing alterations to the habitat or the acute or chronic effects of hazardous chemicals
- Potential changes to stream morphology due to adjacent riparian clearing

The Applicant has developed a comprehensive list of EPMs that would cover the mitigation necessary to avoid or minimize impacts to fish and aquatic invertebrates. Implementation of these EPMs is assumed throughout the impact analysis that follows for the Project. A complete list of EPMs for the Project is provided in Appendix F. General EPMs for the Project that relate to fish and aquatic resources include the following:

- GE-1: Clean Line will train personnel on health, safety, and environmental matters. Training will include practices, techniques, and protocols required by federal and state regulations and applicable permits.
- GE-3: Clean Line will minimize clearing vegetation within the ROW, consistent with a Transmission Vegetation Management Plan filed with NERC, and applicable federal, state, and local regulations. The TVMP may require additional analysis under NEPA depending on whether and under what conditions DOE decides to participate in the Project.
- GE-5: Any herbicides used during construction and operations and maintenance will be applied according to label instructions and any federal, state, and local regulations.

- GE-7: Roads not otherwise needed for maintenance and operations will be restored to preconstruction conditions. Restoration practices may include decompacting, recontouring, and re-seeding. Roads needed for maintenance and operations will be retained.
- GE-9: Clean Line will avoid and/or minimize damage to drainage features and other improvements such as ditches, culverts, levees, tiles, and terraces; however, if these features or improvements are inadvertently damaged, they will be repaired and or restored.
- GE-10: Clean Line will work with landowners to repair damage caused by construction, operation, or maintenance activities of the Project. Repairs will take place in a timely manner, weather and landowner permitting.
- GE-11: Clean Line will conduct construction, operation, and maintenance activities to minimize the creation of dust. This may include measures such as limitations on equipment, speed, and/or travel routes utilized. Water, dust palliative, gravel, combinations of these, or similar control measures may be used. Clean Line will implement measures to minimize the transfer of mud onto public roads.
- GE-13: Emergency and spill response equipment will be kept on hand during construction.
- GE-14: Clean Line will restrict the refueling and maintenance of vehicles and the storage of fuels and hazardous chemicals within at least 100 feet from wetlands, surface waterbodies, and groundwater wells, or as otherwise required by federal, state, or local regulations.
- GE-15: Waste generated during construction or maintenance, including solid waste, petroleum waste, and any potentially hazardous materials will be removed and taken to an authorized disposal facility.
- GE-21: Clean Line will maintain construction equipment in good working order. Equipment and vehicles that show excessive emissions of exhaust gases and particulates due to poor engine adjustments or other inefficient operating conditions will be repaired or adjusted.
- GE-27: Clean Line will minimize compaction of soils and rutting through appropriate use of construction equipment (e.g., low ground pressure equipment and temporary equipment mats).
- GE-28: Hazardous materials and chemicals will be transported, stored, and disposed of according to federal, state, or local regulations or permit requirements.
- GE-30: Clean Line will minimize the amount of time that any excavations remain open.

Fish, vegetation, and wildlife EPMs for the Project that relate to fish and aquatic resources include the following:

- FVW-1: Clean Line will identify environmentally sensitive vegetation (e.g., wetlands, protected plant species, riparian areas, large contiguous tracts of native prairie) and avoid and/or minimize impacts to these areas.
- FVW-2: Clean Line will identify and implement measures to control and minimize the spread of non-native invasive species and noxious weeds.
- FVW-3: Clean Line will clearly demarcate boundaries of environmentally sensitive areas during construction to increase visibility to construction crews.
- FVW-4: If construction- and/or decommissioning-related activities occur during the migratory bird breeding season, Clean Line will work with USFWS to identify migratory species of concern and conduct pre-construction surveys for active nests for such species. Clean Line will consult with USFWS and/or other resource agencies for guidance on seasonal and/or spatial restrictions designed to avoid and/or minimize adverse effects.
- FVW-5: If construction occurs during important time periods (e.g., breeding, migration, etc.) or at close distances to environmentally sensitive areas with vegetation, wildlife, or aquatic resources, Clean Line will consult with USFWS and/or other resource agencies for guidance on seasonal and/or spatial restrictions designed to avoid and/or minimize adverse effects.

Water EPMs for the Project that relate to fish and aquatic resources include the following:

- W-1: Clean Line will avoid and/or minimize construction of access roads in special interest waters.
- W-2: Clean Line will identify, avoid, and/or minimize adverse effects to wetlands and waterbodies. Clean Line will not place structure foundations within the Ordinary High Water Mark of Waters of the United States.
- W-3: Clean Line will establish streamside management zones within 50 feet of both sides of intermittent and perennial streams and along margins of bodies of open water where removal of low-lying vegetation is minimized.
- W-4: If used, Clean Line will selectively apply herbicides within streamside management zones.
- W-5: Clean Line will construct access roads to minimize disruption of natural drainage patterns including perennial, intermittent, and ephemeral streams.
- W-6: Clean Line will not construct counterpoise or fiber optic cable trenches across waterbodies.
- W-7: Dewatering will be conducted in a manner designed to prevent soil erosion (e.g., through discharge of water to vegetated areas and/or the use of flow control devices).

In addition, the Applicant would develop and implement the following plans to avoid or minimize impacts:

- Blasting Plan—This plan will describe measures designed to minimize adverse effects due to blasting.
- Restoration Plan—This plan will describe post-construction activities to reclaim disturbed areas.
- Spill Prevention, Control and Countermeasures (SPCC) Plan—This plan will describe the measures designed to prevent, control, and clean up spills of hazardous materials
- Storm Water Pollution Prevention Plan (SWPPP)—This plan, consistent with federal and state regulations, will describe the practices, measures, and monitoring programs to control sedimentation, erosion, and runoff from disturbed areas.
- Transmission Vegetation Management Plan (TVMP)—This plan, to be filed with NERC, will describe how Clean Line will conduct work on its right-of-way to prevent outages due to vegetation. The TVMP may require additional analysis under NEPA depending on whether and under what conditions DOE decides to participate in the Project.

3.20.2.7.2 Impacts Associated with the Applicant Proposed Project

This section identifies the potential impacts on fish, aquatic invertebrates, and aquatic habitat that could occur as a result of the Project. The discussion of potential impacts is broken out into three phases of the Project: (1) construction, (2) operations and maintenance, and (3) decommissioning. The Applicant would conduct each phase of the Project in compliance with applicable state and federal laws, regulations, and permits related to environmental protection. Specific EPMs developed to avoid or minimize impacts are described in Section 3.20.2.7.1.

The impacts discussed in the sections below are common to all aspects of the Project; while the potential impacts associated with specific portions of the Project (e.g., converter stations, AC collection system, HVDC routes) are discussed separately following this general impact discussion. Both direct (i.e., impacts that result from the action and occurs at the same time and place as the action) and indirect (i.e., impacts that result from the action, but which occur later in time or farther in distance) impacts are addressed. The impacts that could result from activities related to the Project would vary in duration.

Construction Impacts

The general construction approach to the Project would be to span waterbodies, avoid placement of structures in riparian areas where possible, minimize in-water construction, and avoid or minimize the need for crossings of waterbodies with equipment or vehicles. The Applicant Proposed Project is described in Section 2.1.2 through 2.1.7. Specific EPMs developed to avoid or minimize impacts are described in Section 3.20.2.7.1.

The main cause of potential impacts on fish and aquatic resources would be ground disturbance linked to construction activities in or adjacent to rivers, streams, ponds, and wetlands. Direct construction impacts that could potentially affect fish and aquatic invertebrate species and their habitats include vegetation clearing, grading, access roads, herbicide use, and handling of fuel and lubricants at stream and river crossings. Indirect construction impacts that could potentially affect fish and aquatic invertebrate species and their habitats include vegetation clearing, grading, access roads, herbicide use, and handling of fuel and lubricants at locations where construction activities would result in sedimentation or contaminant runoff. Vegetation clearing has the potential to increase sedimentation and decrease cover. Increased sedimentation can directly or indirectly suffocate, bury, or limit feeding of fish and aquatic invertebrate species. Grading and access roads have the potential to increase sedimentation, decrease cover, and increase runoff. Increased runoff can alter stream and river hydrology and provide a mechanism for delivery of sediment, herbicides, and fuel and lubricants to streams and rivers. Inadvertent release of contaminants (e.g., oils, lubricants, and fuels that would be used while operating machinery, or herbicides that would be used to control vegetation and invasive species) introduces the potential for those contaminants to concentrate in body tissues of fish and filter-feeding mussels, which can result in death.

To avoid or minimize impacts during the construction phase of the Project, both general EPMs and those specific to fish and aquatic resources, as listed in Section 3.20.2.7.1, would be implemented. Specific to sedimentation and vegetation clearing, detailed EPMs for both construction and ROW maintenance would be in place prior to construction, specifically designed to ensure slope stability, prevent excessive soil erosion, prevent other hazardous runoff to waters, retain low-growing near-stream vegetation, and reduce sedimentation in streams (see Sections 3.14.2.7.1 and 3.20.2.7.1; see Appendix F for a complete list of EPMs). In addition, state permits would need to be obtained prior to construction, which would require that Project actions do not violate state water quality standards and further aid in the protection of aquatic resources, including food resources and spawning and rearing habitat. Furthermore, Clean Line would develop a SWPPP that would control sedimentation, erosion, and runoff, which would be consistent with the state and federal regulations. Specifically regarding increased sediment load from vegetation clearing, Clean Line has committed to maintaining a streamside management zone (EPM W-3, see Sections 2.1.7 and 3.20.2.7.1 and Appendix F of the EIS) of 50 feet on both sides of streams and waterbodies where removal of low-growing vegetation would be minimized, which would aid in protection of the stream environment and reduce the likelihood of excessive sediment loads reaching the streambed. Additionally, Clean Line would develop a TVMP, which would address how vegetation is to be managed in the ROW. The EPMs for both construction and ROW maintenance would be in place prior to construction and for which the Applicant would need approval through the state and federal permitting process. The approval process would ensure that actions with the potential to impact water and aquatic resources would be avoided or minimized.

Specific to spills and hazardous chemical exposures associated with herbicide use and handling of fuel and lubricants, the Applicant would implement EPMs GE-1, GE-5, GE-13, GE-21, and GE-28, as well as the measures that would be outlined in the required SPCCP and SWPPP to minimize these risks. These EPMs include measures that would reduce the risks of accidental spills (e.g., GE-13, GE-21, GE-28), as well as measures that would ensure that herbicides are used in accordance with labeled instructions and any federal, state, and local regulations (i.e., GE-5). In addition, a TVMP would be prepared and would address situations where herbicide use is necessary (e.g., the Applicant would evaluate herbicidal treatment options in consideration of site-specific ecological conditions, surrounding and underlying land uses, and any environmental sensitivities before selecting and applying a control). The Vegetation Program and TVMP would be developed to comply with federal, state, and local regulations and standards for reliability and ROW vegetation clearing and maintenance, including NERC Reliability Standard FAC-003-2 (NERC 2011). The Vegetation Program and TVMP would also comply with relevant regulations applicable to all lands, including, but not limited to the Clean Water Act (CWA) Sections 303(d) and 404 and the Endangered Species Act (ESA) of 1973, as amended in Section 7(a)(2). See Section 3.17 for a detailed discussion of the Vegetation Program and use of herbicides. The TVMP may require additional analysis under NEPA depending on whether and under what conditions DOE decides to participate in the Project. Furthermore, the USFWS and other resource agencies would be consulted if construction efforts occur during time periods that are important to a species (e.g., spawning) or near environmentally sensitive areas with important aquatic resources, to avoid or minimize impacts to species (EPM FVW-5). The Applicant would identify, avoid, and/or minimize adverse effects to wetlands and waterbodies (EPM W-2).

Mortality and Injury. Individual fish or aquatic invertebrates, including eggs, could suffer mortality or injury (be crushed) when in-stream excavation occurs or when vehicles or construction equipment travel through water features. Vehicular traffic at or in the vicinity of stream crossings could cause macroinvertebrates to be reduced in numbers, although they would be expected to recover post construction. To potentially avoid or minimize mortality/injury, the Applicant would minimize construction of access roads in special status waters as described in EPM W-1.

Spills of hazardous materials (e.g., diesel fuel, gasoline, oil, hydraulic fluids, cement water fluids, etc.) into aquatic habitats at crossings of the Project, including transport to downstream areas, could cause the loss or injury of individuals. In addition to direct impacts on fish or aquatic invertebrates, spilled hazardous substances could impact habitat quality and suitability. If hazardous materials reach the waterway, chemical residue could also enter the water column, resulting in hazardous conditions. To minimize the potential for direct discharge of fuels or hazardous materials into waterbodies, the Applicant would restrict refueling and maintenance of vehicles and the storage of fuels and hazardous chemicals within at least 100 feet from wetlands, surface waterbodies, and groundwater wells, or as otherwise required by federal, state, or local regulations as described under EPM GE-14.

Impacts could occur if herbicide application goes beyond its intended target through overspraying or drift with aerial applications, which could result in contact with aquatic areas. If these impacts occur at crossings of the Project, mortality of individual fish or aquatic invertebrate species could occur; likewise, if these impacts occur at downstream locations, mortality would be a potential concern. Herbicides that do not immediately enter a wetland or stream could still be transported downhill or underground into streams, rivers, or wetlands. To avoid overspray or drift, the Applicant would apply herbicides according to label instructions and any federal, state, and local regulations as described under EPM GE-5.

Short-term increases in sediment loads and turbidity within aquatic areas could result from ground disturbance due to construction, erosion, or runoff, and may potentially cause loss or injury of individual fish or aquatic invertebrate species sensitive to siltation during spawning or in other life stages. Sediment deposition in the substrate used for spawning could also alter egg development and survival. Increased sedimentation or erosion could result from in-stream excavation or work being done in adjacent uplands, affecting aquatic species at crossings of the Project or at downstream locations. Sediment entering the waterway would be deposited somewhere downstream of the construction area, and the extent of the effects would be dependent on current flow conditions, the individual river or stream path, and the composition of the substrate and soil disturbed. A SWPPP would be implemented by the Applicant that outlines corrective actions to minimize impacts related to increased sediment loads.

Clearing of forested vegetation adjacent to a waterway has the potential to increase stream temperature, which could potentially affect all stages of fish and aquatic invertebrates. Clearing of trees, shrubs, or other vegetation adjacent to or along a waterway, including in-water vegetation, can reduce the amount of cover available to species prone to hiding from prey, and could result in increased predation. The loss of vegetation along a waterway could affect the survival rate of affected fish and aquatic invertebrate species due to loss of cover (easy target for predators), loss of shade (increased water temperatures), and a decrease in food sources (loss of insect and organic matter deposition in water) (EPA 2003, 2014). Potential impacts associated with the loss of vegetation have the highest potential in Regions 3, 4, 5, and 7 where riparian vegetation is most prevalent.

Additionally, blasting associated with Project construction that occurs in or near streams has the potential to directly affect fish mortality. Fish can be affected even by blasting that does not occur directly in waterbodies. Blasting near water produces shock waves that can be lethal to fish, eggs, and larvae by rupturing swim bladders and addling egg sacs (TranBC 2000). Blasting underground produces two modes of seismic waves: 1) body waves that are propagated as compressional primary waves and shear secondary waves; and 2) surface waves produced when a body wave travels to the earth surface and is reflected back (ADF&G 1991). Seismic waves propagated from ground to water are likely less lethal to fish than those from in-water explosions because some energy is reflected or lost at ground-water interface (ADF&G 1991). To protect fish species, the best approach is to limit the instantaneous hydrostatic pressure change (resulting from nearby blasting) to levels below those known to be harmful to fish. ADF&G (1991) reported that a pressure change of 2.7 psi is the level for which no fish mortality occurs. Based on this information, ADF&G (1991) concluded that fish would sufficiently be protected from blasting on land by limiting overpressures to 2.7 psi.

Shallow bedrock is present throughout all regions of the Project, and blasting may be required in or near streams. However, if blasting is necessary, a Blasting Plan would be employed to minimize adverse effects. In addition, the Applicant would request guidance on seasonal and spatial restrictions for species in aquatic resources from the USFWS and other state resource agencies (EPM FVW-5) concerning blasting activities.

Sensory Disturbance. Direct impacts to fish and aquatic invertebrate species could occur as a result of disturbances caused by activities related to the Project. Sensory disturbances include ground vibration and visible activity, as well as any in-water work that creates pressure waves through the water, potentially injuring internal organs of fish. The presence of humans, vehicles, or equipment could cause fish and other mobile species to avoid suitable habitat by hiding under rocks or vegetation when disturbed, or cause stresses that would disrupt normal and essential life processes such as foraging and breeding. These impacts should be short-term and the aquatic species would likely resume normal behavior soon after any sensory disturbance. The Applicant would request guidance on seasonal and spatial restrictions for species in aquatic resources from the USFWS and other state resource agencies as described under EPM FVW-5.

Habitat Loss and Modification. Construction activities could cause a loss or modification of suitable habitat for foraging, spawning, and refuge habitats, all potentially impacting aquatic resources. A loss of native plants and substrates that are important to natural processes of aquatic species could result from in-stream disturbance and sediment deposition. Vegetation along streambanks provides cover for fish, stability for banks, shade, and an increase in food sources due to the deposition of insects and vegetation into the waterway. Riparian vegetation provides woody material deposited into waterways that fish can use as cover or can help form pools, and aid in stream sediment deposition and movement control. Although some habitat loss or modification would be unavoidable due to some construction activities (e.g., riparian vegetation removal) and installation of stream crossing structures (e.g., armored fords, culverts, bridges), to avoid or minimize the loss or modification of habitat, the Applicant would implement the measures described for EPMs FVW-1, FVW-2, FVW-3, and FVW-5.

If construction activities cause spills of hazardous materials and increased sediment loads, it could impact aquatic habitat. This could occur at or downstream of stream crossings, or downstream of sediment runoff from a nearby road into a stream. A spill of hazardous materials could impact water and soil conditions, thereby affecting the health of aquatic plants and nearby riparian vegetation. To avoid spills of hazardous materials, the Applicant would restrict refueling and maintenance of equipment and vehicles as described under EPMs GE-14 and GE-21. The Applicant would avoid or minimize impacts to environmentally sensitive areas as described under EPMs FVW-1, FVW-3, and FVW-5.

If herbicide application goes beyond its intended target through overspraying or drift with aerial applications, impacts could occur if contact with aquatic resources results in the damage or removal of native plants, which could cause isolated degradation of aquatic habitat. If aquatic vegetation is destroyed or altered, the essential life processes for fish and other aquatic species could be altered, including reproduction, foraging, and predator evasion. To avoid overspray or drift, the Applicant would apply herbicides according to label instructions and any federal, state, and local regulations as described under EPM GE-5.

Construction activities could cause the loss or degradation of riparian trees and herbaceous and shrubby vegetation on the banks of streams or ponds. The loss of vegetation could potentially affect habitat quality by raising the water temperature and increasing sediment loads through erosion, caused by the cutting and sloughing of banks. A considerable increase in both water temperature and the level of siltation in the water column or within the interstitial spaces of substrate could cause aquatic habitats to be suboptimal or inadequate for life processes such as breeding and result in long-term impacts. The Applicant would establish streamside management zones within 50 feet of both sides of intermittent and perennial streams and along margins of bodies of open water where removal of low-lying vegetation is minimized as described under EPM W-3.

Certain alterations of the physical condition of streambeds or banks during construction could cause changes in stream characteristics. This may result in the loss of pools or riffles, erosion of stream banks, and lessening the water quality. In-water structures and debris that normally provide cover from predators could be removed or destroyed, which could result in increased predation of aquatic species. Sedimentation could adversely affect macroinvertebrates, especially benthic organisms, through smothering, reduced filtering feeding rates, toxicity from anaerobic sediments, and increased drift rates. Turbidity within the waterbody could also result in reduced light intensity, as well as reduced dissolved oxygen levels and a change in the pH. The Applicant would avoid altering habitat to the extent practicable by following guidelines in EPMs W-1, W-2, W-3, W-5, W-6, and W-7.

Invasive Species. Construction activities could cause impacts on aquatic resources through the introduction of non-native aquatic plants and animals. Vehicles or equipment at stream crossings could potentially transfer invasive species between different streams during construction. The introduction of non-native plants could alter the habitat due to outcompeting of native plants, which are essential to the native aquatic resources. The introduction of non-native aquatic species (e.g., zebra mussels) could impact native species through competition for resources. In order to minimize impacts, the Applicant would identify, control, and minimize the spread of non-native invasive species to the extent practicable as described under EPM FVW-2. Section 3.17 discusses in detail the potential effects of invasive plant species on native habitats as well as the measures that would be taken to minimize the risk of these effects. The subsection "Construction Impacts" above and Section 3.17 discuss the use of herbicides to control invasive plant species as well as the potential effects of this herbicide use on fish and aquatic species.

Operations and Maintenance Impacts

The direct and indirect effects on fish and aquatic invertebrate resources (e.g., mortality and/or injury, disturbance, habitat loss and/or modification, invasive species) that would occur during the operations and maintenance phase of the Project would generally result from the presence of permanent Project structures, the presence of maintenance personnel and equipment in the area, and vegetation reclamation and maintenance activities that would be conducted. However, the magnitude of these effects would generally be less than what was described above for construction related impacts due to the periodic nature of the require maintenance and reclamation work (see Section 2.1.5 for a detailed description of the estimated operations and maintenance schedule).

During the operations and maintenance phase, the use of both access roads and the ROW for repair and maintenance activities could result in both direct and indirect impacts. In addition, the maintenance activity of ROW clearing in forested riparian areas could result in both direct and indirect impacts to habitat for fish and aquatic invertebrate species. The potential application of herbicides during operation of the Project could result in indirect impacts, and to a lesser extent, direct impacts. Both general EPMs and those specific to fish and aquatic resources as listed in Section 3.20.2.7.1, would be implemented to avoid or minimize impacts to fish and aquatic resources during the operations and maintenance phase of the Project. The subsection "Construction Impacts" above discusses sedimentation and vegetation clearing impacts and the EPMs that would be implemented to avoid or minimize impacts to fish and aquatic resources during the operations and maintenance phase of the Project.

Decommissioning Impacts

Decommissioning of the Project would involve methods similar to those that would be required to construct the Project. As a result, the impacts of decommissioning would be similar to those previously described for construction. The Applicant would follow the same general and resource-specific EPMs during decommissioning that would be implemented during construction. In addition, the Applicant would develop a Decommissioning Plan prior to any decommissioning actions for review and approval by the appropriate state and federal agencies.

Although decommissioning would have short-term adverse impacts to fish and aquatic invertebrate species (similar to what was discussed for construction related impacts), it is assumed that decommissioning of the Project would have long-term beneficial impacts to fish and aquatic invertebrate species and their habitats because it would remove the Project and its related impacts from the environment. However, areas disturbed by the decommissioning activities would still take time to recover from this disturbance (with disturbances in grasslands and croplands recovering within 5 years or less, and recovery in forests taking many decades).

3.20.2.7.2.1 Converter Stations and AC Interconnection Siting Areas

3.20.2.7.2.1.1 Construction Impacts

Construction impacts from the Oklahoma and Tennessee Converter Stations and associated AC Interconnection Siting Area and Tie should be minimal since no major waterbodies or streams are present within the footprint of these areas; however, there are multiple issues that could be a potential concern due to construction activities. If the converter station or AC interconnection siting area is upslope of any waterbodies, there is a potential for runoff to enter the waterway. There is a potential for weeds to spread due to vehicle usage, which could also impact waterbodies. The use of herbicides or an oil spill in areas upslope of a waterbody has the potential to enter the waterway, causing potential impacts to fish and aquatic invertebrate species (see Section 3.20.2.7.2 for a detailed discussion of potential impacts).

3.20.2.7.2.1.1.1 Oklahoma Converter Station Siting Area and AC Interconnection Siting Area

The Oklahoma Converter Station and AC Interconnection Siting Areas are located within Region 1, within the Coldwater watershed. As discussed in Sections 3.10 and 3.17, grasslands and croplands are the dominant habitat types found at these siting areas. As described in Section 3.15, no perennial streams and no major waterbodies are located within the Oklahoma Converter Station Siting Area. Coldwater Creek, a perennial stream, is within 1 mile of the Oklahoma Converter Station Siting Area. Two significant roadways are between the Oklahoma Converter Station Siting Area and Coldwater Creek. Increased sedimentation is not likely to affect Coldwater Creek due to distance and intervening infrastructure; however, if construction occurs near established intermittent waterways, there is the potential for sediment to travel downstream and cause potential impacts to fish and aquatic invertebrate species.

3.20.2.7.2.1.1.2 Tennessee Converter Station Siting Area and AC Interconnection Tie

The Tennessee Converter Station Siting Area is located within Region 7, with the AC Interconnection Tie contained entirely within the Tennessee converter station and the Shelby substation footprints. As discussed in Sections 3.10 and 3.17, croplands and pasture/hay lands are the dominant habitat types found at these siting areas. However, hardwood forests and riparian areas are also present within the ROI for the Tennessee Converter Station Siting Area. As described in Section 3.15, limited surface water features consisting of only a few drainage features, including only 0.21 mile of perennial streams, 1.5 miles of intermittent streams, and no major waterbodies are present within the Tennessee Converter Station Siting Area. Although not within the Tennessee Converter Station Siting Area, Big Creek, a perennial stream, listed as impaired in 2010 for aquatic resources (fish, shellfish, and wildlife values) borders the area.

The Tennessee converter station would be located immediately adjacent to the existing Shelby substation. Approximately 74 acres would be required for the Tennessee converter station (including access road) during construction; it is anticipated that any temporary construction areas would be contained within the footprint of the Tennessee converter station and the Shelby substation. The area contains a variety of habitats that include deciduous forest, pasture/hay, cultivated crops, and woody wetlands. Impacts to aquatic resources would likely be less if the converter station was located away from Big Creek within the croplands and pasture/hay lands, and would be greater if it was located near Big Creek in forested areas (due to the effects of long-term habitat loss from vegetation clearing; the extensive time necessary for forests to regenerate to pre-disturbance conditions and provide sediment retention, shade, and cover; and the impacts associated with edge effects in forested habitats that do not provide sedimentation retention, shade, and cover).

3.20.2.7.2.1.2 Operations and Maintenance Impacts

Potential impacts in the operations and maintenance phase of the Oklahoma and Tennessee converter stations and associated AC interconnection and tie would not substantially differ from the general discussion of operations and maintenance related to the Project, provided in Section 3.20.2.7.2. During the operations and maintenance phase, the use of both access roads and the ROW for repair and maintenance activities could result in both direct and indirect impacts.

3.20.2.7.2.1.2.1 Oklahoma Converter Station Siting Area and AC Interconnection Siting Area

Operation and maintenance activities would not result in long-term impacts to the habitats around the converter station and associated AC Interconnection siting area because no major waterbodies or perennial streams are within the siting area, and downslope streams are approximately one mile away.

3.20.2.7.2.1.2.2 Tennessee Converter Station Siting Area and AC Interconnection Tie

The operations and maintenance activities would result in permanent alteration of terrestrial habitat, but impacts to the aquatic environment could occur. The extent of impacts would depend on the location of the structures, roads, and clearing areas within the siting area. A perennial stream flows adjacent and downslope along the western side of the siting area. Placement of roads and structures that could result in increased sedimentation from operation and maintenance activities could result in long-term direct and indirect impacts to fish and aquatic invertebrate species or their habitat.

3.20.2.7.2.1.3 Decommissioning Impacts

The decommissioning of both converter stations and the AC interconnections would result in short-term impacts, especially in the form of increased sedimentation during structure and road removal, and surface re-contouring activities. Long-term impacts would benefit fish or aquatic invertebrate species and their habitat, by removing effects from operation and maintenance activities, as well as removal of road and cleared areas that impact hydrology and sedimentation. The Applicant would develop a Decommissioning Plan prior to the start of decommissioning that would be submitted for review and approval by the appropriate federal and state resources agencies.

3.20.2.7.2.2 AC Collection System

A detailed description of the AC collection system is provided in Section 2.1.2.3. Impacts for fish and aquatic invertebrate resources were evaluated for the 2-mile-wide ROI of the AC collection system routes. The 2-mile-wide ROI of the AC collection system routes was used to assess potential occurrences of fish and aquatic invertebrate species to evaluate potential downstream impacts from Project activities thoroughly and adequately. Considering the mobility of fish species with the potential to occur within the AC collection system routes, the 2-mile-wide ROI is extensive enough to account for the various ranges of fish species, including the unique and varied habitat that each species potentially occupies as well as the potential downstream transport of sediment and hazardous materials.

3.20.2.7.2.2.1 Construction Impacts

For the AC collection system routes, as stated in Section 3.20.2.7.1, the Applicant would implement EPMs to avoid or minimize effects to waterbodies, and therefore fish and other aquatic species, to the extent practicable. Table 3.20.2-2 details the miles of perennial and intermittent streams, major waterbodies, and the acres of reservoirs, lakes, and ponds found within the 2-mile-wide corridors in each of the AC collection system routes. Table 3.20.2-3 identifies the major waterbodies and associated fish species that may be encountered by each route.

Table 3.20.2-2:
Water Features Potentially Impacted within the 2-Mile-Wide Corridors of the AC Collection System Routes

AC Route Designation	Perennial Streams (miles)	Intermittent Streams (miles)	Major Waterbodies (miles)	Reservoirs, Lakes, and Ponds (acres)	Impacts to Fish that would be unique to this Route
E-1	9.17	100.18	0	33.83	Along with E-2, E-3, SE-1, and SE-3, crosses Palo Duro Creek, which is considered to have impaired dissolved oxygen for fish and wildlife propagation/warm water aquatic community
E-2	13.47	100.05	0.07	148.99	Along with E-1, E-3, SE-1, and SE-3, crosses Palo Duro Creek, which is considered to have impaired dissolved oxygen for fish and wildlife propagation/Warm water aquatic community
E-3	10.06	137.62	0.01	36.71	Along with E-1, E-2, SE-1, and SE-3, crosses Palo Duro Creek, which is considered to have impaired dissolved oxygen for fish and wildlife propagation/Warm water aquatic community
NE-1	24.11	32.97	0.12	141.04	Crosses Beaver River (North Canadian), OK, which is considered to have impaired dissolved oxygen for fish and wildlife propagation/Warm water aquatic community
NE-2	7.75	78.31	0.10	70.77	Crosses Beaver River (North Canadian), OK, which is considered to have impaired dissolved oxygen for fish and wildlife propagation/Warm water aquatic community
NW-1	13.05	110.93	0.09	167.26	Crosses Beaver River (North Canadian) and Coldwater (Frisco) Creek. Beaver Creek is considered to have impaired dissolved oxygen for fish and wildlife propagation/warm water aquatic community
NW-2	31.13	77.72	0.18	119.20	Crosses Beaver River (North Canadian), Goff Creek, and Coldwater (Frisco) Creek. Beaver Creek is considered to have impaired dissolved oxygen for fish and wildlife propagation/warm water aquatic community
SE-1	21.52	75.70	0.04	677.83	Along with E-1, E-2, E-3, and SE-1, crosses Palo Duro Creek, which is considered to have impaired dissolved oxygen for fish and wildlife propagation/warm water aquatic community
SE-2	0.80	26.67	0	97.95	No significant difference between this route and the other routes in regards to the types of fisheries impacts that would likely occur as a result of the route's location and position.
SE-3	14.47	98.54	0.07	768.03	Along with E-1, E-2, E-3, and SE-1, crosses Palo Duro Creek, which is considered to have impaired dissolved oxygen for fish and wildlife propagation/warm water aquatic community. Wolf Creek is crossed by the 2-mile corridor for this route and is designated as an "ecologically unique river or stream segment" and identifies as a reference stream for development of a regionalized index of biotic integrity for Texas and exhibiting high water quality and diverse benthic macroinvertebrate and fish communities
SW-1	0.97	58.06	0	14.24	No significant difference between this route and the other routes in regards to the types of fisheries impacts that would likely occur as a result of the routes' location and position.

Table 3.20.2-2:
Water Features Potentially Impacted within the 2-Mile-Wide Corridors of the AC Collection System Routes

AC Route Designation	Perennial Streams (miles)	Intermittent Streams (miles)	Major Waterbodies (miles)	Reservoirs, Lakes, and Ponds (acres)	Impacts to Fish that would be unique to this Route
SW-2	7.98	125.14	0.08	57.42	Crosses Coldwater (Frisco) Creek.
W-1	6.16	45.09	0.08	9.27	Crosses Coldwater (Frisco) Creek.

GIS Data Source: USGS (2014a)

3.20.2.7.2.2.2 Operations and Maintenance Impacts

During the operations and maintenance phase for the AC collection system, potential impacts to fish and aquatic resources could occur. Potential impacts in the operations and maintenance phase would not substantially differ from the general discussion of operations and maintenance related to the Project in general in Section 3.20.2.7.2. During the operations and maintenance phase, the use of both access roads and the ROW for repair and maintenance activities could result in both direct and indirect impacts to fish and aquatic invertebrate species and their habitats.

Because the area is dominated by grasslands and croplands land cover types, shade impacts from vegetation clearing would likely be minimal; however, maintenance activities involving brush removal and road maintenance could impact streams through increases in sedimentation. The final placement of road-crossing and structures would dictate the level of potential effects operations and maintenance activities may have; highest impacts would be likely to occur where activities are adjacent to fish-bearing streams.

As discussed in Section 3.20.2.7.2.2.1, AC Collection System Route SE-3 includes a portion of Wolf Creek, which is state-designated as a Texas high quality water/exceptional aquatic life/high aesthetic value water. If an access road is required to cross Wolf Creek, additional requirements would be necessary to ensure no adverse impacts occurred while maintaining the access road during operations and maintenance.

3.20.2.7.2.2.3 Decommissioning Impacts

Potential short-term impacts in the decommissioning of the AC transmission lines would not substantially differ from the general discussion of decommissioning related to the Project, provided in Section 3.20.2.7.2. Long-term impacts would benefit fish or aquatic invertebrate species and their habitat by removing effects from operation and maintenance activities, as well as removal of road and cleared areas that impact hydrology and sedimentation. The Applicant would develop a Decommissioning Plan prior to the start of decommissioning that would be submitted for review and approval by the appropriate federal and state resources agencies.

During the decommissioning phase of the Project, all general EPMs and those specific to fish and aquatic resources that were implemented during the construction phase of the Project would continue to be enforced to avoid or minimize impacts to fish and aquatic resources (see Section 3.20.2.7.1 for relevant EPMs).

3.20.2.7.2.3 HVDC Applicant Proposed Route

3.20.2.7.2.3.1 Construction Impacts

The Applicant Proposed Route is described in Sections 2.1.2.2 and 2.4.2. The Applicant Proposed Route would pass through a variety of habitat types, ranging from grassland and croplands habitats to forested and riparian areas (Table 3.20.2-4). The Applicant Proposed Route within Regions 1, 2, and 6 would cross predominantly through grassland and croplands habitats. Forested and riparian habitats become more prevalent within Regions 4 and 5 (as well as within Region 3 and 7 to a lesser extent). Impacts for fish and aquatic invertebrate resources were evaluated within the ROI of the Applicant Proposed Route (1,000-foot-wide corridor). Impacts in Regions 4, 5, and, to a lesser extent, 3 and 7, associated with water temperature and sedimentation would be greater because they include forests and riparian areas with vegetation that would be cleared (Table 3.20.2-4). When considering numbers of stream crossings, stream sensitivity, or potential in-water works areas, Region 3 may have greater impacts than Regions 4 and 5 due to the miles and acres of waterbodies present.

Section 3.15 provides more details associated with perennial and intermittent streams located within the ROI that may necessitate temporary or permanent access stream crossings. Higher numbers of stream crossings increases the potential for sediment or contaminants to be introduced into waterbodies, resulting in potential impacts to aquatic areas where fish and other aquatic species may be present. In addition, Section 3.15 provides more details on the number and miles of special interest surface waters (e.g., National Wild and Scenic Rivers System, Nationwide Rivers Inventory, Oklahoma Outstanding Resource Waters, Oklahoma High Quality Waters, Oklahoma Waters of Recreational and/or Ecological Significance, Oklahoma Scenic River Areas, Arkansas Ecologically Sensitive Waters, Arkansas) that would be crossed or potentially impacted. Special interest surface waters have a high potential to provide aquatic habitat for fish and other aquatic species. These details (i.e., perennial and intermittent streams and special interest surface water) from Section 3.15 were used to develop Table 3.20.2-4 and in assessing and comparing potential impacts to fish and aquatic resources in each region and between the Applicant Proposed Project and DOE Alternatives.

As noted above, several route variations to the Applicant Proposed Route in Regions 2–7 were developed in response to public comments on the Draft EIS; they are described in detail within Appendix M and summarized in Sections 2.4.2.1–2.4.2.7. Because these route variations cross through similar types of habitats compared to the original Applicant Proposed Route, impacts from most of these route variations on fish and aquatic resources would be similar compared to what would occur as a result of the original Applicant Proposed Route. However, a few of the route variations could result in more long-term impacts to habitats given the extent of aquatic habitats or other sensitive areas that would be impacted:

- The following route variations would result in a larger area of impact to wetland habitats (see Section 3.17), thereby potentially resulting in a larger extent of long-term impacts to fish and aquatic resources and their habitats: Link 1, Variation 2, for Region 3; Link 2, Variation 1, for Region 6; and Link 1, Variation 2, for Region 7.
- The following route variations would result in a significant decrease in acreage of impact to wetland habitats compared to the original Applicant Proposed Route (see Section 3.17), thereby potentially resulting in fewer long-term impacts to fish and aquatic resources and their habitats: Link 3, Variation 1, for Region 4; Link 3, Variation 2, for Region 4; Link 1, Variation 2, for Region 5; and Link 1, Variation 2, for Region 7.
- The following route variations would potentially cross more waterbodies, thereby resulting in greater impacts to fish and aquatic resources and their habitats: Link 1, Variation 2, in Region 3 and Link 7, Variation 1, in Region 5.
- The following route variations would potentially cross fewer waterbodies, thereby resulting in fewer impacts to fish and aquatic resources and their habitats: Links 1 and 2, Variation 1, in Region 3; Link 9, Variation 1, in Region 4; Link 1, Variation 2, in Region 5; and Link 1, Variation 2, in Region 7.
- Link 3, Variation 2, in Region 4 would parallel almost four times the length of existing infrastructure compared to the original Applicant Proposed Route, thereby reducing the impacts to areas that have not already been impacted by existing infrastructure, and would cross through areas that contain fewer wetland and waterbody features compared to the original Applicant Proposed Route.

Table 3.20.2-4:
Water Features Potentially Impacted within the ROI for the Applicant Proposed Route

Region	Perennial Streams (miles)	Intermittent Streams (miles)	Major Water Bodies (miles)	Reservoirs, Lakes, Ponds (acres)	Predominant Land Cover	Surface Water Features of Special Interest Crossed
1	5.4	29.3	0.01	49.0	Grassland/herbaceous and croplands	Crosses the Beaver River and multiple tributaries
2	7.3	19.1	0.01	13.6	Grassland/herbaceous and croplands	The route crosses the Cimarron River in an area which is designated as critical habitat by USFWS and the state of Oklahoma. Also is adjacent to the North Canadian River, OK
3	55.3	36.8	0.15	214.8	Grasslands, deciduous forest, and pasture/hay	Crosses the Cimarron River, OK, and tributaries; Deep Fork, Arkansas River, OK; Lake Carl Blackwell, OK;, Eufaula Lake, OK; and Greenleaf Lake, OK
4	18.8	41.9	0.49	93.7	Pasture/hay, deciduous forest, and evergreen forest	Crosses Arkansas River, OK; Lower Illinois River, OK; Sallisaw Creek, OK; Little Lee Creek, OK; Lee Creek, OK; Briar Creek, OK; Lee Creek Reservoir, OK; source-water protection area in Robert S. Kerr Reservoir Watershed, OK; Mulberry River, AR; source-water protection area in Frog-Mulberry watershed, AR; Big Piney Creek, AR; source-water protection area in Dardanelle reservoir watershed, AR
5	11.7	46.6	0.23	70.7	Deciduous forest, pasture/hay, and evergreen forest	Illinois Bayou, AR; source-water protection area in Cadron watershed, AR; Cadron Creek, AR; source-water protection area in Little Red watershed, AR; Little Red River, AR; White River, AR
6	12.5	13.4	0.06	28.6	Croplands	Crosses Cache River and forested wetland areas include Bayou DeView, Caney Creek, L'Anguille River, and Ditches No. 10, 123, and 61, AR; and lower 10 miles of Straight Slough is designated as an Ecologically Sensitive Waterbody. AR
7	4.3	18.3	0.62	21.5	Croplands and deciduous forest	St. Francis River, AR; Mississippi River, TN

3.20.2.7.2.3.2 Operations and Maintenance Impacts

During the operations and maintenance phase for the Applicant Proposed Route, potential impacts to fish and aquatic resources could occur. Potential impacts in the operations and maintenance phase would not substantially differ from the general discussion of operations and maintenance related to the Project, provided in Section 3.20.2.7.2. The use of both access roads and the ROW for repair and maintenance activities could result in both direct and indirect impacts. In addition, the maintenance of ROW clearing in forested riparian areas could result in both direct and indirect impacts to habitat for fish and aquatic invertebrate species. The potential application of herbicides during operation of the Project could result in indirect impacts, and to a lesser extent, direct impacts. During the operations and maintenance phase of the Project, both general EPMs and those specific to fish and aquatic resources, would be implemented to avoid or minimize impacts to fish and aquatic resources. General EPMs for the Project that relate to fish and aquatic resources are defined in Section 3.20.2.7.1.

3.20.2.7.2.3.3 Decommissioning Impacts

Impacts related to the decommissioning of the HVDC portion of the Project would not substantially differ from the general discussion of decommissioning related to the Project in general (see Section 3.20.2.7.2). The short-term impacts during decommissioning of the Applicant Proposed Route would be similar to the impacts that would occur during the construction phase. Structure removal, road decommissioning, and removal of road crossings is likely to have potential impacts to fish and aquatic resources due to increased sedimentation from runoff of disturbed areas and direct impact of removal of in-stream crossing structures. The Applicant would follow the same general and resource-specific EPMs during decommissioning that would be implemented during construction. In addition, the Applicant would develop a Decommissioning Plan prior to any decommissioning actions for review and approval by the appropriate state and federal agencies.

Long-term impacts of Project decommissioning would benefit fish and aquatic invertebrate species due to removal of impacts from Project components, such as roads and road maintenance activities, as well as allowing the vegetation in any cleared ROW areas to regrow.

3.20.2.7.3 Impacts Associated with the DOE Alternatives

This section identifies the potential direct and indirect impacts on fish, aquatic invertebrates, and aquatic habitat related to the DOE Alternatives.

3.20.2.7.3.1 Arkansas Converter Station Alternative Siting Area and AC Interconnection Siting Area

A detailed description of the Arkansas converter station and other terminal facilities is provided in Section 2.4.3.1. Impacts for fish and aquatic invertebrate resources were evaluated for the representative footprints of the converter station and the associated AC interconnection siting areas, as well as the designated ROI for fish and aquatic species.

3.20.2.7.3.1.1 Construction Impacts

The siting area for the Arkansas converter station and AC interconnection has been reduced since the Draft EIS, but still contains drainage features, including no perennial streams, 0.63 mile of intermittent streams, no major waterbodies, and 2.6 acres of reservoirs, lakes, and ponds. Although the siting area for the Arkansas converter station is different than that considered for the previously discussed Oklahoma and Tennessee converter stations, the ultimate footprint of the Arkansas station, if constructed, would be similar to the other stations. In addition, a new substation would be constructed that would interconnect the AC transmission line to an existing 500kV transmission line. This substation will be located near an existing transmission line in an area that is primarily grassland with some forest land. As indicated previously, the Applicant would avoid surface waters to the extent practicable for construction of the station and substation. The construction of the Arkansas converter station and AC interconnection, as well as the substation, would not likely result in any direct impacts to fish and aquatic invertebrate species or their habitat because no major waterbodies are located within the Arkansas Converter Station Alternative and AC Interconnection Siting Areas, as well as the substation. Indirect construction impacts from the Arkansas Converter Station Alternative and AC Interconnection, as well as the substation, should be minimal since no major waterbodies or perennial streams are present within the footprint of these areas; however, if either siting area is upslope of any waterbodies, there is a potential for runoff to enter the waterway. In addition, the use of herbicides or an oil spill in these areas upslope of a waterbody has the potential to enter the waterway, causing potential indirect impacts to fish and aquatic invertebrate species. To avoid overspray or drift, the Applicant would apply herbicides according to label instructions and any federal, state, and local regulations as described under EPM GE-5. To minimize the potential for direct discharge of fuels or hazardous materials into waterbodies, the Applicant would restrict refueling and maintenance of vehicles and the storage of fuels and hazardous chemicals within at least 100 feet from wetlands, surface waterbodies, and groundwater wells, or as otherwise required by federal, state, or local regulations as described under EPM GE-14.

3.20.2.7.3.1.2 Operations and Maintenance Impacts

The operations and maintenance of the Arkansas converter station and AC interconnection, as well as the substation, would not likely result in any direct impacts to fish and aquatic invertebrate species or their habitat because no major waterbodies are located within the footprint of the construction area, or within the interconnection area. During the operations and maintenance phase, if either siting area is upslope of any waterbodies, there is a potential for runoff to enter the waterway. In addition, the use of herbicides or an oil spill in these areas upslope of a waterbody has the potential to enter the waterway, causing potential indirect impacts to fish and aquatic invertebrate species. To avoid overspray or drift, the Applicant would apply herbicides according to label instructions and any federal, state, and local regulations as described under EPM GE-5. To minimize the potential for direct discharge of fuels or hazardous materials into waterbodies, the Applicant would restrict refueling and maintenance of vehicles and the storage of fuels and hazardous chemicals within at least 100 feet from wetlands, surface waterbodies, and groundwater wells, or as otherwise required by federal, state, or local regulations as described under EPM GE-14.

3.20.2.7.3.1.3 Decommissioning Impacts

The impacts during decommissioning of the Arkansas converter station and AC transmission line, as well as the substation, would be similar to the impacts occurring during the construction phase. Decommissioning would not likely result in any direct impacts to fish and aquatic invertebrate species or their habitat because no major waterbodies are located within the footprint of the construction area, or along the interconnection area. The Applicant would develop a Decommissioning Plan prior to the start of decommissioning that would be submitted for review and approval by the appropriate federal and state resources agencies.

3.20.2.7.3.2 HVDC Alternative Routes

Descriptions of the HVDC alternative routes are provided in Section 2.4.3.2. The impacts that could occur to fish and aquatic invertebrate species from construction and operation of the HVDC Applicant Proposed Route are discussed in Section 3.20.2.7.2.3. The expected types of impacts from construction and operation of the HVDC alternative routes in each region would be similar to those for the Applicant Proposed Route. However, because of differences in routing (i.e., location) the potential for impacts may be different (e.g., the route may be closer to or farther from an important stream or river crossing). The discussion in this section focuses on the differential impacts that could occur under each of the HVDC alternative routes compared to the Applicant Proposed Route. Data used in the impacts comparison comes from Section 3.15 and the Surface Water Technical Report (Clean Line 2013b).

3.20.2.7.3.2.1 Construction Impacts

This section describes construction impacts associated with the 1,000-foot-wide ROI of the HVDC alternative routes. Data used in the impacts comparison come from Section 3.15 and the Surface Water Technical Report (Clean Line 2013b). Surface water features are described within a 1,000-foot-wide corridor of the Applicant Proposed Route. The 1,000-foot-wide corridor is a conservative assessment based on potential impacts to surface water from access roads, which would likely extend beyond the ROW (Clean Line 2013b). Analyses are presented for the ROI in Regions 1 through 7. During the construction phase of the Project, the Applicant would implement the EPMs described in Section 3.20.2.7.1 to avoid or minimize impacts to fish and aquatic resources. Table 3.20.2-5 provides a comparison of water body crossings and stream lengths between the HVDC alternative routes and the corresponding links of the Applicant Proposed Route Section 3.15.5 provides for the values of stream lengths crossed by region.

As described in Appendix M, route adjustments were developed for HVDC Alternative Route 3-A, Alternative Route 5-B, Alternative Route 5-E, and Alternative Route 6-A to maintain an end-to-end route with the proposed variations to the Applicant Proposed Route. These route adjustments would cross through similar types of wetlands and habitats compared to the original HVDC alternative routes. HVDC Alternative Routes 5-E and 6-A potentially have a reduction in the number of floodplains from two to one for each route, potentially resulting in fewer impacts to fish and aquatic resources.

3.20.2.7.3.2.2 Operations and Maintenance Impacts

Direct and indirect impacts for the HVDC alternative routes would differ, depending on final location of road crossings, access roads and other ground-disturbing activities and extent of riparian clearing. Alternatives requiring maintenance riparian clearing adjacent to or crossing fish-bearing or perennial streams near fish-bearing streams are likely to have greater impacts than clearing further away from these waters. In addition, HVDC alternative routes with greater lengths of perennial and significant waterbodies within the ROW are likely to have more road-crossings once road and ROW locations have been identified. Alternatives with road locations near streams and at high grades would have greater impacts than those with roads further away and at lower grades due to increased risk of increased runoff and sediment inputs into nearby streams.

During the operations and maintenance phase of the Project, the Applicant would implement the applicable EPMs described in Section 3.20.2.7.1 to avoid or minimize impacts to fish and aquatic resources.

3.20.2.7.3.2.3 Decommissioning Impacts

Decommissioning impacts for the HVDC transmission line would be similar to general decommissioning impacts (see Section 3.20.2.7.2). Removal of infrastructure; including roads, structures, and road crossings, is likely to result in some short-term impacts due to increased sedimentation as a result of ground-disturbance. As is discussed in the general Project decommissioning impacts, long-term benefits such as allowing the vegetation to return to the ROW, removal of road and facility maintenance actions and risks, and removal of road crossings would have an overall benefit to the aquatic community relative to the Project during the operations and maintenance phase.

Table 3.20.2-5:
Summary Information related to Fish Resources for the HVDC Alternative Routes

Region	HVDC Alternative Route	Total Length of Route (miles)	Predominant Land Cover	Differences in Significant Water Body Crossings Between Alternatives and Proposed	Relative Comparison of Streamlengths within the Proposed and Alternative Routes
1	1-A	123	Grassland/ herbaceous	This alternative compares to the Applicant Proposed Route Links 2, 3, 4, and 5. Similar impacts to Applicant Proposed Route; however, includes Sand Creek (listed for DO impairment for Fish and Wildlife/Warm Water Aquatic Community), and does not include Clear Creek nor Otter Creek (both listed for Fish and Wildlife/Warm Water Aquatic Community—Benthic macroinvertebrate bioassessment). This alternative would not cross the impaired section Beaver River (North Canadian), OK—listed for lead impairments for fish consumption.	HVDC Alternative Route 1-A has the highest mileage of intermittent streams, but the lowest mileage of perennial streams compared to the other HVDC route alternatives and the Applicant Proposed Route. The corresponding links of the Applicant Proposed Route have a higher value for perennial streams and reservoirs, lakes, and ponds, but a lower value for intermittent streams and major waterbodies.
	1-B	52	Grassland/herb aceous	This alternative compares to the Applicant Proposed Route Links 2 and 3. Similar impacts to Applicant Proposed Route; however, does not include Clear Creek nor Otter Creek (both listed for Fish and Wildlife/Warm Water Aquatic Community—Benthic macroinvertebrate bioassessment), nor Beaver River (North Canadian), OK—listed for lead impairments for fish consumption.	HVDC Alternative Route 1-B has the lowest acreage of reservoirs, lakes, and ponds compared to the other HVDC route alternatives and the Applicant Proposed Route. The corresponding links of the Applicant Proposed Route have a higher value for intermittent streams, but a lower value for perennial streams, major waterbodies, and reservoirs, lakes, and ponds.
	1-C	52	Grassland/ herbaceous	This alternative compares to the Applicant Proposed Route Links 2 and 3. Similar impacts to Applicant Proposed Route; however, does not include Clear Creek nor Otter Creek (both listed for Fish and Wildlife/Warm Water Aquatic Community—Benthic macroinvertebrate bioassessment), nor Beaver River (North Canadian), OK—listed for lead impairments for fish consumption.	The corresponding links of the Applicant Proposed Route have a higher value for intermittent streams and major waterbodies, but a lower value for perennial streams and reservoirs, lakes, and ponds.
	1-D	33.5	Grassland/herb aceous	This alternative compares to the Applicant Proposed Route Links 3 and 4. Similar impacts to Applicant Proposed Route; however, does not include Otter Creek (listed for Fish and Wildlife/Warm Water Aquatic Community—Benthic macroinvertebrate bioassessment), nor Beaver River (North Canadian), OK—listed for lead impairments for fish consumption. Unlike the Applicant Proposed Route and other corresponding Alternatives, 1-D would not cross the impaired section of Palo Duro Creek, OK.	HVDC Alternative Route 1-D has the lowest mileage of intermittent streams compared to the other HVDC route alternatives and the Applicant Proposed Route. The corresponding links of the Applicant Proposed Route have a higher value for perennial streams, intermittent streams, and reservoirs, lakes, and ponds. Mileage of major waterbodies is equal for both the Applicant Proposed Route and HVDC Alternative Route 1-D.

Table 3.20.2-5:
Summary Information related to Fish Resources for the HVDC Alternative Routes

Region	HVDC Alternative Route	Total Length of Route (miles)	Predominant Land Cover	Differences in Significant Water Body Crossings Between Alternatives and Proposed	Relative Comparison of Streamlengths within the Proposed and Alternative Routes
2	2-A	57	Grassland/ herbaceous	This alternative compares to the Applicant Proposed Route Link 2. Alternative crosses additional impaired water bodies under the Fish and Wildlife Propagation/Warm Water Aquatic Community: Main Creek, OK; Griever Creek, OK; and Cottonwood Creek, OK. Unlike the Applicant Proposed Route, this Alternative would not cross the impaired sections of Buffalo Creek, OK (listed for Fish and Wildlife Propagation/Warm Water Aquatic Community—dissolved oxygen impairment), nor the impaired section of the Cimarron River, OK (Fish and Wildlife Propagation/Warm Water Aquatic Community—selenium impairment; Agriculture—sulfates, total dissolved solids, and chloride impairments).	HVDC Alternative Route 2-A has the highest mileage and acreage for perennial streams, major waterbodies, and reservoirs, lakes, and ponds compared to the other Region 2 alternatives and the Applicant Proposed Route, but the lowest mileage of intermittent streams. The corresponding links of the Applicant Proposed Route have a higher value for intermittent streams, but a lower value for perennial streams, major waterbodies, and reservoirs, lakes, and ponds. HVDC Alternative Route 2-A includes a portion of the Cimarron River, designated as critical habitat by the USFWS and the state of Oklahoma. If an access road were to be required within an area designated as critical habitat, the effects of such access road would be the subject of a consultation with USFWS pursuant to Section 7 of the ESA.
	2-B	30	Croplands	This alternative compares to the Applicant Proposed Route Link 3. Similar impacts to the Applicant Proposed Route; however, would not cross impaired section of Cimarron River, OK (Fish and Wildlife Propagation/Warm Water Aquatic Community—selenium impairment; Agriculture—sulfates, total dissolved solids, and chloride impairments).	The corresponding links of the Applicant Proposed Route have a higher value for intermittent streams, but a lower value for perennial streams and reservoirs, lakes, and ponds. Mileage of major waterbodies is equal for both the Applicant Proposed Route and Alternative Route 2-B. Unlike the Applicant Proposed Route and Alternative 2-A, this Alternative would not cross designated critical habitat on the Cimarron River.
3	3-A	38	Grassland/ herbaceous and deciduous forest	This alternative compares to the Applicant Proposed Route Link 1. Unlike the Applicant Proposed Route, this Alternative would not cross Cushing Lake, OK (Surface Water of Special Interest), nor would it cross the following impaired waterbody sections listed for Fish and wildlife impairments Skeleton Creek, Sillwater Creek. This Alternative crosses an additional Surface Water of Special Interest: Lake Carl Blackwell, OK.	The corresponding links of the Applicant Proposed Route has a higher value for intermittent streams and major waterbodies, but a lower value for perennial streams and reservoirs, lakes, and ponds. This Alternative has the highest mileage for perennial streams of any Alternative, but lowest mileage of intermittent streams (same value as 3-B).
	3-B	48	Grassland/ herbaceous and deciduous forest	This alternative compares to the Applicant Proposed Route Links 1, 2, and 3. Unlike the Applicant Proposed Route, this alternative would not cross Cushing Lake, OK (Surface Water of Special Interest), nor would it cross the following impaired waterbody sections listed for Fish and wildlife impairments: Skeleton Creek. This Alternative crosses an additional Surface Water of Special Interest: Lake Carl Blackwell, OK.	HVDC Alternative Route 3-B has the second highest mileage and acreage for perennial streams, and highest mileage for reservoirs, lakes, and ponds compared to the other Region 3 alternatives and the Applicant Proposed Route, but the lowest mileage for intermittent streams (same as 3-A) and major waterbodies. The corresponding links of the Applicant Proposed Route has a higher value for intermittent streams and major waterbodies, but a lower value for perennial streams and reservoirs, lakes, and ponds.

Table 3.20.2-5:
Summary Information related to Fish Resources for the HVDC Alternative Routes

Region	HVDC Alternative Route	Total Length of Route (miles)	Predominant Land Cover	Differences in Significant Water Body Crossings Between Alternatives and Proposed	Relative Comparison of Streamlengths within the Proposed and Alternative Routes
	3-C	122	Grassland/ herbaceous deciduous forest and pasture/hay	This Alternative compares to the Applicant Proposed Route Links 3, 4, 5, and 6. This Alternative would not cross the following impaired waterbody sections listed for Fish and wildlife impairments: Skeleton Creek, OK; Stillwater Creek, OK. This Alternative would cross the following additional stream sections listed fish and wildlife impairments: Butler Creek, OK; Dirty Creek, OK	HVDC Alternative Route 3-C has the highest mileage for intermittent streams compared to the other Region 3 alternative routes and the Applicant Proposed Route, but the lowest acreage of reservoirs, lakes, and ponds. The corresponding links of the Applicant Proposed Route has a higher value for perennial streams, major waterbodies, and reservoirs, lakes, and ponds, but a lower value for intermittent streams.
	3-D	39	Primarily pasture/hay and deciduous forest and grassland/ herbaceous	This Alternative compares to the Applicant Proposed Route Links 5 and 6. Unlike the Applicant Proposed Route, this Alternative would not cross Cushing Lake, OK (Surface Water of Special Interest). This Alternative would not cross the following impaired waterbody sections listed for Fish and wildlife impairments: Skeleton Creek, OK; Stillwater Creek, OK. This Alternative would cross the following additional stream sections listed fish and wildlife impairments: Butler Creek, OK; Dirty Creek, OK.	The corresponding links of the Applicant Proposed Route has a higher value for perennial streams and major waterbodies, but a lower value for intermittent streams and reservoirs, lakes, and ponds.
	3-E	8.5	Pasture/hay and deciduous forest	This Alternative compares to the Applicant Proposed Route Link 6. Unlike the Applicant Proposed Route, this Alternative would not cross Cushing Lake, OK (Surface Water of Special Interest). This Alternative would not cross Skeleton Creek, OK; listed for fish and wildlife impairments. This Alternative would cross the following additional stream sections listed fish and wildlife impairments: Dirty Creek, OK.	HVDC Alternative Route 3-E has the highest mileage of waterbodies compared to the other Region 3 alternatives and the similar mileage as the Applicant Proposed Route. The corresponding links of the Applicant Proposed Route has a lower value for perennial streams, intermittent streams, and reservoirs, lakes, and ponds. Mileage of major waterbodies is equal for both the Applicant Proposed Route and Alternative Route 3-E.
4	4-A	58	Deciduous forest and pasture/hay	This Alternative compares to the Applicant Proposed Route Links 3, 4, 5, and 6. Additional Surface Waters of Special Interest are crossed: Bushy Creek, OK; Webbers Creek, OK; and two additional source-water protection area crossings in the Frog-Mulberry watershed. It does not cross Briar Creek, OK or Lee Creek Reservoir, OK.	HVDC Alternative Route 4-A has the lowest total mileage of waterbodies compared to the other Region 4 alternatives and the Applicant Proposed Route. The corresponding links of the Applicant Proposed Route have a higher value for perennial streams, intermittent streams, major waterbodies, and reservoirs, lakes, and ponds.

Table 3.20.2-5:
Summary Information related to Fish Resources for the HVDC Alternative Routes

Region	HVDC Alternative Route	Total Length of Route (miles)	Predominant Land Cover	Differences in Significant Water Body Crossings Between Alternatives and Proposed	Relative Comparison of Streamlengths within the Proposed and Alternative Routes
	4-B	79	Deciduous forest and pasture/hay	This alternative compares to the Applicant Proposed Route Links 2–8. Additional Surface Waters of Special Interest are crossed: Bushy Creek, OK; and two additional source-water protection area crossings in the Frog-Mulberry watershed. It does not cross Briar Creek, OK; Lee Creek Reservoir, OK; or the source-water protection area crossing in the Robert S. Kerr Reservoir watershed.	HVDC Alternative Route 4-B has the lowest mileage and acreage of perennial streams and reservoirs, lakes, and ponds compared to the other Region 4 alternatives and the Applicant Proposed Route, but the highest mileage of intermittent streams. The corresponding links of the Applicant Proposed Route have a higher value for perennial streams, major waterbodies, and reservoirs, lakes, and ponds, but a lower value for intermittent streams.
	4-C	3	Deciduous forest and pasture/hay	This alternative compares to the Applicant Proposed Route Link 5. This alternative does not vary significantly in Surface Waters of Special Interest Crossed (does not crossing the source-water protection area crossing in the Robert S. Kerr watershed).	HVDC Alternative Route 4-C has the highest mileage of perennial streams and waterbodies compared to the other Region 4 alternatives and the Applicant Proposed Route. The corresponding links of the Applicant Proposed Route have a higher value for intermittent streams, but a lower value for perennial streams and reservoirs, lakes, and ponds. Mileage of major waterbodies is equal for both the Applicant Proposed Route and HVDC Alternative Route 4-C.
	4-D	25	Pasture/hay and deciduous forest	This alternative compares to the Applicant Proposed Route Link 4. This alternative does not vary significantly in Surface Waters of Special Interest Crossed; however it does have two additional crossings in the source-water protection area for the Frog-Mulberry watershed.	HVDC Alternative Route 4-D has the second-lowest mileage of perennial streams, but second highest mileage for reservoirs, lakes, and ponds, compared to the other Region 4 alternatives and the Applicant Proposed Route. The corresponding links of the Applicant Proposed Route has a higher value for perennial streams and major waterbodies, but a lower value for intermittent streams and reservoirs, lakes, and ponds.
	4-E	37	Pasture and evergreen forest	This alternative compares to the Applicant Proposed Route Links 8 and 9. This alternative has one additional crossing of a Surface water of special interest: a crossing of a source-water protection area intake stream in the Dardanelle Reservoir watershed.	HVDC Alternative Route 4-E has the lowest mileage of intermittent streams compared to the other Region 4 alternatives and the Applicant Proposed Route, but it the highest acreage of reservoirs, lakes, and ponds. The corresponding links of the Applicant Proposed Route have a higher value for perennial streams, intermittent streams, and major waterbodies, but a lower value for reservoirs, lakes, and ponds.
5	5-A	13	Evergreen forest and deciduous forest	This alternative compares to the Applicant Proposed Route Link 1. No significant difference in significant surface water crossings.	HVDC Alternative Route 5-A has the lowest mileage of waterbodies (along with HVDC Alternative Route 5-E) compared to the other Region 5 alternatives and the Applicant Proposed Route. The corresponding links of the Applicant Proposed Route have a higher value for perennial streams, major waterbodies, and reservoirs, lakes, and streams, but a lower value for intermittent streams.

Table 3.20.2-5:
Summary Information related to Fish Resources for the HVDC Alternative Routes

Region	HVDC Alternative Route	Total Length of Route (miles)	Predominant Land Cover	Differences in Significant Water Body Crossings Between Alternatives and Proposed	Relative Comparison of Streamlengths within the Proposed and Alternative Routes
	5-B	71	Pasture/hay and deciduous forest	This alternative compares to the Applicant Proposed Route Links 3, 4, 5, and 6. Additional crossings: East Fork Cadron Creek, AR; Cypress Creek, AR (fisheries impaired for copper and zinc), and West Fork Point Remove Creek, AR (Turbidity impairment).	HVDC Alternative Route 5-B has the highest mileage of perennial streams and intermittent streams compared to the other Region 5 alternatives and the Applicant Proposed Route. The corresponding links of the Applicant Proposed Route have a lower value for perennial streams, intermittent streams, major waterbodies, and reservoirs, lakes, and ponds.
	5-C	9	Deciduous forest) and pasture/hay	This alternative compares to the Applicant Proposed Route Links 6 and 7. No additional crossings of water bodies of special interest.	HVDC Alternative Route 5-C has the lowest mileage of perennial streams and intermittent streams compared to the other Region 5 alternatives and the Applicant Proposed Route, but the highest mileage of major waterbodies. The corresponding links of the Applicant Proposed Route have a higher value for perennial streams and intermittent streams, but a lower value for major waterbodies and reservoirs, lakes, and ponds.
	5-D	22	Deciduous forest and croplands	This alternative compares to the Applicant Proposed Route Link 9. Additional crossings: Departee Creek, AR.	HVDC Alternative Route 5-D has the highest acreage of reservoirs, lakes, and ponds compared to the other Region 5 alternatives and the Applicant Proposed Route. The corresponding links of the Applicant Proposed Route have a lower value for perennial streams, intermittent streams, major waterbodies, and reservoirs, lakes, and ponds.
	5-E	36	Pasture/hay and deciduous forest	This alternative compares to the Applicant Proposed Route Links 4, 5, and 6. Additional crossing: East Fork Cadron Creek, AR.	HVDC Alternative Route 5-E has the lowest mileage of major waterbodies (along with 5-A) and the lowest acreage of reservoirs, ponds, and lakes compared to the other Region 5 alternatives and the Applicant Proposed Route. The corresponding links of the Applicant Proposed Route have a higher value for major waterbodies and reservoirs, lakes, and ponds, but a lower value for perennial streams and intermittent streams.
	5-F	22	Pasture/hay and deciduous forest	This alternative compares to the Applicant Proposed Route Links 5 and 6. Additional crossings: East Fork Cadron Creek, AR.	The corresponding links of the Applicant Proposed Route have a higher value for major waterbodies and reservoirs, lakes, and ponds, but a lower value for perennial streams and intermittent streams.
6	6-A	16	Croplands	This alternative compares to the Applicant Proposed Route Links 2, 3, and 4. No significant difference from the Applicant Proposed Route.	HVDC Alternative Route 6-A has the lowest acreage of reservoirs, lakes, and ponds compared to the other Region 6 alternatives and the Applicant Proposed Route. The corresponding links of the Applicant Proposed Route have a higher value for perennial streams, intermittent streams, major waterbodies, and reservoirs, lakes, and ponds.

Table 3.20.2-5:
Summary Information related to Fish Resources for the HVDC Alternative Routes

Region	HVDC Alternative Route	Total Length of Route (miles)	Predominant Land Cover	Differences in Significant Water Body Crossings Between Alternatives and Proposed	Relative Comparison of Streamlengths within the Proposed and Alternative Routes
	6-B	14	Croplands and woody wetlands	This alternative compares to the Applicant Proposed Route Link 3. No significant difference from the Applicant Proposed Route.	HVDC Alternative Route 6-B has the highest acreage of reservoirs, lakes, and ponds compared to the other Region 6 alternatives and the Applicant Proposed Route. The corresponding links of the Applicant Proposed Route have a higher value for perennial streams and major waterbodies, but a lower value for intermittent streams and reservoirs, lakes, and ponds.
	6-C	23	Croplands	This alternative compares to the Applicant Proposed Route Links 6 and 7. This alternative would not cross the L'Anguille River, AR, which is listed on the National Park Service Nationwide Rivers Inventory.	HVDC Alternative Route 6-C has the lowest mileage of perennial streams, intermittent streams, and major waterbodies compared to the other Region 6 alternatives and the Applicant Proposed Route. The corresponding links of the Applicant Proposed Route have a higher value for perennial streams, intermittent streams, and major waterbodies, but a lower value for reservoirs, lakes, and ponds.
	6-D	9	Croplands	This alternative compares to the Applicant Proposed Route Link 7. No significant difference between from the Applicant Proposed Route.	HVDC Alternative Route 6-D has the highest mileage of perennial streams and intermittent streams compared to the other Region 6 alternatives and the Applicant Proposed Route. The corresponding links of the Applicant Proposed Route have a higher value for major waterbodies, but a lower value for perennial streams and intermittent streams. Acreage of reservoirs, lakes, and ponds is equal for both the Applicant Proposed Route and HVDC Alternative Route 6-D.
7	7-A	43	Croplands and woody wetlands	This alternative compares to the Applicant Proposed Route Link 1. No significant difference from the Applicant Proposed Route.	HVDC Alternative Route 7-A has the highest values for all of these areas compared to the other Region 7 alternatives and the Applicant Proposed Route. The corresponding links of the Applicant Proposed Route have a lower value for perennial streams, intermittent streams, major waterbodies, and reservoirs, lakes, and ponds.
	7-B	9	Croplands, deciduous forest, and pasture/hay and shrub/scrub	This alternative compares to the Applicant Proposed Route Links 3 and 4. No significant difference from the Applicant Proposed Route.	HVDC Alternative Route 7-B has the lowest mileage of perennial streams and intermittent streams compared to the other Region 7 alternatives and the Applicant Proposed Route. The corresponding links of the Applicant Proposed Route have a higher value for perennial streams, intermittent streams, and reservoirs, lakes, and ponds. Mileage of major waterbodies is equal for both the Applicant Proposed Route and HVDC Alternative Route 7-B.

Table 3.20.2-5:
Summary Information related to Fish Resources for the HVDC Alternative Routes

Region	HVDC Alternative Route	Total Length of Route (miles)	Predominant Land Cover	Differences in Significant Water Body Crossings Between Alternatives and Proposed	Relative Comparison of Streamlengths within the Proposed and Alternative Routes
	7-C	24	Croplands, pasture/hay, and deciduous forest	This alternative compares to the Applicant Proposed Route Links 3, 4, and 5. No significant difference from the Applicant Proposed Route.	HVDC Alternative Route 7-C has the lowest acreage of reservoirs, lakes, and ponds compared to the other Region 7 alternatives and the Applicant Proposed Route. The corresponding links of the Applicant Proposed Route have a higher value for perennial streams, and reservoirs, lakes, and ponds, but a lower value for intermittent streams. Mileage of major waterbodies is equal for both the Applicant Proposed Route and HVDC Alternative Route 7-C.
	7-D		Croplands, pasture/hay, and shrub/scrub	This alternative compares to the Applicant Proposed Route Links and 5. No significant difference from the Applicant Proposed Route.	The corresponding links of the Applicant Proposed Route have a higher value for intermittent streams and reservoirs, lakes, and ponds, but a lower value for perennial streams. Mileage of major waterbodies is equal for both the Applicant Proposed Route and HVDC Alternative Route 7-D.

3.20.2.7.4 Best Management Practices

The Applicant has developed a list of EPMs intended to avoid or minimize impacts to fish or aquatic invertebrate species. A complete list of EPMs for the Project is provided in Appendix F; those EPMs that would specifically minimize the potential for impacts to fish or aquatic invertebrates are summarized in Section 3.20.2.7.1. In addition to these EPMs, DOE has identified a BMP that would expand EPM FVW-2 to include the following:

- The Applicant will identify, control, and minimize the spread of non-native, invasive species and noxious weeds to the extent practicable, including ensuring that in-water equipment and vehicles are cleaned between waterbodies to minimize the chance of transferring non-native species between waterbodies.

This BMP would be warranted because without proper implementation of EPM FVM-2, the spread of non-native, invasive species (e.g., zebra mussels) could cause adverse impacts through competition with native species for limited resources. The spread of non-native plants could cause habitat alteration if native plants are outcompeted; many of which are necessary to native aquatic fish and aquatic invertebrates. If in-water equipment and vehicles are not cleaned between use if different waterbodies, and non-native species are transferred between waterbodies, native species could be outcompeted for resources or lose habitat critical to their survival, and potentially be eliminated from a waterbody.

3.20.2.7.5 Unavoidable Adverse Impacts

The Applicant would implement EPMs to avoid or minimize impacts; however, some adverse impacts would occur even with the implementation of the measures. Unavoidable impacts include the potential loss or alteration of aquatic habitat in smaller streams that may require culverts or vehicle crossings, potential loss or disturbance to riparian vegetation along streams on private or public lands where the ROW is adjacent to the stream, and potential short-term sedimentation effects on aquatic resources as a result of vehicular traffic causing disturbances within or adjacent to streams. Although these impacts have the potential to occur, the likelihood of occurrence would be limited through implementation of the EPMs.

3.20.2.7.6 Irreversible and Irretrievable Commitment of Resources

The potential long-term loss or alteration of aquatic habitat in smaller streams that may require road crossings would last throughout the life of the Project, or at least through the duration of use of the access roads; however, gradual recovery of habitat may occur once the road crossing was removed and the stream restored to original conditions. There is the potential that the loss or alternative of aquatic habitat could be permanent because the exact state of recovery is not known (e.g., substantial changes related to climate, land-use, and/or watershed hydrology may occur during the 80 year lifespan of the Project), and aquatic habitat is subject to long-term climatic regimes and changes in land-use and watershed hydrology. Therefore, it is reasonable to assume that some portions of the aquatic habitat for fish and aquatic invertebrate species in these smaller streams would be irreversibly and irretrievably impacted.

3.20.2.7.7 Relationship between Local Short-term Uses and Long-term Productivity

The Project would result in a short-term disturbance to aquatic resources; however, these impacts should not affect the long-term productivity of populations of fish and other aquatic species. The short-term impact of introducing non-native invasive species would be negligible; however, over time, long-term productivity would be affected and species could be eliminated from their native habitat.

3.20.2.7.8 Impacts from Connected Actions

3.20.2.7.8.1 Wind Energy Generation

A wind farm has multiple possible components: wind turbine generators, underground collection cables, substations, generation tie lines, operations and maintenance buildings, meteorological towers, new permanent access roads, and temporary workspaces. The new access roads potentially cross streams, drainages, or waterways. Wind farm construction could require stormwater controls such as ditches, which could alter natural drainage patterns (Clean Line 2014). New culverts may be installed across small streams or natural drainages (Clean Line 2014). Construction of the access roads may also require the removal of vegetative cover, which could impact aquatic species and their habitats. The WDZs contains multiple perennial waterbodies in Oklahoma and Texas. Important recreational fish species and aquatic invertebrates potentially occur within the WDZs.

Impacts to aquatic resources could occur from construction activities including vegetation clearing, grading, construction and use of access roads, herbicide use, and fuel and lubricant handling. Potential impacts can be classified into three categories: mortality/injury, sensory disturbance, and habitat loss/modification. Impacts would be similar to general impacts from construction described above in Section 3.20.2.7.2.

3.20.2.7.8.2 Optima Substation

As there are no waterbodies within the location for the future Optima Substation, there would be no impacts to fish and aquatic invertebrate species.

3.20.2.7.8.3 TVA Upgrades

Potential impacts of concern to fish and aquatic invertebrate species from the required TVA upgrades, like the Project, could include mortality of individuals, sensory disturbance, and aquatic habitat disturbance or modification by construction or operations and maintenance activities associated with the new transmission line. Generally, the construction or operations and maintenance of the new 500kV transmission line, would have impacts similar to the Project, although on a smaller scale. These impacts may include mechanical damage and/or removal of vegetation by heavy machinery, potential introduction of invasive species from construction equipment or spread of existing invasive species, alteration of hydrology during road construction, which could affect fish and aquatic invertebrate species habitat, sedimentation from grading, access roads, and stream crossings, and contamination from herbicide drift or runoff or from accidental spills of fuels or lubricants that could cause mortality or injury of fish and aquatic invertebrate species. These potential impacts would be short term except for habitat loss at sites used for access (i.e., roads and stream crossings) and fish and aquatic invertebrate species mortality.

The required TVA upgrades to existing facilities (including existing transmission lines and existing substations) would require fewer construction activities to complete than the new 500kV transmission line. Existing TVA facilities already experience operations and maintenance activities. As a result, potential impacts would be expected to be less substantial in areas affected by upgrades to existing TVA facilities than in areas where the new 500kV transmission line would be constructed.

TVA would consider potential impacts to fish and aquatic invertebrate species and their habitats during the siting of the new 500kV transmission line and while planning the upgrades to existing transmission facilities. TVA would avoid impacts to these species and their habitats to the extent practicable.

3.20.2.7.9 Impacts Associated with the No Action Alternative

Under the No Action Alternative, DOE assumes for analytical purposes that the Project would not be constructed. Impacts to fish and aquatic invertebrate species and their habitats would be consistent with current levels of disturbance related to natural conditions in the environment, such as annual changes in stream flow, erosion, and wildfires. No disturbances would occur due to the Project, including disturbances in waterbodies that could affect fish and aquatic invertebrate species and their habitats. No disturbances related to construction vehicles, equipment, or access roads would affect aquatic resources. No impacts related to the Project would occur related to the removal of vegetation or the use of herbicides.

4. Cumulative Impacts

Cumulative impacts result from the "incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (federal or non-federal) or person undertakes such other actions"; they can result from "individually minor but collectively significant actions taking place over a period of time" (40 CFR 1508.7). This chapter describes the identification of past, present, and reasonably foreseeable future actions and provides an evaluation of potential cumulative impacts. Because of the nature of the past, present, and reasonably foreseeable future actions identified, available quantitative data on their potential environmental impacts are limited and, as a result, primarily qualitative evaluations of potential cumulative impacts are presented in this chapter.

Section 4.1 provides broad criteria for identifying actions that could cause cumulative impacts when combined with those of the Project. Section 4.2 presents specific criteria used to identify projects of potential interest, which are then presented by the regions used to define and evaluate the Project in Chapter 3. Section 4.3 presents cumulative impacts, and an overview of the methodology for evaluating cumulative impacts is presented in Section 4.3.1. Sections 4.3.2 through 4.3.20 provide the cumulative impacts for each of the environmental resource areas evaluated in Chapter 3. Numbering of the resource area evaluations (Sections 4.3.2 through 4.3.20) corresponds with numbering of resource area evaluations in Chapter 3 (Sections 3.2 through 3.20) for ease of reference.

4.1 Physical and Temporal Boundaries of Cumulative Impacts

The potential for cumulative impacts depends on both spatial and temporal factors within the environment, which can vary among resource areas. For example, the geographical ROI for cumulative impacts could be limited to the area of disturbance for soil resources but include all vantage points for visual resources. The geographic ROI for cumulative impacts includes the locations in which direct and indirect impacts of the Project would occur on all resource areas; i.e., the locations of the ROIs described for each resource area in Chapter 3. The topic of cumulative impact ROIs and how they might compare with the Project ROIs is addressed further in Section 4.1.1.1. Because the Project ROIs vary by resource area and because the ROI for cumulative impacts can be more extensive than for just the Project, a conservatively large geographic area was evaluated using professional judgment when attempting to identify the past, present, and reasonably foreseeable future actions for the cumulative impacts evaluation.

The temporal boundaries of cumulative impacts are generally defined by the Project's construction phase and operations and maintenance phase (i.e., about 36 to 42 months for construction and an expected 80 years, or more, for operations and maintenance), which could begin as early as 2016. Past, present, and reasonably foreseeable future actions with elements coinciding or overlapping with that timeframe, as well as satisfying spatial criteria, would frame the actions with potential to have cumulative impacts with the Project. For most resource areas, the potential impacts evaluated in Chapter 3 are dominated by those that might occur during the Project's construction. If past, present, and reasonably foreseeable future actions are of a similar nature, with impacts occurring primarily during construction, then the temporal boundaries of primary interest for an applicable resource area generally would be when construction periods coincide or overlap. This approach requires flexibility because reasonably foreseeable future actions are often not associated with firm schedules. Even in the case of the Project, starting construction as early as 2016 is only an estimate. As a result, evaluations in this chapter make the reasonably conservative assumption that other actions could possibly coincide or overlap with those of the Project unless there is information to the contrary.

4.1.1 Overview of Project and Connected Actions

As described in Chapter 2, the Applicant Proposed Project would include an overhead ±600kV HVDC electric transmission system and associated facilities. This transmission system would have the capacity to deliver approximately 3,500–4,000 MW, primarily from renewable energy generation facilities in the Oklahoma and Texas Panhandle regions, to load-serving entities in the Mid-South and Southeast United States. This would require an interconnection with TVA in Tennessee and potentially include an interconnection with the Midcontinent Independent System Operator in Arkansas.

If the decision is made to construct the Applicant Proposed Project and DOE elects to continue its participation, DOE Alternatives include an Arkansas converter station and alternative route segments for the HVDC transmission line. This chapter uses "the Project" to refer to elements of the Applicant Proposed Project and/or DOE Alternatives when differentiation between the two is not necessary and recognizing that what would be built could be a combination of project elements.

Connected actions to the Applicant Proposed Project have been identified, as described in Section 2.5, and potential impacts related to these actions are addressed by each resource area in Chapter 3. One of these connected actions includes the construction and operation of reasonably foreseeable future wind energy generation facilities that would interconnect with the Applicant Proposed Project. These wind power facilities are anticipated to be located in parts of the Oklahoma Panhandle and Texas Panhandle within approximately 40 miles of the western converter station in Texas County, Oklahoma. Clean Line anticipates that electricity generated by these facilities would constitute the majority of the transmission capacity of the transmission line. Neither Clean Line nor DOE knows the exact location of wind projects that would be connected to the Project. Further, it is foreseeable that wind power would also be developed in areas not currently under analysis in this EIS. As a result, in an attempt to provide meaningful impacts analysis of wind energy generation that would connect to the Project, Chapter 3 includes a high-level analysis of impacts from wind energy generation within an area of approximately 40 mile radius surrounding the Oklahoma Converter Station Siting Area. Within this radius, wind development would be expected to occur in Oklahoma (Beaver, Cimarron, and Texas counties) and Texas (Hansford, Ochiltree, and Sherman counties).

In addition to the wind energy generation facilities, other connected actions involve facility additions and upgrades to third-party systems that would be required to accommodate the Project. As discussed in Section 2.5.2, TVA would need to make substation and transmission line upgrades to accommodate interconnection of the Project to the TVA transmission system in Tennessee. The eastern portion of the Project would interconnect to the existing substation operated by TVA in Shelby County, Tennessee. TVA would make the necessary upgrades to its system, which would include construction of approximately 37 miles of new 500kV transmission line in western Tennessee and upgrades to approximately 350 miles of existing transmission lines, mostly in central and western Tennessee, along with modifications to several substations. These upgrades are evaluated as connected actions in this EIS and the results are also presented in Chapter 3. In addition, a future substation, tentatively named Optima, would be needed at the western end of the HVDC transmission line and would be located within a few miles of the Oklahoma converter station and partially within the Oklahoma AC Interconnection Siting Area. Construction and operation of the future Optima substation is also evaluated as a connected action in this EIS with the results presented in Chapter 3.

4.1.1.1 Region of Influence

DOE used resource-specific ROI boundaries throughout this EIS (Section 3.1). For example, the ROI for the examination of air quality and climate change impacts (Section 3.3) of the Project goes beyond the Project boundaries to encompass residential areas and schools. DOE also used a resource-based ROI to consider the cumulative effects of the Project combined with other projects.

For this reason the ROI for cumulative impacts is generally defined by the same overall ROI as described in Section 3.1 for the Project. Since the intent of defining an ROI is to bound the geographic area that potentially could be impacted, any impacts of the Project outside of a resource-specific ROI would be expected to be minimal, with negligible cumulative impacts with other actions. There are exceptions or instances where an ROI considered for cumulative impacts could be larger than that for the Project, but the ROIs described in Section 3.1 for both the Applicant Proposed Project and the DOE Alternatives provide a baseline starting point.

Several of the resource sections of Chapter 3 include modifications to the ROI described in Section 3.1. The following statements describe instances where the resource-specific ROI varies from the description of the ROI in section 3.1. If the ROI for a resource is not included below, its ROI is the same as described in Section 3.1.

Air Quality and Climate Change. As identified in Section 3.3.3, the ROI for air quality impacts is conservatively estimated at approximately 300–500 feet from the principal construction activities that would be occurring within the baseline ROIs (Applicant Proposed Project or DOE Alternatives) identified in Section 3.1. This includes areas and populations sensitive to air emissions such as residential areas and higher populations of children or elderly. It is also noted that cumulative impacts of air pollutants can extend over a much wider area than the ROI mentioned in Section 3.1. For example, air pollutants can travel relatively large distances, and when the quantities are relatively large, measurable impacts can be identified several states away or even intercontinentally. However, for emissions on the scale of the Project and the previously identified present and reasonably foreseeable future actions, the evaluation of cumulative impacts for air quality planning is typically evaluated on the scale of air quality control regions (AQCRs), which are on the scale of one or more counties, or portions of counties. For GHGs, as noted in Section 3.3.3, the impacts are on a global scale.

Electrical Environment. As presented in Section 3.4.8, the electrical environment ROI considered in this document is a total of 300 feet on either side of centerline for the HVDC transmission lines (Applicant Proposed Route and HVDC alternative routes) and AC collection system routes. As described in Section 3.4.11, electrical effects associated with AC converter stations can be reduced or eliminated by the use of various equipment and construction methods, so they were not evaluated separately from the overhead transmission lines that enter and exit the stations.

Environmental Justice. As described in Section 3.5.3, the ROI for identifying low-income and minority populations consists of the Census Blocks or Census Block Groups within or intersected by the baseline ROIs (Applicant Proposed Project or DOE Alternatives) identified in Section 3.1.

Geology, Paleontology, Minerals, and Soils. For the evaluation of geology, paleontology, and minerals, Section 3.6.1.3 adds area to the baseline ROI identified in Section 3.1. Specifically, an additional 1,500-foot buffer was added to both sides of the 1,000-foot-wide Applicant Proposed Route or HVDC alternative routes creating a 4,000-foot-wide corridor for identifying oil and gas wells and mines and a 1,500-foot buffer was added on the

Oklahoma, Tennessee, and Arkansas Converter Station Siting Areas for potential expansion of oil, gas, and mineral extraction operations. The baseline ROI elements in Section 3.1 were used for the evaluation of soils.

Groundwater. For the purpose of identifying water wells, area was added to the baseline ROIs as described in Section 3.7.3.1 to account for possible effects of blasting should it be required during construction. Specifically, the groundwater ROI includes expanding the outer bounds of the Oklahoma, Tennessee, and Arkansas converter station siting areas by 150 feet on all sides, and expanding the 1,000-foot-wide corridors of the Applicant Proposed Route and the HVDC alternative routes by 150 feet on both sides to create 1,300-foot-wide corridors.

Historic and Cultural Resources. The ROI for the evaluation of historic and cultural resources contains the same baseline elements described in Section 3.1, but for evaluating potential visual effects to historic and cultural resources, Section 3.9.3 expands the HVDC and AC transmission line routes to a 1-mile-wide corridor (i.e., a 0.5-mile zone on either side of the proposed centerline) and for converter station locations, extends the ROI outward 0.5 mile from the site.

Socioeconomics. The ROI for socioeconomics, as presented in Section 3.13.3, encompasses 33 counties in the four states where the Project components (AC converter stations, HVDC transmission lines, and the AC collection system) would be located. Twenty-nine of the 33 counties are crossed by the HVDC transmission line routes; the other four counties are only crossed by one or more of the AC collection system routes. In some cases, particularly where larger communities are located in adjacent or nearby counties, impacts would also likely occur outside the 33 counties due to the availability of services, housing, and workers. To address such instances, an additional or secondary ROI is considered in the socioeconomic impact analysis that includes portions of counties where no components of the Project would be located. This additional area consists of six MSAs that are either partially included in or adjacent to the primary ROI. The potentially affected MSAs are (1) Oklahoma City MSA for Region 3, (2) Tulsa MSA for Region 3, (3) Fort Smith MSA for Region 4, (4) Little Rock-North Little Rock-Conway MSA for Region 5, (5) Jonesboro MSA for Region 6, and (6) Memphis MSA for Region 7.

Special Status Wildlife and Fish Species. For special status wildlife species, Section 3.14.1.3 adds the following to the baseline ROI elements described in Section 3.1:

- Lesser prairie-chicken—A 3-mile-wide addition from each edge of the 1,000-foot-wide corridor of the Applicant Proposed Route, HVDC alternative routes, and AC collection system when they coincide with the estimated occupied range of the LEPC or known occurrences of LEPC leks.
- Whooping crane—A 15-mile-wide buffer addition from each edge of the 1,000-foot-wide corridor of the Applicant Proposed Route and the HVDC alternative routes when they are within the mapped whooping crane 95 percent migration corridor.
- Protected bat species—A 1.5-mile-wide addition from each edge of the 1,000-foot-wide corridor of the Applicant Proposed Route and the HVDC alternative routes in proximity of known occurrences of bat species designated as candidate, threatened, or endangered under the ESA.
- Interior least tern—A 5-mile-wide addition from each edge of the 1,000-foot-wide corridor of the Applicant Proposed Route and the HVDC alternative routes in proximity of known occurrences of interior least tern nesting sites.

For special status fish, aquatic invertebrate, and amphibian species, Section 3.14.2.3 adds the following to the baseline ROI elements described in Section 3.1:

- A 3-mile buffer (1.5 miles upstream and 1.5 miles downstream) is added to the 1,000-foot-wide ROI of the Applicant Proposed Route and HVDC alternative routes along waterbodies that have known occurrences of candidate, threatened, or endangered species under the ESA.

Transportation. The description of the transportation ROI (Section 3.16.3.1) incorporates the baseline ROI elements described in Section 3.1, then makes modifications as follows:

- Roadway transportation resources—A 6-mile buffer is added to each side of the centerlines of the Applicant Proposed Route, HVDC alternative routes, and the AC collection system routes.
- Railroads—Identified based on the potential encroachment within the above expanded ROI.
- Airports and airstrips—Identified based on a 4-mile-wide corridor from the HVDC transmission line and AC collection system route centerlines.

Visual Resources. As described in Section 3.18.3, the ROI for visual resources includes the baseline ROI elements described in Section 3.1, but expands the corridors associated with the transmission line routes (i.e., the Applicant Proposed Route, AC collection system routes, and HVDC alternative routes) to 6 miles, 3 miles on either side of the referenced centerline. The ROI for visual resources also includes a 3 mile buffer from the boundary of the converter stations and interconnection siting areas.

The preceding discussion is focused on the ROIs considered in the Project's affected environment and impacts discussions of Sections 3.2 through 3.20, but cumulative impacts may encompass greater areas in some instances, based on professional judgment. Air quality and surface water are examples of resource areas that could have very large ROIs for cumulative impacts when consideration is given to the distances that pollutants may travel and comingle with those from other sources. But these are also resource areas for which the Plains & Eastern Project would be expected to have only minor, if any, impacts, and these impacts would be associated primarily with construction. These are also examples in which professional judgement had a primary role in determining the size of the ROI to consider for cumulative impacts.

4.2 Past, Present, and Reasonably Foreseeable Future Actions

Past actions are those actions that occurred within the geographic ROI of cumulative impacts and have shaped the current environmental conditions in the Project regions. For the purposes of this EIS, actions that have occurred in the past and their impacts are now part of the existing environment and are included in the affected environment described in Chapter 3. As such, they are included in the cumulative impact analysis. Past actions are identified in this chapter only if it appears they may have occurred after the timeframe captured in the Chapter 3 description of the affected environment.

The following sections summarize the present and reasonably foreseeable future actions that have been identified, which may possibly contribute to cumulative impacts. Present actions include those that are currently under construction and may impact any of the same resources as the Project and that would occur in the same space and time as identified by the Project. To avoid speculating about other future actions, reasonably foreseeable future actions for this evaluation are those that are actively proposed or planned and would occur in the same space and time as identified by the Project. Actions of possible interest were first identified by looking at a broad range of actions that are occurring or might reasonably occur in the same general area as components of the Project. Counties where components of the Project would be located, as well as adjacent counties, were often used to define the general area of review. Sources used to identify possible actions included the following:

- An action was identified during the public outreach or scoping process for this EIS or during preliminary public outreach efforts by the Applicant. Other projects in a position to attract public attention or publicity (i.e., high-profile) in the local region, such as relatively large bridge, highway, or oil and gas pipeline projects, also were considered.
- An action was identified by federal or state agencies or by county planning offices during the EIS scoping process.
- A permit application for an action has been submitted to an appropriate permitting agency such as a state or local air quality agency.
- State, federal, county, or local agencies or commercial entities have publically announced an action is moving forward into more detailed planning or design (this could include the preparation of environmental review documentation).

Considering the list of actions obtained from the above sources, DOE then screened the actions based on when they could possibly occur and whether they would be located where they could impact any of the same resources as the Project. The present and reasonably foreseeable future actions identified by region in the sections below were those that passed this screening. Actions identified through public outreach or scoping or based on their high-profile nature (the first bullet above) may be addressed even if they are outside the Project ROI. Many of the actions identified in this section consist of state-planned road work. For purposes of this evaluation, it is assumed that, unless identified otherwise, the state road projects in Oklahoma, Arkansas, and Tennessee, are maintenance or rehabilitation activities performed on existing roads and structures within existing ROWs and, accordingly, do not involve areas of new land use. The information available for these projects is often limited, consisting of little more than maps of planned work areas. However, the assumption is based on what would be expected from most road projects (more maintenance than new construction), titles of projects where available (e.g., pavement rehabilitation or widen and resurface), and maps showing work locations coinciding with existing roadways. Also, reviewed maps consistently have a unique designation for locations of new road construction.

The present and reasonably foreseeable future actions are identified and described by Project region (i.e., Regions 1 through 7). The locations of these actions are provided in Figure 4.2-1 (located in Appendix A). Section 4.3 provides the cumulative impacts information for each of the environmental resource areas evaluated in Chapter 3. Cumulative impacts analysis must be conducted within the context of the resource areas. The Council on Environmental Quality (CEQ) guidance regarding the consideration of cumulative effects states: “The magnitude and extent of the effect on a resource depends on whether the cumulative effects exceed the capacity of the resource to sustain itself and remain productive” (CEQ 1997). For each resource area, the section provides a summary of the cumulative impacts that could occur from the Project and present and reasonably foreseeable future actions. The individual resource area discussions include identification of the Project region where cumulative impacts would be greatest for that resource.

Tables 4.2-1a and 4.2-1b provide a summary listing of the present and reasonably foreseeable future actions described in more detail below and the resource areas for which cumulative impacts might be expected. The actions are identified by region. Table 4.2-1a presents the first 10 resource areas and Table 4.2-1b presents the remaining nine. In the instances where a resource area does not contain a check (is blank) for a specific action, no cumulative impact is expected to occur.

The discussion of present and reasonably foreseeable future actions that follows includes identification of several proposed pipeline projects; however, it does not specifically identify all potential actions associated with the expanding natural gas industry, which is described in Section 3.6.1, for portions of Oklahoma and Arkansas (particularly Regions 4 and 5). Because of the ongoing expansion of the industry, DOE expects that present and future actions in areas affected by the Plains & Eastern Project, will include activities such as natural gas exploration, including drilling, and well construction and that the number of wells identified in Section 3.6.1 will increase. The impacts from the Plains & Eastern Project on those expanding operations is expected to be similar to those described in Section 3.6.1.

4.2.1 Region 1—Present and Reasonably Foreseeable Future Actions

Region 1 is referred to as the Oklahoma Panhandle Region and includes the Applicant Proposed Route and HVDC Alternative Routes 1-A through 1-D, as well as the Oklahoma converter station and its associated AC interconnection. The AC collection system routes are also at the western end of Region 1. The region includes Texas, Beaver, Harper, and Woodward counties in Oklahoma; and Hansford, Ochiltree, and Sherman counties in Texas. The area is primarily rural; small towns are scattered throughout the region. The wind energy generation projects that would be connected to the Project via the AC collection system routes are analyzed as connected actions in each of the resource area discussions in Chapter 3 and, as a result, are not identified here as present and reasonably foreseeable future actions.

Oklahoma Gas and Electric—OG&E has two actions in Region 1 that could have cumulative impacts with the Project, and which are summarized as follows:

- *Hitchland-Woodward 345kV Transmission Line.* OG&E recently constructed about 100 miles of new 345kV transmission line from its Woodward District Extra High Voltage Substation, located south of Woodward, Oklahoma, north and west through the Oklahoma Panhandle to a Southwestern Public Service interconnection point at the Beaver-Texas County line. The 200-foot-wide ROW corridor has steel monopole structures with a typical height of up to 170 feet and 1,200-foot spans between structures (OG&E 2014a). The transmission line, put into service on May 1, 2014 (Xcel Energy 2014), runs the same path as the Applicant Proposed Route through Beaver County, then at a point about 2 miles east of the Beaver-Harper County line, veers to the southeast, away from the Applicant Proposed Route and toward the Woodward Substation. The impacts associated with the Hitchland-Woodward 345kV transmission line would be similar in nature to those impacts from the Project, but on a smaller scale, being restricted to a much shorter length of transmission line.
- *Beaver County Substation.* The OG&E Beaver County Substation is the western connecting point for the Hitchland-Woodward transmission line described above and was put into service on May 1, 2014, along with the transmission line (Xcel 2014). It is at the western edge of Beaver County and, like the transmission line in this area, is located within the ROI for the Applicant Proposed Route. The substation was proposed as a new 345kV terminal for interconnecting with a non-specific wind generating facility within OG&E's service territory (SPP 2013). The route for an interconnecting wind farm has not been proposed, but impacts of wind farm construction would be consistent with those already addressed in this document (Chapter 3) as a connected action.

Because the above transmission line and substation were completed prior to the initiation of the Project, the construction activities would not contribute to cumulative impacts, and any impacts have been captured in all areas of Chapter 3's characterization of the affected environment. In this evaluation of cumulative impacts, construction of these projects is considered to be a precursor to the Project, but their continued presence, operation, and maintenance are considered.

Oklahoma Department of Transportation—OKDOT is planning or has implemented several actions within the vicinity of Region 1 and the AC collection system. OKDOT actions that could have cumulative impacts with the Project are summarized as follows:

- *Hackberry Creek Bridge.* A new replacement bridge is proposed to be constructed over Hackberry Creek in Texas County, Oklahoma. The total length of the project is 0.25 miles, including the bridge and approaches. The OKDOT put out a bid request in September 2013. The proposed work involves concrete work, paving, saw cut, and excavation (Oklahoma Bid Network 2013). The activity is located on county road NS-107, 3.2 miles south of State Highway 3 and about 2.8 miles north of Link 2 of the Applicant Proposed Route. The location also lies between HVDC Alternative Routes 1-A/1-C, about 2.7 miles to the north, and HVDC Alternative Route 1-B, about 0.6 mile to the south.
- *OKDOT (8-Year) FFY-2014 through FFY-2021 Construction Work Plan.* The latest OKDOT 8-Year Construction Work Plan (OKDOT 2013a) was reviewed for possible road and bridge work in the Region 1 vicinity. According to the Work Plan, projects identified for completion in the first three years of the plan (i.e., federal fiscal year [FFY] 2014 through 2016) should be considered firm, or locked-in, with changes being made only through a formal program revision process; projects in the fourth year have low flexibility and are being prioritized and evaluated for transition into the "locked-in" group; and those in the last four planning years have moderate flexibility in terms of scope, schedule, and budget and have varying levels of project development. Region 1 is located entirely within OKDOT Division 6 and the Division 6 Construction Work Plan Map (OKDOT 2013b), with project locations, was the source of project-specific information used in this evaluation. OKDOT projects from the Work Plan documents considered to possibly coincide with ROIs of the Project are identified by location, moving generally from west to east, as follows:

    - SH-136 from Guymon south to the Oklahoma/Texas State Line. This 13-mile stretch of highway is more than 5 miles from the west end of the Applicant Proposed Route, but would be crossed by AC Collection System Routes NW-1, W-1, and SW-2 where they overlap. Planned activities on this highway segment include (1) grade, drain, and surface a 2.5-mile segment on the south side of Guymon (FFY 2020), (2) widen and resurface a 3.5-mile segment near the center of the 13-mile stretch (FFY 2019), (3) perform work on a bridge over Frisco Creek (FYY 2018), and (4) grade, drain, and surface a 5-mile segment north from the State line (FFY 2019/2020).
    - US-54/64 between Guymon and Hooker. This 20-mile stretch of highway is more than 10 miles northwest from the nearest segment of the Applicant Proposed Route, but would be crossed by AC Collection System Routes NE-1 and NW-2. Planned activities on this highway segment include (1) perform work on a bridge over Pony Creek (FFY 2016), (2) resurface about 5 miles of the road to the southwest of Hooker (FFY 2019), and (3) grade, drain, and surface more than 2 miles of the road on the northeast side of Guymon (FFY 2021).

1 Map ID numbers provided with project titles can be found on Figure 4.2-1 (located in Appendix A).

This page intentionally left blank.

- SH-3 from Guymon east to the Texas/Beaver County Line. This 30-mile stretch of highway would be crossed by AC Collection System Routes NE-1/NW-2, NE-2, and E-3, and its eastern end parallels Route E-3 and Routes 1-A/1-C, running 0.9 mile south of E-3 and 0.5 mile north of 1-A/1-C. Planned activities on this highway segment include (1) resurface 7 miles of the road beginning about 7 miles east of Guymon and running east (FFY 2020), and (2) resurface 3 miles of the road starting 9 miles west of the Texas/Beaver County Line and running east (FFY 2021). AC Collection System Route NE-2 would cross the larger road resurfacing; the smaller road resurfacing is in the proximity of E-3 and 1-A/1-C as identified above.
- SH-23 at the Oklahoma/Texas State Line. A planned activity to widen and resurface a 2-mile segment of the road starts 1 mile south of the State Line and runs north (FFY 2017). The northern extent of the planned activity is about 1 mile southeast of Link 2 of the Applicant Proposed Route.
- SH-149 between US-283 and State Highway 46. There is a planned activity to put a bridge over the Beaver River in this road segment (FFY 2014). The work area lies about 1.5 miles south of HVDC Alternative Route 1-A.
- US-183 from Buffalo south to the Harper/Woodward County Line. This 17-mile stretch of highway would be crossed by Link 5 of the Applicant Proposed Route and HVDC Alternative Route 1-A in Harper County. Planned activities on this highway segment include (1) grade, drain, bridge, and surface 5 miles of road beginning about midway in the stretch and running north (FFY 2021), (2) perform work on a bridge over Gyp Creek (FFY 2018), (3) grade, drain, bridge, and surface a 4-mile segment starting 4.6 miles north of the county line and running north (FFY 2016), and (4) widen and resurface a 4.6-mile segment starting at the county line and running north (FFY 2020). HVDC Alternative Route 1-A would cross the first activity's highway segment and the Applicant Proposed Route would cross over the fourth activity's highway segment.

4.2.2 Region 2—Present and Reasonably Foreseeable Future Actions

Region 2 is referred to as the Oklahoma Central Great Plains Region and includes the Applicant Proposed Route and HVDC Alternative Routes 2-A through 2-B. The region extends through Woodward, Major, and Garfield counties in Oklahoma. These counties are mostly rural; the largest communities are the towns of Woodward and Fairview.

Oklahoma Gas and Electric—The Region 2 OG&E planned activity that could have cumulative impacts with the Project is summarized as follows:

- *Woodward-Thistle 345kV Transmission Line.* OG&E is currently constructing new electric transmission facilities in west-central Oklahoma. The activity involves the construction of roughly 90 miles of new double-circuit 345kV transmission line connecting OG&E's Woodward District Extra High Voltage Substation with the Thistle Substation near the Oklahoma-Kansas border. The transmission line's alternative routes run north and east from south of Woodward, Oklahoma, to the Oklahoma-Kansas border about 2 miles southeast of Hardtner, Kansas. The structures consist of steel monopole with a typical height of 150 feet and approximately 1,200-foot spans between the structures. It is expected to be in service by December 2014. This new electrical transmission line crosses Link 1 of the Region 2 Applicant Proposed Route approximately 6 to 8 miles east of Mooreland, Oklahoma, and one of the OG&E line alternative routes in this area appears to be within the 1,000-foot-wideROI for HVDC Alternative Route 2-A for roughly 20 miles before veering to the northeast. The other OG&E alternative route in this area stays well north after crossing the Applicant Proposed Route (OG&E 2011).

The impacts associated with the Woodward-Thistle 345kV transmission line would be similar in nature to those impacts from the Project, but on a smaller scale, being restricted to a much shorter length of transmission line.

Glass Mountain Crude Oil Pipeline. The Glass Mountain Crude Oil Pipeline is a joint venture between SemGroup Corporation and Gavilon, LLC to build a 210-mile crude oil pipeline that extends through both Regions 2 and 3. The new pipeline was designed to have an initial capacity of approximately 140,000 barrels per day and 440,000 barrels of intermediate storage. The pipeline consists of two laterals: the first lateral originating near the town of Alva in Woods County, Oklahoma, and the second lateral originating near the town of Arnett in Ellis County, Oklahoma. The laterals intersect near Cleo Springs in Major County, Oklahoma, and the line continues east to Gavilon's Cushing (Oklahoma) facility (SemGroup 2014a). The constructed pipeline was put into service in February 2014 (SemGroup 2014b). Link 2 of the Region 2 Applicant Proposed Route and HVDC Alternative Route 2-A would cross the pipeline lateral from Alva in the area of the Woodward-Major county line. The pipeline from Cleo Springs to Cushing would be crossed several times by the Applicant Proposed Route and HVDC alternative routes within Region 3.

Oklahoma Department of Transportation. As described for Region 1, the latest OKDOT 8-Year Construction Work Plan (OKDOT 2013a) was reviewed for possible road and bridge work in the Region 2 vicinity. Region 2 is located within OKDOT Divisions 4 and 6 and the corresponding Construction Work Plan Maps (OKDOT 2013b, 2013c), with project locations, was the source of specific information for planned activities used in this evaluation. OKDOT planned activities from the Work Plan documents that could have cumulative impacts with the Project are summarized by location, moving generally from west to east, as follows:

- *SH-50B East of Woodward, Oklahoma.* OKDOT planned activities include a bridge and approach over Bull Creek on SH-50B almost 7 miles east of Woodward (FYY 2021). Link 1 of the Region 2 Applicant Proposed Route would run northwest-southeast about 0.2 to 0.3 mile west of the Bull Creek bridge location.
- *US-60 Southwest of Cleo Springs, Oklahoma.* There is a planned activity for a bridge and approaches at the Cimarron River about 2 miles southwest of Cleo Springs (FYY 2017). The work area lies as close as about 0.6 mile north of HVDC Alternative Route 2-A.

The above planned activities are those within about 2 miles of the Project routes and are both in OKDOT Division 6. Other OKDOT planned activities within about 2 to 6 miles of the Project include bridges and approaches over the North Canadian River on both State Highways 34 and 60 in Woodward and Major counties, respectively; bridge and road resurfacing work on SH-3/US-270 in southeast Woodward County and on US-412 in northwest Major County; widening and resurfacing of SH-8 in north-central Major County; and a bridge and approaches at Turkey Creek on SH-132, southwest of Enid, Oklahoma, in Garfield County (OKDOT District 4). The OKDOT 8-Year Construction Work Plan identifies numerous other road maintenance and bridge repair or replacement activities at greater distances from the Project, but these relatively small construction-type activities would have little potential for cumulative impacts at the greater distances (i.e., these relatively small construction-type activities would be expected to have an ROI similar to the Project and at the greater distance the ROIs would not overlap).

Mammoth Plains Wind Farm Project. The Mammoth Plains Wind Project would be located in Dewey and Blaine Counties, Oklahoma. It is a 199 MW proposed wind farm owned by NextEra Energy Resources of Juno Beach, Florida. A Power Purchase Agreement is in place as of November 2013 between NextEra and SPS, an Xcel Energy company (KEIN 2014). At its closest (the northeast corner), the property designated for this wind farm (Xcel Energy 2013) is approximately 14 miles south of Link 2 of the Region 2 Applicant Proposed Route. Xcel Energy describes the energy from the Mammoth Plains Wind Project as being targeted for its New Mexico and Texas customers (Amarillo Globe News 2013), so it would not be expected to use transmission lines associated with the Project and so is not considered a connected action.

4.2.3 Region 3—Present and Reasonably Foreseeable Future Actions

Region 3 is referred to as the Oklahoma Cross Timbers Region and includes the Applicant Proposed Route and HVDC Alternative Routes 3-A through 3-E. Region 3 extends through Garfield, Kingfisher, Logan, Payne, Lincoln, Creek, Okmulgee, and Muskogee counties in Oklahoma. Large communities in Region 3 include Stillwater, Cushing, Drumright, and Muskogee.

Oklahoma Department of Transportation. As described for Region 1, the OKDOT 8-Year Construction Work Plan (OKDOT 2013a) was reviewed for possible road and bridge work in the Region 3 vicinity. Region 3 is located within OKDOT Divisions (from west to east) 4, 3, 8, and 1 and the corresponding Construction Work Plan Maps (OKDOT 2013c, 2013d, 2013e, 2013f), with activity locations, was the source of specific information for planned activities used in this evaluation. OKDOT activities from the Work Plan documents that could have cumulative impacts with the Project are summarized by location, moving generally from west to east, as follows:

- *SH-51, East from US-81 in Kingfisher and Logan counties, Oklahoma.* There are a series of bridge activities planned for this 30-mile stretch of east-west highway in the northern portions of the two counties. The last five to the east, consisting of one in Kingfisher County and four in Logan County are over Skeleton Creek (FFY 2017), Bridge Creek (FFY 2018), West Beaver Creek (FFY 2017), Middle Beaver Creek (FFY 2017), and East Beaver Creek (FFY 2018). The Applicant Proposed Route, running northwest-southeast, would cross SH-51 about 1 mile east of the Skeleton Creek Bridge, then turn to the east, running about 5 miles south of the last four bridge activities. HVDC Alternative Route 3-A/3-B would cross SH-51 about midway between the Bridge Creek and West Beaver Creek bridges, about 2 miles from each, then turn to the east, running about 0.3 mile south of the last three bridge activities.
- *SH-51 Western Payne County, Oklahoma.* There is an OKDOT planned activity for a bridge and approaches on SH-51 at an unnamed creek about 5.5 miles east of the Logan-Payne county line (FYY 2017) HVDC Alternative Route 3-A/3-B would run about 0.3 mile southwest of the bridge location.
- *SH-33 at North Little Avenue in Payne County, Oklahoma.* An OKDOT planned activity to modify the intersection and rehabilitate pavement on SH-33 (FYY 2018) is about 2 miles east of Link 4 of the Region 3 Applicant Proposed Route.
- *SH-99 in Northeast Corner of Lincoln County, Oklahoma.* An OKDOT planned activity calls for bridges and approaches on SH-99 at Sand Creek and an unnamed creek to the north of Sand Creek (FYY 2021). Link 4 of the Region 3 Applicant Proposed Route would run east-west about 0.2 mile south of the Sand Creek Bridge and about 1.1 miles south of the unnamed creek.
- *SH-66 from Depew to Bristow, Creek County, Oklahoma.* The stretch of SH-66 from Depew to Bristow is to be graded, drained, and surfaced under two planned activities: (1) the first mile from Depew (FFY 2019), and (2) the rest of the way to the Bristow city limits (FFY 2021). HVDC Alternative Route 3-C would cross SH-66 near the dividing point between the two activities.
- *SH-16 East from SH-48, Creek County, Oklahoma.* There are several OKDOT planned activities along SH-16: (1) a widening and resurfacing activity for the stretch of road from SH-48 to 6 miles to the east (FFY 2020), (2) a bridge and approaches activity at Skull Creek near the east end of the 6-mile stretch (FFY 2014), and (3) a

bridge and approaches activity at Chicken Creek about 2 miles further east and south (FFY 2018). Link 4 of the Region 3 Applicant Proposed Route would be about 1 mile to the northeast of the first project's eastern extent and also about 1 mile to the northeast of both bridge activities.

- *US-75A from Beggs to the County Line (7.5 miles to the north), Okmulgee County, Oklahoma.* The stretch of US-75A is to be graded, drained, and surfaced (FFY 2016). Link 4 of the Region 3 Applicant Proposed Route would cross US-75A about 2 miles north of Beggs.
- *US-75 North of Okmulgee, Okmulgee County, Oklahoma.* Three activities are planned for this segment of US-75 that runs north from the community of Okmulgee across SH-16 to a point about 2 miles north of SH-16: (1) left turn lane intersection modifications from Okmulgee to about Preston (FFY 2020), (2) left turn lane intersection modifications from about Preston to 2 miles north of SH-16 (FFY 2017), and (3) bridge and approaches for the overpass over SH-16 (FFY 2016). Link 4 of the Region 3 Applicant Proposed Route would cross US-75 at about the northern extent of the third activity and would be about 1.6 miles to the northeast of the overpass location. HVDC Alternative Route 3-C would cross US-75 in the first activity's highway segment.
- *US-62, Northwest Corner of Muskogee County, Oklahoma.* OKDOT plans two bridge and approaches activities on US-62 at Cane Creek crossings: (1) about 1.3 miles south of where US-62 joins SH-72 and turns south (FFY 2015), and (2) about 1.6 miles east of SH-72 (FFY 2015). Link 5 of the Region 3 Applicant Proposed Route would cross US-62 about 0.1 mile north of the first activity and run parallel to and 1.5 miles south of the section of US-62 where the second activity is located.
- *US-69 North of Muskogee-McIntosh County Line, Oklahoma.* OKDOT plans a pavement rehabilitation project on 8.5 miles of US-69 north of the county line (FFY 2020). HVDC Alternative Route 3-C/3-D would cross US-69 about 1.2 miles north of the county line.

As with Region 2, the above planned activities are those within about 2 miles of the Project routes. The OKDOT 8-Year Construction Work Plan identifies more than 20 other road maintenance and bridge repair or replacement activities within about 2 to 6 miles of the Project routes, but these relatively small construction-type activities are judged to have little potential for cumulative impacts at the greater distances. In Kingfisher County, these other OKDOT planned activities include resurfacing and bridge work on SH-51. In Logan County, there are bridge activities on SH-74 and SH-74D. In Payne County, there are bridge activities on State Highways 51 and 33, and resurfacing on US-177 and SH-18. In Lincoln County, there are bridge activities on US-177 and SH-105, SH-18, and SH-99. In Creek County, there are two bridge activities on SH-16. In Okmulgee County, there is a bridge activity on US-62. In Muskogee County, there are bridge activities on SH-10 and US-62, US-69, and US-26, and surfacing activities on SH-10A and US-64.

Glass Mountain Crude Oil Pipeline. See the activity description in Section 4.2.2. The activity extends through both regions.

Bridge Replacement. The USACE is replacing the Highway 151 Bridge over the Keystone Dam. The construction started in October 2013 and will proceed for 13 months (USACE 2013). The road will be closed to traffic during that time. At its closest, Link 4 of the Region 3 Applicant Proposed Route would be about 17 miles southeast from this action. This action is outside the ROI but was evaluated because of its high-profile nature.

R.L. Jones Jr. Airport (Jones Riverside Airport). The Jones Riverside Airport in southwest Tulsa has been approved for several updates to occur over the 2014 to 2018 timeframe. Rehabilitation work is being completed at the Jones Riverside Airport. The planned activities include widening and asphalt overlays on runways and improvements to sewer, drainage, and roadway infrastructure (Arnold 2014). The airport, in Tulsa County, is located about 17 miles north of Link 4 of the Region 3 Applicant Proposed Route.

Oklahoma Gas and Electric. The Region 3 OG&E planned activity that could have cumulative impacts with the Project is summarized as follows:

- Seminole to Muskogee Transmission Line. OG&E has constructed or is constructing several new electric transmission facilities in east-central Oklahoma. This activity involved the construction of a new, double-circuit 345kV electrical transmission line connecting the existing OG&E Seminole Power Plant substation in Seminole County to the existing Muskogee Power Plant substation in Muskogee County. The activity is approximately 125 miles with a 150-foot-wide right-of-way corridor. The typical structure height is 90 feet with an 800-foot span between structures. The activity was completed in December 2013 (OG&E 2014b). The Applicant Proposed Route and the HVDC alternative routes cross this new transmission line in the area south-southeast of Muskogee, Oklahoma. Since this transmission line is already in service, its construction would not contribute to cumulative impacts with the Project, but impacts of the transmission line's presence, operation, and maintenance are considered. As described for two planned activities in Region 1 (Section 4.2.1), construction of the transmission line is considered a precursor to the Project and it is noted that impacts from its recent construction have been captured in the Chapter 3 affected environment.

Diamond Pipeline. In August 2014, Plains All American Pipeline announced its intention to construct the Diamond Pipeline to deliver crude oil from its Cushing, Oklahoma, terminal to the Valero Memphis Refinery in Tennessee (Plains All American 2014). Plains All American Pipeline has a long-term shipping agreement with Valero, which holds an option to become a partner in the Diamond Pipeline. The 440-mile, 20-inch pipeline would have a capacity of up to 200,000 barrels per day and is expected to be completed in early 2017 (Diamond Pipeline, LLC 2015). Portions of the proposed Diamond Pipeline's route from Cushing to Memphis would parallel the same general route as the Plains & Eastern transmission line in Regions 3, 4, and 5. The routes, or portions of the routes, appear to overlap in the center of Region 3, the eastern end of Region 4, and the western half of Region 5. The pipeline path veers to the south of the Plains & Eastern transmission line route in the area of the Oklahoma-Arkansas border, then swings back north before again veering south in the eastern side of Region 5 and staying well to the south of Regions 6 and 7 of the transmission line route on its continued path to Memphis.

4.2.4 Region 4—Present and Reasonably Foreseeable Future Actions

Region 4 is referred to as the Arkansas River Valley Region and includes the Applicant Proposed Route, including the Lee Creek Variation, and HVDC Alternative Routes 4-A through 4-E. Region 4 extends through Muskogee and Sequoyah counties in Oklahoma and through Crawford, Franklin, Johnson, and Pope counties in Arkansas. Large communities in the region include Sallisaw, Fort Smith, and Clarksville.

Oklahoma Department of Transportation. The OKDOT 8-Year Construction Work Plan (OKDOT 2013a) was reviewed for possible road and bridge work in the Oklahoma portion of Region 4, which is entirely within OKDOT Division 1. The corresponding Construction Work Plan Map (OKDOT 2013f), with activity locations, was the source of specific information for planned activities used in this evaluation. OKDOT activities from the Work Plan documents that could have cumulative impacts with the Project are summarized by location, moving generally from west to east, as follows:

- *SH-10A in Muskogee and Sequoyah Counties, Oklahoma.* An activity is planned to grade, drain, and surface the stretch of SH-10A that runs between SH-10 and SH-100. At its closest, Link 1 of the Region 4 Applicant Proposed Route would be about 1.7 miles southwest of the activity location.
- *I-40 near its Junction with SH-82, Sequoyah County, Oklahoma.* There are two OKDOT planned activities along this section of I-40: (1) a bridge and approach activity over Vian and Little Vian Creeks (FFY 2020), and (2) 6 miles of pavement rehabilitation (FFY 2019/2020). At its closest, Link 3 of the Region 4 Applicant Proposed Route would be about 1.5 miles northeast of this section of I-40.
- *I-40 along the South Side of Sallisaw, Sequoyah County, Oklahoma.* There are multiple OKDOT planned activities along this section of the highway: (1) 5 miles of pavement rehabilitation (FFY 2014), (2) a bridge and approach over Big Sallisaw Creek (FFY 2019), (3) a bridge and approach over a county road and railroad (FFY 2018), and (4) the I-40/US-64 interchange. This section of I-40 runs about 3 to 3.5 miles south of Link 3 of the Region 4 Applicant Proposed Route.
- *US-64 West of Sallisaw, Sequoyah County, Oklahoma.* OKDOT has a bridge and approaches activity at Big Sallisaw Creek (FFY 2014). The site is about 2.4 miles south of Link 3 of the Region 4 Applicant Proposed Route.
- *US-59 in Sallisaw, Sequoyah County, Oklahoma.* An activity is planned to grade, drain, and surface 3.5 miles of US-59, north from its intersection with US-64 (FFY 2016). Link 3 of the Region 4 Applicant Proposed Route would cross the highway location at about 2.6 miles north of US-64.
- *SH-101 East of Sallisaw, Sequoyah County, Oklahoma.* OKDOT has a bridge and approaches activity planned at an unnamed creek (FFY 2019). The proposed site is about 0.6 mile north of Link 3 of the Region 4 Applicant Proposed Route.

The above planned activities are generally those within about 2 miles of the Project routes. The exception is the group associated with the segment of I-40 running along the south side of Sallisaw. Although 3 or more miles away from the Applicant Proposed Route, activities in this section of roadway are identified specifically because concerns were raised during the EIS scoping process about potential impacts due to road construction on the US-64/I-40 interchange in this region. The OKDOT 8-Year Construction Work Plan identifies one other road maintenance activity within about 2 to 6 miles of the Project routes, but it would have little potential for cumulative impacts at the greater distances. This other planned activity is another pavement rehabilitation project on a 7.6-mile stretch of I-40 to the southeast of Sallisaw.

New Hydroelectric Power Plant. A new hydropower plant has been proposed by the Cherokee Nation, with a location on the Arkansas River at the existing W.D. Mayo Lock and Dam, south of Muldow (Dandridge 2012) and about 9 miles southwest of Fort Smith. Per a 2014 article (Maxwell 2014), a spokesman for the Cherokee Nation describes the power plant project as being only in the planning stage with no concrete plans yet developed. The 2014 article was triggered by the U.S. House of Representatives May 2014 release of a Water Resources Reform and Development Act Conference Report (U.S. House of Representatives 2014), which acted to lift "a federal halt on the Cherokee Nation's ability to construct, operate and market power for a hydropower facility on the W.D. Mayo Lock and Dam" (Maxwell 2014). The Water Resources Reform and Development Act of 2014, Public Law 113-121, was subsequently passed on June 10, 2014 and authorizes (in Section 1117) the Cherokee Nation of Oklahoma to design and construct one or more hydroelectric generating facilities at the W.D. Mayo Lock and Dam and to market the electricity generated from any such facility. The proposed hydropower plant site is approximately 12 miles south of Link 3 of the Region 4 Applicant Proposed Route.

Arkansas State Highway and Transportation Department. The AHTD publishes "Status of Improvement" maps (status maps) for each of its districts showing the status of roadway activities as "completed, under construction, programmed, or deferred" and, as applicable, new roadway construction. Most of the information presented here comes from these maps, which are in the form of individual maps for the counties within each district. Region 4 of the Applicant Proposed Route would pass through AHTD District 4 (Crawford and Franklin counties) and part of District 8 (specifically Johnson and Pope counties). This evaluation of cumulative impacts considered whether ROIs of the Project would cross or be in proximity to roadway activities either in the "programmed" or "deferred" categories, assuming those could be the activities occurring in the future. Roadway activities identified as "under construction" were not included in the evaluation because the activities, unless identified as new roadway construction, consist of maintenance or rehabilitation of existing structures. By their nature, they would be expected to be relatively short term and likely complete by the time the Project started. Once complete, impacts associated with use of the roads would be expected to be the same as before construction (i.e., consistent with the affected environment characterization). The maps contain no information on specific dates or detailed information on the nature of the roadway improvements, but those that could have cumulative impacts with the Project as well as planned activities identified through other sources are summarized by District and County as follows:

- *AHTD District 4, Crawford County, Arkansas.* Activities shown on the status map for Crawford County (AHTD 2014a) that could have cumulative impacts with the Project include (1) programmed bridge work on SH-59 at Lee Creek, (2) programmed work on I-40 from the Oklahoma-Arkansas state line east to just west of Dyer, (3) programmed road work on I-540 from Alma north to Mountainburg, (4) deferred work on US-71 from Alma north to a point southwest of Mountainburg, and (5) new construction of US-71 from Alma south, to the east of Kibler, and to the Arkansas River southeast of Fort Smith. HVDC Alternative Route 4-A would pass within about 2 miles south of the first activity. Link 6 of the Applicant Proposed Route would cross the second and fifth activity segments. HVDC Alternative Route 4-A/4-B/4-D would cross the third and fourth activity segments. A new section of US-71, south of the Arkansas River (i.e., south of the fifth activity above) and between US-22 and existing US-71, is currently under construction (to be completed in 2014) and almost 9 miles from the nearest segment of the Applicant Proposed Route (AHTD 2012).
- *AHTD District 4, Franklin County, Arkansas.* The status map for Franklin County (AHTD 2014a) shows no programmed or deferred activities being crossed by or adjacent to the Applicant Proposed Route or the alternative routes. The closest is programmed road work on SH-23 that begins over 4 miles to the north of HVDC Alternative Route 4-B and then extends northward.
- *AHTD District 8, Johnson County, Arkansas.* Activities shown on the status map for Johnson County (AHTD 2014b) that could have cumulative impacts with the Project are limited to programmed road work on I-40 from its junction with SH-164 east to just beyond where it crosses SH-352 (Wire Road). HVDC Alternative Route 4-E would roughly parallel this segment of I-40 at distances of 0.5 to 0.9 mile to the south until it veers to the north and crosses I-40 just east of the AHTD activity's eastern end.
- *AHTD District 8, Pope County, Arkansas.* The status map for Pope County (AHTD 2014b) shows no programmed or deferred activities being crossed by or adjacent to the Region 4 Applicant Proposed Route or the alternative routes. The closest is programmed road work on a short segment of SH-7 about 5 miles to the east of Link 9 of the Region 4 Applicant Proposed Route.

Diamond Pipeline. See the Diamond Pipeline description in Section 4.2.3. The path of the Diamond Pipeline appears to overlap portions of the Plains & Eastern transmission line route in Regions 3, 4, and 5.

4.2.5 Region 5—Present and Reasonably Foreseeable Future Actions

Region 5 is referred to as the Central Arkansas Region and includes the Applicant Proposed Route and HVDC Alternative Routes 5-A through 5-F and the Arkansas converter station alternative. Region 5 extends through Pope, Conway, Van Buren, Cleburne, White, and Jackson counties in Arkansas.

Arkansas State Highway and Transportation Department. As described in more detail in the Region 4 discussion, the AHTD “Status of Improvement” maps (status maps) were reviewed for roadway activities that could involve impacts cumulative with the Project. Region 5 of the Applicant Proposed Route would pass through AHTD District 8 (specifically Pope, Conway, Van Buren, and Faulkner counties) and District 5 (Cleburne, White, and Jackson counties). Road activities from the Status of Improvement maps or other sources that could have cumulative impacts with the Project are summarized by District and County as follows:

- *AHTD District 8, Pope County, Arkansas.* The status map for Pope County (AHTD 2014b) shows no programmed or deferred activities being crossed by, or adjacent to the Region 5 Applicant Proposed Route or the alternative routes. The closest is programmed road work on a short segment of SH-27 about 2.4 miles to the north of Link 1 of the Region 5 Applicant Proposed Route. Although not shown on the status map, the AHTD has announced plans to construct a Highway 7 bypass to the west of Dover (Crabtree 2013). At its closest, Link 1 of the Region 5 Applicant Proposed route would be about 3 miles to the north of the Highway 7 bypass.
- *AHTD District 8, Conway County, Arkansas.* Activities shown on the status map for Conway County (AHTD 2014b) that could have cumulative impacts with the Project include (1) programmed work on SH-247 from the Pope-Conway county line east to its junction with SH-213 and (2) programmed road work on SH-92 from 2.9 miles east of the junction with SH-9 east to the Conway-Van Buren county line. HVDC Alternative Route 5-B would run roughly parallel with the first activity as close as 0.8 mile to the south of the road. Link 3 of the Region 5 Applicant Proposed Route would run roughly parallel with the second activity as close as 0.9 mile to the south of the road.
- *AHTD District 8, Van Buren County, Arkansas.* Activities shown on the status map for Van Buren County (AHTD 2014b) that could have cumulative impacts with the Project are limited to programmed road work on US-65 from Bee Branch to about 3 miles south. At its nearest, Link 3 of the Region 5 Applicant Proposed Route would be about 1.7 miles to the south of the activity’s southern end.
- *AHTD District 8, Faulkner County, Arkansas.* Activities shown on the status map for Faulkner County (AHTD 2014b) that could have cumulative impacts with the Project are limited to programmed road work on SH-285 from its junction with SH-124 to about 4 miles south. At its nearest, HVDC Alternative Route 5-B would be about 1 mile to the north of the activity’s northern end.
- *AHTD District 5, Cleburne County, Arkansas.* The status map for Cleburne County (AHTD 2014c) shows no programmed or deferred activities being crossed by or adjacent to the Region 5 Applicant Proposed Route or the alternative routes.
- *AHTD District 5, White County, Arkansas.* The status map for White County (AHTD 2014c) shows no programmed or deferred activities being crossed by or adjacent to the Region 5 Applicant Proposed Route or the alternative routes.
- *AHTD District 5, Jackson County, Arkansas.* Potentially cumulative activities shown on the status map for Jackson County (AHTD 2014c) are limited to programmed road work on US-167 in the small segment of the road going through the western edge of the county. Link 9 of the Region 5 Applicant Proposed Route would cross the road segment.

Central Arkansas Natural Gas Pipeline Enhancement Project. CenterPoint Energy Gas Transmission Company, LLC is proposing the Central Arkansas Natural Gas Pipeline Enhancement Project for the transportation of natural gas to the central Arkansas cities and towns of Conway, Mayflower, Maumelle, North Little Rock, and Little Rock. After the pre-filing proceeding began CenterPoint Energy Gas Transmission Company, LLC changed its name to Enable Gas Transmission, LLC (Enable) effective July 30, 2013. As part of the Central Arkansas Natural Gas Pipeline Enhancement Project, Enable is proposing the installation of approximately 28 miles of 12-inch-diameter natural gas pipeline and ancillary facilities in Pulaski and Faulkner counties in Arkansas. The proposed pipeline, to be named Line BT-39, will be constructed primarily on a new alignment and will provide replacement transmission service for a portion of two existing natural gas pipelines (Lines B and BT-14). Construction was proposed to begin in March 2014 (CenterPoint Energy 2014), but the EA for the action was not released by FERC until mid-April 2014. FERC granted the requested authorizations with conditions in July 2014 (FERC 2014). Although Enable has not announced a new construction start date, it is assumed this action is still reasonably foreseeable and could occur at the same time as the Project of before the Project. The closest point of this new pipeline is approximately 16 miles south of the HVDC Alternative Route 5-B. The southern-most point of the proposed pipeline is more than 30 miles from the route. This action is outside the ROI but was evaluated because of its high-profile nature. Steps in the construction process include clearing, grading and trenching; stringing and welding pipe segments together; depositing the pipeline, backfilling and testing; and restoration (CenterPoint Energy 2013).

Diamond Pipeline. See the Diamond Pipeline description in Section 4.2.3. The path of the Diamond Pipeline appears to overlap portions of the Plains & Eastern transmission line route in Regions 3, 4, and 5.

4.2.6 Region 6—Present and Reasonably Foreseeable Future Actions

Region 6 is referred to as the Cache River and Crowley's Ridge Region and includes the Applicant Proposed Route and HVDC Alternative Routes 6-A through 6-D. Region 6 extends through Jackson, Cross, and Poinsett counties in Arkansas.

Arkansas State Highway and Transportation Department. As described in more detail in the Region 4 discussion, the AHTD "Status of Improvement" maps (status maps) were reviewed for roadway activities that could involve impacts cumulative with the Project. In Region 6, the Applicant Proposed Route would pass through AHTD District 5 (specifically Jackson County), District 10 (Poinsett County), and District 1 (Cross County). Planned activities from the status maps or other sources that could have cumulative impacts with the Project are summarized by District and County as follows:

- *AHTD District 5, Jackson County, Arkansas.* Activities shown on the status map for Region 6 in Jackson County (AHTD 2014c) that could have cumulative impacts with the Project are limited to programmed work on four bridge structures on SH-14 near the community of Amagon. Two of the bridge structures are at the Cache River crossing and the other two are about 1 mile to the east over wetlands areas on the west side of Amagon. HVDC Alternative Route 6-B would run adjacent to SH-14 along this same stretch of road and cross over or very near to these bridge structures.
- *AHTD District 10, Poinsett County, Arkansas.* The status map for Poinsett County (AHTD 2014d) shows no programmed or deferred activities being crossed by or adjacent to the Region 6 Applicant Proposed Route or the alternative routes. The closest activity is a short segment of SH-1 within the community of Harrisburg, which is more than 5 miles north of HVDC Alternative Route 6-C.

- *AHTD District 10, Craighead County, Arkansas.* Although not crossed by routes of the Project, Craighead County to the north of Poinsett County was identified as having several planned road tasks, primarily in the Jonesboro area, being recently completed or started. These included the US-67 extension at SH-226 intersection and the widening of Highway 226 east to US-49 (AHTD 2013). The reference identified these tasks as either being completed or starting construction in 2012. These road construction activities are more than 20 miles north of the Region 6 routes.
- *AHTD District 1, Cross County, Arkansas.* Planned activities shown on the status map for Region 6 in Cross County (AHTD 2014e) that could have cumulative impacts with the Project are limited to programmed work on four bridge structures on SH-42 between Hickory Ridge and Cherry Valley. Link 6 of the Region 6 Applicant Proposed Route would run roughly parallel to and 2 miles north of the eastern half of this road segment where two of the bridge activities are located. Programmed road work on SH-163 to the southeast of Cherry Valley doesn't get closer than about 3.5 miles from the Applicant Proposed Route.

Rebuild 161kV Transmission Line from Trumann to Trumann West, Arkansas. Entergy Arkansas, Inc. plans to rebuild the 161kV transmission line from Trumann to Trumann West by replacing the current wooden structures with steel monopoles. This transmission line replacement is proposed for 2021 (Entergy 2013). This transmission line runs generally north-south compared to the east-west direction of the Project. The nearest segment of the Trumann to Trumann West transmission line is approximately 10 miles north of the Applicant Proposed Route. Because the activity includes replacement of structures, the impacts associated with the transmission line rebuild would be similar to those anticipated for the Project, although on a smaller, more localized scale.

US-63, Poinsett County, Arkansas. The FHWA, in cooperation with the AHTD, is studying an access road located adjacent to US-63 between Marked Tree and Payneway, Arkansas, in Poinsett County. An Environmental Assessment was completed in January 2012 (FHWA and AHTD 2012). US-63 between I-55 to the southeast and Jonesboro to the northwest is to be converted to I-555 in the future. The section of Highway 63 has already been upgraded to meet interstate criteria with the exception of a short segment to the west of Marked Tree that crosses the St. Francis River floodway (designated the St. Francis Sunken Lands), which does not have access control. This highway access road will support local traffic by providing an alternative route across the floodway so that access to Highway 63 can be controlled and the conversion to I-555 completed. The FHWA and AHTD action includes six bridges, which will span the St. Francis River and numerous water bodies within the St. Francis Sunken Lands, and will require some new ROW over what has been established for Highway 63. The roadway typical cross-section consists of two 10-foot-wide travel lanes, one in each direction, with 4-foot-wide outside shoulders. The total length of the action is approximately 4.7 miles. At its closest, the proposed access road segments are more than 2 miles to the north of Link 8 of the Region 6 Applicant Proposed Route and about 4 miles from HVDC Alternative Routes 6-C/6-D. However, an access road segment is only about 0.8 mile to the northwest of to HVDC Alternative Route 7-A.

4.2.7 Region 7—Present and Reasonably Foreseeable Future Actions

Region 7 is referred to as the Arkansas Mississippi River Delta and Tennessee Region and includes the Applicant Proposed Route, HVDC Alternative Routes 7-A through 7-D, and the Tennessee converter station. Region 7 extends through Poinsett and Mississippi counties in Arkansas and Tipton and Shelby counties in Tennessee.

Arkansas State Highway and Transportation Department. As described in more detail in the Region 4 discussion, the AHTD "Status of Improvement" maps (status maps) were reviewed for roadway activities that could involve impacts cumulative with the Project. Region 7 of the Applicant Proposed Route would pass through AHTD District 10 (specifically Poinsett and Mississippi counties). Road activities from the status maps or other sources that could have cumulative impacts with the Project are summarized by District and County as follows:

- *AHTD District 10, Poinsett County, Arkansas.* Actions shown on the status map for Region 7 in Poinsett County (AHTD 2014d) that could have cumulative impacts with the Project are limited to programmed work on a short segment of US-63 within the community of Marked Tree. HVDC Alternative Route 7-A would be 0.7 mile to the southeast of the near end of the road segment.
- *AHTD District 10, Mississippi County, Arkansas.* Actions shown on the status map for Region 7 in Mississippi County (AHTD 2014d) that could have cumulative impacts with the Project are limited to programmed work on an almost 17-mile section of I-55 from the Mississippi-Crittenden county line north to a point between Marie and Keiser. Link 1 of the Region 7 Applicant Proposed Route would cross I-55 in the southern portion of this segment and HVDC Alternative Route 7A would run adjacent and parallel to a 3.5-mile segment of the I-55 segment before crossing it in the northern portion.

Great River Super Site, Osceola, Arkansas. The Great River Super Site in Osceola, Arkansas, is a 4,800-acre site owned by Entergy and private entities. This site is part of the State of Arkansas, Mississippi County Economic Development Area. All environmental clearances (i.e., Phase I Environmental Site Assessments) have been completed and the area is planned to be developed for heavy industry. The site has direct access to the Mississippi River. Anticipated industries to develop in this area include steel industries (Mississippi County Economic Development 2014). The northern-most point of HVDC Alternative Route 7-A would be only about 0.4 mile to the southwest of the 4,800-acre site; Link 2 of the Region 7 Applicant Proposed Route would be about 11 miles to the south.

I-69 Expansion, Tennessee. I-69 is a multi-state highway, planned to connect Canada and Mexico and its route includes western Tennessee. Segments of I-69 in north and south Tennessee have been completed, others are under construction, and the Tennessee Department of Transportation expects completion of some segments to stretch well into the future. Current construction work of segments in Union City will likely not be completed until the 2017 time frame and it may be a 10-year program to complete segments that would extend it south to Troy. That would leave only the middle 65-mile section between Dyersburg and Millington to complete Tennessee's portion of the route. There was no federal funding designated for this transportation project as of February 2013, so no schedule has been established, but the plans are still being considered by the TNDOT (Dyersburg State Gazette 2013). The middle section of the I-69 activity, from Dyersburg to Millington, would go through the ROI of the Project, which ends just to the northeast of Millington. Current plans show the I-69 route running to the west of US-51/SH-3 near Millington (TNDOT 2014) where it would cross Link 3 of the Region 7 Applicant Proposed Route as well as HVDC Alternative Routes 7-B and 7-C.

Green Meadows Development at Munford, Tennessee. Concerns were raised during the EIS scoping process that a housing development was planned that should be considered in the cumulative impacts for this EIS. This development (the Green Meadows Development) is a planned community being constructed by the Green Meadows Development Corporation in Munford, Tennessee. The planned community will eventually consist of 695 single family homes with multiple construction phases and varying lot and house sizes over a 370-acre parcel. The development will also include a small commercial district (e.g., retail and shopping center, restaurants, and professional space), community parks, several ponds, and a Green Belt walking trail system. A retirement community along with fitness center, tennis courts, and a pool is also planned as part of this planned community (Green Meadows 2014). It was reported in mid-2012 that building approvals had been obtained and Phase 1 construction, including utilities, would begin in 2013 (Epley 2012). However, Tipton County property assessment data for 2014 indicate there are still no water, sewer, or gas utilities serving the parcel, and it is still classified as a farm (Tipton County 2014), so it appears Phase 1, if started, is not yet complete. The 370-acre parcel appears to be about 0.2 mile away from the eastern end of HVDC Alternative Route 7-D and 2 miles from the east end of the Region 7 Applicant Proposed Route.

Southern Gateway Project, Tennessee. The TNDOT conducted broad studies to determine the feasibility of a new Mississippi River bridge in the metropolitan Memphis, Tennessee area. These studies included the Mississippi River Crossing Feasibility and Location Study (Wilbur Smith Associates 2006), which was completed in June 2006 and identified potential locations for a new bridge. These studies collected preliminary data on the existing highway transportation system, natural environment and socio-economic characteristics of the area. The feasibility study focused on highway corridors and several bridge locations were screened based on their potential environmental and community impacts, engineering issues and estimated cost. These studies determined that a new bridge is feasible and recommended how to move forward to the next level of detail.

The Southern Gateway Project is a continuation of these earlier studies and is being developed through a collaborative effort of multiple agencies, including TNDOT, AHTD, Mississippi Department of Transportation (MSDOT), Memphis and West Memphis Metropolitan Planning Organizations (MPOs), and the FHWA. One of the potential river crossing corridors considered in a 2011 “Purpose and Need” study (TNDOT 2011) for the Southern Gateway Project is designated Corridor V1-7 and crosses the Mississippi River in the area of the Tipton-Shelby county line in Tennessee. This is the northern-most of the crossing corridors described in the study and, from west to east, starts in Arkansas at the junction of I-55 and US-63 and proceeds eastward, with a slight loop to the north, then southeast to just west of Millington in Tennessee. Were this corridor selected, it would require a new bridge and connecting roadways plus about 1 mile of new rail line in the Millington area. An EIS for the Southern Gateway Project will be developed that will outline the anticipated costs, benefits, and impacts of the alternatives, and is expected to be completed in 2015 (TNDOT 2011). Corridor V1-7 goes as far north as about the Crittenden-Mississippi county line in Arkansas before dipping back to the southeast. At its northern-most extent, Corridor V1-7 appears to be about 3 miles south of Link 1 of the Region 7 Applicant Proposed Route and about 4 miles south at the respective river crossings. Corridor V1-7 would, however, likely cross HVDC Alternative Route 7-C before ending on the west side of Millington. Other possible corridors addressed in the Purpose and Need study are all in the immediate area of Memphis or to its south and no closer than about 8 to 10 miles from routes of the Project.

4.3 Resource Area Cumulative Impacts

4.3.1 Evaluation Methodology

4.3.1.1 Cumulative Impacts Presentation

Cumulative impacts within each of the Chapter 3 resource areas are discussed in the sections that follow. Each resource area includes a discussion of the potential impacts from the present and reasonably foreseeable future actions described in Section 4.2 that could be cumulative with those of the Project. Each resource area discussion first summarizes the Project’s potential impacts for the resource area, as were identified and described in the applicable methodology section of Chapter 3. If both the Project and the applicable present or reasonably foreseeable future actions would be expected to impact a resource, then there would be potential for cumulative impacts.

The discussion of potential cumulative impacts does not attempt to describe the impacts for every action for each region, because of the wide range of affected environments in Regions 1 through 7 and the large number of present and reasonably foreseeable future actions identified in Section 4.2. Rather, the evaluation and discussion follows DOE's graded approach by focusing on those projects within each region that would have the highest potential for significant impacts to the specific resource area. In addition, the nature of the information generally available for the actions identified in Section 4.2 limits the evaluation of cumulative impacts to qualitative analyses.

4.3.2 Agricultural Resources

Agricultural resource impacts of concern for the Project are associated with the potential for direct impacts to agricultural land and structures from construction and to agricultural operations given the long-term presence of Project components and their need for periodic maintenance. Also of concern are potential indirect impacts to agricultural production on adjacent lands due to the presence of transmission infrastructure changing aerial application patterns of fertilizers, insecticides, and herbicides; and economic impacts to farmers and ranchers due to the impacts to agricultural lands (such as reduced productivity).

To the extent that the present and reasonably foreseeable future actions described in Section 4.2 involve new disturbance of agricultural lands, their impacts could be additive with those of the Project. Impacts during construction could involve additional loss of vegetation and soil at construction sites and along travel routes; possible temporary loss of the use of structures such as barns, ponds, and silos; and possible curtailment of actions such as animal feeding operations. These types of construction-related impacts likely would be short term, although it is possible that loss of the use of structures could be long-term. During operations and maintenance, if the actions were for new electrical transmission lines, buried oil or natural gas pipelines, or similar actions, agricultural activities could resume to a large extent on most disturbed areas, but there would likely be some constraints and limitations. This could include land use limitations within ROWs, physical interference with agricultural equipment operations, and periodic loss of access during maintenance activities. Also during operations, permanent structures such as electric transmission structures and conductors could affect aerial spraying activities often used in agricultural areas. This could involve requiring the spraying to be performed at higher altitudes resulting in more chance for overspray or drift that could affect adjoining properties, or it could eliminate aerial spraying in some areas. There could also be effects on the economic value of livestock production by a combination of decreasing forage land available and by increasing management costs of controlling noxious and invasive vegetation species introduced during construction and costs of moving livestock around project-related structures and ROWs. All of these types of impacts could be cumulative with those of the Project if they were to occur within the same landowner's property or if measured in terms of the overall quantity of crops or livestock produced from the region.

Many of the actions identified in Section 4.2, particularly those associated with upgrades or maintenance actions for existing roadways, bridges, or airports, would not be expected to involve any substantial disturbance of agricultural lands and, accordingly, would be unlikely to affect agricultural resources.

As described in Sections 3.2.4 and 3.2.5, agriculture is the predominant land use in each of the seven regions. However, the counties in which Regions 1 and 2 are located have the highest percentages of agricultural land, averaging more than 90 percent, in comparison to the counties in other regions. Regions 3 and 6 are the next closest, with the counties averaging more than 70 percent agricultural land. The average amount of agricultural land in the other three regions varies from 36 to 49 percent. The actions identified in Section 4.2 for Regions 1 and 2 also include several projects that would involve new land disturbance. Therefore, the present and reasonably foreseeable future projects identified for Regions 1 and 2 would likely have a higher potential for impacts to agricultural resources that would be cumulative with impacts of the Project. As described in Sections 4.2.1 and 4.2.2, both regions have OG&E transmission line planned activities as well as a new OG&E substation in Region 1. Potential impacts to agricultural resources for these actions would be the same as summarized above and described in detail in Section 3.2.6 for the Project. The Glass Mountain Crude Oil Pipeline project in Region 2 would be expected to have impacts similar to a transmission line action in the sense that it has a linear construction and agricultural uses could resume to some extent after construction was complete. But, there would be greater ground disturbance expected for the oil pipeline action, which increases the potential for invasive weeds to establish.

Region 2 also contains the Mammoth Plains Wind Farm project and its potential impacts to agricultural resources would be similar to the connected action described in detail in Section 3.2.6.8. Some agricultural lands would be taken out of service during construction, but because of the large distance between wind turbines, the land taken out of service would be very small in comparison to the total wind farm area. After construction was complete and agricultural activities reestablished in the disturbed areas, only a minimal area of existing agricultural land would be permanently removed from production. As described in Section 3.2.6.8 for connected actions, wind farm developers are typically able to microsite turbines and other facility components to avoid displacing or damaging agricultural structures, including irrigation system components.

4.3.3 Air Quality and Climate Change

Air quality and climate change impacts of concern for the Project, as described in Section 3.3.6, are associated primarily with construction and include the following:

- Fugitive dust emissions
- Exhaust from construction equipment exhausts
- Portable concrete batch plant emissions
- Vehicle exhaust for work travel and movement of supplies

Air quality and climate change impacts during operations and maintenance of the Project would be limited to the emission of small amounts of pollutants associated with combustion of fossil fuels for work vehicles and maintenance equipment.

The present and reasonably foreseeable future actions described in Section 4.2 are similar to the Project in that the air emissions associated with the Section 4.2 actions would also be primarily from construction actions and would therefore result in effects similar to those listed above. None of the identified actions involve long-term operations with notable air emission sources. Based on available information, transportation related projects (i.e., roadway maintenance, bridge replacement, airport improvements, and even new road construction) are not anticipated to result in significant increases in traffic over what would occur without the activities. By its intended purpose, the Great River Super Site industrial park development in Region 7 is a possible exception to the earlier statement that the present and reasonably foreseeable future actions involve no notable long-term air emission sources. However, no specific future actions were identified for this site at the current time. Construction air emissions from the present and reasonably foreseeable future actions would be cumulative with those of the Project if they were to occur at the same time and in the same general area. However, most of the actions would involve air emissions, like the Project, characterized as intermittent and short term, with only minor temporary impacts on air quality in the vicinity of the construction activities.

As described in Section 3.3.5, the counties in the vicinity of the Memphis metropolitan area represent the only area along the general route of the Project that is currently classified as nonattainment with respect to any of the air quality standards. This area, consisting of Shelby County, Tennessee, Crittenden County, Arkansas, and the northern portion of De Soto County, Mississippi, is characterized as a marginal nonattainment area with respect to the 8-hour ozone standard. As a result, all actions occurring in this area that require some type of federal approval are subject to provisions of Transportation Conformity regulations (40 CFR 93 Subpart A) or General Conformity regulations (40 CFR 93 Subpart B), and sufficiently large actions are required to explicitly demonstrate conformity with State Implementation Plans (SIPs) for air quality; these regulatory requirements are in place specifically for the purpose of addressing cumulative impacts. Regions 6 and 7 of the Applicant Proposed Route are the closest of any of the regions to the nonattainment area and, therefore, might be considered the regions where cumulative air quality impacts could have the most serious adverse impacts. Present and reasonably foreseeable future actions in Regions 6 and 7 also happen to include some of the largest construction activities of any identified in Section 4.2. Specifically, US-63 access road construction in Region 6 and the I-69 extension and the Southern Gateway Project in Region 7 represent significant construction efforts. A construction date for the US-63 action was not available, but it is assumed it could be in the same time as the Project. Fugitive dust emissions would be localized; if construction overlapped between the US-63 action and the Project, short-term exhaust from vehicles and equipment could be additive but short-term and localized. It is unlikely that the two Region 7 actions (i.e., the I-69 extension and the Southern Gateway Project) would have construction impacts cumulative with the Project because neither of the actions have firm schedules; because of their large scale both are likely many years away. Also, based strictly on where most of the corridors for the Southern Gateway Project are being considered, its ultimate location, if implemented, will likely be south of the Project.

As was identified in Sections 3.3.5.3 through 3.3.5.5, air quality monitors in Regions 3, 4, and 5 show ozone levels that exceed NAAQS, so existing emissions sources that reach those monitors have a cumulative impact of exceeding the NAAQS. However, in several cases, the monitors nearest the Project were 30 or 40 miles away and were located much closer to urban centers (such as Oklahoma City and Little Rock). Monitors closer to the Project (e.g., those near Tulsa) are more relevant, yet are still well outside the ROI of the construction projects and are dominated by emissions from other sources. Therefore, while the combination of the Project and other actions would generate cumulative impacts on air quality near the Project, the Project itself would have a negligible contribution (and are also temporary and therefore do not contribute to air quality impacts on a continued basis).

For GHGs, as mentioned in Section 3.3.6.8, approximately 40 percent of national GHG emissions are from the power generation sector, and therefore actions such as the one connected to the Project—i.e., the development of wind farms for power generation, which emit almost no pollutants—can cumulatively have a significant positive impact by avoiding emissions (and are typically promoted for this very reason). In general and as identified in Section 3.3.6.8, actions connected to the Project—i.e., the development of wind farms—would generate relatively few emission during construction, and possibly more than the construction of the identified present and reasonably foreseeable future actions as well, although the locations of the emissions reductions may be completely different from the locations of the construction emissions.

Climate change is the modification of climate over time, whether due to natural causes or as a result of human activities. Climate change cannot be represented by single annual events or individual anomalies. For example, a single large flood event or particularly hot summer is not an indication of climate change. However, unusually frequent or severe flooding, or several consecutive years of abnormally hot summers over a large region, may be indicative of climate change.

The Intergovernmental Panel on Climate Change (IPCC) is the leading international, multi-governmental scientific body for the assessment of climate change. The United States is a member of the IPCC and participates in the IPCC working groups. IPCC's Fifth Assessment Report (AR5) has identified that "Consistent with the Fourth Assessment Report (AR4), it is assessed that more than half of the observed increase in global average surface temperature from 1951 to 2010 is very likely [90–100% probability] due to the observed anthropogenic increase in [well-mixed] GHG concentrations" (IPCC 2013). The leading United States scientific body on climate change is the U.S. Global Change Research Program (USGCRP). Thirteen federal departments and agencies (EPA, DOE, Department of Commerce, DOD, USDA, Department of the Interior, Department of State, DOT, Department of Health and Human Services, NOAA, National Science Foundation, Smithsonian Institution, and Agency for International Development) participate in the USGCRP, which began as a presidential initiative in 1989 and was mandated by Congress in the *Global Change Research Act of 1990* (Public Law 101–606).

The USGCRP issued its Third National Climate Assessment (NCA), *Global Climate Change Impacts in the United States,* in 2014, summarizing the impacts climate change has already had on the United States and what projected impacts climate change may have in the future. The report includes a breakdown of overall impacts by resource and impacts described for various regions of the United States.

The USGCRP has concluded that (USGCRP 2014):

- The "global climate is changing and this change is apparent across a wide range of observations. The global warming of the past 50 years is primarily due to human activities" (USGCRP 2014, p 20).
- "Carbon dioxide made up 84 percent of U.S. greenhouse gas emissions in 2011. Forty-one percent of these emissions were attributable to liquid fuels (petroleum), followed closely by solid fuels (principally coal in electric generation), and to a lesser extent by natural gas. The two dominant production sectors responsible for these emissions are electric power generation (coal and gas) and transportation (petroleum)." "If emissions from electric generation are allocated to their various end-uses, transportation is the largest CO_2 source, contributing a bit over one-third of the total, followed by industry at slightly over a quarter, and residential use and the commercial sector at around one-fifth each" (USGCRP 2014, p 652).
- Impacts extend beyond atmospheric climate change alone, and include changes to water resources, transportation, agriculture, ecosystems, and human health.

Climate change has modified the environment in the area around the Project and is projected to cause additional changes. The Second and Third NCAs identify climate change impacts that have occurred in the continental Great Plains and Southeast. Key messages of the Third NCA with respect to the Great Plains and Southeast include the following (Shafer et al. 2014; Carter et al. 2014):

- "Rising temperatures are leading to increased demand for water and energy. In parts of the region, this will constrain development, stress natural resources, and increase competition for water among communities, agriculture, energy production, and ecological needs" (Shafer et al. 2014).

- “Changes to crop growth cycles due to warming winters and alterations in the timing and magnitude of rainfall events have already been observed; as these trends continue, they will require new agriculture and livestock management practices” (Shafer et al. 2014).
- “Landscape fragmentation is increasing, for example, in the context of energy development activities in the northern Great Plains. A highly fragmented landscape will hinder adaptation of species when climate change alters habitat composition and timing of plant development cycles” (Shafer et al. 2014).
- “Communities that are already the most vulnerable to weather and climate extremes will be stressed even further by more frequent extreme events occurring within an already highly variable climate system” (Shafer et al. 2014).
- “The magnitude of expected changes will exceed those experienced in the last century. Existing adaptation and planning efforts are inadequate to respond to these projected impacts” (Shafer et al. 2014).
- “Sea level rise poses widespread and continuing threats to both natural and built environments and to the regional economy” (Carter et al. 2014).
- “Increasing temperatures and the associated increase in frequency, intensity, and duration of extreme heat events will affect public health, natural and built environments, energy, agriculture, and forestry” (Carter et al. 2014).
- “Decreased water availability, exacerbated by population growth and land-use change, will continue to increase competition for water and affect the region’s economy and unique ecosystems” (Carter et al. 2014).

4.3.4 Electrical Environment

Electrical environment impacts of concern for the Project, as described in Section 3.4.11, are associated with operation of AC and DC transmission lines and include the following:

- AC or DC electric fields that exists around charged objects (in this case, the transmission lines) and which are stronger near the charged object and decrease with distance
- AC or DC magnetic fields generated by an electric current, or flow of electrical charges (in this case, through the transmission lines), and which decrease in intensity with distance
- Audible noise cause by the natural phenomenon of electrical discharge, or corona, from energized surfaces such as a transmission line conductor
- Radio and television noise interference when electromagnetic energy from corona discharges includes the same frequencies as radio and television bands
- Ozone and air ions created by corona from a transmission line

The above effects are all associated with energized transmission lines so there would be no electrical effects of concern from potentially cumulative actions during construction.

The present and reasonably foreseeable future actions described in Section 4.2 include several for construction and operation of new electrical transmission lines. These are the only actions that potentially would involve electrical impacts cumulative with those of the Project. Present and reasonably foreseeable future actions with these traits are limited to Regions 1, 2, and 3. The Region 6 Trumann to Trumann West transmission line is outside of the electrical environment ROI and therefore too far to have additive effects with the Project. No electrical transmission line projects are identified for Regions 4, 5, or 7. In Regions 1, 2, and 3 the actions of interest are all OG&E transmission line actions: Hitchland-Woodward in Region 1, Woodward-Thistle in Region 2, and Seminole-Muskogee in Region 3. In Region 1, the OG&E line runs parallel to the Applicant Proposed Route through Beaver County. In Region 2, the OG&E line crosses Link 1 of the Applicant Proposed Route and one of the OG&E alternatives appears to parallel portions of HVDC Alternative Route 2-A. In Region 3, the OG&E line crosses the Applicant Proposed Route as well as the HVDC alternative routes.

These OG&E actions are all high voltage AC transmission lines, whereas the Project is an HVDC transmission line (with associated high voltage AC collector lines and interconnections). Transmission lines within the United States are operated either as DC (Direct Current or constant/static/fixed frequency of 0 Hertz) or AC (Alternating Current or alternating frequency of 60 Hertz). Static electric and magnetic fields (such as those created by HVDC transmission lines) are also naturally present in the earth's environment. For example, the earth creates a natural static electric field in fair weather and underneath clouds, and a natural static magnetic field allows compass needles to point to the magnetic North Pole. However, AC electric and magnetic fields only occur near AC electrical sources (such as AC transmission lines and electrical appliances). Electric and magnetic fields produced by AC electrical sources reverse direction at a frequency of 60 cycles per second (60 Hertz) whereas static fields are constant and do not change direction. Comparisons between DC and AC fields may therefore not be straightforward, especially when combining fields from both DC and AC sources.

The OG&E transmission lines have 345kV capacities and, individually, their electrical impacts would be expected to be similar to impacts from the 345kV double circuit AC interconnection line associated with the Oklahoma converter station described in Section 3.4.11.2.1 and the 345kV single circuit AC collection system routes described in Section 3.4.11.2.2. However, as described in Section 3.4.11, impacts at or near ground level can vary substantially based on the height of the structure and on the structure/line configuration as well as the electrical energy transmitted. The loading (or anticipated MW capacity) will specifically impact magnetic field levels.

Areas where transmission lines of the Project and present and reasonably foreseeable future actions would potentially have cumulative impacts are limited to crossing points and collocated stretches (with centerlines within about 600 feet of one another). The evaluation of impacts from the Project considered other transmission lines already present in the Project regions and, in Section 3.4.10, states that electrical effects from existing transmission lines may influence the electrical effects associated with the Project's transmission line and that those effects could be additive or subtractive. Section 3.4.10 then indicates that because the route for the HVDC transmission line has not yet been selected and because of the numerous existing transmission lines in the various regions, calculations of the combined electrical effects were not performed at this time. The same holds true for the newly identified transmission line actions. However, without performing calculations, it can be reasoned that locations where transmission line routes crossed would likely be sites of the highest cumulative impacts, but the affected area would be contained within the limits of the generated fields, which are relatively small as described in Section 3.4. On the other hand, collocated transmission line routes would require adequate separation so the magnitude of the cumulative effects would be less, but the area affected would be greater as described in Section 3.4.

4.3.5 Environmental Justice

Disproportionately high and adverse effects to low-income and minority populations can result if actions cause disproportionately high and adverse human health or environmental effects to minority or low-income populations. Section 3.5.5 identifies locations within the ROI for this resource where Census data indicate locations with a high percentage of minority or low-income residents. Minority populations include individuals who are Black or African American, American Indian and Alaska Native, Asian, Native Hawaiian and other Pacific Islander, other non-white race, or persons of two or more races and Hispanic or Latino (CEQ 1997). For the evaluation in this EIS, minority population areas of concern are those where 50 percent or more of the population within the Census Block is minority or if the percentage of the minority population is 10 percent or more above the minority population of the county as a whole. Low-income population areas of concern are those where 20 percent or more of the households within the Census Block Group have incomes below the poverty level.

For the impact evaluations of the Project (Section 3.5.6), it was concluded for each of the Project components that while there is potential for impacts, it is anticipated that such impacts would not be disproportionately high and adverse and would affect all populations in the ROI equally. Accordingly, the Project would not result in disproportionately high and adverse effects to minority or low-income populations. The significance of "disproportionately high and adverse effects" is identified in Section 3.5.1 and the methods used in evaluating potential impacts for the Project are presented in Section 3.5.6.1. The present and reasonably foreseeable future actions described in Section 4.2 could involve cumulative environmental justice concerns if, in combination with the Project, impacts were raised to a "disproportionately high and adverse" level as described in Section 3.5.6.1.

In the Section 3.5.6.2.3 discussion of impacts associated with the HVDC Applicant Proposed Route, it is noted that potential low-income and minority populations are identified in all of the counties crossed in Regions 4, 5, 6, and 7. In the other regions, only some of the counties have qualifying minority and low-income populations. Accordingly, Regions 4, 5, 6, and 7 would be most likely to present cumulative impacts that could raise environmental justice concerns. In the case of Regions 4, 5, and 6, identified present and reasonably foreseeable future actions are, with a single exception, limited to road maintenance plus a hydroelectric plant proposed in Region 4 that is 12 miles from the nearest Project route (although within a county affected by the Project), a natural gas pipeline project in Region 5 that is 16 miles from the nearest Project route, and a rebuilt transmission line in Region 6 that is 10 miles from the nearest Project route. The pipeline project is outside the counties affected by the Project and therefore not expected to contribute to impacts that would be cumulative with those of the Project. The roadway activities might be considered no more than short-term changes to an existing source of impacts (i.e., impacts associated with traffic and highway operations). Based on the best available information, it is not known whether the hydroelectric plant would result in disproportionately high and adverse effects to low-income and minority populations. Because the hydroelectric plant and the Project would affect different areas of the same county, separated by many miles, they would not affect the same individuals of the population. For these reasons, it is unlikely that impacts from any of these actions or activities could combine with those of the Project to reach disproportionately high and adverse levels.

The single Region 4 and 5 exception to the preceding is the Diamond Pipeline action, which would overlap with the Plains & Eastern Project in the center of Region 3, the eastern end of Region 4 and the western half of Region 5. Most impacts associated with the Diamond Pipeline action would occur during construction, as is the case with the Plains & Eastern Project. The impacts of both projects could affect the same population and that population could include a high percentage of minority or low income residents. If the combination of impacts from the two projects were raised to a "disproportionately high and adverse level," there could be cumulative environmental justice concerns. After construction, there could be similar cumulative land use concerns if ROW restrictions for the two projects impacted the same landowners.

In the case of Region 7, it has two of the largest scale present and reasonably foreseeable future actions of any of the regions (the I-69 expansion and the Southern Gateway Project). However, as described in Section 4.3.3 on cumulative air quality impacts, the two large projects (I-69 and Southern Gateway) currently do not have firm schedules so are unlikely to be constructed in the same time frame, and the Southern Gateway action is unlikely to be in the same area as the Project's construction so there would be little potential for cumulative impacts. Region 7 also has two development areas planned: an industrial park (Great River Super Site) and a housing community (Green Meadows). Based on the best available information, it is not known whether these development areas would result in impacts to low-income and minority populations. Because of the relatively small size and large distance between the Great River Super Site and the Project, disproportionately high and adverse cumulative impacts to low-income and minority populations are not anticipated. The Green Meadows development would occur in an area of Tipton County identified as farmland (Epley 2012), which is still classified as a farm in the Tipton County property assessment of 2014 (Section 4.2.7), and is, therefore, not anticipated to displace low-income and minority populations. As a result, disproportionately high and adverse cumulative impacts to low-income and minority populations from the development and the Project are not anticipated.

4.3.6 Geology, Paleontology, Minerals, and Soils

Consistent with the presentation of the affected environment and impacts in Chapter 3, this section's discussion is presented in two separate groupings: (1) geology, paleontology, and minerals; and (2) soils.

4.3.6.1 Geology, Paleontology, and Minerals

Geology, paleontology, and mineral impacts of concern for the Project, as described in Section 3.6.1.6, include the following:

- Geologic hazards in the form of seismicity, landslides, subsidence related to karst, and seismically induced liquefaction
- Paleontological resources and the potential for loss of important fossils as a result of the Project's ground-disturbing activities or from vandalism or unauthorized collection given the increased access generated by the Project
- Mineral resources and the potential for the Project to interfere with existing mineral extraction operations, reduce access to underlying minerals, and interfere with future mineral extraction operations

Most impact evaluations are performed to assess the effects of the Project on the site's natural conditions. For geology, however, an evaluation of concern is the potential for damage to the Project from the natural geological conditions or characteristics of the Project site. As such there would be no cumulative impacts from other present or reasonably foreseeable future actions because, like the Project, the actions described in Section 4.2 would not be expected to increase geologic hazards. Landslide hazards are the exception in that they are evaluated both for the possibility of adverse impacts to the Project and for the Project to aggravate natural conditions such that landslide risks are increased for other entities or properties. For the Project, the potential to impact landslide risks would occur only during construction and this would also be the expected case for present and reasonably foreseeable future actions. In addition, other actions would have to be quite close to the Project (i.e., within its ROI) to have cumulative impacts on landslide risks.

The Project's potential impact (Section 3.6.1.6) on mineral resources is addressed by identifying the following EPMs that would be implemented by the Applicant: (1) the Project would be designed to avoid crossing any active oil or gas well pads or impeding access to these such resources; (2) the Applicant would work with landowners and operators of active oil and gas wells, utilities, and other infrastructure to identify and verify the location of Project components and to minimize adverse impacts; and (3) the Applicant would coordinate with landowners to site access roads and temporary work areas to minimize impacts to existing operations and structures to the extent practicable. Since no adverse impacts to mineral resources were identified in the evaluation of the Project, there would be no contribution to cumulative impacts.

No known fossil bed sites have been identified within the ROI of the Project, but it is recognized that grading and excavation activities have the potential to uncover and impact paleontological resources. To minimize the potential for such impacts personnel will be trained in the practices, techniques, and protocols required by federal and state regulations and applicable permits (EPM GE-1 in Appendix F). In accordance with EPMs, construction footprints would also be minimized, which would reduce the potential for impact to paleontological resources. In this case, any present or reasonably foreseeable future action located within the ROI and involving ground-disturbance would be expected to have the same potential to impact paleontological resources as the Project. These impacts would be cumulative only to the extent that increases in the amount of ground disturbed might be expected to increase the probability for encountering paleontological resources. There is no means to evaluate how much the probability might change, but it would be expected to be minimal.

Considering the above limitations or conditions on what actions could be cumulative with those of the Project, it appears landslide-prone areas in the ROI could be locations where cumulative actions could occur. Regions 3, 4, 5, and 7 are the only regions identified in Section 3.6.1.6 with areas of moderate or high susceptibility for landslides and the Project would avoid sloped areas whenever practicable. It is assumed that the road maintenance work identified in Section 4.2 for Regions 3, 4, 5, and 7 would not involve areas of new ground disturbance, so landslide conditions would not be aggravated even if the work took place in areas of concern. With the road work eliminated, only the OG&E Seminole-Muskogee transmission line and the Diamond Pipeline actions in Region 3 would appear to involve construction action within the Project's ROI. However, since construction of the Region 3 OG&E transmission line has already been completed, its construction activities would not contribute to cumulative impacts (Section 4.2.3) and any crossed areas of landslide risk would have been stabilized to protect the equipment. The portion of the Diamond Pipeline action that appears to overlap the Plains & Eastern Project in Region 3 is outside the areas with moderate or high susceptibility for landslides. Therefore, no cumulative impacts with respect to increasing landslide risks would be expected.

In Region 4, the possible hydroelectric plant is well outside the Project's ROI and the only other construction actions are the new section of Highway 71 south from Alma, Oklahoma and the Diamond Pipeline. Link 6 of the Applicant Proposed Route crosses the path where the new road is planned but the applicable area to the south of Alma has only mild slopes, so no landslide risks would be expected. The Diamond Pipeline path appears to overlap or be very near HVDC Alternative Route 4-E at the eastern end of the region in an area of moderate susceptibility to, and low incidence of landslides, so landslide risks would be minor. In Region 5, two of the construction actions (the Highway 7 Dover bypass and the Enable Central Arkansas Natural Gas Pipeline Enhancement Project) are outside the Project's ROI; the third (the Diamond Pipeline) would be near the Plains & Eastern Project in the western half of Region 5, an area of moderate susceptibility to, and low incidence of landslides, so landslide risks would be minor.

Several of the present and reasonably foreseeable future actions in Region 7 involve construction actions; however, the Great River Site and the Green Meadows developments are both outside the Project's ROI. The I-69 Extension and the northern-most corridor (i.e., Corridor V1-7) being evaluated for the Southern Gateway Project would cross the Applicant Proposed Route or one of the HVDC alternative routes, but both in areas just outside of Millington, Tennessee, where there is farming and scattered housing developments, without significant slopes. Landslide risks would not be expected in these areas.

4.3.6.2 Soils

Soil impacts of concern for the Project, as described in Section 3.6.2.6 and which could involve cumulative impacts, include the following:

- Designated Farmlands—Construction disturbance could result in a decrease in productivity and quality of designated farmland and in places of permanent structures some farmland could be taken out of production.
- Soil Limitations—Site specific soil conditions could result in the following: (1) exposure of erosion-prone soil to conditions of increased erosion potential; (2) soil with high compaction potential would be susceptible to compaction from construction vehicles and equipment; and (3) disturbance of areas of steep slopes could cause increased erosion hazards.

Per the Section 3.6.2.6 evaluations, designated farmlands are present to some degree within the ROI of each of the Project's primary components, which includes the Applicant Proposed Route and the HVDC alternative routes in each of the regions. Similarly, soils with high compaction potential and with moderate to high wind erosion potential are present within each ROI and soil with high water erosion potential is present in most. With respect to designated farmland, the evaluations in Section 3.6.2.6 conclude that construction disturbance could result in a decrease in the productivity and quality of designated farmland. Because of the prevalence of designated farmland, the present and reasonably foreseeable future actions described in Section 4.2 that involve new ground disturbance would be expected to involve impacts that could be additive with those of the Project. Similarly with regard to the soil limitations of concern, other actions involving ground disturbance would be expected to have cumulative impacts. In this case, the cumulative impacts would be additional soil areas of increased erosion potential and of susceptibility to compaction.

Many of the actions identified in Section 4.2, particularly those associated with upgrades or maintenance actions for existing roadways, bridges, or airports, would be expected to involve minimal, if any, new disturbance of ground and, accordingly, would be unlikely to affect designated farmland or soil limitations. As has been noted in preceding evaluations, the transmission line and pipeline activities identified in Section 4.2 for Regions 1, 2, and 3, are representative of present and reasonably foreseeable future actions that could involve new ground disturbance within the ROI of the Project. Accordingly, these are the actions and regions most likely to involve cumulative impacts to designated farmlands and soil limitations. As mitigating factors, these Section 4.2 actions, like the Project, are linear (long, narrow) activities with relatively small amounts of ground disturbance considering the amount of area crossed. Also, once the construction is complete and disturbed ground has been recovered, use of the disturbed ground can be resumed to some extent and adverse impacts lessened.

4.3.7 Groundwater

Groundwater impacts of concern for the Project are associated with the potential for groundwater contamination, changes to infiltration rates, effects on water availability, and physical damage to well systems. As noted in the Section 3.7.6 discussion of impacts, these concerns would be limited primarily to the construction phase of the Project. The present and reasonably foreseeable future actions described in Section 4.2 for each of the regions would present similar concerns and, likewise, would appear to present possible concerns primarily during construction. Accordingly, there were no specific actions identified that would appear to involve long-term operations that could adversely affect groundwater, including no actions that would be expected to use large quantities of water during long-term operations.

The actions identified in Section 4.2 would be expected to involve the presence of the same type of potential contaminants (primarily fuels and lubricants in equipment) during construction and to implement the same type of measures to ensure those contaminants were not released. The actions would be expected to involve relatively minor changes to infiltration rates and, to decrease their own liability, would be expected to take precautions to ensure that equipment movement and excavations did not unknowingly damage well systems. As with typical construction activities, water likely would be needed for actions such as dust suppression, soil compaction, equipment cleaning, and concrete formulation. However, like the Project, these water demands would be relatively minor and short term. Potential impacts to groundwater from construction of the Project and from construction of the actions described in Section 4.2 would be minor.

Of the actions described in Section 4.2, it is estimated that Regions 3 and 7 could have the greatest potential for cumulative impacts with the Project. None of the specific actions identified in Section 4.2 would be expected to have high water use or high potential for groundwater contamination during operations and maintenance, so potential impacts during construction would be the primary concern and actions in Regions 3 and 7 appear to be associated with the greatest number and size of construction actions. Region 3 has many road tasks planned, an action to replace a dam bridge, an action to improve airport pavements, construction of another transmission line, and construction of two crude oil pipelines. Possibly the largest single action in the region, the dam bridge, is scheduled to be completed prior to the construction start of the Project. The road, transmission line, and pipeline actions involve only modest construction efforts, with relatively small disturbances scattered over a large area, just as with the Project.

Region 7 is the smallest region in terms of the length of the Applicant Proposed Route, but has some of the largest potential actions. Specifically, the I-69 extension and the Southern Gateway Project represent significant construction efforts. Also the Great River Super Site is being developed as an industrial park that could ultimately involve a wide range of industrial activities. However, it is likely that neither of the first two actions would have construction impacts cumulative with the Project. The I-69 extension in the area of the Project lacks a firm schedule and is likely many years away. The Southern Gateway Project may also be many years away since the EIS has yet to be completed and, based strictly on where most of the corridors are being considered, its ultimate location, if implemented, will likely be south of the Project. The Great River Super Site can only be identified as involving potential cumulative impacts because the reference material does not identify any specific actions currently being planned or initiated; it is simply being identified as a location where industrial actions may take place. Construction and operation of heavy industries, such as a steel industry, would be expected to include use of hazardous materials that could pose a threat of groundwater contamination if spilled or leaked, similar to the threat posed by fuels and lubricants that would be present during construction of the Project. Like the Project, any new heavy industry would be expected to incorporate the structures, plans, and procedures required by environmental regulations to minimize the potential to cause groundwater contamination. Heavy industries may also have high water demands, but being adjacent to the Mississippi River, it is likely that high volume uses such as for cooling would come from surface water rather than groundwater. The other action of note in Region 7, the Green Meadows housing development, is also outside of the ROIs for groundwater and would not be expected to involve impacts to groundwater other than contributing to consumptive uses.

4.3.8 Health, Safety, and Intentional Destructive Acts

As described in Section 3.8.5, the impact areas of potential concern from the Project in the category of health, safety, and intentional destructive acts include the following: (1) worker and public health and safety, including management of hazardous materials, (2) aircraft and rail operations, (3) fire hazards, (4) natural events and disasters, (5) intentional destructive acts, and (6) protection of children. The last item, protection of children, is addressed in a manner similar to what is described in Section 4.6.2 for environmental justice in that it addresses whether the Project could cause disproportionately high and adverse effects on child health and safety. Section 3.8.5 describes potential effects of the Project in these impact areas during construction, operations and maintenance, and decommissioning.

The above impact areas can only be addressed in very general terms or based on statistical records from previous implementation of similar actions (i.e., historical records). Regardless, adverse effects are not expected to worsen from any of the present and reasonably foreseeable future actions described in Section 4.2. Essentially any work action is associated with a certain level of risk to workers and to the public. Accordingly, the more work is being done, the higher the probability there will be injuries or even fatalities while that work is being performed. Restated, the greater the amount of work and the greater the number of workers involved, the greater the number of incidents that would be predicted, based on statistical records, for a given amount of time. In the sense that these numbers of predicted incidents would increase, then the Section 4.2 actions are cumulative, but more significantly there would be a high concern if expected rates of health and safety incidents for any action were expected to increase because of synergistic or proximity effects of another action. There is no reason to expect this type of cumulative impacts would occur. The impact area of natural events and disasters provides a good example of this reasoning. The more work and people in a single area, the greater the number of injuries that would be expected if hit by an intense earthquake or violent weather, but the probability or risk of an intense earthquake or violent weather striking that area does not change.

The impact area of aircraft operations might be considered an outlier to the preceding discussion because increasing the number of structures, such as for transmission lines, in any area might be considered as increasing the risk of collisions with individual aircraft. Similarly, helicopters may be used during the Project for surveying, structure installation, and line and conductor stringing. If other transmission line projects were to be constructed at the same time and in the same area, there could be an increased risk of aircraft accidents from such operations.

4.3.9 Historic and Cultural Resources

Historic and cultural resource impacts of concern for the Project are associated with following types of resources and applicable impacts:

- Archaeological sites—These sites are primarily vulnerable to soil-disturbing activities, but in rare cases the site's relationship to the surrounding environment is an essential characteristic and could be subject to visual impacts.
- Historic properties (buildings, structures, objects, and landscape features)—Assuming the Project would avoid any direct impacts to these properties, impacts could involve introduction of non-historic visual or, occasionally, auditory elements.
- Tribal lands or historic properties of religious and cultural significance to an Indian Tribe (as determined from background research and Indian Tribe consultations per Section 3.9.2)—These could be subject to impacts from direct physical disturbances or from changes to the visual surrounding, auditory field, or other characteristics of their setting.

Although sufficient information is available to complete this EIS, it is recognized in the Section 3.9.6 evaluation of impacts that detailed information on the historic and cultural resources that could be within the Project ROI is currently limited and that more detailed assessments will be made prior to construction.

The assessment of potential impacts for the Project is based on regional geography and archaeological, historic, and tribal resources available from background research, primarily of information on file with the respective SHPOs and the NPS. Based on the available information, Section 3.9.6.2.3.1 presents descriptions of the potential for construction activities to encounter historic and cultural resources within each region's ROI. Region 7 is described as having the potential for numerous historic and cultural resources, while Regions 3, 4, 5, and 6 contain a moderate number of resources. Region 7 contains 13 inventoried archaeological sites and 40 inventoried historic buildings (although none are on the NRHP), which is the most inventoried sites for any of the regions. This may be attributed to there being more surveys in the Region 7 area that happen to have some overlap with the Project ROI, but for purposes of this discussion it is assumed that actions in Region 7 would be most likely to involve cumulative impacts. Although regions are singled out in this discussion as having higher potential for adverse impacts, it should be noted that the evaluations of impacts in Section 3.9.6 conclude that with proper precautions, such as implementing appropriate cultural resource surveys and incorporating micrositing adjustments as needed in Project engineering, adverse impacts to cultural resources would be resolved by avoidance, minimization, or mitigation throughout all Project regions.

To the extent that the present and reasonably foreseeable future actions described in Section 4.2 involve new ground disturbance or changes in the visual or auditory characteristics of the area, their impacts on historic or cultural resources could be additive with those of the Project. However, unless ground disturbance areas overlapped or were in very close proximity to one another, visual changes were in the same viewshed, and sound changes were close enough to be additive, the impacts would be on different sites. Accordingly, as described for several other resource areas, cumulative impacts would be more likely to involve increased potential to adversely impact historic or cultural resources in general, rather than the same resource site.

The Section 4.2 actions in Region 7 include two of the largest scale present and reasonably foreseeable future actions of any of the regions (the I-69 expansion and the Southern Gateway project) as well as two development areas, one as an industrial park (Great River Super Site) and another as a housing community (Green Meadows). The only other action identified in Section 4.2 consists of road maintenance, which would not be expected to involve significant new ground disturbances. As described in Section 4.3.3 on cumulative air quality impacts, the two large actions are unlikely to be constructed in the same time frame as the Project's construction, and the Southern Gateway project is unlikely to be constructed in the same area, so there would be little potential for cumulative impacts. With regard to the two development areas, there could be cumulative impacts during construction, but nothing has been identified of specific consequence in either area and given their stage of development, both areas have likely been surveyed for resources.

4.3.10 Land Use

The evaluation of potential land use impacts associated with the Project is focused on the types of existing land uses within the transmission line ROWs, converter station construction sites, and other land areas that would change by being tied up for the operational life of the Project. It differentiates between those areas of fully dedicated Project use (e.g., sites of converter stations, structures, and permanent access roads) from ROW areas where existing land use may continue after construction, but with certain limitations. It also addresses potential effects of those land areas where Project use or disturbance would only occur during construction, including areas used for such things as equipment staging, temporary access roads, tensioning and pulling sites, and fly yards.

To the extent that the present and reasonably foreseeable future actions described in Section 4.2 involve new land uses, their impacts could be cumulative with those of the Project. Like the Project, impacts of the Section 4.2 actions could involve land use changes during construction that would be relatively short term and others that would last for the duration of the action. Other transmission line tasks, such as those identified for Regions 1, 2, and 3, would be expected to have a similar distribution of short- and long-term impacts to those of the Project.

Many of the actions identified in Section 4.2, particularly those associated with upgrades or maintenance actions for existing roadways, bridges, or airports, would be expected to involve minimal, if any, changes to existing land uses and, accordingly, would be unlikely to generate impacts that would be cumulative with the potential impacts from the Project. As has been noted in other evaluations, the transmission line actions identified in Section 4.2 for Regions 1, 2, and 3, may be the best examples of present and reasonably foreseeable future actions that could involve new ground disturbance and changes in land use within the ROI of the Project, which is the area where Project impacts, if more than negligible, would be expected to occur. Accordingly, these are the actions and regions most likely to involve cumulative impacts to land use. Potential impacts to land use for these actions would be very similar to those described in detail in Section 3.10.6 for the Project. Land uses in areas affected by the other transmission line actions would be expected to be similar, although with different distributions in percentages of land cover and development levels than described in Section 3.10.6 for the Project. The Section 4.2 actions, like the Project, are primarily long, narrow activities with relatively small amounts of ground disturbance considering the amount of area crossed, which tends to minimize the amount of land use changes on a regional basis. Also, once the construction is complete, much of the affected land could return to previous land uses such as agriculture (grazing and crops); however, there would be new restrictions on land uses that would be permitted in the future within the ROW including limitations on buildings or structures, on changes to grading and land contours, and on some infrastructure like fences and irrigation lines. Other transmission lines crossing or running adjacent to those of the Project could also exacerbate ROW-type limitations because of the odd shaped parcels or narrow bands of land created by the intersecting or parallel ROWs. Such parcels could be outside of the ROW and therefore have no land use restrictions, but their size or configuration could effectively limit the types of land use that would be feasible.

4.3.11 Noise

Noise impacts for the Project are identified at NSAs receiving unacceptably high levels of noise during construction or operations. For construction activities the evaluation in Section 3.11.6 uses limits set by the Federal Highway Administration of the U.S. Department of Transportation for its construction projects, which are 90 dBA L_{eq} for daytime activities and 80 dBA L_{eq} for nighttime activities. For operation and maintenance activities, the Project is evaluated against a guideline set by EPA of 55 dBA L_{dn}. The methodology in Section 3.11.6 used noise modeling techniques to determine critical distances from the noise sources, which are defined as the distance at which limits are first met. Examples of the critical distance values used in the Project evaluation include (1) for construction of HVDC transmission lines, within 100 feet would be at or above the daytime noise level limit of 90 dBA L_{eq} and 325 feet for the nighttime noise level limit of 80 dBA L_{eq}, and (2) the critical distance for operation and maintenance noise from the HVDC transmission lines would be 130 feet to be at or above the noise level limit of 55 dBA L_{dn}. Adverse impacts would be expected if NSAs are located within the critical distances of construction, which is assessed from the Project's representative ROW limit and of operation, which is assessed from the representative ROW centerline.

All of the present and reasonably foreseeable future actions described in Section 4.2 involve sources of noise that, when considered in conjunction with the Project, could result in potential cumulative noise impacts at the NSAs. The magnitude of potential cumulative noise impacts directly corresponds to the proximity of the actions described in Section 4.2 relative to the Project and the noise generated by the Section 4.2 actions. As a general rule, doubling the amount of sound energy at a location would increase received sound levels by 3 dBA. If one source is approximately 10 dBA louder than another source then it will dominate the other sound source. Also, doubling the distance from a linear noise source decreases the sound level by about 3 dBA and doubling the distance from a point source decreases the sound level by about 6 dBA.

In comparing the number of NSAs in Regions 1 through 7, Table 3.11-8 in Section 3.11.6.2.3 identifies Region 4 as having the greatest number of NSAs within daytime and nighttime critical distances (i.e., the distances within which NSAs would experience excessive noise levels) for construction of HVDC transmission lines. Based on this, it might be assumed that present and reasonably foreseeable future actions in Region 4 would have a greater potential for adverse cumulative impacts than in other regions. However, with the exception of the Diamond Pipeline action, most of the Section 4.2 actions in Region 4, consisting of numerous roadway projects and construction of a hydroelectric plant, are more than 0.5 mile from components of the Project, so cumulative noise impacts would be limited. Region 3 contains the next highest number of NSAs and Section 4.2 actions in Region 3 include multiple roadway and bridge maintenance actions that are within 0.5 mile of Project components (either segments of the Applicant Proposed Route or HVDC alternative routes) as well as a portion of the Diamond Pipeline action. In several instances, the Project routes cross the roadway segment identified for action, and in the central part of Region 3, the path of the Diamond Pipeline could overlap the Plains & Eastern Project. There are no implementation dates identified for the Arkansas road activities, but if the Project and an Arkansas road activity or the Diamond Pipeline action were to occur at the same time at a crossing point (a conservative assumption for cumulative impacts to occur), there are some approximations of construction noise that could be made with regard to potential impacts. If the roadway maintenance action or Diamond Pipeline action involved noise levels as high as those projected for construction of the Project, then the criteria evaluated in Section 3.11.6 would increase by up to 3 dBA. This would act to expand the critical distances beyond the 100 feet for the daytime noise level of 90 dBA L_{eq} and 325 feet for the nighttime noise level of 80 dBA L_{eq} and the increased area would potentially encompass additional NSAs into the area of potential adverse impacts. However, the expanded critical distances would be less than double those used for the Project, because doubling the distance would act to reduce noise levels by about 6 dBA. Accordingly, there would be potential for cumulative impacts, but they would not be expected to involve large numbers of additional NSAs. Moreover, the amount of time the Project would be a crossing point with some other action, such that noise sources would coincide, would be relatively small.

The Section 4.2 present and reasonably foreseeable future actions in Region 3 also include a transmission line activity that would be crossed by the Project. In this case the Seminole to Muskogee transmission line is already constructed, so associated noise would not be cumulative with the Project. Noise associated with operation and maintenance of the Seminole to Muskogee line could be cumulative with the Project, but would be expected to be minor.

4.3.12 Recreation

Potential recreation impacts of concern for the Project, as described in Section 3.12.6, include possible direct effects from construction such as the interruption of recreational activities (including hunting, fishing, wildlife viewing, hiking, camping, and canoeing) due to temporary closure of a recreational area or interruptions from noise, human activity, or visual disturbance in a recreational area. After construction, potential long-term impacts of concern include effects to the scenic landscape of a recreational area, both from the transmission lines and structures and from the changes in vegetation and habitat associated with the ROW, along with periodic interruption of recreational activities that might be caused by maintenance activities. Also of concern over the long-term would be the potential to cause indirect impacts such as decreased use of the recreation area from users opting for a similar recreation area without transmission lines or associated facilities. This last effect could be accompanied by increased visitation at other recreational sites in the area, which could be detrimental to other recreational sites (if overloaded). The impact evaluations in Section 3.12.6 conclude that no components of the Project would permanently preclude use of or access to any existing recreation areas.

To the extent that the present and reasonably foreseeable future actions described in Section 4.2 could involve similar effects on the same recreational sites, their impacts could be additive with those of the Project. For example, any other construction action in similar proximity to a recreation area could have the same potential for interruptive impacts (noise, visual disturbance, access restrictions) as the Project. Per the Section 3.12.5 descriptions of the seven regions, Region 4 appears to encompass the greatest number and variety of recreational areas, including the following Oklahoma and Arkansas areas (from Section 3.12.5.4):

- Robert S. Kerr Lake and Webber Falls Reservoir
- Ozark-St. Francis National Forest
- Ozark National Forest WMA
- Frog Bayou WMA
- Ozark Lake WMA
- Arkansas Scenic Byways: State Highway 540/Boston Mountains Scenic Loop; State Highway 23/Pig Trail Byway; and State Highway 21/Ozark Highlands Scenic Byway
- Arkansas Scenic Highways: State Highway 220, State Highway 59, Interstate Highway 40, U.S. Highway 71
- The Trail of Tears National Historic Trail
- Portions of the Lee and Little Lee creeks wild and scenic rivers managed by the OWRB and listed on the NRI

Therefore, it is assumed the present and reasonably foreseeable future actions identified for Region 4 would likely have the highest potential for recreation impacts that would be cumulative with impacts of the Project.

As was described in the preceding discussion of cumulative noise impacts, the Section 4.2 actions in Region 4 consist of numerous roadway activities, in both Oklahoma and Arkansas, construction of a hydroelectric plant, and construction of the Diamond Pipeline. However, the only Region 4 activities within 0.5 mile of the Project components are the road actions planned within Crawford County, Arkansas, and the Diamond Pipeline, which could overlap portions of the Plains & Eastern Project in Johnson and Pope counties, Arkansas. Of the road projects, two are crossed by the Applicant Proposed Route and two others are crossed by the HVDC alternative routes. Several of the recreation areas identified within Region 4 are located in Crawford County, so cumulative impacts on those areas would be possible. No implementation dates are identified for the Arkansas road actions, but if the Project and an Arkansas road action in Crawford County were to occur at the same time (a worse case assumption), there could be cumulative impacts. Since the applicable Section 4.2 actions are road activities, interruption of access to recreation areas could occur. The noise and visual disturbances associated with road maintenance or construction actions could also be cumulative impacts. Once road maintenance tasks were complete, no additional impacts of a cumulative nature would be expected. However, one of the Crawford County actions identified in Section 4.2 is for a new road, so its completion could represent a new long-term impact similar to the Project in that its presence could involve detrimental impacts to the scenic landscape. With regard to the Diamond Pipeline, similar cumulative impacts could occur, but of the Region 4 recreation areas identified above, only Big Piney Creek is located where there could be cumulative impacts with the Project, i.e., in the eastern portion of Region 4.

4.3.13 Socioeconomics

The socioeconomic impact analysis for the Project in Section 3.13.6 evaluated potential impacts to population, economic conditions, including the agricultural sector, housing, property values, community services, including law enforcement and fire protection, medical facilities and education, and tax revenues. Section 4.2 identifies a number of present and reasonably foreseeable future actions that could contribute to cumulative impacts, including other transmission lines, oil and natural gas pipelines, other energy facilities, and road and highway improvement activities.

In cases where other construction activities coincide in space and time with the Project, there would likely be an increase in the projected influx of temporary workers and increased demand for temporary housing resources and goods and services. Peak temporary increases in population for the Project are expected to range from less than 0.1 percent (Region 7) to 1.6 percent (Region 1) of the existing 2012 populations for the affected regions. These potential impacts and associated cumulative effects would be short term and temporary. Operation of the Project facilities would require an estimated permanent staff of about 87 workers spread across the different regions. This expected permanent employment would not likely have a noticeable effect on existing short- or long-term population trends and demand for housing and goods and services.

Local expenditures, employment, and construction-related earnings from the Project would have a positive impact on the local economy and employment for the duration of construction. These positive impacts would be increased if other ongoing and reasonably foreseeable future construction actions were to coincide in time with the Project. The resulting cumulative effects would be positive and short term. Long-term economic impacts from the Project would be primarily associated with operation and maintenance-related expenditures of materials and supplies and ad valorem tax revenues. Economic impacts associated with operation and maintenance would be small, especially when compared to the construction-related and ad valorem tax impacts, and the incremental addition of these impacts to other ongoing and reasonably foreseeable future actions would be relatively minor.

Viewed in conjunction with the Project, the combined impacts of the present and reasonably foreseeable future actions identified in Section 4.2 are unlikely to noticeably affect overall agricultural production and employment in the affected counties. Cumulative impacts could, however, be potentially significant for individual agricultural operations due to direct impacts to agricultural land and structures from construction and to agricultural operations given the long-term presence of Project components and their need for periodic maintenance, and as further discussed in Section 4.3.2.

A temporary influx of construction workers associated with other ongoing and reasonably foreseeable future construction actions that coincide in time with the Project could add to the demand for temporary housing resources and goods and services. Viewed in conjunction with the Project, this could result in shortages in housing for temporary construction workers in some locations depending on actual construction schedules (which would be affected by permitting processes, prevailing economic conditions, and the availability of construction contractors), as well as demand from other sectors of the economy, including the oil and gas and travel and tourism industries. This is especially likely to be the case in Region 1 where there is limited housing availability. Unlike other regions of the HVDC Applicant Proposed Route, there are no large communities within 2 hours commuting distance of Region 1 and economic development organizations in the Oklahoma Panhandle region have identified a potential shortage in permanent housing in and around the city of Guymon in Texas County. The potential for a shortage of temporary housing in Region 1 is increased by the fact that the Project includes multiple components (i.e., converter station, AC collection system, and HVDC transmission line) that could feasibly be under construction at the same time or with overlapping times. This potential issue is further exacerbated by the potential construction and operation of the future wind energy facilities in Region 1 that are evaluated as connected actions to the Project in Section 3.13.6.8.

The actions in Region 1 (Section 4.2) consist of two by OG&E (a transmission line and a substation) and several planned by the OKDOT. The OG&E actions are complete and in service, so cumulative impacts associated with housing demand would not be expected. Review of the latest OKDOT 8-Year Construction Work Plan (OKDOT 2013a) identified a number of potential road and bridge actions in Region 1. Currently planned to take place over multiple years (2014 through 2021), one or more of the planned actions could coincide in time with the Project and potentially add to the demand for temporary housing resources and goods and services in and around Region 1. Incremental additions in demand associated with planned OKDOT activities would be small compared to housing demand associated with the Project, with potential demand reduced if the planned work were performed by OKDOT employees or construction companies based in nearby areas. For the purpose of socioeconomic analysis and demand on resources, it is reasonably assumed local workers are already established within their communities and would not contribute to cumulative impact.

The temporary relocation of construction workers to the socioeconomic ROI would create increased demand for community services such as education, medical facilities, municipal services, police, and fire in addition to retail services. Other ongoing and reasonably foreseeable future construction actions that coincide in time with the Project could add cumulatively to this demand. These potential cumulative effects would be short term and temporary given the nature of construction associated with linear facilities. Workers would relocate to new locations once the majority of their work is completed in an area and they relocate to another segment of an activity. Construction associated with converter stations would occur in a given location and construction workers would not be considered transient in nature, although cumulative impacts would still be considered short term and temporary. Peak periods of cumulative impact would occur when transmission line and convertor station construction schedules coincide.

Construction of the Project would generate sales and use tax revenues through expenditures on construction supplies and equipment. Construction of the other reasonably foreseeable future actions identified in Section 4.2 would likely result in similar short-term increases in tax revenues, depending on the size and nature of the activity. This would also be the case with ad valorem revenues, with other activities potentially adding to the increase in ad valorem tax revenues in the affected counties.

4.3.14 Special Status Fish, Aquatic Invertebrate, and Amphibian Species

Consistent with the presentation of the affected environment and impacts in Chapter 3, this section's discussion is presented in two separate groupings: (1) special status terrestrial wildlife species, and (2) special status fish, aquatic invertebrate, and amphibian species.

4.3.14.1 Special Status Terrestrial Wildlife Species

Impacts of concern to special status wildlife species from the Project include mortality or injury of individuals (e.g., collisions, electrocution, or habitat clearing), temporary or long-term displacement by disturbance (i.e., human activity, noise), and habitat loss or fragmentation by Project construction or operation and maintenance activities. Because the spatial and temporal (i.e., seasonal presence) distribution of special status species varies by Project region, potential impacts also would vary by region. Special status species in the Project's ROI are discussed in Section 3.14.1.4 and distribution of these species by region is discussed in Section 3.14.1.5.

To the extent that the present and reasonably foreseeable future actions described in Section 4.2 involve mortalities or new disturbances of habitat used (e.g., for breeding, nesting, brood-rearing, wintering, or foraging) by special status wildlife species, impacts could be additive with those of the Project. Impacts during construction could include loss of habitat from land clearing, temporary disturbance displacement, and possible mortality or injury by vehicles and construction equipment. Most of these impacts would be short term except for habitat loss on sites used for Project structures or access (i.e., roads). During operations and maintenance of the Project, activities could impact special status wildlife species through periodic disturbance (i.e., human activity, noise) and habitat modification (e.g., mowing, cutting, or herbicide spraying of vegetation in ROWs). If present and reasonably foreseeable future actions involved the erection of aboveground structures such as transmission structures, powerlines, and wind turbines, mortality and injury of wildlife species from collisions and electrocutions could occur. Construction and operation and maintenance impacts could be cumulative with those of the Project.

Many of the actions identified in Section 4.2, particularly those for upgrades and maintenance for existing roadways, bridges, or airports would either not involve significant disturbances of new land or would be limited to disturbances along existing disturbed ROWs (e.g., road widening). Most of these types of actions also would not involve construction of aboveground structures that could pose a hazard to special status wildlife species. Therefore, many of these actions would not result in cumulative impacts.

As described in Sections 3.14.1.4 and 3.14.1.5, special status wildlife species occur in each of the seven regions. In Region 1, species that could be affected are the piping plover, whooping crane, lesser prairie chicken, bald eagle, and golden eagle. The reasonably foreseeable future bridge and road activities in Region 1 are unlikely to have cumulative impacts on these species as work would be limited to existing disturbances (i.e., road ROWs) or cause minor new disturbances adjacent to the existing ROWs (e.g., road widening). The Project could have cumulative impacts to other reasonably foreseeable future electrical transmission projects in Region 1, potentially impacting the lesser prairie chicken, whooping crane, and golden eagle. The lesser prairie chicken occupies the grassland/herbaceous vegetation that is common throughout Region 1. The primary migratory route for whooping cranes occurs to the east of Region 1. The golden eagle is a both a seasonal and year-around resident in Region 1.

The reasonably foreseeable future bridge and road actions in Region 2 are unlikely to have cumulative impacts on these species as work would be limited to existing disturbances (i.e., road ROWs) or cause minor new disturbances adjacent to the existing ROWs (e.g., road widening). Potential impacts to whooping cranes, interior least terns, lesser prairie chickens, and bald eagles from the Project could be cumulative with similar impacts from reasonably foreseeable future electrical transmission lines and wind energy projects in Region 2.

Special status species that could be potentially impacted in Region 3 include the gray bat, Sprague's pipit, piping plover, whooping crane, interior least tern, American burying beetle, and bald eagle. The reasonably foreseeable future bridge and road actions in Region 3 are unlikely to have cumulative impacts on these species as work would be limited to existing disturbances (i.e., road ROWs) or cause minor new disturbances adjacent to the existing ROWs (e.g., road widening). To the extent that these actions would not impact special status species, impacts from the Project would not be cumulative. The Glass Mountain and particularly the yet-to-be-completed Diamond Pipeline would involve new land disturbance and could involve cumulative impacts with those from the Plains & Eastern Project.

Four protected bat species, northern long-eared bat, Ozark big-eared bat, gray bat, and Indiana bat, and several protected bird species including the Sprague's pipit, interior least terns, piping plovers, and bald eagle potentially occur in the ROI in Region 4. In addition, the American burying beetle potentially occurs in the ROI. Considering that most of the reasonably foreseeable future actions in Region 4 consists of road and bridge tasks in eastern Oklahoma and in western Arkansas represent actions on existing disturbances (i.e., road ROWs), impacts of the Project are unlikely to be cumulative. One of the Region 4 road actions, however, is for construction of a new segment of US-71 and the Diamond Pipeline action would similarly involve new construction. Impacts of Project actions could be cumulative in specific areas of the new road and pipeline construction.

All four protected bat species, interior least tern, piping plover, and bald eagle potentially occur in the ROI in Region 5. Reasonably foreseeable future actions in Region 5 include road maintenance and construction, a gas transmission pipeline, and an oil pipeline. To the extent that the road actions would occur in existing disturbed ROWs, no cumulative impacts are expected. Any impacts of the Project could be cumulative with impacts from any new road or oil pipeline construction. No cumulative impacts are anticipated to the impacts of the gas transmission pipeline as the nearest point of construction is 16 miles.

In Region 6, three species of protected bats (northern long-eared bat, gray bat, and Indiana bat) potentially occur in the ROI. The interior least tern, piping plover, and bald eagle also occur with the ROI. With the exception of a potential new access road (4.7 miles) to be constructed along US-63 in Poinsett County, Arkansas, reasonably foreseeable future road and bridge actions in Region 6 would occur in or along existing disturbed road ROWs and no cumulative impacts are expected. The Project may have some cumulative impacts with construction of the access road in Poinsett County related to land clearing of vegetation.

Region 7 traverses eastern Arkansas to the termination of the Project in Shelby County, Tennessee. Two of the four protected species of bats potentially occur in the ROI as well as the interior least tern and bald eagle. The potential impacts of the Project could be cumulative with the impacts of several other reasonably foreseeable future actions in Region 7 (see Section 4.2.7). An industrial development in Osceola, Arkansas on 4,800 acres and a 370-acre residential and commercial development in Munford, Tennessee could have impacts to special status species from habitat loss and disturbance. The expansion of I-69 and the Southern Gateway Project in Tennessee could have impacts similar to the Project.

4.3.14.2 Special Status Fish, Aquatic Invertebrate, and Amphibian Species

Impacts of concern to special status fish, aquatic invertebrate, and amphibian species from the Project include mortality of individuals, sensory disturbance, aquatic habitat disturbance or modification by Project construction or operation and maintenance activities. Because the spatial distribution of special status species varies by Project region, potential impacts also would vary by region. Special status species in the Project's ROI are discussed in Section 3.14.2.4 and distribution of these species by Project region is discussed in Section 3.14.2.5.

To the extent that the present and reasonably foreseeable future actions described in Section 4.2 involve mortalities of special status species or new disturbances of aquatic habitat used by special status fish, aquatic invertebrate, and amphibian species, impacts could be additive with those of the Project. Impacts during construction could include loss of habitat or mortality from in stream disturbances and habitat degradation (e.g., sedimentation, vegetation clearing). Most of these impacts would be short term, although removal or modification of vegetation along stream banks or shorelines could cause longer term impacts. During operations and maintenance of actions, activities could impact special status fish, aquatic invertebrate, and amphibian species through in stream disturbance and habitat modification (e.g., sedimentation). Accidental spraying of herbicides in aquatic habitat or runoff of chemicals into waterbodies could cause mortalities.

Many of the actions identified in Section 4.2, particularly those for upgrades and maintenance for existing roadways and airports would not involve disturbances of aquatic habitats. Most of these types of projects also would not involve construction near aquatic habitats (e.g., stream banks or shorelines) and would not be a hazard to special status fish, aquatic invertebrate, and amphibian species. Therefore, many of these actions would not create cumulative impacts. Potential bridge actions may involve disturbances of aquatic habitats and could create cumulative impacts.

As described in Sections 3.14.2.4 and 3.14.2.5, special status fish, aquatic invertebrate, and amphibian species occur in each of the seven Regions. In Region 1 and 2, species that could be affected are the Arkansas darter and Arkansas River shiner. The bridge actions over the Beaver River on SH-149 (Region 1), Bull Creek on SH-50B (Region 2), and Cimarron River on SH-60 (Region 2) could have cumulative impacts on the Arkansas darter and Arkansas River shiner from potential habitat disturbance during construction but would be limited to the crossing locations. The Project could have cumulative impacts to other reasonably foreseeable future electrical transmission actions in Regions 1 and 2, but potential impacts would be limited to aquatic habitats crossed by the actions. Potential cumulative impacts are expected to be minor as disturbances to aquatic habitat would either not occur at river crossings or be short term and done under specific protocols to limit impacts, such as the EPMs and other measures described in Section 3.14.2.7.

Special status fish species that could be potentially impacted in Region 3 include the Arkansas River shiner and the Arkansas darter. Several reasonably foreseeable future bridge actions as well as the Diamond Pipeline are proposed in Region 3 (see Section 4.2.3). The Arkansas River shiner is known to occur in streams and rivers in Kingfisher, Logan, Payne, and Okmulgee counties; the Arkansas darter is expected to be outside the Region 3 ROI, and impacts from these actions, including the potential for increased sedimentation into streams and rivers during construction, would be of potential concern. Any impacts of the Project could be cumulative with potential impacts that could occur from the construction of bridges over, or pipelines across, streams and rivers in Region 3 that contain potential habitat for the Arkansas River shiner or Arkansas darter. The Project could have cumulative impacts to other reasonably foreseeable future electrical transmission actions in Region 3, but potential impacts would be limited to aquatic habitats crossed by the projects. Potential cumulative impacts are expected to be minor as disturbances to aquatic habitat would either not occur at river crossings or be short term and done under specific protocols to limit impacts.

Two special status fish species, the Arkansas darter and the Ozark cavefish, are known to occur north of the Region 4 ROI, but because of their mobility are also considered to be of potential concern in Region 4. Five protected aquatic invertebrate species, spectaclecase, speckled pocketbook, Neosho mucket, scaleshell mussel, and snuffbox potentially occur in the ROI in Region 4 in the state of Arkansas. The reasonably foreseeable future actions in Region 4 consist of road and bridge tasks in eastern Oklahoma and in western Arkansas that represent actions on existing disturbances (i.e., road ROWs) or bridges (SH-59, Lee Creek), so effects on aquatic habitats would be unlikely, but possible. The proposed Diamond Pipeline would involve new disturbances and would be in the same area as the Plains & Eastern Project in the eastern end of Region 4. Any adverse impacts from the road or pipeline actions would be limited to the crossing location and would be cumulative with impacts of the Project.

Nine protected fish and aquatic invertebrate species, yellowcheek darter, pink mucket, speckled pocketbook, scaleshell mussel, fat pocketbook, snuffbox, Curtis' pearlymussel, Ozark hellbender, and rabbitsfoot potentially occur in the ROI in Region 5 in Arkansas. Reasonably foreseeable future actions in Region 5 include road maintenance and construction, a gas transmission pipeline, and an oil pipeline. To the extent that the road projects would occur in existing disturbed ROWs and no construction or impacts would occur in aquatic habitats, no cumulative impacts are expected. Any impacts of the Project could be cumulative with impacts from any construction associated with new roads or the Diamond Pipeline. No cumulative impacts are anticipated to the impacts of the gas transmission pipeline as the nearest point of construction is 16 miles from the HVDC transmission line routes.

In Region 6, five protected aquatic invertebrate species, pink mucket, scaleshell mussel, fat pocketbook, snuffbox, and rabbitsfoot potentially occur in the ROI in Arkansas. Several actions involve work on existing bridge structures in Jackson and Cross counties. These would be unlikely to result in any disturbance or degradation of the aquatic habitat underneath the bridges, but if they did, the Project could have cumulative impacts with these actions. The bridge and road construction associated with Highway 63 in Poinsett County, Arkansas, could have impacts to aquatic invertebrates (fat pocketbook) where six bridges would be constructed to span the St. Francis River and associated waterbodies. The impacts of the Project could be cumulative with the potential impacts of the Highway 63 bridge and road construction.

The Project in Region 7 traverses eastern Arkansas, crosses the Mississippi River, to the end of the Project in Shelby County, Tennessee. Three protected species, the pallid sturgeon, fat pocketbook, and snuffbox potentially occur in the ROI. The potential impacts of the Project would not be cumulative with the impacts of several other reasonably foreseeable future actions in Region 7 (see Section 4.2.7). An industrial development in Osceola, Arkansas, on 4,800 acres and a 370-acre residential, commercial development in Munford, Tennessee, and I-69 expansion would not have impacts on the pallid sturgeon, the fat pocketbook mussel, or the snuffbox. The Project is unlikely to impact these species in Region 7. The fat pocketbook mussel occurs northwest of the ROI and construction across the Mississippi River would not affect the pallid sturgeon. The snuffbox mussel has the potential to occur in the ROI, but the closest documented occurrences are to the north of the ROI. Therefore, any impacts of the Southern Gateway Project in Tennessee (potential new bridge across the Mississippi) would not have impacts cumulative with the Project.

4.3.15 Surface Water

Surface water impacts of concern for the Project are associated with the potential for runoff and receiving water contamination, changes to runoff rates, disturbances to surface water or drainage channels, and effects on water availability. As noted in the Section 3.15.6 discussion of impacts, these concerns would be limited primarily to the construction phase of the Project. The present and reasonably foreseeable future actions described in Section 4.2 for each of the regions would present similar concerns and, likewise, would appear to present possible concerns primarily during construction. There were no specific actions identified that would appear to involve long-term operations that could adversely affect surface water. The possible new hydroelectric power plant identified in Region 4 would likely involve long-term impacts to surface water, but at 12 miles from the nearest segment of the Applicant Proposed Route (and farther from other Project components), it is unlikely that its impacts would be cumulative with those of the Project. The effect on water availability is the possible exception to there being long-term impacts, but even in this area of concern, the actions currently identified for evaluation of possible cumulative impacts include none that would be expected to involve use of large quantities of water during long-term operations.

The actions identified in Section 4.2 would involve typical construction activities and, compared to the Project, would be expected to involve the presence of the same type of potential contaminants (primarily fuels and lubricants in equipment) during construction and to implement the same type of measures to ensure those contaminants were not released. The actions would be expected to involve relatively minor changes to runoff rates and, to decrease their own liability and comply with Clean Water Act and other relevant regulations, would be expected to take precautions to minimize damage or alterations to surface water or drainage channels. As with typical construction activities, water would be needed for actions such as dust suppression, soil compaction, equipment cleaning, and concrete formulation. However, like the Project, these water demands would be relatively minor and short term. Potential impacts to surface water from construction of the Project and from construction of the actions described in Section 4.2 would be minor, even if they were to occur in the same time and place such that impacts were cumulative.

Of the actions described in Section 4.2, it is estimated that Regions 3 and 7 could have the greatest potential for cumulative impacts with the Project. As described in Section 3.15.5.4, Region 4 has the greatest number of surface waters of special interest, but the present and reasonably foreseeable future actions described in Section 4.2 for Region 4 are relatively minor, limited primarily to roadway maintenance.

Region 3 has many road actions planned, replacement of a dam bridge, improvement of airport pavements, construction of another transmission line, and construction of oil pipelines. Possibly the largest single action in the region, the dam bridge, is scheduled to be completed prior to the construction start of the Project and the road, transmission line, and pipeline actions involve only modest construction efforts, with relatively small disturbances scattered over a large area, just as with the Project.

Region 7 is the smallest region in terms of the length of the Applicant Proposed Route, but has some of the largest potential actions. Specifically, the I-69 extension and the Southern Gateway Project represent significant construction efforts. Also the Great River Super Site is being developed as an industrial park that could ultimately involve a wide range of industrial activities. However, it is likely that the I-69 and Southern Gateway actions would not have construction impacts cumulative with the Project. The I-69 extension in the area of the Project lacks a firm schedule and likely is many years away. The Southern Gateway Project may also be many years away since the EIS for that project has yet to be completed and, based strictly on where most of the corridors are being considered, its ultimate location, if implemented, will likely be well south of the Project. The Great River Super Site can only be identified as involving potential cumulative impacts because the reference material does not identify any specific projects activities being planned or initiated; it is simply being identified as a location where industrial actions may take place. Construction and operation of heavy industries, such as a steel industry, would be expected to include use of hazardous materials that could pose a threat of surface water contamination if spilled or leaked, similar to the threat posed by fuels and lubricants that would be present during construction of the Project. Like the Project, any new heavy industry would be expected to incorporate the structures, plans, and procedures required by environmental regulations to minimize the potential to cause surface water contamination. Heavy industries may also have high water demands and, because of the location adjacent to the Mississippi River, it is likely that high volume uses such as for cooling would come from surface water. The other action of note in Region 7, the Green Meadows housing development, is also outside of the ROI for surface water.

The present and reasonably foreseeable future actions identified for Regions 3 and 7, although possibly greater in scope than actions in other regions, are still typical, for the most part, because they present only minor potential for adverse impacts to surface water. The exception would be the possible construction of a new bridge over the Mississippi River that would be part of the Southern Gateway Project, which would likely involve significant work directly in the river. However, the Project would not involve any similar work in the Mississippi River and would not involve potential for similar river impacts. As a result, the Project would not pose cumulative impacts in this regard even if the actions were to occur at the same time and in close proximity to one another. Possibly the greatest threat to surface waters from the construction actions being considered would be from the accidental release of contaminants such as fuels or lubricants, or failed measures to control stormwater runoff that could then carry sediments from disturbed areas to receiving waters. Having multiple actions in the same area with similar potential for incidents might increase the probability for an accident to occur, but with properly managed construction sites and control measures, the probability would still be low.

4.3.16 Transportation

Transportation impacts of concern evaluated in Section 3.16.6 for the Project are as follows:

- Roadways—increases in traffic would result from workers commuting to work sites and from hauling materials and equipment, and could include incidental congestion and delays
- Railways—there would be potential for vehicle, railroad, or transmission line conflicts at railroad crossings
- Airports and airfields—transmission lines and the associated structures are a navigation issue and potentially hazardous if located too close to operating areas

The Section 3.16.6 evaluation of impacts from the Project does not identify any notable issues with regard to railway crossings or airports and airfields. Standard precautions and requirements would minimize concerns at railroad crossings and there were no airports or airfields identified in close enough proximity to Project components to present a particular concern. Impacts to roadway traffic are, therefore, the primary topic for this discussion of cumulative impacts.

The methodology used to evaluate potential impacts to roadway traffic from the Project consists primarily of developing LOS rankings representative of existing traffic conditions and traffic conditions with the Project during construction (the Project's period of highest traffic loading). These "before and after" rankings were developed for the roadways that would likely be used by the Project within the expanded ROI. As described in Section 3.16.4.1, these rankings measure the quality of service of a roadway and are set up comparable to academic grades with LOS-A indicating the best and LOS-F indicating the worst operation conditions. According to national guidelines, an LOS-C or better is acceptable on rural roadways and an LOS-D is considered the minimum acceptable within urban areas.

Evaluations for the Project, including the HVDC alternative routes, typically resulted in a LOS decrease of one-level for the evaluated roadways, although in some cases there was no LOS drop. (Also, there were drops of two levels in some of the connected action evaluations.) Locations of primary concern identified in this manner were roadway segments where Project traffic could result in LOS-D conditions (no LOS-F roadways were predicted). The LOS-D conditions were predicted for 12 roadway segments in Region 4 of the Applicant Proposed Route, one roadway segment in Region 5, and 10 roadway segments in Region 7. LOS-D conditions were also predicted in the Tennessee converter station evaluation, which considered the same roadways as the Region 7 evaluation. As would be expected, the evaluations of the HVDC alternative routes had the same or very similar results as the Applicant Proposed Route because they generally considered the same roadways.

Roadways in the vicinity of components of the Project that have existing LOS-C conditions are logically found in or near urban areas. Dropping those levels to LOS-D might still be considered acceptable levels of traffic based on national guidelines. It should be noted that local jurisdictions can establish specific guidelines and requirements that differ from the national guidelines. Based on the evaluation in Section 3.16.6, it is assumed that the most likely areas where there could be cumulative traffic impacts of concern are the areas of Regions 4, 5, and 7. This evaluation of cumulative impacts looks at Regions 4 and 7 because they had the highest number of roadway segments dropping to an LOS-D. Region 5 consists mostly of forested lands, open agricultural lands, and rural residential developments, so it is expected that potential impacts to roadway traffic would not be of major concern.

Although no traffic loading estimates are available, to the extent that the present and reasonably foreseeable future actions described in Section 4.2 involve traffic increases, their impacts could be additive with traffic increases of the Project. The Section 4.2 actions in Region 4 consist of numerous roadway actions in both Oklahoma and Arkansas, construction of a hydroelectric plant, and construction of an oil pipeline. The hydroelectric plant location is outside of the expanded roadway ROI, so it is not likely that the two actions would have significant traffic effects on the same roadway sections (i.e., the further apart, the more likely traffic associated with either action would be spread out over many roads, lessening impacts). However, all of the Region 4 roadway actions identified in Section 4.2 are within, or have portions within, the expanded ROI. Because these other actions consist primarily of road maintenance work, potential impacts to existing roadway traffic are compounded; the actions could involve added traffic moving to and from work sites as well as the congestion and delays inherent with the work. For the most part, the Region 4 roadway projects would be expected to be relatively small and occur over a number years. Since these are actions undertaken by the respective state transportation agencies, it is reasonable to assume they would be planned and implemented in a manner to minimize impacts on existing traffic flow. Further, because of the state agency's involvement, there should be mechanisms in place that would allow for coordination such that impacts to area traffic and the Project are minimized. The oil pipeline (Diamond Pipeline) route in Region 4 would only be near the potential routes of the Plains & Eastern Project in the eastern end of the region. However, within this region, there are two Arkansas communities (Ozark and Clarksville) where road segments would drop to LOS-D from the Plains & Eastern Project; therefore, transportation impacts of the oil pipeline action could be cumulative.

Similar to Region 4, the present and reasonably foreseeable future actions described in Section 4.2 for Region 7 do not include estimates of traffic loading. The Region 7 roadway maintenance actions would be expected to have the same type of concerns and potential impacts as described above for Region 4 if they were to occur at the same time as construction actions for the Project. The I-69 extension and the Southern Gateway Project in Region 7 represent significant construction efforts, but are potentially many years from construction. Both projects could reasonably involve increases to roadway traffic that would be cumulative with those of the Project were they to occur in the same general area, at the same time. However, neither action currently has a well-defined schedule and, based on where most of the corridors for the Gateway Project are being considered, its ultimate location, if implemented, would likely be well south of the Project. Other Region 7 present and reasonably foreseeable future actions include the two development areas: Great River Super Site for industrial and Green Meadows for housing. Increases in construction traffic and even commercial traffic in the case of the Great River Super Site could be cumulative with Project construction traffic if they occurred at the same, but no defined activities or schedules were identified to gauge the likelihood of this occurring.

4.3.17 Vegetation Communities and Special Status Plant Species

The Project's potential impacts of concern to vegetation communities and special status plant species are associated with several different types of activities. Project actions and potential impacts of concern are summarized in the following:

- Clearing and grading—Potential impacts include mechanical damage and/or removal of vegetation by heavy machinery, compaction of soils thereby reducing its water-holding capacity and inhibiting plant growth, and introduction of invasive species from construction equipment or spread of existing invasive species on newly cleared land.
- Placement of structural foundations—Potential impacts include mechanical damage and/or removal of vegetation.
- Access road construction—Potential impacts include alteration of hydrology, which could affect plant growth, mechanical damage, and/or removal of vegetation.
- Excavation for grounding wires, fiber optic regeneration cables, and transmission line structural foundations—Potential impacts include mechanical damage and/or removal of vegetation by heavy machinery, compaction of soils thereby reducing its water-holding capacity and inhibiting plant growth, long-term conversion of forested and shrublands to herbaceous cover type within ROWs, which includes effects of habitat fragmentation, and introduction of invasive species from construction equipment or spread of existing invasive species on newly cleared land.
- Blasting—Potential impacts include mechanical damage of vegetation.
- Herbicide use—Potential impacts include contamination from herbicide drift or runoff that could stunt plant growth or inhibit the onset of growth.
- Hazardous materials handling—Potential impacts include contamination from accidental spills of hazardous substances, such as fuels and lubricants, which could stunt plant growth or inhibit the onset of growth.

To the extent that the present and reasonably foreseeable future actions described in Section 4.2 involve new disturbance of vegetated lands, their impacts could be additive with those of the Project. Impacts during construction could involve additional loss of vegetation, damage or inhibition of native vegetation with potential for introduction of invasive or noxious species, and segmentation of habitat. Many of these construction-related impacts would be short term, but vegetation loss in areas of structures and access roads would be long-term. During operations and if the actions were for new electrical transmission lines, buried oil or natural gas pipelines, or similar actions, vegetation could reestablish on most disturbed areas. However, in ROWs vegetation would be managed so maintenance activities would not be affected, especially in forested areas where trees could restrict access or, in the case of transmission lines, adversely affect operations if allowed to reestablish. Similarly, woody vegetation (shrubs or trees) would be restricted above oil or natural gas pipelines to prevent root damage to the pipeline. As described in

Section 3.17.5, two federally-protected plant species have the potential to occur along the ROI of the Project and state-recognized special status plants may also occur. Special status plant species could be impacted the same as other vegetation unless, as described for the Project, plant surveys are carried out prior to construction activities and there is a commitment to mark special status species and avoid them to the maximum extent possible. All of these types of impacts could be cumulative with those of the Project if they were to occur within the same vegetation community.

Many of the actions identified in Section 4.2, particularly those associated with upgrades or maintenance actions for existing roadways, bridges, or airports, would be expected to involve only minor amounts, if any, of new disturbance to vegetation communities and, accordingly, would be unlikely to affect vegetation or special status plant species. Therefore, those projects would not create cumulative impacts to the Project and are not addressed further in the following discussions of individual regions.

In Regions 1 and 2, the Hitchland-Woodward and Woodward-Thistle Transmission Line actions, respectively, could have similar impacts of the Project, but on a smaller scale, being restricted to a much shorter length of transmission line. Impacts from the transmission lines could be cumulative with the impacts of the Project. The Mammoth Plains Wind Farm Project in Region 2 is 14 miles from the closest corridor of the Project, and therefore is unlikely to have cumulative impacts to vegetation. No federal or state threatened or endangered plant species are known to occur in the ROI in Regions 1 or 2. Therefore, the Project would have no cumulative impacts on any special status plant species.

No cumulative impacts would likely occur in Region 3 and no federal or state threatened or endangered plant species are known to occur in the ROI in Region 3.

Region 4 occurs in eastern Oklahoma and western Arkansas. The actions in Oklahoma and most in Arkansas would not involve cumulative impacts. No federal or state threatened or endangered plant species are known to occur in the ROI in the Oklahoma portion of Region 4. In Crawford County, of western Arkansas, and in Johnson and Pope counties, slightly farther to the east, new construction on Highway 71 and the Diamond Pipeline, respectively, could involve new disturbance of land and vegetation and impacts could be cumulative with those of the Project depending the selected alternative routes. Six different Arkansas state-listed threatened and endangered plant species are known to occur in one or more of Crawford, Johnson, and Pope counties (Table 3.17-4 in Section 3.17.5.4.2). Potential impacts to these species from the Project could be cumulative with potential highway and pipeline construction but could be mitigated by conducting surveys and avoiding known populations.

In Region 5, most present and reasonably foreseeable future actions would be unlikely to have impacts to vegetation that are cumulative with the Project. The Central Arkansas Natural Gas Pipeline Enhancement Project (natural gas pipeline) would be 16 miles from the nearest route alternative of the Project and would not have impacts cumulative with the Project. The Diamond Pipeline action, however, would follow the same general path in the western half of Region 5 as the Plains & Eastern Project. Thirteen special status plant species occur in Region 5. Potential impacts to these species from the Project could be cumulative with the pipeline construction, but could be mitigated by conducting surveys and avoiding known populations.

As was described in Section 4.3.3 with respect to air quality, the present and reasonably foreseeable future actions in Regions 6 and 7 include some of the largest construction activities of any identified in Section 4.2. Accordingly, it is assumed that Regions 6 and 7 actions could have the highest potential for vegetation community impacts that are cumulative with those of the Project. The US-63 access road construction in Region 6 and the I-69 extension and the Southern Gateway Project in Region 7 represent significant construction efforts. A construction date for the work on US-63 was not available, but it is assumed it could be in the same time as the Project. With regard to the two actions in Region 7, it is likely there would only be cumulative impacts on a general, regional basis (i.e., contribute to loss of vegetation in the region). The I-69 extension lacks a firm schedule and likely is many years away, and the Southern Gateway Project may also be many years away because the EIS has yet to be completed, but both actions could reasonably involve loss of regional vegetation that would be cumulative with vegetation losses associated with the Project as well as any other action that expands urban area. Also, based on where most of the corridors for the Gateway Project are being considered, its ultimate location, if implemented, would likely be well south of the Project. Other Region 7 actions include two development areas, one as an industrial park (Great River Super Site) and another as a housing community (Green Meadows) where loss of vegetation would be expected from construction, although in this case the land area being converted appears to consist mostly of agricultural land. Two special status plant species occur in Region 6 and the Arkansas portion of Region 7. Six special status plant species potentially occur in the ROI of the Tennessee portion of Region 7. Potential impacts to these species from the Project could be cumulative if populations of those species occur in areas impacted by the present and reasonably foreseeable future construction projects. Impacts could be mitigated by performing plant species surveys and avoiding any identified populations.

4.3.18 Visual Resources

The Chapter 3 evaluation of the Project's impacts on visual resources uses concepts and tools from the Bureau of Land Management's Visual Resource Management system on lands other than National Forest. The evaluation of visual impacts to National Forest land (applicable only to HVDC Alternative Route 4-B) follows the U.S. Forest Service's Scenery Management System to determine whether Scenic Integrity Objectives and landscape character goals would be met. The evaluation methodology is presented in Section 3.18.6.1 and, for areas not crossing National Forest land, entails a process of rating the existing scenic quality of the landscape and the sensitivity of the viewers, then evaluating impacts from the Project at key observation points (KOPs), which are selected based on a separate set of criteria. The evaluation results in assigning impact ratings ranging from low to high with several intermediate levels, including a central "moderate" rating. For purposes of this evaluation of cumulative impacts, the Chapter 3 evaluations identify "high impacts" where Project components would be dominant or readily apparent from KOPs and would introduce form, line, color, and texture changes inconsistent with the existing landscape. The overall impact ratings are a combination of visual, scenery, and sensitive viewer impacts that individually have the following criteria for when "high" impacts occur:

- Visual Impacts—Where Project components are dominant or readily apparent from KOPs. Project components would introduce form, line, color, and texture changes that are inconsistent with the existing landscape.
- Impacts to Scenery—Distinct or Common landscapes substantially altered by the Project (i.e., where similar facilities do not exist in the landscape).
- Impacts to Sensitive Viewers—Where the Project is dominant with a view and highly noticeable by the casual observer, or where the Project introduces a high level of contrast to the existing landscape.

Based on the Chapter 3 evaluations of potential impacts to visual resources, Region 4 could be characterized as having the highest combination of scenic landscape and viewer concern and, correspondingly, as the region that would experience the highest potential for visual impact from the Project. As described in Section 3.18.6.2.3, the Region 4 Applicant Proposed Route contains a high density of existing landscape of the highest scenic quality (i.e., Distinct), there are 44 KOPs in Region 4 compared to 17 for the next highest region (Region 5), and potential impacts from the Project are rated at “high” at 11 of the Region 4 KOPs compared to the next highest region (also Region 5), which would have only five “highly” impacted KOPs. The HVDC alternative routes within Region 4, evaluated in Section 3.18.6.3.2 contain similar characteristics and with regard to HVDC Alternative Route 4-B, segments of the Project would cross USFS land and would include areas that would not comply with Scenic Integrity Objectives. Based on these characteristics, it is reasonable to assume that present and reasonably foreseeable future actions within Region 4 would have a higher potential for adverse impacts to visual resources than other regions, which could then be cumulative with those of the Project. For that reason, the following discussion focuses primarily on potential cumulative impacts in Region 4 and also considers other Regions.

The actions described in Section 4.2.4 for Region 4 are primarily roadway actions in Oklahoma and Arkansas. The Cherokee Nation Hydroelectric Power Plant and the Diamond Pipeline action are the only non-road actions identified in Region 4. The hydroelectric project is about 12 miles from the nearest segment of the Applicant Proposed Route or HVDC alternative routes and likely would not be visible from any of the KOPs that could be affected by the Project. The Region 4 roadway and pipeline actions are within 2 to 3 miles of the Project routes and are all reasonably close to, and likely visible from, at least one KOP. For example, OKDOT road work on I-40 (near Highway 82) is near to Vian Lake and Highway 82 KOPs; and the OKDOT road work on the more eastern section of I-40, as well as Highways 64, 59, and 101 are all near the Sallisaw KOP. In Arkansas, AHTD road work on Highway 59 is near three KOPs (Fire Tower Lookout, Trail of Tears Route 59, and Route 220 Scenic Highway) and the road work on I-540 and Highway 71 (roughly parallel to one another) are near three other KOPs (Frog Bayou Creek, Route 71 Scenic Byway, and Alma). The path of the Diamond Pipeline would be in close proximity to the Plains & Eastern Project only in Johnson and Pope counties at the eastern end of the region; 13 KOPs have been identified in this portion of Region 4. Visual impacts from the roadway and pipeline actions to these and other KOPs in Region 4 would be cumulative with those from the Project if they occurred at the same time. Exceptions would be in those instances where an evaluated KOP indicated no impacts from the Project. For example, the OKDOT planned activity on Highway 10A extends to a point that is quite close (less than 2 miles) to the Tenkiller State Park KOP, but the overall impact of the Project (for either the Applicant Proposed Route or HVDC Alternative Route 4-A/4-B) at that location is “no impact.” As a result, the Project would have no cumulative visual impacts with the Highway 10A activity at that KOP.

Although the roadway and pipeline actions in Region 4 could involve visual impacts cumulative with those of the Project, with a single exception, these actions would be short-term visual intrusions involving construction vehicles, equipment, workers, and possibly visible dust, mostly in areas where viewers would be accustomed to seeing vehicle traffic. Also, as relatively short duration impacts, they would not be directly comparable to the overall impacts or ratings given to KOPs in Chapter 3 because those ratings are based on the long-term presence of structures (primarily transmission line structures) associated with the Project. Accordingly, the roadway and pipeline actions could have cumulative impacts with the Project, but they would not be expected to affect the overall impact ratings associated with long-term operations under the Project. The exception identified above for involving short-term impacts, is the roadway activity involving construction of a new section of Highway 71. This planned section of new road would start near the community of Alma and extend southward to loop around the east side of Kibler. In this segment, the new road would cross Link 6 of the Region 4 Applicant Proposed Route and be very near the Alma KOP. The overall impact rating at the Alma KOP from the Project is “moderate” (Table 3.18-12) and visual impacts of the new section of Highway 71 would be cumulative over the long-term with those of the Project.

Outside of Region 4, a majority of the present and reasonably foreseeable future actions described in Section 4.2 consist of road work or other actions not involving high structures and, as such, potential impacts to visual resources would likely be much more localized than those associated with the Project. Notable exceptions would be the transmission line actions and the wind farm development that involve tall structures like the Project. The Region 2 wind farm action is about 14 miles from the nearest component of the Project so cumulative visual impacts, if any, would be expected to be minor. With regard to other transmission line actions, the OG&E Hitchland-Woodward Transmission Line in Region 1 and the OG&E Seminole to Muskogee Transmission Line in Region 3 have both been recently completed and the Chapter 3 evaluation of visual impacts includes the presence of existing transmission lines in those areas when rating the impacts of the Project. There is no similar mention of existing transmission lines in Chapter 3 in the area that would be crossed by the OG&E Woodward-Thistle Transmission Line in Region 2 because it is still under construction.

4.3.19 Wetlands, Floodplains, and Riparian Areas

The Project's potential impacts of concern to wetlands, floodplains, and riparian areas are associated with several different types of activities. Project actions and potential impacts of concern include:

- Clearing and grading—Potential impacts include sedimentation and turbidity from activities adjacent to wetlands, alteration of hydrology, placement of fill or dredging in wetlands, and alteration of hydrology in floodplains and riparian areas.
- Herbicide use—Potential impacts include contamination from herbicide runoff that could reach wetlands or riparian areas through overland runoff paths.
- Placement of structural foundations—Potential impacts include alteration of hydrology, placement of fill or dredging in wetlands, long-term conversion of forested wetlands to shrubby or herbaceous cover type within the ROW, and in floodplains there could be changes in flood grade or elevations.
- Tensioning of lines—Potential impacts include sedimentation and turbidity from activities adjacent to wetlands.
- Construction equipment usage—Potential impacts include mechanical damage/crushing of wetland vegetation; compaction of wetland or floodplain soils, potentially reducing soil's water-holding capacity; and introduction of invasive species from construction equipment.
- Excavation and dewatering within wetlands or riparian areas for grounding wires, fiber optic regeneration cables, and transmission line structural foundations—Potential impacts include mechanical damage/crushing of wetland or riparian vegetation and alteration of hydrology.
- Blasting—Potential impacts include alteration of hydrology and sedimentation and turbidity from activities adjacent to wetlands.
- Hazardous materials handling—Potential impacts include contamination from accidental spills into wetlands or which could reach wetlands through overland runoff paths.
- Wastewater discharges from concrete batch plants—Potential impacts include contamination which could reach wetlands through overland runoff paths.

Because wetlands, floodplains, and riparian areas are attributes or features of the land, the present and reasonably foreseeable future actions described in Section 4.2 most likely to affect these features are those involving new land disturbances. Or, in the case of wetlands and riparian areas, they could be affected by contaminated runoff from projects, with or without new land disturbance. Impacts of the Project and the present and reasonably foreseeable future actions in Section 4.2 actions could be cumulative in the general sense (e.g., the combined acreage of impacted wetlands in a region is increased) or they could be cumulative in terms of a specific wetland, floodplain, or riparian area, depending on the physical proximity of the actions. In the case of floodplains, actions not in close proximity, but crossing floodplains of the same surface water feature, could have cumulative impacts by individually altering flood levels over a wide area and the affected areas overlap.

In Regions 1 and 2, transmission line actions would have impacts similar to the Project (although on a smaller scale because of the much shorter length) and could have cumulative impacts to wetlands, floodplains, and riparian zones. However, those impacts generally would be limited to locations where the wetland, floodplain, or wetland was crossed and in some cases construction in such locations could be avoided by spanning the area. Several road actions include bridges, which may have some impacts to wetland, floodplain, or riparian areas in a localized area if it is new construction. However, the potential impacts (disturbance of wetland, floodplain, or riparian vegetation or sedimentation from runoff), are expected to be small and would not overlap impacts of the Project.

Actions in Regions 3 and 4, where the number of potential wetland, floodplain, and riparian area crossings are the highest of any of the regions (Section 3.19.5) could have a higher likelihood of affecting such areas. Present and reasonably foreseeable future actions in Regions 3 and 4 include multiple road maintenance actions, a bridge replacement, and improvements at an existing airport (Section 4.2). All of which would be expected to primarily involve work on already disturbed land. No new structures would be expected as part of these actions, so no changes in flood elevations or floodplains would be expected. As with the Project, construction equipment would carry fuels and lubricants that could result in contaminated stormwater runoff if accidentally released and not quickly cleaned up. Otherwise, there would be minimal potential for adverse impacts to wetlands and riparian areas from these maintenance- and refurbishment-types of actions. In addition, the bridge and airport actions are well removed (each about 17 miles) from the nearest segment of the Applicant Proposed Route.

The present and reasonably foreseeable future actions in Regions 3 and 4 also include a transmission line, a hydroelectric plant, and oil pipelines. The transmission line would be expected to involve potential impacts very similar to those described in Section 3.19.6.1 for the Project, although at a smaller scale. Also, because the transmission line location is crossed by the Applicant Proposed Route as well as the HVDC alternative routes, there could be cumulative impacts to the same wetlands, floodplains, or riparian areas. The hydroelectric plant, being on the Arkansas River, could involve impacts to wetlands, floodplains, and riparian areas, but because the proposed plant site is about 12 miles from the nearest component of the Project, any cumulative impacts would likely not be to the same specific wetlands, floodplains, or riparian areas. The general path of the Diamond Pipeline is much the same as the Plains & Eastern Project in the central portion of Region 3 and the eastern end of Region 4, so there could be cumulative impacts to the same wetlands, floodplains, or riparian areas. Because the pipeline construction would involve a continuous stretch of disturbed ground (i.e., no air spans by which some ground areas might be avoided, as with a transmission line), impacts could potentially be greater than those of the Project.

Region 5 actions consist of road actions that would occur in existing disturbed ROWs. To the extent that these actions are not adjacent to wetlands, floodplains, and riparian areas and would not cause sedimentation or alter the hydrology, the Project would not contribute to cumulative impacts. The Central Arkansas Natural Gas Pipeline Enhancement Project is 16 miles from the nearest possible route alternative and any impacts would be not be cumulative with any impacts to wetlands, floodplains, or riparian areas along the Project. The general path of the Diamond Pipeline is much the same as the Plains & Eastern Project in the western half of Region 5, so there could be cumulative impacts to the same wetlands, floodplains, or riparian areas.

The present and reasonably foreseeable future actions in Region 6 include road and bridge actions and a rebuild of a transmission line. The transmission line could have cumulative impacts to the Project if wetlands, floodplains, and riparian areas occur at the location where the two actions cross. Most of the road and bridge actions involve work in existing road ROWs and on existing bridge structures and no impacts to wetlands, floodplains, and riparian areas are expected. Proposed road and bridge construction in Poinsett County, Arkansas for the Highway 63 access road (4.7 miles) would include six bridges and a new road that would cross the St. Francis River and adjacent waterbodies (see Section 4.2.6). Several Project alternative routes are in the general vicinity (0.8 to 4 miles) of the construction. Potential impacts could be cumulative with the road and bridge construction if any of these alternative routes are selected for the Project.

Region 7 actions include some of the largest construction activities along the Project ROI. The I-69 extension and the Southern Gateway Project in Region 7 represent significant construction efforts, but are potentially many years from construction. Both actions could reasonably involve loss of regional wetlands, floodplains, and riparian areas that would be cumulative with losses associated with the Project as well as any other action that expands the urban area. Also, based on where most of the corridors for the Southern Gateway Project are being considered, its ultimate location, if implemented, would likely be well south of the Project. Other Region 7 present and reasonably foreseeable future actions include two development areas, one as an industrial park (Great River Super Site) and another as a housing community (Green Meadows) where loss of wetlands, floodplains, and riparian areas could occur, although most of the land area being developed appears to be agricultural land. Potential impacts to wetlands, floodplains, and riparian areas from the Project would likely be cumulative only on a general, regional basis unless specific alternative routes near these projects were selected.

4.3.20 Wildlife, Fish, and Aquatic Invertebrates

Consistent with the presentation of the affected environment and impacts in Chapter 3, this section's discussion is presented in two separate groupings: (1) wildlife, and (2) fish and aquatic invertebrates.

4.3.20.1 Wildlife

As identified in Section 3.20.1.7.1, wildlife resources evaluated include important recreational species, migratory birds, reptiles and amphibians, and mammal species known to occur or have the potential to occur within the ROI. Wildlife impacts of concern for the Project are as follows:

- Potential impacts from short or long-term displacement of wildlife species
- Fragmentation of wildlife habitat, including significant grassland habitat in central Oklahoma
- Potential disturbance to known populations and/or suitable habitat for wildlife species
- Potential impacts to old growth forests
- Potential impacts to wildlife movement, migratory birds and flyways (including the Mississippi Flyway, Audubon-designated Important Bird Areas, or other federal or state designated bird areas)
- Potential for avian collisions and/or electrocution
- Potential impacts of invasive plant species on wildlife habitats

Potential impacts would vary by region because the spatial and temporal (i.e., seasonal presence) distribution of wildlife species varies by Project region (1 through 7). Wildlife species in the Project's ROI are discussed in Section 3.20.1.3 and distribution of these species by Region is discussed in Section 3.20.1.5.

To the extent that the present and reasonably foreseeable future actions described in Section 4.2 involve wildlife mortalities or injuries, displace wildlife by disturbance (short- or long-term), and disturb habitats used by wildlife species (e.g., for breeding, nesting, brood-rearing, wintering, or foraging), impacts could be additive with those of the Project. Impacts during construction could include loss of habitat from land clearing, temporary disturbance displacement, and possible mortality or injury by vehicles and construction equipment. Most of these impacts would be short term except for habitat loss on sites used for project structures, access (i.e., roads), or ROW maintenance. During operations and maintenance of projects, activities could impact wildlife species through periodic disturbance (i.e., human activity, noise) and habitat modification (e.g., mowing, cutting, or herbicide spraying of vegetation in ROWs) as well as continuous disturbance via the presence of transmission lines and structures. If present and reasonably foreseeable future actions involved the erection of aboveground structures such as transmission structures, power lines, and wind turbines, mortality and injury of wildlife species from collisions and electrocutions could occur. Construction and operation and maintenance impacts could be cumulative with the Project.

Many of the actions identified in Section 4.2, particularly those for upgrades and maintenance for existing roadways, bridges, or airports would either not involve significant disturbances of new land or would be limited to disturbances along existing disturbed ROWs (e.g., road widening). Most of these types of actions also would not involve construction of aboveground structures that could pose a hazard to wildlife species (e.g., migratory birds or bats). Therefore, those actions would not create cumulative impacts and are not addressed further in the following discussions of individual regions.

Because the climate and vegetation varies from west to east, the wildlife species present in each Region also varies from west to east. The wildlife species that could be impacted are described in Sections 3.20.1.4 and 3.20.1.5. Potential impacts to wildlife from the Project could be cumulative with similar impacts from reasonably foreseeable future electrical transmission lines and wind energy developments in Regions 1 and 2.

Considering that most of the reasonably foreseeable future actions in Region 4 consist of road actions, impacts could be cumulative in specific areas where road actions consist of new construction and could cause wildlife mortality, disturbance, and habitat loss. Similarly, impacts from construction of the Diamond Pipeline could be cumulative if it could cause wildlife mortality, disturbance, and habitat loss.

In Region 5, any impacts of the Project could be cumulative with impacts from any new road construction as well as with impacts from construction of the Diamond Pipeline. No cumulative impacts are anticipated to the impacts of the gas transmission pipeline as the nearest point of construction is 16 miles.

In Region 6, a potential new access road (4.7 miles) to be constructed along US-63 in Poinsett County, Arkansas would be expected to involve cumulative impacts to wildlife related to land clearing of vegetation.

Region 7 traverses eastern Arkansas to the termination of the project in Shelby County, Tennessee. The potential impacts to wildlife of the Project could be cumulative with the impacts of several other reasonably foreseeable future actions in Region 7 (see Section 4.2.7). An industrial development in Osceola, Arkansas on 4,800 acres and a 370 acre residential and commercial development in Munford, Tennessee could have impacts to wildlife species from mortality, habitat loss, and disturbance. The expansion of I-69 and the Southern Gateway Project in Tennessee could have impacts similar to the Project that would be cumulative.

4.3.20.2 Fish and Aquatic Invertebrates

As identified in Section 3.20.2.7.1, aquatic resources evaluated include river, stream, or creek crossings as well as any perennial waterbodies within the ROI. Fish and aquatic invertebrate impacts of concern for the Project are as follows:

- Potential impacts from construction activities, vehicles, equipment, and access roads on aquatic species and their habitats
- Potential impacts from permanent removal of vegetation or temporary mechanical damage to vegetation
- Possible spread and/or introduction of invasive plants or listed noxious weed species from the use of construction equipment at waterbody crossings
- Potential impacts associated with ROW vegetation maintenance, including the use of herbicides during operation of the Project
- Potential for sediment loading and introduction of chemicals from spills in aquatic habitat, causing alterations to the habitat or the introduction of hazardous materials.
- Potential changes to stream morphology due to adjacent riparian clearing

Impacts of concern to fish and aquatic invertebrate species from the Project include mortality of individuals and aquatic habitat disturbance or modification by Project construction or operation and maintenance activities. Because the spatial distribution of species varies by Project region, potential impacts also would vary by region. Fish and aquatic invertebrate species in the Project's ROI are discussed in Section 3.20.2.3 and distribution of these species by Project region is discussed in Section 3.20.2.5.

To the extent that the present and reasonably foreseeable future actions described in Section 4.2 involve mortalities of fish and aquatic invertebrate species or new disturbances of aquatic habitat used by fish and aquatic invertebrate species, impacts could be additive with those of the Project. Impacts during construction could include loss of habitat or mortality from in-stream disturbances and habitat degradation (e.g., sedimentation, vegetation clearing). Most of these impacts would be short term, although removal or modification of vegetation along stream banks or shorelines could cause longer term impacts. During operations and maintenance of projects, activities could impact fish and aquatic invertebrate species through in-stream disturbance and habitat modification (e.g., sedimentation). Accidental spraying of herbicides in aquatic habitat also could cause mortalities.

Many of the actions identified in Section 4.2, particularly those for upgrades and maintenance for existing roadways and airports would not likely involve disturbances of aquatic habitats. Most of these types of actions also would not involve construction near aquatic habitats (e.g., stream banks or shorelines) and would not be a hazard to fish and aquatic invertebrate species considering the standard requirements for management and control of runoff from construction sites. Therefore, many of these actions would not create cumulative impacts. Potential bridge actions may involve disturbances of aquatic habitats and could create cumulative impacts.

The Project could have cumulative impacts with other present and reasonably foreseeable future electrical transmission actions in the regions, but potential impacts would be limited to aquatic habitats crossed by the actions. Potential cumulative impacts are expected to be minor as disturbances to aquatic habitat would either not occur at river crossings or be short term and done under specific protocols to limit impacts.

Reasonably foreseeable future actions in Regions 3, 4, and 5 include construction of the Diamond Pipeline, which could have impacts to fish and aquatic invertebrates where the pipeline would cross or approach aquatic habitats. Such impacts could be cumulative with those of the Plains & Eastern Project. Potential cumulative impacts are expected to be minor because they would be short term and done under specific protocols to limit impacts.

Reasonably foreseeable future actions in Region 5 also include a gas transmission pipeline; however, no cumulative impacts are anticipated to the impacts of the gas transmission pipeline as the nearest point of construction is 16 miles.

The potential impacts of the Project would not be cumulative with the impacts of several reasonably foreseeable future actions in Region 7 (see Section 4.2.7). An industrial development in Osceola, Arkansas on 4,800 acres and a 370-acre residential, commercial development in Munford, Tennessee, and Interstate 69 expansion would not have impacts to aquatic habitats. Construction of the Project across the Mississippi River would not affect aquatic habitats as equipment would not be in the river. Therefore, any impacts of the Southern Gateway Project in Tennessee (potential new bridge across the Mississippi) would not have impacts cumulative with the Project.

6.3 GIS Data Sources

This section provides source information for GIS data used or referenced in the development of the EIS, including those used to produce the maps in Appendix A. The data files are not provided on the Reference CD accompanying the EIS because the file sizes can be very large and the files also require specialized software to view. The data sources that were analyzed are available at the links provided below.

79 FR 19974. "Endangered and Threatened Wildlife and Plants; Determination of Threatened Status for the Lesser Prairie-Chicken." U.S. Fish and Wildlife Service, Department of the Interior. April 10, 2014. <http://www.gpo.gov/fdsys/pkg/FR-2014-04-10/pdf/2014-07302.pdf#page=2>.

AGFC (Arkansas Game and Fish Commission). 2014. "Wildlife Management Areas (AGFC-owned and leased land)." Received from Wesley Cleland at Arkansas Game and Fish Commission on August 27.

7. Glossary

100-Year Floodplain	The area that would be inundated by a flood with a recurrence interval of once in 100 years, on average. This can also be stated as areas that have a 1 percent chance of being flooded in a given year. (See Floodplain.)
600kV DC Transmission Line	A transmission line with a capacity of approximately 600 kilovolts of direct-current electricity.
AADT (Annual Average Daily Traffic)	The total volume of traffic passing a point or segment of a roadway facility in both directions for 1 year divided by the number of days in the year.
AC Collection System	AC collection system is made up of thirteen 2-mile-wide routes in Oklahoma (Beaver, Cimarron, and Texas counties) and Texas (Hansford, Ochiltree, and Sherman counties) within which four to six AC transmission lines would be sited; depending on the location of future wind energy development. The AC collection system would collect energy from generation resources. Components of the AC collection system include: • ROW easements for the transmission line, with a typical width of approximately 150 to 200 feet • Tubular or lattice steel structures used to support the transmission line • Electrical conductor • Communications/control and protection facilities (optical ground wire (OPGW), static wire, and fiber optic regeneration sites)
AC/DC (Alternating Current/Direct Current)	An alternating current (AC) power line alternates as a rate of 50 to 60 times a second (Hz), while a direct current (DC) power line produces a static electric field that does not alternate.
Access road	Roads constructed to each structure site first to build the tower and line, and later to maintain and repair it. Access roads are built where no roads exist. Where county roads or other access is already established, access roads are built as track roads to the structure site except where they pass through cultivated land. There, the road is restored for crop production after construction is completed.
Advisory Council on Historic Preservation	Established by the National Historic Preservation Act in 1966, the Advisory Council on Historic Preservation is an independent Federal agency that promotes the preservation, enhancement, and productive use of the advisory agency for the president and congress on historic preservation policy.
Aerial Photography	Used to identify and verify land uses within the Project corridors and ROWs.
Affected Environment	The affected environment section of the EIS describes the baseline conditions with regard to a specific resource to provide the context for understanding the environmental impacts associated with the Project.
Agriculture	Agriculture: The science, art, or practice of cultivating the soil, producing crops, and raising livestock. A land use characterized by land cultivated for crop production and raising livestock.
Alluvium	Deposits left by flowing water, usually clay, silt, sand, or gravel.
Alternative	Options that a federal agency considers to address the significant issues and meet the purpose of and need for a proposed project in an environmental analysis. Also used to describe other routes under consideration.
Alternative Route Adjustment	As a result of the “route variations” developed for the Applicant Proposed Route in response to public comments on the Draft EIS, DOE and Clean Line developed route adjustments for the Regions 3, 5, and 6 HVDC alternative routes to re-establish the continuity with the Applicant Proposed Route in these regions.

Alternative Routes	Multiple individual transmission line routes that each traverse from point A to point B in a separate and distinct way. In addition to the Applicant Proposed Route, DOE has identified and compared two to six alternative routes within each of the seven geographic regions: • Region 1: Oklahoma Panhandle in Texas, Beaver, Harper, and Woodward counties, Oklahoma • Region 2: Oklahoma Central Great Plains in Woodward, Major, and Garfield counties, Oklahoma • Region 3: Oklahoma Cross Timbers in Garfield, Kingfisher, Logan, Payne, Lincoln, Creek, Okmulgee, and Muskogee counties in Oklahoma • Region 4: Arkansas River Valley in Sequoyah County, Oklahoma and Crawford, Franklin, Johnson, and Pope counties, Arkansas • Region 5: Central Arkansas in Pope, Conway, Van Buren, Faulkner, Cleburne, White, and Jackson counties, Arkansas • Region 6: Cache River, Crowley's Ridge Area, and St. Francis Channel in Jackson, Cross, and Poinsett counties • Region 7: Arkansas Mississippi River Delta and Tennessee in Poinsett and Mississippi counties, Arkansas and in Tipton and Shelby counties, Tennessee
Anthropogenic	Made by people or resulting from human activities.
APE (Area of Potential Effect)	The geographic area or areas within which an undertaking may directly or indirectly cause changes in the character or use of historic properties, if any such properties exist. Additionally, the APE is influenced by the scale and nature of an undertaking and may be different for different kinds of effects caused by the undertaking (36 CFR 800.16(d)).
APP (Avian Protection Plan)	A plan, consistent with Avian Power Line Interaction Committee (APLIC) guidelines that describes a program of specific and comprehensive actions that, when implemented, would reduce the risk of avian mortality.
Applicant	Clean Line Energy Partners LLC of Houston, Texas, the parent company of Plains and Eastern Clean Line LLC and Plains & Eastern Clean Line Oklahoma LLC (collectively referred to as Clean Line or the Applicant in the Plains and Eastern Environmental Impact Statement).
Applicant Proposed Project	Based on Clean Line's proposal to DOE, the basic elements include converter stations in Oklahoma and Tennessee, AC interconnections at each converter station, an AC collection system, and an HVDC transmission line from the Oklahoma Panhandle to western Tennessee. The Applicant Proposed Project is described in Sections 2.1.2 through 2.1.7.
Applicant Proposed Route	The single route alternative defined by Clean Line to connect the converter station in the Oklahoma Panhandle Region to the converter station in western Tennessee. The Applicant Proposed Route is defined in Section 2.4.2. Alternatives to the Applicant Proposed Route are described as part of the DOE Alternatives in Section 2.4.3.
Aquatic	Occurring in, or closely associated with, water.
Arkansas Converter Station Alternative AC Interconnection Siting Area	A 2-mile-wide corridor within which one or more potential AC transmission line route(s) would be sited from the Arkansas converter station alternative to an interconnection point(s) (5 acres) to an existing 500kV transmission line. The interconnection would also include a new substation at the point where the new AC interconnection line would tap the existing 500kV line. The footprint of this substation is estimated to be between 25 and 35 acres
Arkansas Converter Station Alternative Siting Area	An approximate 360-acre siting area in Pope County, Arkansas, within which the converter station and associated AC switchyard (20 to 35 acres total) and access road(s) would be sited.
ARPA (Archaeological Resources Protection Act)	Prohibits unauthorized collecting and excavation at archaeological sites on federal and tribal lands.
Attainment Area	An area considered to have air quality as good as or better than the National Ambient Air Quality standards as defined in the Clean Air Act.

Audible Noise	The natural phenomenon of corona from a transmission line can create audible noise. Audible noise is measured in decibels (dB) of sound pressure with respect to the threshold of human hearing. The decibel is a dimensionless unit used to compare the level of some quantity to a reference level and it always needs a reference quantity to have meaning.
Bedrock	Solid rock beneath the soil and superficial rock (rock fragments or unconsolidated rock materials).
BGEPA (Bald and Golden Eagle Protection Act)	A law that prohibits the take, possession, selling, purchasing, bartering, or transporting of live or dead bald or golden eagles, or any parts, nests, or eggs of these birds.
BIA (Bureau of Indian Affairs)	Established in 1824, the Bureau of Indian Affairs is responsible for the administration and management of 55 million surface acres and 57 million acres of subsurface minerals estates held in trust by the United States of American Indian, Indian tribes, and Alaska Natives.
Big Game	Large animals that may be taken by hunters, pursuant to local government restrictions and regulations.
Biological Assessment	A Biological Assessment documents a federal agency's conclusions and the rationale to support those conclusions regarding the effects of the proposed action on protected resources. Although there are no statutory or regulated contents for a Biological Assessment recommended elements are identified in 50 CFR §402.12(f).
Biological Opinion	A document that states the opinion of the U.S. Fish and Wildlife Service as to whether a federal action is likely to jeopardize the continued existence of listed species or result in the destruction or adverse modification of critical habitat. The USFWS opinion is based on the review of a Biological Assessment.
Blading	Use of a bulldozer, grader, or other construction equipment to level or shape a travel surface.
BMPs (Best Management Practices)	Some resource sections have included BMPs. In these resources, implementation of the EPMs would not be able to completely avoid or minimize potential adverse effects resulting from construction, operations and maintenance, and decommissioning of the Project. BMPs have been identified to further avoid or minimize these potential adverse effects. The ROD or other appropriate Federal decision document would include conditions of approval (e.g., BMPs) imposed by DOE or other agency that has a decision to make or a consultation responsibility (e.g., TVA, USACE, USFWS) regarding the Project. The DOE-Applicant participation agreement would require a monitoring plan to ensure implementation of all such conditions of approval.
Border Zone	A zone on each side of the wire zone to the edge of the ROW, maintained to exclude tall vegetation. Vegetation within the border zone is limited to low-growing grasses, legumes, herbs, crops and shrubs where the conductor is 50 feet or less from the ground.
CAA (Clean Air Act)	The federal law that defines the Environmental Protection Agency's responsibilities for protecting and improving the nation's air quality and the stratospheric ozone layer. The last major change in the law, the Clean Air Act Amendments of 1990, was enacted by Congress in 1990. Legislation passed since then has made several minor changes. The Clean Air Act was incorporated into the United States Code as Title 42, Chapter 85.
Candidate Species	Taxa for which the U.S. Fish and Wildlife Service has on file sufficient information on biological vulnerability and threat(s) to support issuance of a proposal to list, but issuance of a proposed rule is currently precluded by higher priority listing actions (61 FR 7596-7613;February 28, 1996).
Capacity	Refers to the amount of power a transmission facility (line, transformer, etc.) can reliably deliver. Capacity is measured in megawatts and is limited by the current (in amperes) that the facility can carry or the minimum voltage levels present at a substation (under either steady-state or outage conditions).
CDE (Carbon Dioxide Equivalent)	Carbon dioxide equivalency is a quantity that describes, for a given mixture and amount of greenhouse gas, the amount of carbon dioxide that would have the same global warming potential, when measured over a specified timescale (generally, 100 years).

Centerline	A line on a map or flagged on the ground that indicates the location of a linear feature such as a road or a transmission line. The linear feature is further defined by its total width, either for construction or operation, which is bisected into two equal parts by the centerline.
Century Farm	State-level Century Farms programs provide recognition to self-nominated agricultural operators who can document at least 100 years of continuous operation of a farm or ranch by a single family. These programs are honorary, voluntary, and do not afford legal protections.
CEQ (Council on Environmental Quality)	Coordinates federal environmental efforts and works closely with agencies and other White House offices in the development of environmental policies and initiatives. CEQ was established within the Executive Office of the President by Congress as part of the National Environmental Policy Act of 1969 (NEPA) and additional responsibilities were provided by the Environmental Quality Improvement Act of 1970.
Circuit	An electrical device that provides a path for electrical current to flow, or along which an electrical current can be carried. In the case of high-voltage transmission, a set of wires energized at transmission voltages extending beyond a substation which has its own protection zone and set of breakers for isolation.
Clean Line	Clean Line Energy Partners LLC of Houston, Texas, is the parent company of Plains and Eastern Clean Line LLC and Plains and Eastern Clean Line Oklahoma LLC (collectively referred to as Clean Line). Clean Line develops long-haul transmission lines to connect renewable energy resources in North America to communities and cities that lack access to affordable renewable power.
CO (Carbon Monoxide)	An odorless and colorless gas formed from one atom of carbon and one atom of oxygen. CO is typically released as an air emission from internal combustion engines.
Colluvium	Rock fragments, sand, etc., that accumulate on steep slopes or at the foot of cliffs.
Concrete Batch Plant	Concrete would be obtained from commercial ready-mix concrete producers to the extent practicable. In locations where haul times exceed 45 minutes, concrete would be dispensed from portable concrete batch plants located within a multi-use construction yard. The batch plants would consist of bins of materials that when combined in a mixer, form concrete (e.g., sand, water, aggregate, cement, etc.). Concrete would be required for construction of foundations for transmission structures, foundations for transformers and electrical equipment at converter stations, and foundations at fiber optic regeneration sites. Concrete would be delivered to structure sites and ancillary facilities in concrete trucks.
Conductor	The wire cable strung between transmission towers through which electric current flows.
Contrast	The degree of visual change that occurs in the landscape due to the construction and operations and maintenance of a project.
Contrast Rating	A method of analyzing the potential visual impacts of Project components.
Connected Actions	Connected actions are those that are “closely related” to the proposal. Actions are considered connected if they automatically trigger other actions which may require environmental impact statements, cannot or will not proceed unless other actions have been taken previously or simultaneously, or are interdependent parts of a larger action and depend on the larger action for their justification (40 CFR 1508.25).

Converter Station	Converter stations are similar to a typical AC substation, with additional equipment to convert between AC and DC. Ancillary facilities such as communications equipment and cooling equipment would be required at each converter station. In addition, AC transmission lines would connect each converter station to the existing grid. Each converter station would include: • DC switchyard • DC smoothing reactors • DC filters • Valve hall(s) (which contain the power electronics for converting AC to DC and vice versa) • Ancillary building(s) (containing control and protection equipment, cooling, etc.) • AC switchyard • AC filter banks • AC circuit breakers and disconnect switches • Transformers
Cooperating Agency	Any federal agency other than a lead agency which has jurisdiction by law or special expertise with respect to any environmental impact involved in a proposal (or a reasonable alternative) for legislation or other major Federal action significantly affecting the quality of the human environment. The selection and responsibilities of a cooperating agency are described in 40 CFR 1501.6. A state or local agency of similar qualifications or, when the effects are on a reservation, an Indian Tribe, may by agreement with the lead agency become a cooperating agency (40 CFR 1508.5).
Corona	Corona occurs in regions of high electric field strength on conductors, insulators, and hardware when sufficient energy is imparted to charged particles to cause ionization (molecular breakdown) of the air.
Corresponding Links	Links or portions of the Applicant Proposed Route similar in length to the alternative routes. Alternative routes are compared to corresponding links of the Applicant Proposed Route in the impact analysis for each resource.
Criteria Pollutants	The U.S. Environmental Protection Agency has set NAAQS for seven principal pollutants, which are called "criteria" pollutants. The six air pollutants listed below are criteria pollutants for which the agency has developed NAAQS: • Sulfur Dioxide (SO_2) • Carbon monoxide (CO) • Nitrogen Dioxide (NO_2) • Ozone (O_3) • Particulate matter with a diameter equal to or smaller than 10 micrometers (PM_{10}) • Particulate matter with a diameter equal to or smaller than 2.5 micrometers ($PM_{2.5}$) • Lead and its compounds (measured as lead)
Critical Habitat	For Endangered Species Act (ESA)-listed species consists of: (1) the specific areas within the geographical area occupied by the species, at the time it is listed in accordance with the provisions of section 4 of the act on which are found those physical or biological features (constituent elements) (a) essential to the conservation of the species and (b) which may require special management considerations or protection; and (2) specific areas outside the geographical area occupied by the species at the time it is listed in accordance with the provisions of section 4 of the act, upon a determination by the Secretary that such areas are essential for the conservation of the species (ESA §3 (5)(A)). Designated critical habitats are described in 50 CFR §17 and 226.
CRP (Conservation Reserve Program)	CRP lands are administered by the USDA Farm Service Agency. The CRP provides technical and financial assistance to eligible farmers and ranchers to address soil, water, and related natural resource concerns on their lands in an environmentally beneficial and cost-effective manner. The CRP encourages farmers to convert highly erodible cropland or other environmentally sensitive acreage to vegetative cover, such as tame or native grasses, wildlife plantings, trees, filter strips, or riparian buffers. Farmers receive an annual rental payment for the term of the multi-year contract.

Cultural Modification	Human/man-made modifications to the landscape.
Cultural Resources	The term “cultural resource” includes all landscapes, buildings, sites, districts, structures, or objects that have been created by or associated with humans and are considered to have historical or cultural value. Cultural resources also include Traditional Cultural Properties.
Culvert	A corrugated metal or concrete pipe used to carry or divert runoff water from a drainage; usually installed under roads to prevent washouts and erosion.
Cumulative Effects (Impacts)	Effects that result when the effects of an action are added to or interact with other effects in a particular place and within a particular time. Such impacts may individually have minor impacts, but collectively may have significant impacts.
Current	The amount of electrical charge flowing through a conductor (as compared to voltage, which is the force that drives the electrical charge), which is measured in amperes or amps.
CWA (Clean Water Act)	The framework that regulates water quality standards and pollutant discharges into waters of the United States. Sections 303d and 305b require that water quality of streams, rivers, and lakes are assessed on a regular basis, that waters found to be in violation of water quality standards are listed as impaired, and that priorities be set for actions to improve the water quality.
dB(A)	Sound levels measured as A-weighted decibels. Used to measure sound level via a logarithmic unit used to describe a ratio and weighted based on the human response to sound.
Decibel (dB)	A decibel is a unit for expressing relative difference in power, usually between acoustic signals, equal to 10 times the common logarithm of the ratio of two levels.
Decommissioning	Removal of Project facilities at the end of the operational life of the facilities.
Dewatering	Removal or draining groundwater or surface water from a construction site by pumping or evaporation.
Direct Effects or Direct Impacts	Direct effects are those caused by the Project at the same time and place as the impact, such as soil disturbance.
Distance Zone	A subdivision of the landscape as viewed from an observer position. The subdivision (zones) includes foreground-middleground (0-3 miles), background (3 miles or more) and seldom seen.
Distribution Line	The structures, insulators, conductors, and other equipment used to deliver electricity directly to the customer, including commercial facilities, small factories, or residences.
DOE (U.S. Department of Energy)	DOE is the lead federal agency for the preparation of this Plains & Eastern EIS. DOE has prepared this EIS pursuant to NEPA, the Council on Environmental Quality (CEQ) NEPA regulations (40 Code of Federal Regulations [CFR] Parts 1500 through 1508), and the DOE NEPA implementing regulations (10 CFR Part 1021). DOE’s purpose and need for agency action is to implement Section 1222 of the EPAct.
DOE Alternatives	DOE has chosen to analyze potential environmental impacts for several alternatives in addition to the Applicant Proposed Project. These alternatives include an Arkansas converter station and alternative routes for the HVDC transmission line. The DOE Alternatives are described in Section 2.4.3.
DOE’s Proposed Action	To participate, acting through and in consultation with the Administrator of Southwestern, in the Applicant Proposed Project in one or more of the following ways: designing, developing, constructing, operating, maintaining, or owning a new electric power transmission facility and related facilities located within certain states in which Southwestern operates, namely Oklahoma, Arkansas, and possibly Texas.
Double-Circuit Transmission Line	A transmission line composed of six electrical phases (two independent circuits of three phases each) and two lightning protection shield wires. One of the lighting protection shield wires is a steel overhead ground wire, and the other is an optical ground wire (OPGW).
Early Successional (or Early Seral)	An immature forest often characterized by a single-age class and open canopies; stands are between 1 and 30 years old.

Ecoregion	Area where the ecosystems, and the type, quality, and quantity of environmental resources are generally similar as defined by the analysis of patterns and composition of biotic and abiotic phenomena including geology, physiography, vegetation, climate, soils, land use, wildlife, and hydrology.
Edge Effect	The gradual to abrupt transition from one habitat type to a different habitat type. Edge effects can include obvious changes in the structure of vegetation, such as an abrupt change from forest to herbaceous cover, but the effects can be more subtle and include differences in temperature, humidity, and plant and wildlife species use of an area.
EIS (Environmental Impact Statement)	Part of compliance with the National Environmental Policy Act (NEPA), an EIS is a comprehensive public document that analyzes the impacts of a major federal action that may significantly affect the quality of the human environment. When complete, it is a tool for decision making as the EIS describes the positive and negative environmental effects of a proposed action, describes alternative actions and provides an analysis of environmental impacts and ways to mitigate such impacts across all alternatives considered in detail.
Emergent	Plants that have their bases submerged in water.
EMF (Electric and Magnetic Fields)	Fields describing properties of a location or point in space and its electrical environment, including the forces that would be experienced by a charged body in that space by virtue of its charge or the movement of charges. The voltage, which is the “pressure,” produces an electric field that moves the electricity through wires. The current produces a magnetic field, which is a measure of how much electricity is flowing. Thus, wherever there is electric current flowing (including through any type of wiring), there is both an electric and a magnetic field.
Endangered species	Any species officially listed pursuant to the Endangered Species Act (ESA) (16 USC § 1531 et seq.) by the U.S. Fish and Wildlife Service or NOAA Fisheries as being in danger of extinction throughout all or a significant portion of their range.
Energy	In the electric utility industry, it represents the amount of power used or transmitted over a given amount of time.
Environmental Justice	As defined by the EPA, environmental justice is the fair treatment and meaningful involvement of all people regardless of race, color, sex, national origin, or income with respect to the development, implementation and enforcement of environmental laws, regulations, and policies. Executive Order 12898 was issued in 1994 and directs federal agencies to identify and address the disproportionately high and adverse human health or environmental effects of their actions on minority and low-income populations, to the greatest extent practicable and permitted by law.
EPA (Environmental Protection Agency)	The EPA is a federal agency that was created in 1970 for the purpose of protecting human health and the environment. The EPA is recognized to have jurisdiction by law and/or has special expertise in environmental laws, Executive Orders, and NEPA assessment and procedures. Under Section 309 of the Clean Air Act, the EPA is required to review and publicly comment on the environmental effects of major federal actions, including actions that are the subject of EIS documents. If the EPA determines that the action is environmentally unsatisfactory, it is required by Section 309 to refer the matter to the CEQ.
Ephemeral Stream	A stream that flows only in direct response to precipitation and whose channel is at all times above the water table.
EPMs (Environmental Protection Measures)	EPMs are measures developed by the Applicant to avoid or minimize potential adverse effects of the Project resulting from construction, operations and maintenance, and decommissioning. EPMs are an integral part of the Project and their implementation was assumed throughout the impact analysis of the EIS.
ERS (U.S. Department of Agriculture Economic Research Service)	The mission of the ERS is to inform and enhance public and private decision making on economic and policy issues related to agriculture, food, the environment, and rural development.

Federal Aviation Act	This act was passed to continue the Civil Aeronautics Board as an agency of the United States, to create a Federal Aviation Agency, to provide for the regulation and promotion of civil aviation in such manner as to best foster its development and safety, and to provide for the safe and efficient use of the airspace by both civil and military aircraft, and for other purposes (P.L. 85-726, 72 Stat. 731).
Farmland of Statewide Importance	This is land, in addition to prime and unique farmland, that is of statewide importance for the production of food, feed, fiber, forage, and oil seed crops. Criteria for defining and delineating this land are to be determined by the appropriate state agency or agencies. Generally, additional farmlands of statewide importance include those that are nearly prime farmland and that economically produce high yields of crops when treated and managed according to acceptable farming methods. Some may produce as high a yield as prime farmlands if conditions are favorable. In some states, additional farmlands of statewide importance may include tracts of land that have been designated for agriculture by state law.
Fault	A planar fracture or discontinuity in a volume of rock, across which there has been significant displacement along the fractures as a result of earth movement. Energy release associated with rapid movement on active faults is the cause of most earthquakes. A fault line is the surface trace of a fault, the line of intersection between the fault plane and the Earth's surface.
Feasible	Capable of being accomplished in a successful manner within a reasonable period of time, taking into account economic, environmental, legal, regulatory, technical, and safety factors.
Federally Listed	Species listed as Threatened or Endangered pursuant to the Endangered Species Act (ESA) (16 USC § 1531 et seq.) by the U.S. Fish and Wildlife Service or NOAA Fisheries.
FHWA (U.S. Department of Transportation, Federal Highway Administration)	The Federal Highway Administration is an agency within the Department of Transportation that would be responsible for issuing encroachment permits if the proposed Project crosses federally funded highways.
Fiber Optic Regeneration Sites	As a data signal passes through fiber optic cable, the data signal degrades with distance. The signal must be regenerated or amplified every 180 to 200 miles at fiber optic regeneration sites. A typical fiber optic regeneration site is approximately 100 feet by 100 feet with a fenced area of approximately 75 feet by 75 feet.
Floodplain	That portion of a river valley adjacent to the stream channel which is covered with water when the stream overflows its banks during flood stage.
Fly yard	A Project-material staging area used specifically to support helicopter use.
Forb	An herbaceous plant that is not a grass or not grasslike.
Forest/Woodland	A habitat type characterized by being dominated by trees. Forests are densely covered by trees and have a continuous or nearly continuous canopy and little shade reaching the forest floor. In a woodland, trees are more widely scattered and sunlight reaches the floor, often supporting an understory of shrubs, grasses, and/or forbs.

FPPA (Farmland Protection Policy Act)	The Farmland Protection Policy Act (FPPA) authorizes the USDA to develop criteria for identifying the effects of federal programs on the direct or indirect conversion of farmland to nonagricultural uses. For the purposes of the law, federal programs include construction projects—such as highways, airports, dams, and federal buildings—sponsored or financed in whole or part by the federal government and the management of federal lands. Federal agencies are directed to: (1) use the developed criteria, (2) identify and take into account the adverse effects of federal programs on the preservation of farmland, (3) consider appropriate alternative actions that could minimize potential adverse effects to farmland, and (4) ensure that such federal programs, to the extent practicable, are compatible with state and local units of government, as well as private programs and policies, so that farmland is protected. Farmland protected by the FPPA is either: (1) prime or unique farmland, which is not already committed to urban development or water storage, or (2) other farmland, which is of statewide or local importance as determined by the appropriate local governmental agency with the concurrence of the Secretary of Agriculture. Farmland subject to FPPA is not required to be currently used for cropland. Farmland can be forestland, pastureland, cropland, or other land.
Fragmentation	The breaking up of contiguous areas of vegetation/habitat into smaller patches.
FSA (Farm Service Agency)	The Farm Service Agency ensures the well-being of American agriculture, the environment, and the American public through the administration of farm commodity programs; farm ownership, operating, and emergency loans; conservation and environmental programs; emergency and disaster assistance; and domestic and international food assistance.
Fugitive Dust	Visible emissions released from sources other than stacks; for instance, dust blown from storage piles, road dust, or emission leaking from sides of buildings or open areas in buildings.
Gauss	A unit of magnetic induction.
GHG (Greenhouse Gas)	Any gas that absorbs infrared radiation in the atmosphere. Greenhouse gases include, but are not limited to, carbon dioxide, methane, nitrous oxide, and ozone.
GIS (Geographical Information System)	A computer representation of data that is geographically distributed in three dimensions. These data can be generated and displayed to show their physical location. Each data set with a certain type of information constitutes a “layer” in the GIS. GIS layers can be superimposed to show the spatial relationships of different items.
Grasslands	Habitat types dominated by grasses (family Poaceae) with little woody vegetation or other forbs. In the regions of influence, most grasslands are dominated by introduced grass species, though some native grasslands are present.
GRP (Grassland Reserve Program)	The GRP was established to prevent grazing and pasture land from being converted into cropland, used for urban development, or developed for other non-grazing uses. Participants in the program voluntarily limit future development of their grazing and pasture land, while still being able to use the land for livestock grazing and activities related to forage and seed production.
Habitat Types	Generally described as place(s) where a plant or animal naturally or normally lives or grows. Habitat types also includes the physical elements of the environment, as well as the biotic elements that a given species interacts with.
Hazardous Materials	Defined in various ways under a number of regulatory programs, can represent potential threats to both human health and the environment when not properly managed. Includes hazardous waste.
High Voltage	Lines with 230kV or above electrical capacity.
Historic	Period wherein non-native cultural activities took place, based primarily upon European roots, having no origin in the traditional Native American culture(s).

Historic Property	Any prehistoric or historic district, site, building, structure, or object included in, or eligible for inclusion in, the National Register of Historic Places maintained by the Secretary of the Interior.
HVDC (High Voltage Direct Current) Transmission Line	Unlike an AC transmission line, the voltage and current on a direct current (DC) transmission line are not time varying, meaning they do not change direction as energy is transmitted. DC electricity is the constant, zero-frequency movement of electrons from an area of negative (-) charge to an area of positive (+) charge. HVDC transmission facilities include: • ROW easements for the transmission line, with a typical width of approximately 150 to 200 feet • Tubular and lattice steel structures used to support the transmission line • Electrical conductor and metallic return • Communications/control and protection facilities (optical ground wire [OPGW, static wire,] and fiber optic regeneration sites)
Hydric Soils	Soils that formed under conditions of saturation, flooding, or ponding long enough during the growing season to develop anaerobic conditions in the upper part. These soils are typically associated with jurisdictional wetlands, which must meet three required criteria: hydric soils, wetland hydrology, and hydrophytic vegetation, except in "difficult wetland situations" where not all criteria are evident.
Hydrology	The science of dealing with the properties, distribution, and circulation of water.
Hz (Hertz)	The unit of frequency in cycles per second; power systems in the U.S. operate with a frequency of 60 Hz.
Indian Tribe	An Indian tribe, band, nation, or other organized group or community, including a native village, regional corporation, or village corporation, as those terms are defined in section 3 of the Alaska Native Claims Settlement Act (43 USC 1602), which is recognized as eligible for the special programs and services provided by the United States to Indians because of their status as Indians. Government-to-government consultation is required for any project between the federal government and the government of any potentially impacted tribe.
Indirect Effects	Effects caused by the action that are later in time or farther removed in distance, but are still reasonably foreseeable. Indirect effects may include growth-inducing effects and other effects related to induced changes in the pattern of land use, population density or growth rate, and related effects on air and water and other natural systems, including ecosystems.
Insulator	A ceramic or other non-conducting material used to keep electrical circuits from jumping over to ground.
Intentional Destructive Acts	Security of the components of the Project facilities can involve a variety of different regulatory and reporting structures, authorities, and agencies. Intentional acts of destruction, sabotage, vandalism, theft, or other mischief, whether from terrorist activities or other criminal behavior, would be addressed through law enforcement and Project design protocols.
Interconnections	The electric transmission system provides a pathway for power among interconnected power producers, or generators, and distribution companies, or load. For power generation and delivery electric transmission interconnections are required. The Project includes are three possible points of interconnection: the Oklahoma Southwestern Public Service/Southwest Power Pool Interconnection, the Arkansas/Entergy/Mid-Continent Independent System Operator Interconnection, and the Tennessee Valley Authority Interconnection. System planning studies and system impact studies are required for interconnection.
Intermittent or Seasonal Stream	One which flows only at certain times of the year when it receives water from springs or from some surface source such as melting snow in mountainous areas.
Invasive Species	A species that is not native to the habitat under consideration and whose introduction causes, or is likely to cause, economic or environmental harm (Executive Order 13112). Invasive plants are typically adaptable, aggressive, and have a high reproductive capacity.

Invertebrates	Animals that lack a back bone and are represented by a wide variety of taxonomic groups in freshwater environments.
Irreversible and Irretrievable Commitment of Resources	A commitment of resources is irreversible when its primary and secondary impacts limit the future options for a resource. An irretrievable commitment refers to the use or consumption of a resource that is neither renewable nor recoverable for use by future operations.
KOP (Key Observation Point)	Viewing locations chosen to be generally representative of visually sensitive areas where it can be assumed that viewers may be affected by a change in the landscape setting from the Project. Views from KOPs are described by distance zones and are based on perception thresholds (changes in form, line, color, and texture).
kV (kilovolt)	One thousand volts (see volt).
Landslide	Any mass-movement process characterized by downslide transport of soil and rock, under gravitational stress, by sliding over a discrete failure surface; or the resultant landform. Can also include other forms of mass wasting not involving sliding (rockfall, etc.).
Lattice Tower	A freestanding steel framework tower that is often used to support electrical transmission lines with voltages above 100 kilovolts.
L_{dn}	The day-night sound level comprised of average hourly L_{eq} sound levels with a 10 dB penalty added to sound levels at night.
Lead Agency	The agency or agencies preparing, or having taken primary responsibility for preparing an environmental document as required by NEPA. For the Plains & Eastern Clean Line Transmission Project, DOE is the lead agency
L_{eq}	The energy averaged sound level for a given period of time.
Lithic Scatter	Consists of stone material that has been left behind or dropped and can include stone tools such as projectile points, knives, or simply debris from stone tool manufacture or lithic procurement activities.
Load	The amount of electrical power or energy delivered or required at any specified point or points on a system. Load originates primarily at the energy-consuming equipment of customers.
MBTA (Migratory Bird Treaty Act)	A law enacted in 1918 that prohibits pursuing, hunting, taking, capturing, killing, possessing, selling, bartering, purchasing, delivering, transporting, and receiving any migratory birds, parts, nests, or eggs.
mG (MilliGaus)	A unit used to measure magnetic field strength; one- thousandth of a gauss.
Migratory Bird	A bird that moves seasonally to different ranges to maximize breeding and feeding opportunities.
Mineral Resources	In the ROI, the primary mineral resource production is from the fossil fuels oil, natural gas, and coal. Additional minerals mined include limestone, building stone, sand and gravel, gypsum, clay and shale, granite, volcanic ash, tripoli, salt, bentonite, iron ore, and chat.
Mitigation	(1) Avoiding or reducing possible adverse impacts to a resource by limiting the timing, location, or magnitude of an action and its implementation. (2) Rectifying possible adverse impact by repairing, rehabilitating or restoring the affected environment or resource. (3) Reducing or eliminating adverse impacts by preservation and maintenance operations during the life of an action.
MSA (Metropolitan Statistical Area)	MSAs have at least one urbanized area with 50,000 or more residents, plus adjacent territory that has a high degree of social and economic integration with the core as measured by commuting ties. These areas represent larger communities that form regional markets for labor, goods and services, and information. MSAs typically include an urbanized node and economically related surrounding counties.

Multi-use Construction Yards	Multi-use construction yards are for staging of construction personnel and equipment and for material storage to support construction activities. Multi-use construction yards would be used for temporary concrete batch plants, where needed. The multi-use construction yards would be located outside of the ROW at intervals of approximately 25 miles. Typical sites would include areas designated for a field office, crew parking, sanitation, waste management, fueling, equipment wash, material storage, and equipment storage.
MW (Megawatts)	A megawatt is one million watts, or one thousand kilowatts; an electrical unit of power.
NAAQS (National Ambient Air Quality Standards)	Established by the U.S. Environmental Protection Agency, the NAAQS represent maximum acceptable concentrations that generally may not be exceeded more than once per year, except the annual standards, which may never be exceeded (40 CFR 50).
NAGPRA (Native American Graves Protection and Repatriation Act)	NAGPRA was established in 1990 to provide a means for museums and curation facilities to return certain collected items to Native American and Native Hawaiian groups. The act pertains to the repatriation of human remains, funerary objects, sacred objects, and objects of cultural patrimony. Federal grants are awarded to indigenous groups and institutions holding collections under the act to assist in the repatriation process, which is overseen by the Native American Graves Protection and Repatriation Review Committee.
National Emissions Standards for Hazardous Air Pollutants	National Emission Standards for Hazardous Air Pollutants (NESHAPS) are stationary source standards for hazardous air pollutants. Hazardous air pollutants (HAPs) are those pollutants that are known or suspected to cause cancer or other serious health effects, such as reproductive effects or birth defects, or adverse environmental effects. NESHAPs are found in 40 CFR Part 61 and 40 CFR Part 63.
National Scenic Byway	To be designated as a National Scenic Byway, a road should have at least one of six scenic byway intrinsic qualities (archaeological, cultural, historic, natural, recreational, and scenic) that is regionally significant (DOT 2008). The Federal Highway Administration is responsible for administering the National Scenic Byways Program (23 USC 162) through the Intermodal Surface Transportation Efficiency Act of 1991 (IS TEA; PL 102-240). A scenic byway is a public road with special scenic, historic, recreational, cultural, archaeological, and/or natural qualities that have been recognized as such through legislation or official declaration. Easements associated with scenic byway ROWs may prohibit construction of transmission structures or other structures that degrade the scenic quality of the road.
National Wild and Scenic Rivers System	A system of nationally designated rivers and their immediate environments that have outstanding scenic, recreational, geologic, fish and wildlife, historic, cultural, or other similar values and are preserved in a free-flowing condition.
NEPA (National Environmental Policy Act of 1969)	Federal statute that contains procedures to ensure that federal agency decision makers take environmental factors into account. The two major purposes of the NEPA process are citizen involvement and better informed decisions. The act establishes national environmental policy and goals for the protection, maintenance, and enhancement of the environment, and it provides a process for implementing these goals within the federal agencies. The act also establishes the Council on Environmental Quality (CEQ) and requires an environmental impact statement on all major Federal actions significantly affecting the quality of the human environment (42 USC 4332 2(2)(C)).
New Source Performance Standards	Section 111 of the Clean Air Act authorized the EPA to develop technology based standards which apply to specific categories of stationary sources. These standards are referred to as New Source Performance Standards (NSPS) and are found in 40 CFR Part 60. The NSPS apply to new, modified and reconstructed affected facilities in specific source categories such as manufacturers of glass, cement, rubber tires and wool fiberglass. The NSPS are developed and implemented by EPA and are delegated to the states. However, even when delegated to the states, EPA retains authority to implement and enforce the NSPS.
NHL (National Historic Landmark)	A historic property that the Secretary of the Interior has designated a National Historic Landmark.

NHPA (National Historic Preservation Act of 1966, as amended)	Act directing federal agencies to consider the effects of their programs and projects on properties listed or eligible for listing on the National Register of Historic Places. If a proposed action might impact any archaeological, historical, or architectural resource, this act mandates consultation with the proper agencies.
NHTs (National Historic Trails)	A congressionally designated trail that is an extended, long-distance trail, not necessarily managed as continuous, that follows as closely as possible and practicable the original trails or routes of travel of national historic significance.
Nitrogen Oxide	A group of compounds consisting of various combinations of nitrogen and oxygen atoms.
No Action Alternative	This Plains & Eastern EIS analyzes a No Action Alternative, under which DOE would not participate with Clean Line in the Project. DOE assumes for analytical purposes that the Project would not move forward and none of the potential environmental effects associated with the Project would occur.
NOI (Notice of Intent)	A public notice, published in the *Federal Register*, that an environmental impact statement will be prepared and considered in the decision making for a proposed action. It also provides background information on the proposed project in preparation for the scoping process.
Nonattainment Area	An area that does not meet air quality standards set by the Clean Air Act for specified localities and periods.
Noxious Weed	A legal term, meaning any plant officially designated by a federal, state, or local agency as injurious to public health, agriculture, recreation, wildlife, or property.
NPS (National Park Service)	Established in 1916, the purpose of the National Park Service is to "conserve the scenery and the natural and historic objects and the wild life therein and to provide for the enjoyment of the same in such a manner and by such means as will leave them unimpaired for the enjoyment of future generations".
NRCS (Natural Resources Conservation Service)	The NRCS is a federal agency within the Department of Agriculture and is a conservation leader in all natural resources; ensuring that private lands are conserved, restored, and more resilient to environmental challenges. NRCS is recognized to have jurisdiction by law and/or has special expertise in the following areas: a. Farmland Protection Policy Act (7 USC 4201 et seq.; 7 CFR Part 658) b. Watershed and Flood Prevention Act, Public Law 83-566, as amended (16 USC 1001–1009) c. Wetland Reserve Program (16 USC 3837, et seq.) d. Grassland Reserve Program (16 USC 3838N-3838q.) e. Healthy Forests Restoration Act of 2003, Public Law 108–148 (16 USC § 6501) f. The 1996 U.S. Farm Bill, Public Law 104–127 (110 Stat. 888–1197)
NRHP (National Register of Historic Places)	The official register of districts, sites, buildings, structures, and objects significant in American history, architecture, archaeology, and culture, established by the National Historic Preservation Act of 1966, as amended, and maintained by the National Park Service on behalf of the Secretary of the Interior.
NSTs (National Scenic Trails)	A congressionally designated trail that is a continuous and uninterrupted extended, long-distance trail so located as to provide for maximum outdoor recreation potential and for the conservation and enjoyment of the nationally significant resources, qualities, values, and associated settings and the primary use or uses of the areas through which such trails may pass.
NWR (National Wildlife Refuge)	NWRs are administered by the USFWS under the National Wildlife Refuge System Administration Act (16 USC 668dd). The National Wildlife Refuge System's purpose is to administer a national network of lands and waters for the conservation, management, and restoration of fish, wildlife, and plant resources and their habitats for the benefit of present and future generations. Each NWR is to be managed to fulfill the specific purposes for which the refuge was established. This act allows easements or ROWs for power lines so long as it is determined the power line is compatible with the purposes for which an NWR was established.
Oklahoma AC Interconnection Siting Area	An approximate 870-acre corridor within which an AC transmission interconnection route from the Oklahoma converter station to the future Optima Substation would be sited.

Oklahoma Converter Station Siting Area	An approximate 620-acre area in Texas County, Oklahoma, within which the converter station and associated AC switchyard (45 to 70 acres total) and access road(s) would be sited.
OPGW (Optical Ground Wire)	Optical ground wire would be installed to protect the transmission line from direct lightning strikes. The ground wires and structures would transfer current from the lightning strikes though the ground wires and structures into the ground.
OSHA (Occupational Safety and Health Administration)	OSHA has jurisdiction over most occupational health and safety issues within each state crossed by the Project. Industrial construction and routine workplace operations are governed by the Occupational Safety and Health Act of 1970, specifically 29 CFR 1910 (general industry standards) and 29 CFR 1926 (construction industry standards).
Original Applicant Proposed Route	Throughout the Final EIS, the term "original Applicant Proposed Route" refers to the centerline of the representative ROW that was shown and analyzed in the Draft EIS.
Outage	Events caused by a disturbance on the electrical system that requires the provider to remove a piece of equipment or a portion or all of a line from service. The disturbances can be either natural or human-caused.
Overstory	The overstory is a layer of tall mature trees that rise above the shorter understory trees, including the trees in a timber stand.
Ozone	Relatively unstable form of oxygen (O_3) that is associated with the corona discharge of high-voltage transmission lines. Rapidly recombines back to the more stable oxygen (O_2).
Palustrine	National Wetlands Inventory system that includes wetlands dominated by trees, shrubs, and persistent emergent plants associated with water bodies that cover less than 20 acres or with water less than 6.6 feet deep.
Parturition Areas	Areas where habitat is appropriate for female big game animals to seclude themselves while giving birth to young in late spring or early summer. Such areas are usually characterized by ample hiding cover and forage.
Peak Hour	The hour of the day that observes the highest traffic volumes for a roadway or intersection. Typically two peak hours are reported, one in the AM and one in the PM.
Perennial Stream	One that flows with water present continuously during an average water year.
Physiographic	Pertaining to the features and phenomena of nature.
Plant Protection Act	Under the Plant Protection Act of 2000 (7 USC 104), which encompasses the Federal Noxious Weed Act of 1974 (7 USC 2801 et seq.), the federal government lists 137 regulated noxious weeds. States typically have their own noxious weed lists and county weed control boards or districts that monitor weed infestations and provide guidance on weed control.
Prevention of Significant Deterioration	Federal pre-construction review for affected sources located in attainment areas for air quality. It is intended to prevent a new source from causing air quality to deteriorate beyond acceptable levels.
Prime Farmland	As defined by the USDA (7 CFR §657.5), prime farmland is land that has the best combination of physical and chemical characteristics for producing food, feed, forage, fiber, and oilseed crops and is available for these uses (the land could be cropland, pastureland, rangeland, forest land, or other land, but not urban built-up land or water).

Programmatic Agreement (PA)	DOE is developing a Programmatic Agreement (PA) pursuant to 36 CFR 800.14(b) to address its obligations under NHPA Section 106, including government-to-government consultation with Indian Tribes and Nations that may attach religious and cultural significance to historic properties that may be affected by the undertaking, and consultation with the Arkansas, Oklahoma, Tennessee, and Texas SHPOs as well as the Federal agencies listed above. Clean Line will also be a party to the PA (Appendix P). The PA addresses resource identification and evaluation, assessment of effects, and resolution of effects, including avoidance, minimization, and mitigation. Development of a PA under 36 CFR 800.14(b) is appropriate for the Project because its potential effects on historic properties are multi-state and regional in scope, because of the complex nature of the undertaking, and because effects on historic properties cannot be fully determined prior to approval of the undertaking. In such situations, the regulations allow development of a PA to address the identification of historic properties and resolution of adverse effects in a phased approach (36 CFR 800.14(b)).
Project (the)	A broad term that generically refers to elements of the Applicant Proposed Project and/or DOE Alternatives when differentiation between the two is not necessary. The term also refers to whatever combination of project elements that would be built if a decision was made by DOE to participate with Clean Line.
Purpose and Need	Under the National Environmental Policy Act of 1969 (NEPA), the need to take an action may be something the agency identifies itself, or it may be a need to make a decision on a proposal brought to it by someone outside of the agency, for example, an applicant for a permit. Alternatives are measured against how well they meet the underlying need and best achieve the purposes to be attained. DOE's purpose and need for agency action is to implement Section 1222 of the EPAct. To that end, DOE needs to decide whether and under which conditions it would participate in Clean Line's proposed Project.
Raptor	A bird of prey such as eagles, hawks, falcons, or owls.
Reclamation	Returning disturbed lands to a form and productivity that will be ecologically balanced.
Reliability	Transmission systems must be built with sufficient levels of redundancy to enable the transmission system to reliably operate in the event of the loss of any single element (i.e., transmission line segment or substation element).
Representative ROW (Right-of-Way)	The analysis of impacts for the HVDC Applicant Proposed Route, AC Collection System, and HVDC alternative routes were based on a representative 200-foot ROW (100 feet on either side of a representative centerline). Quantitative data regarding the resources directly intersected by the representative 200-foot-wide ROW were used to analyze the potential impacts of the Project.
Revegetation	The reestablishment and development of self-sustaining plant cover. On disturbed sites, this normally requires human assistance, such as reseeding.
Riparian Areas	Vegetation communities that occur adjacent to waterways such as streams, rivers, springs, ponds, lakes, or tidewater and that provide habitat for numerous plant and animal species. They generally occupy transitional areas between aquatic and upland habitats and may function as vegetative buffers for aquatic resources.
Riverine System	Wetland inventory system that includes wetlands not dominated by trees, shrubs, or persistent emergents that are contained within a river channel.
Rivers and Harbors Act	Section 10 of the act prohibits the unauthorized obstruction or alteration of any navigable water of the U.S. without a permit from the U.S. Army Corps of Engineers.
Roadless area	An area of undeveloped public land within which there are no improved roads maintained for travel by means of motorized vehicles intended for highway use.
ROD (Record of Decision)	The ROD is the formal agency decision document for the EIS process. DOE's ROD would announce and explain DOE's decision on whether to participate in the Project and describe any conditions, such as mitigation commitments, that would need to be met. DOE may issue a ROD no sooner than 30 days after EPA's Notice of Availability for the Final EIS is published in the *Federal Register.*

ROI (Region of Influence)	To examine the potential impacts of the Project components, the EIS examines the area potentially affected by the Applicant Proposed Project and the DOE Alternatives. The EIS defines the area potentially affected by the Project as the ROI. A description of the ROI is provided in Section 3.1. The ROI may be expanded or modified on a resource specific basis where appropriate as described in each resource section.
Route Variation	Modifications DOE and Clean Line made to the Applicant Proposed Route in Regions 2–7 in response to public comments on the Draft EIS. For each comment that specifically requested a re-routing consideration, DOE reviewed the information supplied with the comment and coordinated with Clean Line through a series of formal data requests. For each comment that provided new information indicating a potential conflict between a route and resources not known at the time of the Draft EIS, DOE reviewed the comment and related data request responses from Clean Line, and determined the feasibility of developing route variations to avoid those areas (e.g., previously unknown residences or structures, environmentally or culturally sensitive areas). In each instance, any consideration of a route variation needed to remain consistent with the routing criteria used for route development. Throughout the Final EIS, the term “route variation” refers to the centerline of the revised representative ROW. With one exception, route variations involve changes to the centerline outside of the 1,000-foot corridor that DOE analyzed in the Draft EIS. DOE included Applicant Proposed Route Link 5, Variation 1, which is within the 1,000-foot corridor analyzed in the Draft EIS, as a route variation so that DOE’s analyses of the representative ROW would be consistent with Clean Line’s application for a certificate of public convenience and necessity with the Tennessee Regulatory Authority.
Sage-Grouse Lek	A location used by male sage-grouse, generally every year, to assemble during the mating season and engage in competitive displays that attract females.
Scenery	The aggregate of features that give character to a landscape.
Scenic Byway	A public road having special, scenic, historic, recreational, cultural, archeological, and/or natural qualities that have been recognized as such through legislation or some other official declaration.
Sensitivity Levels	Measures (e.g., high, medium, low) of public concern for the maintenance of a particular existing landscape.
Scoping (Public Scoping)	A formal part of the federal environmental analysis process required under NEPA where issues are identified for detailed analysis. Scoping includes, but is not limited to, a formal scoping period early in the analysis process in which members of the public are invited to review the proposed action and identify possible issues or concerns with the project. Public scoping begins with the issuance of a Notice of Intent (NOI) in the *Federal Register* and includes public meetings in the vicinity of the Project. For the Plains & Eastern EIS, public scoping began with DOE’s publication of the NOI on December 21, 2012. The public scoping period continued for ninety days through March 21, 2013. DOE held 13 public scoping meetings in communities along the proposed and alternative routes and five interagency meetings during the scoping period.
Section 106 of the NHPA	Under Section 106 of the National Historic Preservation Act of 1966, as amended, federal agencies must identify and evaluate cultural resources and consider the impact of undertakings they fund, license, permit, or assist on historic properties eligible for inclusion in the National Register of Historic Places. The federal agencies must afford the State Historic Preservation Officer and the Advisory Council on Historic Preservation the opportunity to comment on these undertakings.
Section 1222 of EPAct (Energy Policy Act of 2005)	Section 1222 of the EPAct, in relevant part, authorizes the Secretary of Energy, acting through and in consultation with the Administrator of Southwestern (provided the Secretary determines that certain statutory requirements have been met), to participate with other entities in designing, developing, constructing, operating, maintaining, or owning new electric power transmission facilities and related facilities located within any state in which Southwestern operates.
Sedimentation	The deposition or accumulation of sediment.
Seismic Hazards	Seismic hazards include faults and seismicity. Seismicity refers to the intensity and geographic and historical distribution of earthquakes.

Sensitivity Levels	Sensitivity levels are the measure of public concern for scenic quality. Public lands are assigned high, medium, or low sensitivity levels.
Seral	Pertaining to the stages of ecological succession occurring in communities of plants and animals until the climax is reached.
SHPO (State Historic Preservation Office[r])	Created under Section 101 of the NHPA to survey and recognize historic properties, review nominations for properties to be included in the National Register of Historic Places, review undertakings for the impact on the properties as well as support federal organizations, state and local governments, and the private sector. States are responsible for setting up their own SHPO; therefore, each SHPO varies slightly on rules and regulations.
Shrubland	A habitat type characterized by woody vegetation smaller than trees (in general, having multiple main stems and being less than 20 feet in height and six inches diameter at breast height at maturity).
Single-Circuit Transmission Line	A transmission line composed of three electrical phases and two lightning protection shield wires. One of the lightning protection shield wires is a steel overhead ground wire and the other is typically an optical ground wire (OPGW).
SIO (Scenery Integrity Objective)	To describe the goals of a landscape relative to its assumed natural state: Very High (Unaltered), High (Appears Unaltered), Moderate (Slightly Altered), Low (Moderately Altered), and Very Low (Heavily Altered). When discussing SIOs, the degree of alteration is measured in terms of visual contrast with the surrounding natural landscape.
SMS (Scenery Management System)	The SMS provides an overall framework for the orderly inventory, analysis, and management of scenery. The system applies to all national forests and grasslands administered by the Forest Service and to Forest Service management activities. This system applies only to HVDC Alternative 4-B that crosses the Ozark National Forest. The SMS process uses particular ecosystems as the environmental context for aesthetics.
SO_2 (Sulfur dioxide)	Sulfur dioxide is one of a group of highly reactive gasses known as "oxides of sulfur."
Soil Compaction	Operation of motorized vehicles on moist soils, especially heavy equipment, is likely to cause compaction of the surface layer, which may increase runoff, decrease infiltration and aeration, and reduce soil productivity by making it more difficult for plant roots to establish or obtain soil moisture and nutrients.
Soil Erosion	The movement of soil particles, usually as a result of wind or water forces. Many factors affect soil erosion, including soil grain size, cohesion factor, soil moisture content, type and amount of vegetative cover, precipitation amount and intensity, steepness of slope, and wind speed.
Soil Liquefaction	Liquefaction may occur when loose, cohesionless, and water-saturated soils lose strength and stiffness in response to stress, such as the ground shaking from an earthquake, causing the soil to behave like a liquid. It is most often observed in fluvial, lacustrine, or eolian deposits of Holocene age or younger that have not compacted or cohered. Liquefaction potential in a soil layer increases with decreasing fines content and plasticity of the soil. Cohesionless soils having less than 15 percent (by weight) of particles smaller than 0.005 millimeter, a liquid limit less than 35 percent, and an in situ water content greater than 0.9 times the liquid limit may be susceptible to liquefaction. Liquefaction is more likely to occur in soil/sediment layers with at least 80 to 85 percent saturation and located within 50 feet of the ground surface.
Span Length	The distance between two transmission support structures traveled by the conductors, measured either horizontally or along the conductors from the end of one insulator string to the end of the next insulator string.
Special Status Species	Species of plants or animals that have been designated by government agencies as needing special monitoring, conservation, or protection, usually due to declining populations. This group includes federally endangered and threatened species as well as other designations.
Species	A group of interbreeding individuals not interbreeding with another such group; similar and related species are grouped into a genus.

Staging Area	A fenced, generally flat location where materials, equipment, and vehicles are stored prior to their use in construction of the transmission line or its ancillary facilities.
Stray Voltage	Stray voltage is an extraneous voltage that appears on grounded surfaces in buildings, barns, and other structures, including utility distribution systems.
Structures	The structures used to support the HVDC or AC transmission lines would be constructed of either tubular or lattice steel and would typically range in height from 120 to 200 feet. Preliminary engineering indicates that most structures would be less than 160 feet when using lattice structures and would tend to be less than 140 feet when using monopole structures.
Subsidence (Soil)	Subsidence hazards involve either the sudden collapse of the ground to form a depression or the slow movement downward or compaction of the sediments near the earth's surface. The most common types of subsidence are the subsidence due to erosion of soil or rock and collapses involving the dissolution of carbonate rocks (limestones) beneath the surface.
Substation	A fenced site containing switching and transformation equipment needed to transform one voltage to another and for protecting and controlling transmission and distribution lines. A substation is used to raise voltages for long distance transmission and to lower transmission voltage for distribution to the end users.
Switches	Devices used to mechanically disconnect or isolate equipment; found on both sides of circuit breakers.
System planning	System planning evaluates the operations of the electric transmission system and uses that information to assess future transmission system needs. System planning studies were required to study the interconnections and between the Applicant Proposed Project and the existing electrical grid.
Tap	The point at which a transmission line is connected to a substation or other electrical device to provide service to a local load.
TCP (Traditional Cultural Property)	A property that is eligible for the NHRP because of its association with cultural practices or beliefs of a living community that (a) are rooted in that community's history, and (b) are important in maintaining the continuing cultural identity of the community.
Temporary Construction Areas	Temporary construction areas would be required to support construction. Temporary multi-use construction yards and fly yards (landing areas for helicopters used during construction) would be used for staging construction personnel and equipment, and for storage of materials to support construction activities. Tensioning or pulling sites and wire-splicing sites would also be staged at 2- to 3-mile intervals along the Project ROW.
Tennessee Converter Station Siting Area	An approximate 220-acre area in Shelby County, Tennessee, within which the converter station and associated AC switchyard (45 to 60 acres total), access road(s), and substation upgrades (also referred to as direct assignment facilities) including additional bays, breakers, switches, line relays, and interchange meters would be sited.
Tensioning or Pulling Areas	Tensioning or pulling sites would be used for the tensioning equipment to establish and maintain tension on the ground wire or conductor while they are fastened to the structures. Tensioning or pulling sites would be approximately 2 to 3 miles apart and would be entirely within the ROW or partially outside the ROW.
Terrestrial	Occurring on land.
TES (Threatened and Endangered Species)	Threatened and endangered species listed or candidates for listing under the federal Endangered Species Act (ESA).
THPO (Tribal Historic Preservation Office[r])	Tribal officials tasked with advising and assisting Federal agencies in carrying out responsibilities under Section 106 of the NHPA.
Threatened Species	Those species officially listed by the U.S. Fish and Wildlife Service that are likely to become endangered within the foreseeable future throughout all or a significant portion of their range (ESA §3(20)).

Topsoil	The uppermost soil layer, generally ranging from a few inches to less than one foot in thickness. Topsoil is the site of greatest organic content, contains the most soil nutrients, and supports the greatest amount of plant life.
Toxic air Pollutants	Chemicals and chemical classes which often have carcinogenic, mutagenic, or other especially hazardous properties and are typically subsets of criteria pollutants.
Transformers	Electrical equipment usually contained in a substation that is needed to change voltage on a transmission system.
Transmission Line	A system of structures, wires, insulators, and associated hardware that carry electric energy from one point to another in an electric power system. Lines are operated at relatively high voltages varying from 69kV up to 765kV, and are capable of transmitting large quantities of electricity over long distances.
Trip	A single or one-direction vehicle movement with either the origin or the destination inside the study site.
Turbidity	The state or condition of opaqueness or reduced clarity of a fluid due to the presence of suspended matter.
TVA (Tennessee Valley Authority)	TVA is a federally owned corporation that provides electricity to about 9 million people in parts of seven southeastern states. TVA is recognized to have jurisdiction by law by virtue of the approvals that would need to be obtained from TVA before interconnecting the Project to the transmission system TVA operates in the Tennessee Valley region.
Understory	Foliage layer beneath the forest canopy. Young trees that are growing beneath the tall mature trees in a timber stand.
Undertaking	A federal undertaking is defined as a decision involving federal expenditure of funds or issuance of permit, license, or other approval.
USFS (U.S. Department of Agriculture, Forest Service)	A federal agency under the Department of Agriculture that manages 193 million acres of public land for multiple uses and benefits and for the sustained yield of renewable resources such as water, forage, wood, recreation, fish and wildlife habitat, wilderness areas, and archaeological, paleontological and historical sites.
USFWS (U.S. Fish and Wildlife Service)	USFWS is a bureau within the Department of Interior whose mission is to conserve, protect, and enhance fish, wildlife, and plants and their natural habitats for the continuing benefit of the American people. USFWS is recognized to have jurisdiction by law and/or has special expertise in the following areas: • Endangered Species Act (16 USC § 1531et seq.) • Migratory Bird Treaty Act (16 USC § 703 et seq.) • Bald and Golden Eagle Protection Act (16 USC § 668 et seq.) • The National Wildlife Refuge System Administration Act (16 USC § 668dd–68ee) • Executive Order 13186 and DOE and USFWS Memorandum of Understanding
Vegetation Communities	A combination of dominant plant species that live together in the same region or on the same landform.
Viewing Location	Public and private areas (including Key Observation Points) within a landscape where a project could be visible and where concerns for changes to the landscape exist.
Viewshed	The landscape that can be directly seen under favorable atmospheric conditions, from a viewpoint or along a transmission corridor.
Visual Elements	Form, line, color and texture of an existing landscape. Contrast in the landscape is determined by comparing visual elements of the existing landscape with the visual elements of the Project (i.e., transmission structures, converter stations, access road, etc.).
Visual Resources	Visible features of the landscape (e.g., land, water, vegetation, animals, structures, and other features).

Visual Sensitivity	A measure of viewer concern for scenic resources and potential changes to the resource and is based on volume of use, frequency of views and viewing duration.
Volt	The international system unit of electrical potential and electromotive force—a measure of electrical "pressure."
Voltage	The electrical potential difference between two points expressed in volts; the driving force that causes a current to flow in an electrical circuit.
VRM (Visual Resource Management) System	The Bureau of Land Management system identified four VRM Classes (I through IV) with specific management prescriptions for each class. The system is based on an inventory of the existing scenic quality, viewer sensitivity, and viewing distance zones. The management class for a given area is typically arrived at by comparing the scenic quality, visual sensitivity, and distance zone with the overall goals set forth for the area.
Watershed	The area that drains to a common waterway.
WDZ (Wind Development Zone)	Twelve wind development zones were identified to consider potential connected actions for the Project. These zones are areas within a 40-mile-radius of the Oklahoma Converter Station Siting Area with adequate wind resource and in which wind energy developers may consider future development of wind energy facilities.
Wetlands	The USACE and EPA jointly define wetlands as "Those areas that are inundated or saturated by surface or ground water (hydrology) at a frequency and duration sufficient to support, and that under normal circumstances do support, a prevalence of vegetation (hydrophytes) typically adapted for life in saturated soil conditions (hydric soils). Wetlands generally include swamps, marshes, bogs, and similar areas (CFR 328.3 and 40 CFR 232.2(r))."
Wire Splicing Sites	Conductors and shield wires are strung into their supporting structures over a length of two reels. The wire from the two reels is mechanically joined at the wire ends with a temporary wire-gripping sleeve (stringing sock) which passes through the stringing blocks. After the wire is strung and secured, the stringing sock is replaced with a compression splice connector. The location of the splice connector installation is the wire splicing site. Typical wire splicing sites include a wire splicing truck and a line truck to facilitate installation and are located within the ROW.
Wire Zone	A linear zone under the transmission wires and extending 10 feet beyond them and maintained in vegetation cover less than 5 feet high.
WMA (Wildlife Management Area)	Wildlife Management Areas are lands that are protected for conservation of sensitive resources and for their recreation opportunities.
Waters of the United States	Broadly defined by statute, regulation, and judicial interpretation to include all waters that were, are, or could be used in interstate commerce such as rivers, streams (including ephemeral streams), reservoirs, lakes, and adjacent wetlands. The USACE Wetlands Delineation Manual and its current supplements must be used to determine whether an area has sufficient wetland characteristics to be a water of the United States.
WRP–Wetland Reserve Program	The NRCS Wetlands Reserve Program (WRP) is a voluntary program offering landowners the opportunity to protect, restore, and enhance wetlands on their property. The program provides technical and financial support to help landowners with their wetland restoration efforts.
Zoning	Regulations used to guide growth and development; typically involve legally adopted restrictions on uses and building sites in specific geographic areas to regulate private land use.
