The Applicant Proposed Route in Region 6 is approximately 54 miles long. Approximately 0.3 mile (0.5 percent) is parallel to existing transmission lines and 7 miles (12.7 percent) is parallel to existing roads. The land cover in the 200-foot-wide representative ROW for Region 6 is listed in Table 3.10-20. The land cover in the representative ROW consists of approximately 1,056 acres (79.6 percent) cultivated crops. Typical crops include winter wheat, soybeans, rice, and corn (NASS 2013).

In Link 7, approximately 0.5 acre (less than 1 percent of the representative ROW) crosses the Singer Forest Natural Area easement and approximately 0.3 acre crosses the St. Francis Sunken Lands WMA. The natural area and WMA share approximate boundaries. This area would be temporarily unavailable for other uses (primarily hunting) during construction in this location. Hunting and wildlife viewing may also be temporarily reduced in areas near construction due to noise and removal of vegetation; this would be an indirect short-term impact. The representative ROW of Link 7 includes a parcel of land enrolled in the WRP totaling approximately 0.3 acre. Five agricultural structures (one in Link 4 and four in Link 6) are present in the representative ROW.

Outside the ROW, tensioning or pulling areas totaling approximately 115.6 acres would be required during construction and would be temporarily unavailable for other uses. The land cover in these areas is primarily cultivated crops. No existing structures are present in these areas.

Table 3.10-19:
Land Cover in the Applicant Proposed Route—Region 5

Land Cover[1]	Link 1		Link 2		Link 3		Link 4		Link 5		Link 6		Link 7		Link 8		Link 9		Total

One route variation to the Applicant Proposed Route was developed in Region 6 in response to public comments on the Draft EIS. The route variation is described in Appendix M and summarized in Section 2.4.2.6. The variation is illustrated in Exhibit 1 of Appendix M. Link 2, Variation 1, would parallel parcel boundaries more closely to minimize impacts to agricultural operations than the original Applicant Proposed Route Link 2. The representative ROW for this variation would cross approximately 15 acres more crop land. It should be noted that a route adjustment was made for HVDC Alternative Route 6-A to maintain an end-to-end route with this variation.

3.10.6.2.3.1.7 Region 7

The Applicant Proposed Route in Region 7 is approximately 43 miles long. Approximately 0.3 mile (0.6 percent) is parallel to existing transmission lines and 4 miles (9.4 percent) is parallel to existing roads. The land cover in the 200-foot-wide representative ROW for Region 7 is listed in Table 3.10-21. The land cover in Region 7 is generally dominated by cultivated crops, although there is more variation than in Region 6. The land cover in the representative ROW consists of 691.8 acres (66.2 percent) cultivated crops, 86.8 acres (8.3 percent) of developed, open space, 79.1 acres (7.6 percent) of deciduous forest, 59.5 acres (5.7 percent) of woody wetlands, and 52.7 acres (5.0 percent) of shrub/scrub land. All other land cover types represent less than five percent of the total representative ROW.

Table 3.10-21:
Land Cover in the Applicant Proposed Route—Region 7

Land Cover[1]	Link 1		Link 2		Link 3		Link 4		Link 5		Total

1 The values in the table do not reflect the minor changes that would result from application of the minor route variations and adjustments.
Source: Jin et al. (2013)

The representative ROW of Link 1 includes a parcel of land enrolled in the WRP totaling approximately 2 acres. Two agricultural structures are present in the representative ROW for Applicant Proposed Route Link 5 and one other structure (type unknown) is present in the representative ROW for Link 1.

Outside the ROW, tensioning or pulling areas totaling approximately 162.4 acres would be required during construction and would be temporarily unavailable for other uses. The land cover in these areas is primarily cultivated crops. No existing structures are present in these areas.

Three route variations to the Applicant Proposed Route were developed in Region 7 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.7. The variations are illustrated in Exhibit 1 of Appendix M. A description of the impacts of the variations compared to the original Applicant Proposed Route follows. Link 1, Variation 1, would parallel more parcel boundaries to minimize impacts to agricultural operations compared to the original Applicant Proposed Route Link 1, and would cross two fewer parcels but 5 acres more crop land. Link 1, Variation 2, would cross four fewer parcels and also follow parcel boundaries more closely to avoid impacts to agricultural operations, including center pivot irrigation, a precision-leveled field, and aerial spraying to these fields. The representative ROW for this variation would cross approximately 8 acres less crop land. Link 5, Variation 1, would cross three more parcels and approximately 2 acres more forest land than the original Applicant Proposed Route as well as move the route farther from a new residential area.

3.10.6.2.3.2 Operations and Maintenance Impacts

Within the transmission line ROW (200 feet wide by 720 miles long), only the transmission structures, fiber optic regeneration sites, and access roads would remain. For lattice structures, the operational footprint would be four to six structures per mile, and each foundation would measure 28 feet by 28 feet (less than 0.02 acre). Assuming 720 miles of lattice structures, the operational footprint would be 86 acres. Each structure would be 120 to 200 feet tall. For tubular pole structures, the operational footprint would be five to seven structures per mile, each 49 square feet, up to 5.6 acres total. Each structure would be 120 to 160 feet tall. Lattice crossing structures, which would be required in limited situations, would each have a structural footprint of 64 feet by 64 feet (approximately 0.09 acre) and each structure would be 350 feet tall. Guyed structures would also be required in limited situations, and would each have a structural footprint (not including guy wires) of 7 feet by 7 feet (0.001 acre) and each structure would be 120 to 200 feet tall. Impact calculations assumed lattice structures would be used for a conservative estimate of potential impacts.

The estimated four fiber optic regeneration sites would remain, each consisting of a fenced area 75 feet wide by 75 feet long (0.13 acre) including a control building 12 feet by 32 feet. The estimated operational footprint for all four sites is 0.8 acre. A permanent access road to the fenced area, a power supply to the control building, and a backup power generator and fuel supply would also remain.

It is anticipated that all existing roads and existing roads with repairs/improvements would be retained for operations and maintenance of the Project. It is estimated that approximately 75 percent of the new overland roads with no improvements and 90 percent of the new overland roads with clearing and new bladed roads would be retained for operations and maintenance access. These roads would be up to 20 feet wide, and would total an estimated 1,851 acres. Access roads that are not needed for operations and maintenance of the Project would be restored (GE-7).

In total, approximately 1,938 acres would be required for the operation of the HVDC transmission line, including 86 acres for the structures, 1,851 acres for the roads, and 0.8 acre for the fiber optic regeneration sites. All other land in the ROW could return to most previous land uses, primarily agriculture (grazing and crops). As noted in Section 2.1.5.1, limitations on land uses would be described in individual landowner easement agreements, and these agreements could be modified in the easement based on site-specific conditions and/or coordination with landowners. Land uses that generally may not be permitted in the ROW include constructing buildings or structures, changing the grading and land contours such that the ground surface elevation within the ROW would change and alter the required electrical clearance, and installing fences or irrigation lines without coordination with the Applicant. All of the tensioning or pulling areas and other temporary construction areas could return to existing uses once construction has been completed.

Because the locations of access roads for the HVDC transmission line are not known at this time, it is possible that the access roads could be located in such a way that small areas of agricultural land would be isolated and no longer practicable to be used for farmland or grazing.

As described in Section 2.3, the Applicant's routing criteria included maximizing opportunities for paralleling existing compatible infrastructure. In segments where that is not practical, the route would bisect parcels and may thereby limit larger types of new development in a particular area.

Pursuant to the NERC Reliability Standard FAC-003, during operations and maintenance, the ROW would be maintained according to a Transmission Vegetation Management Plan developed for the Project. The TVMP may require additional analysis under NEPA depending on whether and under what conditions DOE decides to participate in the Project. Vegetation within the wire zone would be limited to low-growing grasses, legumes, herbs, crops, and shrubs where the conductor is 50 feet or less from the ground. Tall shrubs and short trees would be permitted in the border zone (i.e., to the edge of the ROW). Tree-trimming and brush removal would be conducted as needed to maintain the vegetation within the ROW.

During operations and maintenance, the transmission line would be inspected regularly and as necessary using fixed-wing aircraft, helicopters, ground vehicles, and/or personnel on foot. Maintenance would be performed as needed. Maintenance activities would generally be smaller in scale and more localized than construction activities. Maintenance activities may cause temporary impacts within the ROW such as damage to crops. Access would be restricted during the performance of maintenance activities.

Nearby residents would experience long-term visual impacts from the vegetation removed from the ROW and the permanent (until decommissioning) presence of the transmission structures and lines. Impacts to visual resources are discussed in more detail in Section 3.18.

The permanent impacts by region are summarized in Table 3.10-22 for pole structures. No permanent impacts are described for access roads, because the location of access roads has not yet been determined.

Table 3.10-22:
Impacts During the Operational Phase of the Applicant Proposed Route, by Region

Region	Length (miles)	Estimated Footprint of Structures (acres) [1, 2]
1	116	16.2
2	106	14.8
3	162	22.7
4	126	17.6
5	113	15.8
6	54	7.6
7	43	6.0

1 The values in the table do not reflect the minor changes that would result from application of the minor route variations and adjustments.
2 For a conservative estimate of impacts, the anticipated footprint of structures assumes seven lattice structures per mile; each would have a 28-foot by 28-foot foundation (less than 0.02 acre).

3.10.6.2.3.3 Decommissioning Impacts

Potential impacts during decommissioning of the Project would be similar to those of the construction phase for all Project components. Once the decommissioning is complete, all land could return to the pre-construction land uses described in Section 3.10.4 and Section 3.10.5.

3.10.6.3 Impacts Associated with the DOE Alternatives

This section discusses land use impacts for the DOE Alternatives, which include the Arkansas Converter Station Alternative Siting Area and AC Interconnection Siting Area, the HVDC alternative routes and their associated access roads, multi-use construction yards and other temporary construction areas, and communications sites.

3.10.6.3.1 Arkansas Converter Station Siting Area and AC Interconnection Siting Area

3.10.6.3.1.1 Construction Impacts

The land cover in the Arkansas Converter Station Siting Area consists primarily of deciduous forest (32.8 percent), pasture/hay (26.7 percent), evergreen forest (21.9 percent), and mixed forest (10.0 percent). Although the exact location of the converter station has not yet been determined, construction of this converter station would convert 20 to 35 acres of undeveloped land to a utility land use. An additional 5 to 10 acres would be required for construction only. These areas would be used as laydown areas for equipment during construction. An additional 4.2 acres of undeveloped land would be converted to access roads (2.4 acres permanent, 1.8 acres temporary).

The Arkansas AC interconnect siting area is approximately 1,000 feet wide and the permanent ROW would be 150 to 200 feet wide and approximately 5 miles long with a total acreage of approximately 661.6 acres. During construction, approximately 477.7 acres of primarily pasture/hay land cover would be temporarily converted to an industrial use. Approximately 0.1 mile, or 2.2 percent of the route, would be parallel to existing roads. Table 3.10-23 lists the various types of land cover in the ROW, which is primarily composed of pasture/hay (477.7 aces, or 72.2 percent), evergreen forest (76.0 acres, or 11.5 percent), and deciduous forest (41.6 acres or 6.3 percent).

Table 3.10-23:
Land Cover in the Arkansas AC Interconnect ROW

Land Cover	Acres	%
Deciduous Forest	41.6	6.3
Developed, Low Intensity	3.8	0.6
Developed, Open Space	14.42.8	2.2
Evergreen Forest	76.0	11.5
Grassland/Herbaceous	2.0	0.3
Mixed Forest	0.4	0.0
Open Water	4.5	0.7
Pasture/Hay	477.7	72.2
Shrub/Scrub	15.2	2.3
Woody Wetlands	24.9	3.8
Total	661.6	100.0

Source: Jin et al. (2013)

A 25- to 35-acre site for a substation where the alternative AC transmission line would interconnect with an existing 500kV transmission line would be required, and an additional 5 acres would be temporarily required during the construction phase. This substation will be located near an existing transmission line in an area that is primarily grassland with some forest land.

During construction, within the 661.6-acre ROW, assembly areas for the pole structures (either lattice or tubular structures) would be required, as well as tensioning or pulling sites. An assembly area 150 feet wide by 150 feet long (0.5 acre) for each structure would be required. Assuming five to seven structures per mile would be required, the assembly areas would require up to 17.9 acres within the ROW. Also within the ROW, approximately six tensioning or pulling sites 150 feet wide by 600 feet long would be required (2.0 acres each, minus 1.6 acres outside the ROW, for a total of 10.4 acres). Three wire-splicing sites, each 100 feet by 100 feet (0.2 acres), would require a total of 0.6 acre.

Approximately 1.6 acres of the total 12 acres required for the six tensioning or pulling sites would be located outside the ROW. In total, approximately 120 acres would be required for the construction of the Arkansas converter station and AC interconnect.

Within the ROW, trees would need to be removed. Individual transmission structure sites would be cleared. Hand, mechanized, and chemical clearing may be used. Within or adjacent to the ROW for the transmission line, all trees would be removed. In the border zone adjacent to the ROW, some small trees may remain if they would not pose a risk of falling into the conductors.

3.10.6.3.1.2 Operations and Maintenance Impacts

After construction is complete, only the 20- to 35-acre converter station and 20-foot-wide paved access road would remain; all other temporary construction areas would be returned to their previous use, primarily rangeland. Approximately 35 acres would be fenced. The 25- to 35-acre substation where the alternative AC transmission line would interconnect with the existing 500kV transmission line, and an associated access road, would also remain as a utility use.

Within the 5-mile-long Arkansas AC Interconnect ROW, only the pole structures would remain. For lattice structures, the operational footprint would be 5 to 7 structures per mile for 5 miles, or 25 to 35 structures total, each 28 feet by 28 feet (less than 0.02 acre), up to 0.7 acre total. For tubular structures, the operational footprint would be 5 to 7 structures per mile, or 25 to 35 structures total, each 7 feet by 7 feet (less than 0.1 acre), and less than 0.1 acre total. All structures would be 75 to 180 feet tall. Access roads that are not needed for operations and maintenance of the Project would be restored, and all temporary construction areas could return to previous uses.

All other land in the ROW could return to previous land uses, except that only low-growing vegetation would be permitted in the ROW. Short trees (up to 25 feet in height at maturity) would be permitted adjacent to the ROW. As noted in Section 2.1.5.1, limitations on land uses would be described in individual landowner easement agreements, and could be modified in the easement based on site-specific conditions and/or coordination with landowners. Land uses that generally may not be permitted in the ROW include constructing buildings or structures, changing the grading and land contours such that the ground surface elevation within the ROW would change and alter the required electrical clearance, and installing fences or irrigation lines without coordination with the Applicant. Access would be restricted during the performance of maintenance activities.

Because the locations of access roads to the converter station are not known at this time, it is possible that the access roads could be located in such a way that small areas of agricultural land would be isolated and no longer practicable to be used for farmland or grazing.

3.10.6.3.1.3 Decommissioning Impacts

Potential impacts during decommissioning of the Project would be similar to those of the construction phase for all Project components. Once decommissioning has been completed, all land could return to the pre-construction land uses described in Section 3.10.4 and Section 3.10.5.

3.10.6.3.2 HVDC Alternative Routes

This section discusses the potential impacts within the 200-foot-wide representative ROWs of the HVDC alternative routes during the construction, operations and maintenance, and decommissioning phases of the Project.

3.10.6.3.2.1 Construction Impacts

Construction impacts would be similar to those discussed for the Applicant Proposed Route (Section 3.10.6.2.3.1). The ROW would be temporarily unavailable for existing uses during construction at a specific location.

Construction would begin with clearing and grading for access roads, pole structure sites and assembly areas, wire splicing sites, and tensioning or pulling sites. These areas would not be available for agricultural use during construction at a specific location. Within the ROW, trees would need to be removed. Individual transmission structure sites would be cleared Hand, mechanized, and chemical clearing may be used. For tensioning or pulling sites, clearing would be limited to the removal of larger woody vegetation or dense brush that may interfere with tensioning equipment; grading would also be limited to what is necessary to provide temporary access for tensioning equipment.

Within or adjacent to the ROW for the transmission line, all trees would be removed. In the border zone adjacent to the ROW, some small trees may remain if they would not pose a risk of falling into the conductors.

3.10.6.3.2.1.1 Region 1

Table 3.10-24 presents the land cover in the representative ROW for each of the four HVDC alternative routes in Region 1. Each route is discussed in more detail below.

Table 3.10-24:
Land Cover in the HVDC Alternative Routes—Region 1

Land Cover	AR 1-A		AR 1-B		AR 1-C		AR 1-D	
	Acres	%	Acres	%	Acres	%	Acres	%
Barren Land (Rock/Sand/Clay)	0.8	0.0	0.0	0.0	0.0	0.0	0.0	0.0
Cultivated Crops	288.9	9.6	122.5	9.7	146.8	11.5	113.2	13.8

Source: Jin et al. (2013)

3.10.6.3.2.1.1.1 *Alternative Route 1-A*

HVDC Alternative Route 1-A is approximately 123 miles long and corresponds to Applicant Proposed Route Links 2, 3, 4, and 5. Approximately 5 miles (4.1 percent) would be parallel to existing transmission lines, compared to 1.7 miles (1.4 percent) for the corresponding links of the Applicant Proposed Route. Approximately 9 miles (7.0 percent) would be parallel to existing roads, compared to 8 miles (7.0 percent) for the corresponding links of the Applicant Proposed Route. The land cover within the representative ROW is primarily grassland/herbaceous (approximately 2,265 acres or 75.4 percent). Approximately 168 acres (6 percent of the representative ROW) are school trust lands that would be temporarily unavailable for existing uses, primarily agriculture or oil/gas development. HVDC Alternative Route 1-A has more grasslands and school trust lands than the Applicant Proposed Route. Thirteen agricultural structures, four industrial structures, one commercial structure, one abandoned structure, and one other structure (use unknown) are present in the representative ROW, whereas in the corresponding links of the Applicant Proposed Route, one commercial structure and one agricultural structure are in the representative ROW.

Outside the ROW, tensioning or pulling areas totaling approximately 165 acres would be required during construction and would be temporarily unavailable for other uses. The predominant land cover in these areas is grassland/herbaceous. Approximately 11 acres of school trust lands would be temporarily unavailable for existing uses, primarily agriculture or oil/gas development. No structures are present in the tensioning or pulling areas for HVDC Alternative Route 1-A.

3.10.6.3.2.1.1.2 *Alternative Route 1-B*

HVDC Alternative Route 1-B is approximately 52 miles long and corresponds to Applicant Proposed Route Links 2 and 3. Approximately 0.1 mile, or 0.3 percent of the route, would be parallel to existing transmission lines, which is comparable to the corresponding links of Applicant Proposed Route. Approximately 2 miles, or 3.4 percent of the route, would be parallel to existing roads, which is less than half of that for the corresponding links of the Applicant Proposed Route. The land cover within the representative ROW is primarily grassland/herbaceous (approximately 887 acres or 69.9 percent), similar to Link 3. Approximately 52 acres (4 percent of the representative ROW) has school trust lands that would be temporarily unavailable for existing uses, primarily agriculture or oil/gas development. HVDC Alternative Route 1-B has more school trust lands than the corresponding links of the Applicant Proposed Route. One agricultural structure is present in the representative ROW, whereas no structures are present in the corresponding links of the Applicant Proposed Route (Links 2 and 3).

Outside the ROW, tensioning or pulling areas totaling approximately 46 acres would be required during construction and would be temporarily unavailable for other uses. The predominant land cover in these areas is grassland/herbaceous. No structures are present in the tensioning or pulling areas for HVDC Alternative Route 1-B.

3.10.6.3.2.1.1.3 *Alternative Route 1-C*

HVDC Alternative Route 1-C is approximately 52 miles long and corresponds to Applicant Proposed Route Links 2 and 3. Approximately 0.1 mile, or 0.2 percent of the route, would be parallel to existing transmission lines, which is less than the corresponding links of the Applicant Proposed Route. Approximately 2 miles (4.3 percent) would be parallel to existing roads, which is less than half of that for the corresponding links of the Applicant Proposed Route. The land cover within the representative ROW is primarily grassland/herbaceous (approximately 892 acres or 70.1 percent). Approximately 9 acres (less than 1 percent of the representative ROW) are school trust lands that would be temporarily unavailable for existing uses, primarily agriculture or oil/gas development. HVDC Alternative Route 1-C has more cultivated crops, developed, and open space and less school trust land than the corresponding links of the Applicant Proposed Route. Seven agricultural structures and two industrial structures are present in the representative ROW, whereas no structures are present in the corresponding links of the Applicant Proposed Route (Links 2 and 3).

Outside the ROW, tensioning or pulling areas totaling approximately 60 acres would be required during construction and would be temporarily unavailable for other uses. The predominant land cover is grassland/herbaceous. Approximately 3 acres of school trust lands would be temporarily unavailable for existing uses. No structures are present in the tensioning or pulling areas for HVDC Alternative Route 1-C.

3.10.6.3.2.1.1.4 *Alternative Route 1-D*

HVDC Alternative Route 1-D is approximately 34 miles long and corresponds to Applicant Proposed Route Links 3 and 4. Approximately 0.2 mile, or 0.5 percent of the route, would be parallel to existing transmission lines, compared to 1.4 miles for the corresponding links of the Applicant Proposed Route. The land cover within the ROW is primarily grassland/herbaceous (approximately 569acres or 69.4 percent). Approximately 54 acres (7 percent of the representative ROW) are school trust lands that would be temporarily unavailable for existing uses, primarily agriculture or oil/gas development. HVDC Alternative Route 1-D has comparable land cover but more school trust lands than the corresponding links of the Applicant Proposed Route. Five agricultural structures and one abandoned structure are present in the representative ROW, whereas one commercial structure and one agricultural structure are present in Link 4 of the Applicant Proposed Route.

Outside the ROW, tensioning or pulling areas totaling approximately 29 acres would be required during construction and would be temporarily unavailable for other uses. The predominant land cover is grassland/herbaceous. No structures are present in the tensioning or pulling areas for HVDC Alternative Route 1-D.

3.10.6.3.2.1.2 Region 2

Table 3.10-25 presents the land cover in the representative ROW for each of the two HVDC alternative routes in Region 2. Each alternative route is discussed in more detail below.

Table 3.10-25:
Land Cover in the HVDC Alternative Routes—Region 2

Land Cover	AR 2-A		AR 2-B	
	Acres	%	Acres	%
Barren Land (Rock/Sand/Clay)	0.5	0.0	0.1	0.0
Cultivated Crops	311.6	22.3	440.3	60.5
Deciduous Forest	55.4	4.0	14.6	2.0
Developed, Low Intensity	11.2	0.8	1.0	0.1
Developed, Medium Intensity	3.0	0.2	0.0	0.0
Developed, Open Space	69.5	5.0	22.6	3.1
Evergreen Forest	89.1	6.4	2.0	0.3
Grassland/Herbaceous	833.5	59.7	240.0	33.0
Open Water	5.6	0.4	7.0	1.0
Pasture/Hay	2.6	0.2	0.0	0.0
Shrub/Scrub	14.3	1.0	0.0	0.0
Total	1,396.3	100.0	727.7	100.0

Source: Jin et al. (2013)

3.10.6.3.2.1.2.1 Alternative Route 2-A

HVDC Alternative Route 2-A is approximately 57 miles long and corresponds to Applicant Proposed Route Link 2. Approximately 0.2 mile, or 0.4 percent of the route, would be parallel to existing transmission lines, compared to 0.9 mile for Link 2. Approximately 3 miles (4.9 percent) would be parallel to existing roads, compared to 2 miles for Link 2.The land cover within the representative ROW is primarily grassland/herbaceous (approximately 834 acres or 59.7 percent). Approximately 23 acres (2 percent of the representative ROW) are school trust lands that would be temporarily unavailable for existing uses, primarily agriculture and oil/gas development. HVDC Alternative Route 2-A has more grasslands but fewer cultivated crops and school trust lands than Link 2. Two industrial structures and three agricultural structures are present in the representative ROW, whereas one commercial structure and two industrial structures are present in the representative ROW for the Applicant Proposed Route Link 2.

Outside the ROW, tensioning or pulling areas totaling approximately 84 acres would be required during construction and would be temporarily unavailable for other uses. The predominant land cover is grassland/herbaceous followed by cultivated crops. Approximately 5 acres of school trust lands would be temporarily unavailable for other uses. No structures are present in the tensioning or pulling areas for Alternative Route 2-A.

3.10.6.3.2.1.2.2 Alternative Route 2-B

HVDC Alternative Route 2-B is approximately 30 miles long and corresponds to Applicant Proposed Route Link 3. Less than 0.1 mile, or 0.3 percent of the route, would be parallel to existing transmission lines, which is comparable to Link 3. Approximately 1.5 miles (4.9 percent) of the route would be parallel to existing roads, which is comparable to Link 3.The land cover within the representative ROW is primarily cultivated crops (approximately 440 acres or 60.5 percent). HVDC Alternative Route 2-B has more cultivated crops but less developed open space than Link 3. One commercial structure and two industrial structures are present in the representative ROW, whereas two agricultural structures and one commercial structure are present in the representative ROW for the Applicant Proposed Route Link 3.

Outside the ROW, tensioning or pulling areas totaling approximately 31 acres would be required during construction and would be temporarily unavailable for other uses. The predominant land cover is cultivated crops. No structures are present in the tensioning or pulling areas for HVDC Alternative Route 2-B.

3.10.6.3.2.1.3 Region 3

Table 3.10-26 presents the land cover in the representative ROW for each of the five HVDC alternative routes in Region 3. Each alternative route is discussed in more detail below.

Table 3.10-26:
Land Cover in the HVDC Alternative Routes—Region 3

Land Cover[1]	AR 3-A		AR 3-B		AR 3-C		AR 3-D		AR 3-E	
	Acres	%	Acres	%	Acres	%	Acres	%	Acres	%

Total	919.1	100.0	1,166.6	100.0	2,967.5	100.0	958.8	100.0	207.8	100.0

1 The values in the table do not reflect the minor changes that would result from application of the minor route variations and adjustments.
Source: Jin et al. (2013)

3.10.6.3.2.1.3.1 Alternative Route 3-A

HVDC Alternative Route 3-A is approximately 38 miles long and corresponds to Applicant Proposed Route Link 1. Approximately 0.3 mile, or 0.7 percent of the route, would be parallel to existing transmission lines, compared to 1.7 miles for Link 1. Approximately 2 miles (4.9 percent) of the route would be parallel to existing roads, compared to 3.1 miles for Link 1. The land cover within the representative ROW is primarily grassland/herbaceous (approximately 497 acres or 54.1 percent) and deciduous forest (188 acres or 20.4 percent) and is comparable to Link 1. Three types of state land are present: 22 acres of Lake Carl Blackwell, 13 acres of Oklahoma State University land being used as research area, and 20 acres of school trust lands (use unknown), compared to 48 acres of Oklahoma State University land, and 33 acres of school trust lands in Link 1. These state land areas would be temporarily unavailable for other uses during construction in these locations. One agricultural structure is present in the representative ROW, whereas one industrial structure and one agricultural structure are present in the representative ROW for the Applicant Proposed Route Link 1.

Outside the ROW, tensioning or pulling areas totaling approximately 40 acres would be required during construction and would be temporarily unavailable for other uses. The predominant land cover is grassland/herbaceous. Approximately 0.2 acre of Lake Carl Blackwell and 6 acres of school trust lands (use unknown) are in these areas and would be temporarily unavailable for existing uses. No structures are present in the tensioning or pulling areas for HVDC Alternative Route 3-A.

As described in Appendix M and summarized in Section 2.4.2.3, a route adjustment was developed for HVDC Alternative Route 3-A to maintain an end-to-end route with Applicant Proposed Route Link 1, Variation 2, and Links 1 and 2, Variation 1. The route adjustment is illustrated in Exhibit 1 of Appendix M. The route adjustment parallels more parcel boundaries and crosses less pasture/hay and agricultural land than the original HVDC Alternative 3-A. Land use impacts would generally be the same as for the original HVDC Alternative Route 3-A.

3.10.6.3.2.1.3.2 *Alternative Route 3-B*

HVDC Alternative Route 3-B is approximately 48 miles long and corresponds to Applicant Proposed Route Links 1, 2, and 3. Approximately 1.5 miles, or 3.1 percent of the route, would be parallel to existing transmission lines, which is comparable to the corresponding links of the Applicant Proposed Route. Approximately 2 miles (4.8 percent) would be parallel to existing roads, compared to 3.5 miles for Links 1, 2, and 3. The land cover within the representative ROW is primarily grassland/herbaceous (approximately 645 acres or 55.3 percent) and deciduous forest (219 acres or 18.8 percent) and is comparable to Links 1, 2, and 3. Three types of state land are present: 22 acres of Lake Carl Blackwell, 13 acres of Oklahoma State University land being used as research area, and 15 acres of school trust lands (use unknown), compared to 48 acres of Oklahoma State University land and 60 acres school trust lands in Links 1, 2, and 3. These areas would be temporarily unavailable for existing uses during construction in these locations. One commercial structure and two agricultural structures are present in the representative ROW, compared to one residence, one industrial structure, and two agricultural structures in the representative ROW for the Applicant Proposed Route Links 1, 2, and 3.

Outside the ROW, tensioning or pulling areas totaling approximately 85 acres would be required during construction and would be temporarily unavailable for other uses. The predominant land cover is grassland/herbaceous. Approximately 0.2 acre of Lake Carl Blackwell and 6 acres of school trust lands (use unknown) are in these areas and would be temporarily converted to a utility use. One residence and two industrial structures in the tensioning or pulling areas for HVDC Alternative Route 3-B that may be affected by short-term effects from construction such as noise and dust.

3.10.6.3.2.1.3.3 *Alternative Route 3-C*

HVDC Alternative Route 3-C is approximately 122 miles long and corresponds to Applicant Proposed Route Links 3, 4, 5, and 6. Approximately 1 mile, or 0.8 percent of the route, would be parallel to existing transmission lines, comparable to the corresponding links of the Applicant Proposed Route. Approximately 6 miles (4.5 percent) of the route would be parallel to existing roads, comparable to Links 3, 4, 5, and 6. The land cover within the representative ROW is primarily composed of grassland/herbaceous (approximately 1,061 acres or 35.8 percent), deciduous forest (869 acres or 29.3 percent), and pasture/hay (773 acres or 26.1 percent) and is comparable to Links 3, 4, 5, and 6. Approximately 26 acres of school trust lands and 1 acre of Webbers Falls Lock and Dam and Reservoir would be temporarily unavailable for existing uses during construction at these locations, compared to 53 acres of school trust lands and 4.3 acres of Webbers Falls Lock and Dam and Reservoir in Links 3, 4, 5, and 6. One residence, two industrial structures, one commercial structure, and seven agricultural structures are present in the representative ROW, whereas three agricultural structures, one residence, and one industrial structure are present in the representative ROW for Links 3, 4, 5, and 6.

Outside the ROW, tensioning or pulling areas totaling approximately 221 acres would be required during construction and would be temporarily unavailable for other uses. The land cover is a mix of grassland/herbaceous, deciduous forest, and pasture/hay. Three residences are present in the tensioning or pulling areas for Alternative Route 3-C that may be affected by short-term effects from construction such as noise, dust, and access restrictions.

3.10.6.3.2.1.3.4 *Alternative Route 3-D*

HVDC Alternative Route 3-D is approximately 39 miles long and corresponds to Applicant Proposed Route Links 5 and 6. Approximately 0.5 mile, or 1.2 percent of the route, would be parallel to existing transmission lines, comparable to Links 5 and 6. Approximately 2 miles (4.8 percent) of the route would be parallel to existing roads, comparable to Links 5 and 6. The land cover within the representative ROW is primarily pasture/hay (approximately 492 acres or 51.3 percent) and deciduous forest and grassland/herbaceous (189 acres or 19.7 percent each) and is comparable to Links 5 and 6. Approximately 1 acre of Webbers Falls Lock and Dam and Reservoir would be temporarily unavailable for existing uses during construction at this location, compared to 4.3 acres in Links 3, 4, 5, and 6. One residence and four agricultural structures are present in the representative ROW, whereas one residence and one agricultural structure are present in the representative ROW for the Applicant Proposed Route Links 5 and 6.

Outside the ROW, tensioning or pulling areas totaling approximately 82 acres would be required during construction and would be temporarily unavailable for other uses. The predominant land cover is pasture/hay, followed by deciduous forest. No structures are present in the tensioning or pulling areas for HVDC Alternative Route 3-D.

3.10.6.3.2.1.3.5 *Alternative Route 3-E*

HVDC Alternative Route 3-E is approximately 9 miles long and corresponds to Applicant Proposed Route Link 6. Approximately 0.2 mile, or 2.4 percent of the route, would be parallel to existing transmission lines, comparable to Link 6. Approximately 0.6 mile (7.1 percent) of the route would be parallel to existing roads, comparable to Link 6. The land cover within the representative ROW is primarily pasture/hay (approximately 98 acres or 47.3 percent) and deciduous forest (74 acres or 35.7 percent), whereas Link 6 has a higher percentage of deciduous forest and grasslands. Approximately 1 acre of Webbers Falls Lock and Dam and Reservoir would be temporarily unavailable for existing uses during construction at this location, compared to 4.3 acres in Links 3, 4, 5, and 6. One residence is present in the representative ROW, whereas one agricultural structure is present in the representative ROW for the Applicant Proposed Route Link 6.

Outside the ROW, tensioning or pulling areas totaling approximately 2 acres would be required during construction and would be temporarily unavailable for other uses. The predominant land cover is pasture/hay. No structures are present in the tensioning or pulling areas for HVDC Alternative Route 3-E.

3.10.6.3.2.1.4 Region 4

Table 3.10-27 presents the land cover in the representative ROW for each of the four HVDC alternative routes in Region 4. Each alternative route is discussed in more detail below.

Table 3.10-27:
Land Cover in the HVDC Alternative Routes—Region 4

Land Cover	AR 4-A		AR 4-B		AR 4-C		AR 4-D		AR 4-E	
	Acres	%	Acres	%	Acres	%	Acres	%	Acres	%
Barren Land (Rock/Sand/Clay)	0.0	0.0	1.5	0.1	0.0	0.0	0.0	0.0	0.8	0.1
Cultivated Crops	1.5	0.1	1.5	0.1	0.0	0.0	1.5	0.2	4.1	0.5

Source: Jin et al. (2013)

3.10.6.3.2.1.4.1 Alternative Route 4-A

HVDC Alternative Route 4-A is approximately 58 miles long and corresponds to Applicant Proposed Route Links 3, 4, 5, and 6. Approximately 0.2 mile, or 0.3 percent of the route, would be parallel to existing transmission lines, compared to 0.9 mile for the corresponding links of the Applicant Proposed Route. Approximately 2.5 miles (4.4 percent) of the route would be parallel to existing roads, comparable to Links 3, 4, 5, and 6. The land cover within the representative ROW is primarily deciduous forest (approximately 624 acres or 43.8 percent) and pasture/hay (497 acres 34.9 percent), comparable to Links 3, 4, 5, and 6. Flood control dams constructed by NRCS are adjacent to this route as well as Link 3. Two residences and nine agricultural structures are present in the representative ROW, whereas one residence and one agricultural structure are present in the representative ROW for the Applicant Proposed Route Link 6.

Outside the ROW, tensioning or pulling areas totaling approximately 189 acres would be required during construction and would be temporarily unavailable for other uses. The predominant land covers are pasture/hay and deciduous forest. No structures are present in these areas.

3.10.6.3.2.1.4.2 *Alternative Route 4-B*

HVDC Alternative Route 4-B is approximately 79 miles long and corresponds to Applicant Proposed Route Links 2–8. Less than 0.1 mile, or 0.1 percent of the route, would be parallel to existing transmission lines, compared to 1.2 miles for Links 2–8. Approximately 4 miles (5.5 percent) of the route would parallel existing roads, which is comparable to Links 2–8. The land cover within the representative ROW is primarily deciduous forest (approximately 873 acres or 45.5 percent) and pasture/hay (460 acres or 23.9 percent) and is generally comparable to Links 2–8.

Approximately 387 acres of the Ozark National Forest is within the representative ROW; 230 acres are federally owned and 157 acres are private land within the Ozark National Forest boundary (use unknown). This area also crosses the Ozark National Forest WMA, which shares a boundary with the National Forest. The AGFC regulates hunting in the WMA. Hunting could be temporarily disturbed in and near the ROW during construction (see Section 3.12 for further discussion of impacts to recreation). Whereas most areas within the ROW would only be temporarily unavailable for existing uses, any forested lands in the ROW would not be allowed to return to the existing use after construction is complete because timber would not be a permitted use within the ROW. The Applicant Proposed Route crosses approximately 2.5 acres of the USFS-managed Ozark National Forest and approximately 6 acres of state land (two WMAs) is present in Link 6. Six residences, 1 industrial structure, and 10 agricultural structures are present in the representative ROW, whereas 4 agricultural structures and 1 residence are present in the representative ROW for the Applicant Proposed Route Links 2–8.

The representative ROW crosses the southern boundary of the Ozark National Forest, where federal land and privately held land is a patchwork. The USFS has expressed several concerns regarding this alternative. According to the USFS, the ROW would create linear breaks in National Forest land and could adversely affect timber production. The USFS has also stated that, in places, HVDC Route Alternative 4-B would undermine the use for which the National Forest land was originally acquired, that is conservation of natural resources.

Outside the ROW, tensioning or pulling areas totaling approximately 199 acres would be required during construction and would be temporarily unavailable for other uses. The predominant land covers are deciduous forest and pasture/hay. Approximately 10 acres of federal land and 30 acres of private land in the Ozark National Forest boundary are within these areas and would be temporarily unavailable for existing uses during construction in these locations. No structures are present in the tensioning or pulling areas for HVDC Alternative Route 4-B.

3.10.6.3.2.1.4.3 *Alternative Route 4-C*

HVDC Alternative Route 4-C is approximately 3 miles long and corresponds to Applicant Proposed Route Link 5. If this route is selected, 82.6 acres would be removed from existing uses. None of the route is parallel to existing transmission lines, and Link 5 is parallel to less than 0.1 mile of existing transmission line. Approximately 0.2 mile (6.4 percent) of the route is parallel to existing roads, compared to 0.1 mile for Link 5. Approximately 0.4 mile, or 11 percent of the route, would be parallel to existing infrastructure (within 50 feet) (transmission lines, pipelines, or roads), slightly more than Link 5.The land cover within the ROW is primarily deciduous forest (approximately 32.4 acres or 39.2 percent) and pasture/hay (19.0 acres or 23.0 percent) and is generally comparable to Link 5. One residence is present in the ROW, whereas no structures are present in the representative ROW for the Applicant Proposed Route Link 5.

Outside the ROW, tensioning or pulling areas totaling approximately 25.7 acres would be required during construction and would be temporarily unavailable for other uses. The predominant land covers are deciduous and evergreen forest. No structures are present in the tensioning or pulling areas for HVDC Alternative Route 4-C.

3.10.6.3.2.1.4.4 Alternative Route 4-D

HVDC Alternative Route 4-D is approximately 25 miles long and corresponds to Applicant Proposed Route Links 4, 5, and 6. Less than 0.1 mile, or 0.3 percent of the route, would be parallel to existing transmission lines, compared to 0.3 mile in the corresponding links of the Applicant Proposed Route. Approximately 1.4 miles (5.6 percent) of the route would parallel existing roads, compared to 2.1 miles for Links 4, 5, and 6. The land cover within the representative ROW is primarily pasture/hay (approximately 300 acres or 48.6 percent) and deciduous forest (180 acres or 29.1 percent), which is comparable to Links 4, 5, and 6. HVDC Alternative Route 4-D does not cross any federal or state land, whereas Link 6 crosses approximately 6 acres of state WMAs. One church, one residence, and seven agricultural structures are present in the representative ROW, whereas one residence and one agricultural structure are present in the representative ROW for the Applicant Proposed Route Link 6.

Outside the ROW, tensioning or pulling areas totaling approximately 122 acres would be required during construction and would be temporarily unavailable for other uses. The predominant land covers are pasture/hay and deciduous forest. No structures are present in the tensioning or pulling areas for HVDC Alternative Route 4-D.

3.10.6.3.2.1.4.5 Alternative Route 4-E

HVDC Alternative Route 4-E is approximately 37 miles long and corresponds to Applicant Proposed Route Links 8 and 9. Approximately 0.6, or 1.5 percent of the route, would be parallel to existing transmission lines, compared to 0.1 for Links 8 and 9. Approximately 3.7 miles (10.1 percent) of the route would parallel existing roads, compared to 2.5 miles for Links 8 and 9. The land cover within the representative ROW is primarily pasture/hay (approximately 396 acres or 44.1 percent) and evergreen forest (218.7 acres or 24.4 percent), comparable to Links 8 and 9. Two residences, one industrial structure, two agricultural structures, and two other structures (use unknown) are present in the representative ROW, whereas two agricultural structures are present in the representative ROW for the Applicant Proposed Route Link 9.

Outside the ROW, tensioning or pulling areas totaling approximately 147 acres would be required during construction and would be temporarily unavailable for other uses. The predominant land cover is pasture/hay. No structures are present in the tensioning or pulling areas for HVDC Alternative Route 4-E.

3.10.6.3.2.1.5 Region 5

Table 3.10-28 presents the land cover in the representative ROW for each of the six HVDC alternative routes in Region 5. Each alternative route is discussed in more detail below.

Table 3.10-28:
Land Cover in the HVDC Alternative Routes—Region 5

Land Cover[1]	AR 5-A		AR 5-B		AR 5-C		AR 5-D		AR 5-E		AR 5-F	
	Acres	%	Acres	%	Acres	%	Acres	%	Acres	%	Acres	%

1 The values in the table do not reflect the minor changes that would result from application of the minor route variations and adjustments.
Source: Jin et al. (2013)

3.10.6.3.2.1.5.1 *Alternative Route 5-A*

HVDC Alternative Route 5-A is approximately 13 miles long and corresponds to Applicant Proposed Route Link 1. The route would not be parallel to any transmission lines, and neither would Link 1. Approximately 0.9 mile (6.9 percent) of the route would be parallel to existing roads, compared to 0.7 mile for Link 1. The land cover within the representative ROW is primarily composed evergreen forest (130.4 acres or 42.3 percent) and deciduous forest (78.8 acres or 25.5 percent), comparable to Link 1. No structures are present in the representative ROW of HVDC Alternative Route 5-A, as is the case for the Applicant Proposed Route Link 1.

Outside the ROW, tensioning or pulling areas totaling approximately 65 acres would be required during construction and would be temporarily unavailable for other uses. The predominant land covers are deciduous and evergreen forests. No structures are present in the tensioning or pulling areas for HVDC Alternative Route 5-A.

3.10.6.3.2.1.5.2 *Alternative Route 5-B*

HVDC Alternative Route 5-B is approximately 71 miles long and corresponds to Applicant Proposed Route Links 3, 4, 5, and 6. Approximately 0.2 mile (0.3 percent) of the route would be parallel to existing transmission lines, compared to 0.3 mile for the corresponding links of the Applicant Proposed Route. Approximately 3.3 miles (4.7 percent) of the route would be parallel to existing roads, compared to 3.7 miles for the corresponding links of the Applicant Proposed

Route. The land cover within the representative ROW is primarily pasture/hay (740.3 acres or 42.7 percent) and deciduous forest (479.5 acres or 27.7 percent), compared to Links 3, 4, 5 and 6. Three residences, two industrial structures, and one agricultural structure are present in the representative ROW, whereas two abandoned structures and one other structure (use unknown) are present in the representative ROW for the Applicant Proposed Route Links 4, 5, and 6.

Outside the ROW, tensioning or pulling areas totaling approximately 221 acres would be required during construction and would be temporarily unavailable to other uses. The predominant land cover is pasture/hay. No structures are present in the tensioning or pulling areas for HVDC Alternative Route 5-B.

As described in Appendix M and summarized in Section 2.4.2.5, a route adjustment was developed for HVDC Alternative Route 5-B to maintain an end-to-end route with Applicant Proposed Route Links 2 and 3, Variation 1. The route adjustment is illustrated in Exhibit 1 of Appendix M. The route adjustment crosses approximately 4 acres more agricultural land and approximately 7 acres less forest land than the original HVDC Alternative Route 5-B. Land use impacts would generally be the same as for the original HVDC Alternative Route 5-B.

3.10.6.3.2.1.5.3 *Alternative Route 5-C*

HVDC Alternative Route 5-C is approximately 9 miles long and corresponds to Applicant Proposed Route Links 6 and 7. Less than 0.1 mile, or 0.9 percent of the route, would be parallel to existing transmission lines, compared to 0.1 for Links 6 and 7. Approximately 0.4 mile (4.6 percent) would be parallel to existing roads, compared to 0.5 mile for Links 6 and 7. The land cover within the representative ROW is primarily deciduous forest (99.9 acres or 44.5 percent) and pasture/hay (70.9 acres or 31.6 percent), comparable to Link 7; the representative ROW for Link 6 has more mixed forest. One residence, one commercial structure, and one agricultural structure are present in the representative ROW, whereas one other structure (use unknown) is present in the representative ROW for the Applicant Proposed Route Link 6.

Outside the ROW, tensioning or pulling areas totaling approximately 54 acres would be required during construction and would be temporarily unavailable for other uses. The predominant land covers are pasture/hay and deciduous forest. No structures are present in the tensioning or pulling areas for HVDC Alternative Route 5-C.

3.10.6.3.2.1.5.4 *Alternative Route 5-D*

HVDC Alternative Route 5-D is approximately 22 miles long and corresponds to Applicant Proposed Route Link 9. Less than 0.1 mile (0.2 percent) would be parallel to existing transmission lines, comparable to Link 9. Approximately 1.6 miles (7.3 percent) would be parallel to existing roads, compared to 1.9 miles for Link 9. The land cover within the representative ROW is primarily deciduous forest (246.5 acres or 46.5 percent) and cultivated crops (92.0 acres or 17.4 percent) compared to the representative ROW for Link 9, which has more cultivated crops. No structures are present in the representative ROW, as is the case in the Applicant Proposed Route Link 9.

Outside the ROW, tensioning or pulling areas totaling 89.3 acres would be required during construction and would be temporarily unavailable for other uses. The predominant land cover is deciduous forest. No existing structures are present in the tensioning or pulling areas for Alternative Route 5-D.

3.10.6.3.2.1.5.5 Alternative Route 5-E

HVDC Alternative Route 5-E is approximately 36 miles long and corresponds to Applicant Proposed Route Links 4, 5, and 6. Approximately 0.2 mile (0.5 percent) of the route would be parallel to existing transmission lines, comparable to the corresponding links of the Applicant Proposed Route. Approximately 1.6 miles (4.4 percent) of the route would be parallel to existing roads, comparable to Links 4, 5, and 6. The land cover within the representative ROW is primarily pasture/hay (383.5 acres or 43.3 percent) and deciduous forest (383.5 acres or 43.3 percent), comparable to the representative ROW for Links 4, 5, and 6. Three residences, one industrial structure, and one agricultural structure are in the representative ROW, whereas two abandoned structures and one other structure (use unknown) are present in the representative ROW for the Applicant Proposed Route Links 4, 5, and 6.

Outside the ROW, tensioning or pulling areas totaling 88.4 acres would be required during construction and would be temporarily unavailable for other uses. The predominant land cover is pasture/hay. No structures are present in the tensioning or pulling areas for HVDC Alternative Route 5-E.

As described in Appendix M and summarized in Section 2.4.2.5, a route variation was developed for HVDC Alternative Route 5-E in response to public comments on the Draft EIS to maintain an end-to-end route with Applicant Proposed Route Links 3 and 4, Variation 2. The route adjustment is illustrated in Exhibit 1 of Appendix M. The route adjustment crosses approximately 3 more acres forest land than the original HVDC Alternative Route 5-E, and land use impacts would generally be the same for both.

3.10.6.3.2.1.5.6 Alternative Route 5-F

HVDC Alternative Route 5-F is approximately 22 miles long and corresponds to Applicant Proposed Route Links 5 and 6. Approximately 0.1 mile (0.6 percent) of the route would be parallel to existing transmission lines, compared to 0.2 mile for Links 5 and 6. Approximately 1.2 miles (5.4 percent) of the route would be parallel to existing roads, compared to 1.1 miles for Links 5 and 6. The land cover within the representative ROW is primarily pasture/hay (209.9 acres or 38.6 percent) and deciduous forest (153.2 acres or 28.1 percent), comparable to Links 5 and 6. Two residences are present in the representative ROW, whereas one abandoned structure is present in the representative ROW for the Applicant Proposed Route Link 5 and one other structure (use unknown) is present in the representative ROW for the Applicant Proposed Route Link 6.

Outside the ROW, tensioning or pulling areas totaling 52.1 acres would be required during construction and would be temporarily unavailable for other uses. The predominant land cover is pasture/hay. No structures are present in the tensioning or pulling areas for Alternative Route 5-F.

3.10.6.3.2.1.6 Region 6

Table 3.10-29 presents the land cover in the representative ROW for each of the four HVDC alternative routes in Region 6. The land cover for all the routes is primarily cultivated crops. Each alternative route is discussed in more detail below.

Table 3.10-29:
Land Cover in the HVDC Alternative Routes—Region 6

Land Cover[1]	AR 6-A		AR 6-B		AR 6-C		AR 6-D	
	Acres	%	Acres	%	Acres	%	Acres	%

Total	395.7	100.0	343.7	100.0	565.6	100.0	223.6	100.0

1 The values in the table do not reflect the minor changes that would result from application of the minor route variations and adjustments.
Source: Jin et al. (2013)

3.10.6.3.2.1.6.1 *Alternative Route 6-A*

HVDC Alternative Route 6-A is approximately 16 miles long and corresponds to Applicant Proposed Route Links 2, 3, and 4. None of the route would be parallel to existing transmission lines, compared to 0.1 mile in Links 2, 3, and 4. Approximately 1.6 miles (10.0 percent) of the route would be parallel to existing roads, compared to 1.4 miles for the corresponding links of the Applicant Proposed Route. The land cover within the representative ROW is primarily composed of cultivated crops (328.6 acres or 83.0 percent), comparable to the corresponding links of the Applicant Proposed Route. One residence is present in the representative ROW, whereas one agricultural structure is present in the representative ROW for the Applicant Proposed Route Link 4.

Outside the ROW, tensioning or pulling areas totaling 62.5 acres would be required during construction and would be temporarily unavailable for other uses. The predominant land cover is cultivated crops. No structures are present in the tensioning or pulling areas for Alternative Route 6-A.

As described in Appendix M and summarized in Section 2.4.2.6, a route adjustment was developed for HVDC Alternative Route 6-A to maintain an end-to-end route with Applicant Proposed Route Link 2, Variation 1. The route adjustment is illustrated in Exhibit 1 of Appendix M. The route adjustment reduces the acreage of the route by approximately 4 acres of land, and contains approximately 12 fewer acres of agricultural land than the original HVDC Alternative Route 6-A, and the land use impacts would generally be the same for both.

3.10.6.3.2.1.6.2 *Alternative Route 6-B*

HVDC Alternative Route 6-B is approximately 14 miles long and corresponds to Applicant Proposed Route Link 3. Approximately 0.1 mile (0.9 percent) of the route would be parallel to existing transmission lines, whereas there are no existing transmission lines parallel to the Applicant Proposed Route Link 3. Approximately 1.8 miles (12.4 percent) would be parallel to existing roads, compared to 0.9 mile for Link 3. The land cover within the representative ROW is primarily cultivated crops (272.1 acres or 79.2 percent) and woody wetlands (44.6 acres or 13 percent) compared to 80.7 percent cultivated crops and 3.9 percent woody wetlands in Link 3. One residence is present in the representative ROW, whereas no structures are present in the representative ROW for the Applicant Proposed Route Link 3.

Outside the ROW, tensioning or pulling areas totaling 32.3 acres would be required during construction and would be temporarily unavailable for other uses. The predominant land cover is cultivated crops. No structures are present in the tensioning or pulling areas for Alternative Route 6-B.

3.10.6.3.2.1.6.3 *Alternative Route 6-C*

HVDC Alternative Route 6-C is approximately 23 miles long and corresponds to Applicant Proposed Route Links 6 and 7. Approximately 0.1 mile (0.5 percent) of the route would be parallel to existing transmission lines, comparable to Links 6 and 7. Approximately 2.5 miles (10.7 percent) of the route would be parallel to existing roads, compared to 4.3 miles for Links 6 and 7. The land cover within the representative ROW is primarily cultivated crops (410.6 acres or 72.6 percent), comparable to the Applicant Proposed Route Links 6 and 7, although Link 6 has more deciduous forest and woody wetlands. HVDC Alternative Route 6-C does not cross any federal or state land, compared to the Applicant Proposed Route Link 7 which crosses approximately 0.5 acre of the Singer Forest Natural Area. One agricultural structure is present in the representative ROW, whereas four agricultural structures in the representative ROW for the Applicant Proposed Route Link 6.

Outside the ROW, tensioning or pulling areas totaling 50.7 acres would be required during construction and would be temporarily unavailable for other uses. The predominant land cover is cultivated crops. No structures are present in the tensioning or pulling areas for Alternative Route 6-C.

3.10.6.3.2.1.6.4 *Alternative Route 6-D*

HVDC Alternative Route 6-D is approximately 9 miles long and corresponds to Applicant Proposed Route Link 7. The route would not be parallel to any existing transmission lines, like Link 7. Approximately 0.2 mile (2.5 percent) of the route would be parallel to existing roads, compared to 0.7 mile in the Applicant Proposed Route Link 7. The land cover within the representative ROW is primarily cultivated crops (205.3 acres or 91.8 percent) similar to Link 7. HVDC Alternative Route 6-D does not cross any federal or state land, whereas the Applicant Proposed Route Link 7 crosses approximately 0.5 acre of the Singer Forest Natural Area. No structures are present in the representative ROW, as is the case with the representative ROW for the Applicant Proposed Route Link 7.

Outside the ROW, tensioning or pulling areas totaling 17.8 acres would be required during construction and would be temporarily unavailable for other uses. The predominant land cover is cultivated crops. No structures are present in the tensioning or pulling areas for Alternative Route 6-D.

3.10.6.3.2.1.7 Region 7

Table 3.10-30 presents the land cover in the representative ROW for each of the four HVDC alternative routes in Region 7. Each alternative route is discussed in more detail below.

Table 3.10-30:
Land Cover in the HVDC Alternative Routes—Region 7

Land Cover	AR 7-A		AR 7-B		AR 7-C		AR 7-D	
	Acres	%	Acres	%	Acres	%	Acres	%
Barren Land (Rock/Sand/Clay)	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0
Cultivated Crops	827.8	78.7	86.4	41.2	350.6	53.5	76.8	48.1
Deciduous Forest	0.5	0.0	42.7	20.3	58.4	10.1	15.1	9.4
Developed, Low Intensity	5.7	0.5	0.6	0.3	6.2	1.1	1.4	0.9
Developed, Medium Intensity	0.1	0.0	0.0	0.0	0.9	0.1	0.0	0.0

Total	1,052.0	100.0	209.9	100	578.6	100	159.5	100

Source: Jin et al. (2013)

3.10.6.3.2.1.7.1 *Alternative Route 7-A*

HVDC Alternative Route 7-A is approximately 43 miles long and corresponds to Applicant Proposed Route Link 1. Approximately 0.2 mile (0.4 percent) of the route would be parallel to existing transmission lines, comparable to the Applicant Proposed Route Link 1. Approximately 3.7 miles (8.5 percent) of the route would be parallel to existing roads, compared to 2.7 miles for Link 1. The land cover within the representative ROW is primarily cultivated crops (827.8 acres or 78.7 percent) and woody wetlands (110.5 acres or 10.5 percent), similar to the Applicant Proposed Route Link 1, although the latter has slightly less woody wetlands and more developed open space. No structures are present in the representative ROW, whereas one “other” structure (use not known) is present in the representative ROW for the Applicant Proposed Route Link 1.

Outside the ROW, tensioning or pulling areas totaling 166 acres would be required during construction and would be temporarily unavailable for other uses. The predominant land cover is cultivated crops. No structures are present in the tensioning or pulling areas for HVDC Alternative Route 7-A.

3.10.6.3.2.1.7.2 *Alternative Route 7-B*

HVDC Alternative Route 7-B is approximately 9 miles long and corresponds to Applicant Proposed Route Links 3 and 4. The route would not be parallel to any existing transmission lines, comparable to the Applicant Proposed Route Links 3 and 4. Approximately 1.4 miles (16.0 percent) of the route would be parallel to existing roads, compared to 0.3 mile in the Applicant Proposed Route Links 3 and 4. The land cover within the representative ROW is primarily cultivated crops (86.4 acres or 41.2 percent), deciduous forest (42.7 acres or 20.3 percent), pasture/hay (34.0 acres or 16.2 percent), and shrub/scrub (32.7 acres or 15.6 percent), similar to the Applicant Proposed Route Links 3 and 4, although Link 4 has no deciduous forest. One agricultural structure is present in the representative ROW, whereas no structures are present in the representative ROW for the Applicant Proposed Route Links 3 and 4.

Outside the ROW, tensioning or pulling areas totaling 54 acres would be required during construction and would be temporarily unavailable for other uses. The predominant land cover is cultivated crops. No structures are present in the tensioning or pulling areas for HVDC Alternative Route 7-B.

3.10.6.3.2.1.7.3 *Alternative Route 7-C*

HVDC Alternative Route 7-C is approximately 24 miles long and corresponds to Applicant Proposed Route Links 3, 4, and 5. Approximately 0.7 miles (3.0 percent) of the route would be parallel to existing transmission lines, compared to less than 0.1 mile in the corresponding links of the Applicant Proposed Route. Two miles (8.4 percent) of the route would be parallel to existing roads, compared to 0.7 mile for Links 3, 4, and 5. The land cover within the representative ROW is primarily cultivated crops (350.6 acres or 60.6 percent), pasture/hay (72.2 acres or 12.5 percent), and deciduous forest (58.4 acres or 10.1 percent), whereas the Applicant Proposed Route Links 3, 4, and 5 have more deciduous forest and shrub/scrub. One agricultural structure is present in the representative ROW, whereas two agricultural structures are present in the representative ROW for the Applicant Proposed Route Link 5.

Outside the ROW, tensioning or pulling areas totaling approximately 112 acres would be required during construction and would be temporarily unavailable for other uses. The predominant land cover is cultivated crops. No structures are present in the tensioning or pulling areas for HVDC Alternative Route 7-C.

3.10.6.3.2.1.7.4 *Alternative Route 7-D*

HVDC Alternative Route 7-D is approximately 7 miles long and corresponds to Applicant Proposed Route Links 4 and 5. Approximately 0.1 mile (0.8 percent) of the route would be parallel to existing transmission lines, compared to less than 0.1 mile in the Applicant Proposed Route Links 4 and 5. Approximately 0.3 mile (4.7 percent) of the route would be parallel to existing roads, compared to 0.4 mile for the Applicant Proposed Route Links 4 and 5. The land cover within the representative ROW is primarily cultivated crops (76.8 acres or 48.1 percent), pasture/hay (32.2 acres or 20.2 percent), and shrub/scrub (20.6 acres or 12.9 percent) and is generally comparable to the Applicant Proposed Route Links 4 and 5. No structures are present in the representative ROW, whereas two agricultural structures are present in the representative ROW for the Applicant Proposed Route Link 5.

Outside the ROW, tensioning or pulling areas totaling approximately 30 acres would be required during construction and would be temporarily unavailable for other uses. The predominant land cover is cultivated crops. No structures exist in the tensioning or pulling areas for HVDC Alternative Route 7-D.

3.10.6.3.2.2 Operations and Maintenance Impacts

Impacts from operations and maintenance of the HVDC alternative routes would be similar to those from the Applicant Proposed Route (see Section 3.10.6.2.3).The long-term impacts by region are summarized in Table 3.10-31 for pole structures. No long-term impacts are described for access roads, because the location of access roads has not yet been determined.

Because the locations of access roads to the HVDC alternative routes are not known at this time, it is possible that the access roads could be located in such a way that small areas of agricultural land would be isolated and no longer practicable to be used for farmland or grazing.

Table 3.10-31:
Impacts During the Operational Phase of the Alternative Routes

Region[1]	Length (miles)	Estimated Footprint of Structures (acres)[2]
Region 1		
1-A	123	17.2
1-B	52	7.3
1-C	52	7.3
1-D	34	4.8
Region 2		
2-A	57	8.0
2-B	30	4.2
Region 3		
3-A	38	5.3
3-B	48	10.9
3-C	122	17.0
3-D	39	5.5
3-E	8.5	1.2
Region 4		
4-A	58	8.1
4-B	79	11.1
4-C	3	0.4
4-D	25	3.5
4-E	37	5.2
Region 5		
5-A	13	1.8
5-B	71	9.9
5-C	9	1.3
5-D	22	3.1
5-E	36	5.0
5-F	22	3.1
Region 6		
6-A	16	2.2
6-B	14	2.0
6-C	23	3.2
6-D	9	1.3
Region 7		
7-A	43	6.0
7-B	9	1.3
7-C	24	3.4
7-D	6.5	0.9

1 The values in the table do not reflect the minor changes that would result from application of the minor route variations and adjustments.

2 For a conservative estimate of impacts, the anticipated footprint of structures assumes seven lattice structures per mile; each would have a 28-foot by 28-foot foundation (less than 0.02 acre).

Although the majority of the land in the ROW could return to most previous uses, forested areas such as the ROW within the Lee Creek Variation in Region 4 of the Application Proposed Route or HVDC Alternative Route 4-B, which includes the Ozark National Forest, would not be permitted to return to timber production because trees could interfere with the reliability and safety of the HVDC facilities.

Short trees (up to 25 feet in height at maturity) would be permitted adjacent to the ROW. As noted in Section 2.1.5.1, limitations on land uses would be described in individual landowner easement agreements, and could be modified in the easement based on site-specific conditions and/or coordination with landowners. Land uses that generally may not be permitted in the ROW include constructing buildings or structures, changing the grading and land contours such that the ground surface elevation within the ROW would change and alter the required electrical clearance, and installing fences or irrigation lines without coordination with the Applicant.

3.10.6.3.2.3 Decommissioning Impacts

Potential impacts during decommissioning of the Project would be similar to those of the construction phase for all Project components. Once the decommissioning is complete, all land could return to the pre-construction land uses described in Section 3.10.4 and Section 3.10.5.

3.10.6.4 Best Management Practices

In addition to the EPMs described in Section 3.10.6.1 and Section 3.10.6.7, the following BMPs have been identified to avoid or minimize potential land use impacts:

- In existing forested areas where temporary construction areas require tree clearing, replant with appropriate tree species and/or reclaim temporary construction areas, in coordination with landowners.
- In addition to EPM LU-5, make reasonable efforts to avoid displacing structures on private property.

3.10.6.5 Unavoidable Adverse Impacts

Unavoidable adverse impacts to land uses from the Project include the removal of vegetation and conversion of primarily rangeland and cultivated crops and some forested lands and developed open space to a utility use. The Applicant Proposed Route would result in the conversion of up to approximately 2,598 acres of land to utility use for the life of the Project, including 2,345 acres for access roads, 120 acres for two converter stations, 129 acres for all pole structures, and 4 acres for fiber regeneration sites.

Under the Applicant Proposed Route, 33 structures are present in the representative ROW: 4 residences, 3 commercial structures, 19 agricultural structures, 3 industrial structures, 2 abandoned structures, and 2 other structures (use unknown). These structures may have to be removed if the Project features could not avoid them, although the Applicant will continue to work with affected landowners to minimize the impact of siting the ROW on their property, including micrositing to avoid residences and other structures. Yields from cultivated crops, pasture/hay, and timberlands would be temporarily affected in the construction areas, and uses that are incompatible with the operation of the transmission line, such as tall trees for timber, would be removed from the ROW for the life of the Project. The height of orchard trees within the ROW could be restricted for the life of the Project.

Because the locations of Project access roads are not known at this time, it is possible that the access roads could be located in such a way that small areas of agricultural land would be isolated and no longer practicable to be used for farmland or grazing, resulting in a conversion of additional land from agricultural to non-agricultural use.

If DOE opts to participate in the Project and the Project included the Arkansas converter station, an additional 73 acres would be committed to utility use, including 35 acres for the converter station, 35 acres for the new substation, 2.4 acres for access roads, and 0.7 acre for 5-mile AC interconnect structures.

3.10.6.6 Irreversible and Irretrievable Commitment of Resources

The use of the approximately 2,598 acres for the life of the Project would be irreversible since these areas would be converted to a utility use as transmission structures, access roads, converter stations, or fiber regeneration sites. In addition, some land use restrictions may result within the ROW depending on the limitations determined for each individual landowner's lease agreement. As discussed above, it is possible that some small areas may no longer be practicable for agricultural use depending on the location of Project access roads. Once the Project has been decommissioned, all land could return to previous uses; therefore, there would be no irretrievable commitment of land use resources.

3.10.6.7 Relationship between Local Short-term Uses and Long-term Productivity

Local short-term use effects from the Project would result from the removal of vegetation and conversion of primarily agricultural and undeveloped land to a utility use. Other short-term and local impacts include the disruption to access to local land uses that may occur, such as agriculture, oil and gas development, and residences and businesses during construction.

The short-term impacts would be minimized, however, because of multiple EPMs incorporated into the Project (Appendix F).

EPMs that should ensure long-term productivity of during operations and maintenance of the Project include:

- Clean Line will avoid or minimize adverse effects to surface and subsurface irrigation and drainage systems (e.g., tiles). Clean Line will work with landowners to minimize the placement of structures in locations that would interfere with the operation of irrigation systems (AG-1).
- Agricultural soils temporarily impacted by construction, operation, or maintenance activities will be restored to pre-activity conditions. For example, soil remediation efforts may include decompaction, recontouring, liming, tillage, fertilization, or use of other soil amendments (AG-2).
- Clean Line will consult with landowners and/or tenants to identify the location and boundaries of agriculture or conservation reserve lands and to understand the criteria for maintaining the integrity of these committed lands (AG-3).
- Clean Line will work with landowners and/or tenants to identify specialty agricultural crops or lands (e.g., certified organic crops or products that require special practices, techniques, or standards) that may require protection during construction, operation, or maintenance. Clean Line will avoid and/or minimize impacts that could jeopardize standards or certifications that support specialty croplands or farms (AG-4).
- Clean Line will stabilize slopes exposed by its activities to minimize erosion (GEO-1).

The use of native seed mixes and tree species when revegetating the ROW would increase the likelihood that native grasslands and forestlands would return to their previous conditions. The Project is not expected to have any long-term impacts on land use productivity.

3.10.6.8 Impacts from Connected Actions

3.10.6.8.1 Wind Energy Generation

Based on the maximum capacity of the Project and information from wind energy developers[2], it is estimated that 20 to 30 percent of the potentially suitable land, or between 216,400 and 324,600 acres, would actually be developed for wind energy facilities using transmission capacity from the Project.

It is estimated that during the construction phase, approximately 2 percent of land within a wind energy facility is affected (Denholm et al. 2009). Assuming between 20 and 30 percent of the WDZs would be built out, between 4,328 and 6,492 acres would be temporarily disturbed (2 percent of the 20 percent for the low end, 2 percent of the 30 percent for the high end). This range includes the construction of access roads, turbine pads and foundations, underground collection lines, collector substation, and often a generation tie line. An operations and maintenance building and at least one or two meteorological towers are also typically included.

During the operations and maintenance phase of wind energy facilities, approximately 1 percent or less of the land would be affected (Denholm et al. 2009). For the 12 WDZs, assuming 20 to 30 percent build-out, between 2,164 and 3,246 acres would be disturbed (until decommissioning). Once construction has been completed, temporary construction areas would revert to their previous use. Only turbines, access roads, generation tie-lines (if necessary), substations, and operations and maintenance buildings would remain. Existing land uses, primarily agriculture and grazing, would be expected to return to almost all areas of the facilities, unless deemed incompatible with the operation of a wind farm.

Wind turbines and associated facilities are typically located outside municipal boundaries and densely populated communities. The facilities are also typically microsited to accommodate the wishes of participating landowners, avoid affecting sensitive land uses, and to meet local zoning and other setback requirements, so most residences, businesses, cemeteries, churches, hospitals, and schools and other sensitive uses are expected to be avoided.

Temporary impacts during construction may include increased noise, dust, and traffic. Impacts to rangeland/pasture and cultivated crops would result from disturbing vegetation and soils. Construction would temporarily prevent the existing uses in the construction area, including growing crops and animal grazing. Wind energy developers typically coordinate with landowners to minimize impacts to agricultural operations, such as timing construction to begin after crops are harvested; installing fencing to prevent injuries to, or the loss of, livestock; and types of seed to use during revegetation.

Temporary impacts to transportation infrastructure, such as state and local roadways, as well as to aboveground and subsurface utilities, may occur during construction of wind energy facilities. Wind energy developers would be required to acquire the appropriate state and county permits for work in ROWs, and typically return roadways to the

[2] The Applicant requested confidential information from wind energy developers considering development in the region, including confidential information regarding project nameplate, and proposed general location.

same or improved conditions. Wind energy developers also typically coordinate with landowners and operators of existing utilities to locate these utilities and avoid or minimize impacts to existing structures to the extent practicable.

Wind developers must comply with FAA regulations, including submitting planned turbine locations for approval and installing hazard navigation lighting. FAA would determine whether the turbine locations would compromise the operation of nearby airports. Regional airports and airstrips are identified in Section 3.16.

Wind lease agreements typically include provisions to minimize the losses, including minimizing soil compaction and revegetating temporary construction areas. In addition, the agreements typically stipulate compensation for landowners for any losses, such as damage or loss of crops, gates, fences, landscaping and trees, irrigation, and livestock. Once construction is complete, agricultural operations would be able to continue in most of the wind farm. Agricultural activities such as cultivating crops and livestock grazing are generally permitted up to the wind turbine pads, so only a very minimal area of existing agricultural land would be permanently removed from production. Permanent access roads may change the configuration of fields for crops and grazing.

Oil and gas development could be temporarily affected during construction if access to drilling equipment is prevented. These and more direct impacts to drilling infrastructure are expected to be minimized through coordination with landowners. Once construction is complete, oil and gas development in the vicinity of the wind energy facilities could continue.

If a wind energy facility is developed on school trust lands, the existing uses may be temporarily reduced during construction, but may be able to continue once the wind energy facility is operating, depending on the terms of the lease.

Potential effects on hunting and recreation are discussed in Section 3.12. Potential effects on agriculture are discussed in Section 3.2. Potential effects on airports are discussed in Section 3.16.

3.10.6.8.2 Optima Substation

The future Optima substation is anticipated to be constructed on 160 acres of currently undeveloped land partially within the Oklahoma AC Interconnection Siting Area and near an operating wind energy facility. The land cover of the site is primarily grassland/herbaceous. This area would be converted to a utility use for the life of the Project.

3.10.6.8.3 TVA Upgrades

Land uses in areas affected by the required TVA upgrades could include different distributions of land cover and development levels than described in Section 3.10.6 for the Project. The new 500kV line would be in western Tennessee. The upgrades to existing facilities would mostly be in western and central Tennessee. Upgrades to existing infrastructure would include upgrading terminal equipment at three existing 500kV substations and six existing 161kV substations, making appropriate upgrades to increase heights on 16 existing 161kV transmission lines to increase line ratings, and replacing the conductors on eight existing 161kV transmission lines. These upgrades, with the exception of substation modifications, are linear projects, with relatively small amounts of ground disturbance (except in forested areas where ground disturbance resulting from ROW clearing can impact large areas) considering the amount of area crossed, which tends to minimize the amount of land use changes on a regional basis. Also, once the construction is complete, much of the affected land could return to previous land uses such as agriculture (grazing and crops).

Potential land use impacts associated with the required upgrades to existing TVA facilities are not anticipated to result in significant effects to land use. The degree of potential impacts associated with the new electric transmission line would depend on the types of existing land uses within the 37-mile long transmission line ROW, which would occupy about 785 acres (assuming a ROW width of 175 feet). The majority of the ROW would be disturbed during construction only for both the new transmission line and the upgrades to existing facilities. Areas of fully dedicated use (e.g., sites of converter stations, structures, and permanent access roads) would experience longer-term impacts than ROW areas, where existing land use may continue after construction, with certain limitations. Anticipated effects from upgrades to existing structures, conductor, or substations would be expected to include ground disturbance that is typically limited to the immediate vicinity of the structure, and no changes to the existing utility use. Operations and maintenance impacts would be similar to those described above in Section 3.10.6.2.3.2.

3.10.6.9 Impacts Associated with the No Action Alternative

Under the No Action Alternative, DOE assumes for analytical purposes that the Project would not be constructed. No impacts on land uses on private, federal, state, or tribal lands, or their corresponding land management policies and regulations would occur. The existing land uses within the ROW would be expected to continue.

Contents

Tables

3.11 Noise

This section presents the affected environment related to noise and addresses the potential noise impacts on noise sensitive areas (Noise Sensitive Areas [NSAs]; e.g., residences and schools) from the construction, operations, and decommissioning of the Project. The following subsections describe the regulatory background as it pertains to noise, discuss existing acoustic conditions, and assess potential noise impacts related to the Project.

3.11.1 Regulatory Background

This section describes noise regulations at the federal, state, and local level that may be applicable to the Project.

3.11.1.1 Federal

Two federal regulatory guidelines have been identified for assessing noise impacts from the Project. The EPA guidelines are applicable to operational and maintenance noise from the Project and the DOT guidelines are applicable to construction noise from the Project.

3.11.1.1.1 U.S. Environmental Protection Agency

In 1974, the EPA published a study that includes the only large database of community reaction to noise to which a project can be readily compared called Information on Levels of Environmental Noise Requisite to Protect Public Health and Welfare with an Adequate Margin of Safety (EPA 1974). The EPA has developed widely accepted recommendations for long-term exposure to environmental noise with the goal of protecting public health and safety; however, they are not regulatory limits. Instead, the study evaluates the effects of environmental noise with respect to health and safety, and provides information for state and local governments to use in developing their own ambient noise standards. For outdoor residential areas and other locations in which quiet is a basis for use, the recommended EPA guideline is 55 dBA (or decibels weighted on the A-scale) L_{dn}. The L_{dn} is calculated by averaging the 24-hour L_{eq} levels at a given location after adding 10 decibels to the nighttime period (10:00 p.m.–7:00 a.m.) to account for the increased sensitivity of people to noises that occur at night. For a steady 24-hour noise source such as a converter station, an L_{eq} of 48.6 dBA is equal to the L_{dn} criterion of 55 dBA. The EPA also suggests an L_{eq} (24) of 70 dBA (24-hour) limit to avoid adverse effects on public health and safety at publicly accessible property lines or extents of work areas where extended periods public exposure is possible. The EPA criteria are summarized in Table 3.11-1, which identifies levels of environmental noise below which there is no evidence that the general population would be at risk to EPA-identified health effects.

Table 3.11-1:
Summary of EPA Environmental Noise Guidelines

Location	Level	Effect
All public accessible areas with prolonged exposure	70 dBA $L_{eq(24)}$	Safety/Hearing loss
Outdoor at residential structure and other noise sensitive receptors where a large amount of time is spent	55 dBA L_{dn}	Outdoor activity interference and annoyance
Outdoor areas where limited amounts of time are spent, e.g., park areas, school yards, golf courses, etc.	55 dBA $L_{eq(24)}$	Outdoor activity interference and annoyance
Indoor residential	45 dBA L_{dn}	Indoor activity interference and annoyance
Indoor non-residential	55 dBA $L_{eq(24)}$	Indoor activity interference and annoyance

Source: EPA (1974)

3.11.1.1.2 U.S. Department of Transportation

The DOT has identified criteria for the assessment of short- and long-term construction activities for both stationary and mobile projects, and specifically for linear projects. The Federal Transit Administration (FTA) recommends abatement of construction noise that exceeds absolute noise levels at NSAs. These construction noise criteria take into account the diurnal pattern of construction activities, the absolute noise levels during construction activities, the duration of the construction, and adjacent land use. While these criteria were not developed to address construction noise impacts for power transmission line projects, the guidelines shown in Table 3.11-2 provide reasonable criteria for the construction noise assessment. If these criteria are exceeded, adverse community reaction may result.

Table 3.11-2:
DOT Guidelines for Construction Noise Assessment

Land Use	L_{eq}, 1-hr (dBA)	
	Day	Night
Residential	90	80
Commercial	100	100
Industrial	100	100

Source: FTA (2012)

3.11.1.2 State and Local

The states of Oklahoma, Arkansas, Tennessee, and Texas and the local jurisdictions to which DOE's Proposed Action is in proximity do not have environmental noise regulations with numerical decibel limits applicable to the Project. The EPA guideline of 55 dBA L_{dn}, has therefore been used in the evaluation potential noise impacts associated with the Project.

3.11.2 Data Sources

Data sources used in characterizing the existing acoustic environment and evaluating noise impacts are those provided in Table 3.11-3.

Table 3.11-3:
Noise Analysis Data Sources

Specific Noise Analysis	Data Source
Background sound levels	2011 National Land Cover Database used to characterize land use (e.g., mixed forest, developed land, agriculture, etc.) within the ROI. (GIS Data Source: Jin et al. 2013)
	USGS Topographic Maps (http://nationalmap.gov/ustopo/index.html) used to characterize land relief within the ROI.
	Federal Transit Administration High-Speed Ground Transportation Noise and Vibration Impact Assessment. (FTA 2012)
Predicted project sound levels	DOT Construction Noise Handbook. (FHWA 2006)
	Expected construction equipment is listed in the Project description (Appendix F). Construction sound source levels were obtained from FHWA. (2006)
	Expected operational equipment is listed in the Project description (Appendix F). Operational sound source levels were obtained from the Project Electrical Environment Assessment (Section 3.4 of this EIS).
Noise sensitive receptors	See Section 3.10 of this EIS.

3.11.3 Region of Influence

For noise, the ROI for the Project and connected actions is the same as described in Section 3.1.1.

3.11.4 Affected Environment

The affected environment includes the NSAs in the ROI. As mentioned previously NSAs can include residences, and schools, etc. or other places where quiet is a basis for use. Locations of residences and schools are shown in Figure 1.0-2 located in Appendix A of the EIS. The only two schools within the ROI are within AC Collection System Route E-1, located within the town of Hardesty. Using the applicable noise thresholds for the various Project facilities as a guide, potentially impacted NSAs were identified in the ROI. Conversely for connected actions, some of the ROIs are not known at this time; therefore, potentially impacted NSAs will have to be identified when those ROIs have been defined.

Several route variations to the Applicant Proposed Route in Regions 2–7 were developed in response to public comments on the Draft EIS and are described in Appendix M and summarized in Sections 2.4.2.1–2.4.2.7. The variations are presented graphically in Exhibit 1 of Appendix M. Many of the route variations were developed specifically to increase the distance to NSAs to reduce impacts from construction noise. Nonetheless, the number of NSAs located within the threshold distances of the route variations and adjustments would be similar.

3.11.5 Regional Description

Chapter 2 of this EIS includes detailed descriptions of the routing alternatives broken down by seven geographic regions, or Regions 1 through 7. Construction and operational noise sources vary by region and generally differ based on specific Project components as listed in Section 2.1. Access road construction would be required to construct and maintain the Project components regardless of region. Chapter 2 describes each region and Section 3.10 describes land uses within the ROI.

3.11.5.1 Connected Actions

3.11.5.1.1 Wind Energy Generation

The WDZs are all located within the Oklahoma Panhandle and the adjacent portions of Texas, so the regional description is the same as that of Region 1.

3.11.5.1.2 Optima Substation

The future Optima Substation is partially located within the Oklahoma AC Interconnection Siting Area. There are no NSAs located within 0.75 mile from the future Optima Substation.

3.11.5.1.3 TVA Upgrades

The ROI for the direct assignment facilities (which are included in the Applicant Proposed Project) would occur within the Tennessee Converter Station Siting Area and more specifically within the Shelby Substation. The ROI for the network upgrades, and in particular TVA's future 500kV transmission line, cannot be fully determined at this time. The new 500kV line would be constructed in western Tennessee. The upgrades to existing facilities would mostly be in western and central Tennessee. Upgrades to existing infrastructure would include upgrading terminal equipment at three existing 500kV substations and six existing 161kV substations, making appropriate upgrades to increase heights on 16 existing 161kV transmission lines to increase line ratings, and replacing the conductors on eight existing 161kV transmission lines. Where possible, general impacts associated with the required TVA upgrades are discussed in the impact sections that follow.

3.11.6 Noise Impacts

Noise impacts from the Project are classified as temporary impacts associated with construction and permanent impacts associated with operations and maintenance of the Project.

3.11.6.1 Methodology

Sound is described as a rapid fluctuation or oscillation of air pressure above and below atmospheric pressure creating a sound wave. Sound energy is characterized by the properties of sound waves, which include frequency, wave length, period, amplitude, and velocity. Noise is highly subjective and defined as unwanted sound. It is largely dependent on its magnitude and/or intensity of the sound source, its duration, the proximity of noise-sensitive land uses, and the time of day the noise occurs (i.e., higher sensitivities would be expected during the quieter overnight periods).

The range of frequencies that humans hear can span from 20 to 20,000 Hz; however, humans have varying sensitivities to noise at different frequencies, even though the energy content is the same. The amplitude of a sound wave is measured in terms of its sound pressure level where a logarithmic decibel scale is used. The A-weighting filter attenuates low and high frequency energy to simulate the hearing response of the human auditory system. Sound levels that are A-weighted to reflect human response are designated as dBA.

To take into account sound fluctuations, environmental noise is commonly described in terms of the L_{eq}. The L_{eq} value, conventionally expressed in dBA, is the energy-averaged, A-weighted sound level for the time period of interest. It is defined as the steady, continuous sound level, over a specified time, which has the same acoustic energy as the actual varying sound levels over that same time period. Another common noise descriptor used when assessing environmental noise is the L_{dn}, which includes the addition of 10 dB to noise emitted during the nighttime period (10:00 p.m. to 7:00 a.m.) to account for the increased sensitivity of people to noises that occur at night. The maximum sound level (L_{max}) is the maximum instantaneous sound level as measured during a specified time period. It can also be used to quantify the time-varying maximum instantaneous sound pressure level (as generated by equipment or an activity) or a manufacturer maximum source emission level.

An acoustic analysis was conducted for Project construction and operations and maintenance using criteria and guidelines discussed in Section 3.11.1. The analysis methods included determining a threshold distance from Project construction and operations and maintenance activities for the converter stations, Applicant Proposed Route, AC collection system, and HVDC alternative routes. Each threshold distance correlated with a selected noise criterion; therefore, an NSA located within a threshold distance would experience received sound levels in excess of that criterion.

The analysis of operational noise (long-term impacts) from the converter stations, Applicant Proposed Route, AC collection system, and HVDC alternative routes, was based on a representative centerline as described in Section 3.1. Construction noise (short-term impacts) threshold distances were calculated by generating a composite, or summed, noise level for all construction equipment required for a certain construction phase. Sound attenuation calculations were then completed to determine the distance from the Project ROW at which construction noise would decrease to levels corresponding to the DOT construction noise thresholds. Once this distance was determined, the number of NSAs within that distance from Project construction activities was quantified. The DOT construction noise thresholds were used to determine the threshold distances, which includes a daytime $L_{eq(1\text{-}hr)}$ 90 dBA threshold and a nighttime $L_{eq(1\text{-}hr)}$ 80 dBA threshold, both applicable at residential land uses. A similar methodology was used to evaluate potential noise impacts associated with Project operations, but the EPA 55 dBA L_{dn} noise guideline was used to determine the threshold distance. Threshold distances would vary greatly depending on the Project activity. For instance, during the construction phase, heightened received sound levels would result from use of heavy equipment and helicopters, whereas noise associated with transmission line operation (termed corona noise) would be substantially lower. Where impacts were identified, noise mitigation measures were recommended. The Applicant has developed a comprehensive list of EPMs that will aid in minimizing noise impacts. A complete list of EPMs for the Project is provided in Appendix F; those EPMs that would specifically minimize the potential for noise impacts are listed below:

- GE-6: Clean Line will restrict vehicular travel to the ROW and other established areas within the construction, access, or maintenance easement(s).
- GE-17: Clean Line will consider noise and radio/television interference in the design of bundle configurations and conductors. To minimize noise and radio/television interference, the Applicant will maintain tension on insulator assemblies and protect the conductor surface from damage during construction.
- GE-20: Clean Line will maintain construction equipment in good working order. Equipment and vehicles that show excessive emissions of exhaust gasses and particulates due to poor engine adjustments or other inefficient operating conditions will be repaired or adjusted.
- GE-23: Clean Line will maximize the distance between stationary equipment and sensitive noise receptors consistent with engineering design criteria.
- GE-24: Clean Line will minimize the number and distance of travel routes for construction equipment near sensitive noise receptors.
- GE-25: Clean Line will turn off idling equipment when not in use.

3.11.6.2 Impacts Associated with the Applicant Proposed Project

Impacts include those from construction, operations and maintenance, and decommissioning of the converter stations, AC transmission lines, and HVDC transmission lines. Construction noise levels would be temporary, lasting 36 to 42 months for the Applicant Proposed Project; however, construction would last for much shorter durations of several days to weeks in any given area for the AC transmission lines and HVDC transmission lines and up to 32 months for construction of each converter station. Temporary construction noise can be a source of annoyance for NSAs located nearby and is characterized as a short-term impact. Operational noise is generally lower level but long term in nature and characterized as a long-term impact. The following sections describe construction and operations and maintenance noise impacts expected for the converter stations, AC transmission lines, and HVDC transmission lines.

3.11.6.2.1 Converter Stations

The Applicant Proposed Project includes two proposed converter stations in Oklahoma and Tennessee. Potential noise impacts associated with construction, operations and maintenance, and decommissioning of the converter stations are discussed in the following subsections.

3.11.6.2.1.1 Construction Impacts

Construction of the proposed converter stations would be completed in three stages: site preparation, foundation installation, and erection of the station. Because detailed design has not been completed to date, representative converter station sites were used within the converter station siting areas, located approximately where the HVDC and AC connector lines meet. Each converter station site is assumed to be approximately 50 acres in size for the purposes of this analysis. Construction of the converter stations would require the short-term use of heavy equipment such as cranes, loaders, bulldozers, graders, excavators, compressors, generators, and various trucks. Pile driving is not expected during construction. Construction noise is usually made up of intermittent peaks and continuous lower levels of noise from equipment cycling through use. Noise levels associated with individual pieces of equipment at 50 feet away would generally range between 55 and 85 dBA L_{max} (FHWA 2006). Maximum instantaneous construction noise levels would range from 91 to 95 dBA L_{eq} at 50 feet from any work site. Table 3.11-4 provides noise level data for the three converter station construction stages; the highest construction noise levels are associated with erecting the stations. Predicted L_{eq} values are given at several reference distances to provide an indication of sound levels generated during the various converter station construction stages and how those levels attenuate with distance.

Using the construction stage anticipated to generate the highest noise level (erecting of station), the threshold distance to the DOT construction noise thresholds described in Section 3.11.1 using the methodology described in Section 3.11.6.1, was calculated from each converter station construction area. The threshold distances were determined to be 95 feet and 275 feet for the daytime (90 dBA L_{eq}) and nighttime (80 dBA L_{eq}) thresholds, respectively, so any NSAs located within those distances to the construction areas would potentially experience an exceedance of the DOT guidelines. Review of aerial mapping used to identify NSAs near the analyzed converter station areas indicates that no NSAs would be located within either of these threshold distances, so no exceedances of the DOT guidelines are expected.

Table 3.11-4:
Construction Noise Levels—Converter Stations

Stage	Construction Equipment	Quantity	Reference Noise Level L_{max} at 50 feet	Usage Factor (%)	Composite Sound Pressure Level (L_{eq}) at Distance from Sound Source				
					50 feet	100 feet	200 feet	400 feet	1,000 feet

3.11.6.2.1.2 Operations and Maintenance Impacts

Noise generated from operations and maintenance of the converter stations was analyzed. Converter station maintenance activities are expected to require minimal equipment such as trucks and lifts, which would not generate much noise. Because of the nature of the equipment likely needed for maintenance and the periodic basis that maintenance would be conducted, noise levels associated with converted station maintenance are expected to be low at nearby NSAs.

As mentioned above, detailed design of the converter stations has not been completed at this stage of permitting. Typical equipment that would be installed at the converter stations would include AC filters, coolers, converter valves, chillers, reactors, capacitors, and transformers. The principal noise sources in the converter stations are the transformers with second and third highest sound sources being the filter reactors and valve coolers, respectively.

Converter station noise would propagate and attenuate at different rates depending on the locations and specifications of sound producing equipment. For example, the sound generated by transformers depends on several factors including the transformer size, voltage rating, and design. Table 3.11-5 provides the equipment type, quantity, and sound power level used in assessing noise generated during converter station operation.

Table 3.11-5:
Converter Station Equipment Noise Sources

Equipment Type	Quantity	Sound Power (dBA)
AC Filters	12	77
Filter Capacitor	12	82
Filter Reactor	12	95
Converter Transformers	12	112
Coolers	6	88
Smoothing Reactors	2	72
Valve Coolers	2	92
Chillers	2	77
Converter Valves	2	82

Both converter stations share the same equipment types, quantities, and sound power levels. To the extent practicable, the Applicant would orient the converter stations such that the noisiest side of the station, the AC side, is facing away from the nearest NSA. In addition, sound from the converter station transformers would be partially mitigated by barrier walls on two sides of the transformers each exceeding the transformer height. The valve hall building would be acoustically insulated with metal outer sheeting.

Acoustic modeling was conducted using the information provided in Table 3.11-5 implementing the general configuration planned for the converter stations. The model used was Datakustik's CadnaA version 4.5.151 implementing the International Organization for Standardization standard 9613-2, Acoustics—Attenuation of Sound During Propagation Outdoors (ISO 1996). The engineering methods specified in this standard consist of full octave band algorithms that incorporate geometric spreading due to wave divergence, reflection from surfaces, atmospheric absorption, screening by topography and obstacles, ground effects, source directivity, heights of sources and receptors (i.e., NSAs), seasonal foliage effects, and meteorological conditions. The following subsections provide the results of this acoustic modeling analysis.

3.11.6.2.1.2.1 Oklahoma Converter Station Siting Area and AC Interconnection Siting Area

The analysis conducted for the Oklahoma converter station showed that the predicted sound level at the nearest NSA, located 7,000 feet from the center point of the converter station, inclusive of the assumed background sound level of 43 dBA (L_{dn}), is 48 dBA L_{dn}, which is below the EPA environmental noise guideline of 55 dBA L_{dn}. It should be noted that final design of the converter station has not been completed. Based on the analysis, however, compliance with the EPA noise guideline is expected and NSAs located further away are expected to experience lower sound levels, so no noise impacts are anticipated at the Oklahoma converter station.

The Oklahoma converter station includes one 5-mile 345kV interconnection line. No NSAs are located within the threshold distance for 345kV single circuit transmission lines as described in Section 3.11.6.2.2 and using the methodology described in Section 3.11.6.1.

3.11.6.2.1.2.2 Tennessee Converter Station Siting Area and AC Interconnection Siting Area

The analysis conducted for the Tennessee converter station showed that the predicted converter station sound level at the nearest NSA, located 1,030 feet from the center point of the converter station, inclusive of the assumed background sound level of 43 dBA (L_{dn}), is 53 dBA L_{dn}, which is below the EPA environmental noise guideline of 55 dBA L_{dn}. It should be noted that final design of the converter station has not been completed. Based on the analysis, however, compliance with the EPA noise guideline is expected and NSAs located further away are expected to experience lower sound levels, so no noise impacts are anticipated at the Tennessee converter station.

The Tennessee converter station would include an AC interconnect tie located entirely within the footprints of the Tennessee converter station and Shelby Substation. Sound generated by on-site converter transformers and other facilities will be dominant relative to sound generated by the AC interconnect tie; therefore, noise impacts at NSAs resulting from the interconnect tie are expected to be negligible.

3.11.6.2.1.3 Decommissioning Impacts

Decommissioning noise impacts are expected to be similar to construction noise impacts because similar equipment would be required. However, decommissioning activities would take less time than construction activities, so NSAs would not experience decommissioning noise impacts for as long as those associated with construction. Because no impacts are expected from construction of the Project, and because sound levels with decommissioning would be similar, no impacts are expected from decommissioning.

3.11.6.2.2 AC Collection System

Potential noise impacts associated with the AC collection system for construction and operations and maintenance are discussed in the following subsections.

3.11.6.2.2.1 Construction Impacts

Construction of the AC transmission lines would be completed in stages such as ROW clearing, foundation installation, structure assembly, and conductor stinging. Construction of the AC transmission lines would occur as a series of sequential events distributed over several miles along the transmission line route at any one time. Noise levels associated with individual pieces of equipment at 50 feet would generally range between 55 and 103 dBA L_{max} (FHWA 2006). Maximum instantaneous construction noise levels would range from 88 to 96 dBA L_{eq} at 50 feet from any work site. Table 3.11-6 provides noise level data for the four stages of AC transmission line construction; the highest construction noise levels would be associated with structure assembly and conductor stringing. Similar to data provided for converter station construction, sound levels generated during transmission line construction are provided at a set of reference distances.

It is likely that blasting would be required for some tower installations; however, in these cases, a detailed Blasting Plan would be developed and implemented to avoid noise impacts. Examples of measures that could be included in the Blasting Plan to minimize blasting impacts are:

- Use tamping or stemming into the collars of blast holes and smooth-wall perimeter holes (stemming is defined as inserted material, such as crushed stone, sand, or any other inert objects placed in the top of the blast hole for the purpose of confining explosive charges and limiting rock movement and air-overpressure).
- Use blasting mats.
- Unless otherwise coordinated with landowners and adjacent landowners, plan blasting to take place only between the hours of 10:00 a.m. and 4:00 p.m., Monday through Friday. No blasting shall take place on weekends.
- Notify landowners and tenants, including owners of adjacent utilities or structures, prior to blasting.

Detailed Blasting Plans would be developed for the Project based on site-specific activities and nearby conditions.

Table 3.11-6:
Construction Noise Levels—AC Collection Lines

Stage	Construction Equipment	Quantity	Reference Noise Level L_{max} at 50 feet	Usage Factor (%)	Composite Sound Pressure Level (L_{eq}) at Distance from Sound Source

Source: FHWA (2006)

The calculated threshold distance from each AC transmission line construction area using the methodology in Section 3.11.6.1, was determined to be 100 feet and 325 feet for the daytime (90 dBA L_{eq}) and nighttime (80 dBA L_{eq}) thresholds, respectively. An analysis was conducted to evaluate the number of NSAs within these threshold distances from the transmission line for each transmission line alternative under consideration. The results of this analysis are provided below in Table 3.11-7 by alternative. While noise levels would be elevated during Project construction, noise impacts are considered short-term and temporary. The use of EPMs would aid in minimizing construction noise impacts.

Table 3.11-7:

3.11.6.2.2.2 Operations and Maintenance Impacts

Operations and maintenance impacts include those associated with the AC collection system. Maintenance would include the use of trucks, lifts, or other equipment as needed proximate to the converter stations on a periodic basis along the AC collection system.

The proposed AC transmission lines have the potential to emit noise under certain operating and environmental conditions. Transmission line noise (also called corona noise) is caused by the partial electrical breakdown of the insulating properties of air around the electrical conductors and overhead power lines as described in Section 3.4. When audible, corona-generated noise is often described as a raspy hum or buzz. Corona noise is primarily affected by weather and (to a lesser degree) by altitude and temperature. Audible corona noise from transmission lines occurs primarily in foul weather. Foul weather is a weather condition when there is precipitation or high humidity present that can cause the transmission-line conductors to be wet. In addition, while fog is not a form of precipitation it may cause conductors to be wet. Dry snow, conversely, is a form of precipitation, but it may not cause the conductors to be wet (EPRI 2005). Water droplets on the conductors act as electric field concentrators, and produce a large number of corona discharges, each of them creating a burst of noise. During fair weather conditions, corona noise levels are typically low and often confined to occurrences of scratches or other imperfections on the conductor surface or where dust has settled on the line. Corona activity increases with increasing altitude, and with increasing voltage in the line, but is generally not affected by system loading.

Sound levels emitted from transmission lines are related to line voltage. Audible noise calculations for the AC transmission lines were performed as described in Section 3.4. The methods used to calculate audible noise from transmission lines were developed by DOE, specifically by the Bonneville Power Administration (BPA), and have been validated and used by engineers and scientists for many years. The inputs to the model include such parameters as line voltage, load flow (current), altitude, meteorological conditions, the physical dimensions of the line, conductor diameter, spacing, and height of the conductors and receivers above ground level. The BPA method of calculating audible noise from transmission lines is based on long-term statistical data collected from operating and test transmission lines. This method calculates the L_{50} noise level during rainy conditions of 1 millimeter per hour or more up to 5 millimeters per hour, at which point the sound of rain hitting the ground, foliage, and/or structures masks the audible noise from the line (BPA 1991).

Potential noise impacts resulting from operation of the AC transmission lines were assessed assuming conditions that would generate the highest noise emissions. These conditions are when the conductors are wet and the AC line is at its highest altitude for the proposed alignments, approximately 3,000 feet. The audible noise results were then used to determine threshold distances using the methodology described in Section 3.11.6.1, corresponding to the 55 dBA L_{dn} EPA guideline threshold, for the proposed 345kV and 500kV lines. The threshold distance for the 335kV line was calculated to be 146 feet and the threshold distance for the 500kV line was calculated to be 659 feet. The 500kV lines are required to connect the converter stations to the existing AC grid. A noise impact is assumed to occur if an NSA is located within the identified threshold distances.

All AC collection system routes were analyzed to determine potential noise impacts associated with operation. Of all of the routes under consideration, the only ones with NSAs located within the threshold distance of 146 feet were AC Collection System Routes E-3 and NE-2. Both of these alternatives showed one NSA that would be located within the 146-foot distance corresponding to the EPA guideline threshold of 55 dBA L_{dn} for a transmission line of 345kV line voltage. Therefore, there is the potential that both of those NSAs may experience adverse noise impacts from transmission line operation if those alternatives are constructed; however, impacts would be less under different weather conditions or if the transmission line is located at an altitude less than 3,000 feet.

3.11.6.2.2.3 Decommissioning Impacts

Decommissioning noise impacts are expected to be similar to construction noise impacts because similar equipment would be required. However, decommissioning activities would take less time than construction activities, so NSAs would not experience decommissioning noise impacts for as long as those associated with construction.

3.11.6.2.3 HVDC Applicant Proposed Route

HVDC transmission lines have the potential to result in noise impacts during the construction, operations and maintenance, and decommissioning phases of the Project. The following sections describe the expected impacts from construction and operations and maintenance of the Applicant Proposed Route.

3.11.6.2.3.1 Construction Impacts

Construction impacts from the Applicant Proposed Route would be similar to those sound levels associated with constructing the AC collection system lines. The main difference with construction of the HVDC lines is that construction would cover a much larger area, spanning from the panhandle of Oklahoma through Arkansas and into eastern Tennessee. Project construction of a single segment of HVDC lines is also expected to last 24 months. Construction would last for much shorter durations of several days to weeks in any given area of HVDC transmission lines. The construction process for HVDC transmission lines would be the same as that for the AC collection lines for which noise levels are provided in Table 3.11-6.

It is likely that blasting would be required for some tower installations; however, in these cases, a detailed Blasting Plan would be developed and implemented to avoid noise impacts. Examples of measures that could be included in the Blasting Plan to minimize blasting impacts are:

- Use tamping or stemming into the collars of blast holes and smooth-wall perimeter holes.
- Use blasting mats.

- Unless otherwise coordinated with landowners and adjacent landowners, plan blasting to take place only between the hours of 10:00 a.m. and 4:00 p.m., Monday through Friday. No blasting shall take place on weekends.
- Notify landowners and tenants, including owners of adjacent utilities or structures, prior to blasting.

Detailed Blasting Plans would be developed for the Project based on site-specific activities and nearby conditions.

The Applicant Proposed Route was analyzed using the methodology described in Section 3.11.6.1 to identify NSAs that would be within the nighttime DOT guideline threshold of 80 dBA, a threshold distance of 325 feet, and to the daytime DOT guideline threshold of 90 dBA, a threshold distance of 100 feet. Table 3.11-8 provides the number of NSAs located within these threshold distances by region. The NSAs located within these threshold distances may experience short-term and temporary elevated noise levels during Project construction; the implementation of EPMs would minimize construction noise impacts.

Table 3.11-8:
Construction Noise Impacts for the Applicant Proposed Route by Region

Line Voltage/Structure[1]	Number of NSAs within 100 feet	Number of NSAs within 325 feet
Applicant Proposed Route—Region 1	1	7
Applicant Proposed Route—Region 2	1	15
Applicant Proposed Route—Region 3	6	78
Applicant Proposed Route—Region 4	12	107
Applicant Proposed Route—Region 5	2	47
Applicant Proposed Route—Region 6	6	24
Applicant Proposed Route—Region 7	2	28

1 The values in the table do not reflect the minor changes that would result from application of the minor route variations and adjustments in the Applicant Proposed Route in Regions 2–7.

Twenty-three route variations to the Applicant Proposed Route, Regions 2–7, were developed in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.1–2.4.2.7. Many of the route variations were developed specifically to increase the distance to NSAs to reduce impacts from construction noise. Nonetheless, the number of NSAs located within the threshold distances would be similar, and construction noise impacts would generally be the same as for the original Applicant Proposed Route in Regions 1–7.

3.11.6.2.3.2 Operations and Maintenance Impacts

Operations and maintenance impacts include those associated with maintaining the operability of the HVDC transmission lines. Maintenance would include the use of trucks, lifts, or other equipment as needed proximate to the converter stations on a periodic basis along the AC collection system.

The HVDC transmission lines have the potential to emit environmental noise under certain operating and environmental conditions referred to as corona noise. Unlike AC lines, HVDC transmission lines emit higher noise levels under fair weather conditions than under foul weather, although generally corona noise is lower for HVDC transmission lines in comparison to AC transmission lines of similar voltage operating under foul weather. The noise is lower because of the increased space charge around the transmission line conductors in foul weather, making the effective size of the conductor larger, which reduces the surface gradient and the audible noise produced. HVDC transmission lines, therefore, generate the highest noise emissions during fair weather conditions. Corona activity increases with increasing altitude, and with increasing voltage in the line, and is loudest in a single-polarity operation as opposed to bipolar operation. Negligible audible noise results in a single-polarity negative operation. Section 3.4 discusses in detail the differences between AC transmission line and HVDC transmission line corona noise emissions and how the sound power levels were calculated for these sound sources.

For the purposes of assessing noise impacts at NSAs, conditions corresponding to the highest noise emissions were assumed. Audible noise calculations for the HVDC transmission lines were performed as described in Section 3.4. The audible noise results were then used to determine the threshold distance using the methodology described in 3.11.6.1, corresponding to the 55 L_{dn} EPA guideline for the proposed HVDC lines, which was a distance of 130 feet. Table 3.11-9 provides the number of NSAs within that threshold distance by region.

Table 3.11-9:
Operational Noise Impacts for the Applicant Proposed Route by Region

Line Voltage/Structure[1]	Number of NSAs within 130 feet
Applicant Proposed Route—Region 1	—
Applicant Proposed Route—Region 2	—
Applicant Proposed Route—Region 3	2
Applicant Proposed Route—Region 4	—
Applicant Proposed Route—Region 5	—
Applicant Proposed Route—Region 6	—
Applicant Proposed Route—Region 7	—

1 The values in the table do not reflect the minor changes that would result from application of the minor route variations and adjustments in the Applicant Proposed Route in Regions 2–7.

Sound levels from the HVDC transmission line were also calculated under fair (worst case) and foul weather conditions at various distances from the line, out to 2,000 feet for the highest altitude (3,000 feet) and lowest altitude (200 feet), and assuming flat, open terrain. The results of these additional calculations show that at a distance of 2,000 feet, sound levels would attenuate to 25 dBA under fair weather and 19 dBA under foul weather, assuming an altitude of 3,000 feet; whereas at an altitude of 200 feet, sound levels would attenuate to 22 dBA under fair weather and 16 dBA under foul weather. For comparison, the sound level inside a quiet library is approximately 30 dBA. In addition, considering the conservative measures incorporated into the analysis, received sound levels at NSAs would be expected to be lower on average than those reported.

For the route variations, the number of NSAs located within the threshold distances would be similar, and operation and maintenance noise impacts would generally be the same as for the original Applicant Proposed Route in Regions 1–7.

3.11.6.2.3.3 Decommissioning Impacts

Decommissioning noise impacts are expected to be similar to construction noise impacts because similar equipment would be required. However, decommissioning activities would take less time than construction activities, so NSAs would not experience decommissioning noise impacts for as long as those associated with construction.

3.11.6.3 Impacts Associated with DOE Alternatives

Methods to assess construction and operations and maintenance noise impacts for DOE Alternatives would be the same as described for the Applicant Proposed Route in Section 3.11.6.2.3. The difference is in the location of each alternative relative to nearby NSAs. The following sections describe the number of NSAs that would be impacted by each of the alternatives under consideration.

3.11.6.3.1 Arkansas Converter Station Alternative Siting Area and AC Interconnection Siting Area

Construction, operations and maintenance, and decommissioning of the Arkansas converter station and its associated substation would result in increased noise levels nearby. Construction and operations and maintenance noise impacts are summarized in the following sections.

3.11.6.3.1.1 Construction Impacts

Using the construction stage (erecting of station) anticipated to generate the highest noise level and the methodology described in Section 3.11.6.1, the threshold distance to the DOT construction noise thresholds provided in Table 3.11-4 were calculated from the alternative converter station construction area. The threshold distances were determined to be 95 feet and 275 feet for the daytime (90 dBA L_{eq}) and nighttime (80 dBA L_{eq}) thresholds, respectively, so any NSAs located closer than those distances to the construction area would potentially experience an exceedance of the DOT guidelines. A review of aerial mapping conducted to identify NSAs near the analyzed alternative converter station indicates that no NSAs would be located within either of these threshold distances, so no exceedances of the DOT guidelines are expected.

3.11.6.3.1.2 Operations and Maintenance Impacts

The analysis conducted for the Arkansas converter station showed that the predicted converter station sound level at the nearest NSA, located 710 feet from the center point of the converter station, inclusive of the assumed background sound level of 43 dBA (L_{dn}), is 50 dBA L_{dn}, which is below the EPA environmental noise guideline of 55 dBA L_{dn}. NSAs located further away are expected to experience lower sound levels, so no noise impacts are anticipated at the Arkansas converter station.

In addition, the Arkansas converter station would include a relatively short distance (less than 5 miles in length) 500kV AC transmission interconnection lines. Six NSAs would be located within 659 feet of the Arkansas interconnection line, which using the methodology described in Section 3.11.6.1, corresponds to the threshold distance to the 500kV single circuit AC transmission line.

The Arkansas converter station would also require a new substation located where the 500kV AC transmission interconnection line connects taps the existing Arkansas Nuclear One-Pleasant 500kV line. The new substation is estimated to have a footprint of approximately 25 to 35 acres but would mainly function as a switchyard. There are no transformers or other significant sound sources proposed for installation at the new substation; therefore, no additional noise impacts are expected to result from the operation of the new substation.

3.11.6.3.1.3 Decommissioning Impacts

Decommissioning noise impacts are expected to be similar to construction noise impacts because similar equipment would be required. However, decommissioning activities would take less time than construction activities, so NSAs would not experience decommissioning noise impacts for as long a time period as those associated with construction.

3.11.6.3.2 HVDC Alternative Routes

Construction and operations and maintenance of the HVDC alternative routes would result in increased noise levels nearby. Construction and operations and maintenance noise impacts are summarized in the following sections.

3.11.6.3.2.1 Construction Impacts

Construction impacts for the HVDC alternative routes were calculated using the same methods described for the Applicant Proposed Route. The following sections provide the number of NSAs that would be impacted by construction noise for each alternative by region. A noise impact is assumed to occur if an NSA is located within the identified threshold distances from the work site.

All proposed HVDC alternative routes were analyzed to determine the number of NSAs located within the threshold distance of 325 feet, which corresponds to the nighttime DOT guideline threshold of 80 dBA, and the number of NSAs located within the threshold distance of 100 feet, which corresponds to the daytime DOT guideline threshold of 90 dBA. Table 3.11-10 provides the number of NSAs located within these threshold distances by region and alternative. These NSAs may experience short-term and temporary elevated noise levels during Project construction. The implementation of EPMs would minimize construction noise impacts.

Table 3.11-10:
Construction Noise Impacts by HVDC Alternative Route and Region

Line Voltage/Structure[1]	Number of NSAs within 100 feet	Number of NSAs within 325 feet
AR 1-A	—	5

AR 7-D	0	5

1 The values in the table do not reflect the minor changes that would result from application of the minor route variations and adjustments to Routes 3-A, 5-B, 5-E, and 6-A.

As described in Appendix M and summarized in Section 2.4.2, five route adjustments were developed for HVDC Alternative Routes 3-A, 5-B, 5-E, and 6-A. The HVDC alternative route adjustments were developed to maintain end-to-end routes with the Applicant Proposed Route variations. The number of NSAs located within the threshold distances would be similar, and construction noise impacts would generally be the same as for the original HVDC alternative routes.

3.11.6.3.2.2 Operations and Maintenance Impacts

Operational and maintenance impacts discussed in this section include those associated with the HVDC alternative routes. The methods are the same as those used for the Applicant Propose Route. A noise impact is assumed to occur if an NSA is located within the identified threshold distances from the transmission line centerline. All HVDC alternative routes were analyzed to determine the number of NSAs located within the threshold distance of 130 feet, which corresponds to the EPA guideline threshold of 55 dBA L_{dn}. Table 3.11-11 provides the number of NSAs located within these threshold distances by region and alternative. These NSAs may experience adverse noise impacts from the HVDC alternative routes under certain operational and weather conditions.

1 The values in the table do not reflect the minor changes that would result from application of the minor route variations and adjustments to HVDC Alternative Routes 3-A, 5-B, 5-E, and 6-A.

As described in Appendix M and summarized in Section 2.4.2, five route adjustments were developed for HVDC Alternative Routes 3-A, 5-B, 5-E, and 6-A. The HVDC alternative route adjustments were developed to maintain an end-to-end route with the Applicant Proposed Route variations. The number of NSAs located within the threshold distances would be similar, and operations and maintenance noise impacts would generally be the same as for the original HVDC alternative routes.

3.11.6.3.2.3 Decommissioning Impacts

Decommissioning noise impacts are expected to be similar to construction noise impacts because similar equipment would be required. However, decommissioning activities would take less time than construction activities, so NSAs would not experience decommissioning noise impacts for as long as those associated with construction.

3.11.6.4 Best Management Practices

It is likely that blasting would be required for some tower installations; however, in these cases, a detailed Blasting Plan would be developed and implemented to avoid noise impacts. Examples of measures that could be included in the Blasting Plan to minimize blasting impacts are:

- Use tamping or stemming into the collars of blast holes and smooth-wall perimeter holes (stemming is defined as inserted material, such as crushed stone, sand, or any other inert objects placed in the top of the blast hole for the purpose of confining explosive charges and limiting rock movement and air-overpressure).
- Use blasting mats.
- Unless otherwise coordinated with landowners and adjacent landowners, plan blasting to take place only between the hours of 10:00 am and 4:00 pm, Monday through Friday. No blasting shall take place on weekends.
- Notify landowners and tenants, including owners of adjacent utilities or structures, prior to blasting.

Detailed Blasting Plans would be developed for the Project based on site-specific activities and nearby conditions.

In addition to the Applicant's EPMs, DOE has identified one BMP to address unavoidable noise impacts from the Project (Section 3.11.6.5 below). This BMP would involve the use of a Communications Program that is described in Section 3.1. Noise complaints from construction and/or operation of the Project would be handled via the Applicant's Communications Program.

3.11.6.5 Unavoidable Adverse Impacts

Unavoidable adverse impacts would result from operations and maintenance of the Project as described in Sections 3.11.6.2 and 3.11.6.3. Construction impacts, while a source of potential annoyance to nearby NSAs, would be temporary and avoided to the extent practicable via use of EPMs. Sound levels generated by the converter stations are not expected to exceed the EPA guidelines (e.g., 55 dBA L_{dn}) at nearby NSAs; however, the EPA guidelines would be exceeded at some NSAs from operations and maintenance of the proposed AC and HVDC transmission lines.

Impacts associated with AC collection system would be mainly associated with the operation of the line under foul weather conditions defined as being conditions where the line is saturated with water. These conditions typically occur when rain is of sufficient strength to saturate the line, an approximate rate of 1 millimeter/hour. Because people tend to remain indoors during foul weather, the likelihood of an impact occurring at NSAs diminishes because received sound levels indoors would generally be 10–20 dBA lower. Additionally, under foul weather conditions, ambient sound levels are typically higher because of rain impacting the ground, vegetation, and/or nearby structures. As a result, foul weather may partially or completely mask the sound of the AC transmission lines. The AC transmission line operations and maintenance noise impacts are therefore classified as being unavoidable, but not necessarily adverse.

Unlike AC transmission line noise, noise levels associated with HVDC transmission line operation are highest under fair weather conditions. The likelihood of people being outdoors during peak HVDC transmission line conditions is therefore more likely than with AC transmission lines. Additionally, because transmission lines are a sound source that is elevated above ground, typical mitigation options, such as noise barriers or berms, are not feasible. Impacts discussed in this EIS are associated with conditions corresponding to the highest noise emissions, so impacts are expected to be less during more typical operations and maintenance conditions. Furthermore, people outdoors may experience sound from the HVDC transmission lines, but that sound would be attenuated indoors, where people typically sleep. With windows closed, under fair weather HVDC line conditions, operations and maintenance sound levels would be 10–20 dBA lower than those predicted outside, so sleep disturbance is unlikely.

The Applicant would investigate noise complaints obtained via their Communications Plan.

3.11.6.6 Irreversible and Irretrievable Commitment of Resources

With the implementation of EPMs and identified BMP to resolve potential noise impacts to NSAs, no irreversible or irretrievable commitments of resources related to noise are anticipated.

3.11.6.7 Relationship between Local Short-term Uses and Long-term Productivity

Construction noise would temporarily impact nearby NSAs. Noise levels associated with operations and maintenance of the Project would not impact long-term productivity. Changes in sound level associated with the Project would not be expected to negatively impact current land use and activities.

3.11.6.8 Impacts from Connected Actions

3.11.6.8.1 Wind Energy Generation

The impacts from connected actions include those associated with the wind energy generation facilities that would interconnect to the Project as a result of the Project. The anticipated connected actions are all located within Region 1, in the Oklahoma Panhandle and the adjacent portions of Texas. Although site-specific layouts of wind energy generation facilities in the wind energy development zones identified in Region 1 have yet to be designed, noise impacts from these potential wind energy generation facilities have been qualitatively studied. Noise impacts from the connected actions would result from construction and operations and maintenance of the wind energy generation facilities.

3.11.6.8.2 Construction Noise

Construction noise would result from the use of construction equipment to build the wind energy generation facilities. Construction of wind energy generation facilities typically includes the following stages: site clearing, excavation, foundation work, and wind turbine installation. The layouts and design of each wind energy facility are unknown, so the mix of construction equipment needed, the schedule, and duration of construction noise are also unknown. Nevertheless, construction noise would result from motorized construction equipment used for general construction, some of which is included in Tables 3.11-4 and 3.11-5. Because of the temporary nature of construction noise, construction noise impacts from connected actions are not considered significant as they would not permanently impact nearby NSAs.

3.11.6.8.3 Operational Noise

Noise from operation of wind energy generation facilities would result from the operation of wind turbines, and maintenance of the wind energy developments. Because there are no site-specific plans for the wind energy development areas, it is not possible to analyze noise impacts for each potential wind energy generation development area. Site-specific acoustic analyses would be required for each wind energy development to assess potential impacts to the affected NSAs. Nevertheless, for the purposes of this qualitative discussion, operations and maintenance noise levels at referenced distances are provided for wind turbine types with power output capacities ranging from 1.5MW to 3.5MW in Table 3.11-12. Noise levels associated with modern wind turbine generators are mainly a result of aerodynamic noise produced from air flow and the interaction with the wind turbine tower structure and moving rotor blades. Recent improvements in the design of wind turbine mechanical components and the use of improved noise damping materials within the nacelle, including elastomeric elements supporting the generator and gearbox, have minimized mechanical noise emissions (Hau 2006). The sound levels presented in Table 3.11-12 are approximate values only meant to provide the reader a rough representation of potential noise impacts from one wind turbine operating in isolation over an intentionally conservative acoustically hard surface like pavement. If more than one wind turbine generator is operating in relative proximity, the received sound levels at those set distances would be expected to increase. For example, if two GE 1.5sle turbines are located within 1,000 feet of a given NSA, the resulting sound level would be 3 dBA higher than that listed in Table 3.11-12, or approximately 50 dBA L_{eq}.

Table 3.11-12:
Representative Sound Levels for Selected Wind Turbine Generators

Wind Turbine Generator[1]	Rotor Diameter (meter)	Hub Height (meter)	Megawatts	Sound Power Level (dBA L_W)	Received Sound Level (dBA L_{eq})		
					1,000 feet	1,200 feet	1,500 feet
GE 1.5sle	87	77	1.5	106	47	45	43
Siemens 2.3-101	101	80	2.3	108.5	49	48	46
Siemens 3.0-113	113	99.5	3.0	108.5	50	48	46

1 Includes a k-factor or uncertainty factor of +/- 2 dB for the GE 1.5sle and +/- 1.5 dB for the Siemens turbines
Source: GE (2005), Siemens (2008), Bodwell (2013)

As wind development projects are established in the WDZs, each would be required to proceed through state, local, and other permitting efforts as applicable.

3.11.6.8.4 Optima Substation

There are no NSAs located within 0.75 mile from the future Optima Substation, so noise levels from construction, operations and maintenance, and decommissioning of the substation are not anticipated to result in impacts.

3.11.6.8.5 TVA Upgrades

The ROI for the direct assignment facilities cannot be determined at this time as described in Section 3.11.5.1.3. Where possible, general impacts associated with the required TVA upgrades are discussed in the impacts sections below.

Noise impacts associated with upgrades to existing TVA facilities are not likely to affect NSAs assuming that upgrades would not include addition of transformers or other noise-generating equipment, whereas the required new TVA electric transmission line could cause previously unaffected NSAs to be impacted by noise generated during construction or operations and maintenance. Since the proposed new TVA line is a 500kV AC transmission line, it is expected that construction activities and noise levels would be similar to those described for the Project AC collection system in Section 3.11.6.2.2.1. Construction activities exceeding the FTA guidelines of 90 dBA L_{eq} for daytime activities and 80 dBA L_{eq} for nighttime activities could result in adverse impacts to nearby NSAs. In addition, it is expected that operational noise associated with the TVA line would be similar to noise generated by the Project 500kV AC transmission line as described in Section 3.11.6.2.2.2. Operations and maintenance activities exceeding the EPA guideline of 55 dBA L_{dn} could result in adverse impacts to nearby NSAs.

3.11.6.9 Impacts Associated with the No Action Alternative

Under the No Action Alternative, DOE assumes for analytical purposes that the Project would not be constructed. Accordingly, no impacts related to noise from the Project would occur.

Tables

This page intentionally left blank.

3.12 Recreation

This section provides baseline information regarding outdoor recreation uses on public and private lands that could be affected by the Project. Included within this section is a description of the regulations and standards of federal, state, and local land management agencies that provide recreation opportunities; existing recreational opportunities and activities; and an assessment of potential impacts that might result from the Project.

3.12.1 Regulatory Background

Recreation laws, regulations, and standards relevant to the resources in the ROI are summarized in Table 3.12-1. Permits that may apply to the Project are discussed in further detail in Appendix C. The regulatory background for the ODWC WMAs, AGFC WMAs, ANHC Natural Areas, USFWS NWRs, USFS lands, and USACE lands are described in Section 3.10.

Table 3.12-1:
Recreation Laws and Regulations Applicable to the Project

Statute/Regulation	Agency	Applicability to the Project
Federal		
The National Trails System Act (16 USC § 1241 *et seq.*)	National Park Service (NPS)	The Trail of Tears crosses eight states, including Tennessee, Oklahoma, and Arkansas, and the ROI crosses some portions of the trail in each state. Recreation is available along the trail itself in the form of driving or walking and at developed sites and communities along the trail; however, there are no developed Trail of Tears sites that are crossed by the Project (NPS 2014c). While the ROI would cross the Trail of Tears National Historic Trail, there are no specific permits or authorizations required from the NPS. The Chisholm and Great Western Trail is under consideration for designation as a National Historic Trail (NPS 2015). The proposed Chisholm and Great Western National Historic Trail commemorates the routes followed by upwards of 10 million cattle as they traveled northbound from southern Texas to Kansas and adjacent destinations between 1867 and the 1880s. In recognition of the perceived national importance of these two routes, and in response to public advocacy for the inclusion of these routes in the National Trails System, Congress passed the Omnibus Public Land Management Act of 2009 (Public Law 111-11), which includes a provision (Sec. 5303 of) that calls for a study of "The Chisholm Trail (also known as the 'Abilene Trail'), from the vicinity of San Antonio, Texas ... to Enid, Oklahoma, Caldwell, Kansas, Wichita, Kansas, Abilene, Kansas, and commonly used segments running to alternative Kansas destinations" as well as "The Great Western Trail (also known as the 'Dodge City Trail'), from the vicinity of San Antonio, Texas, north-by-northwest [to] Oklahoma, north through Kansas to Dodge City, and north through Nebraska to Ogallala." In compliance with Public Law 111-11, National Park Service staff led by the National Trails Intermountain Region office in Santa Fe, New Mexico, will complete a feasibility study for the proposed Chisholm and Great Western National Historic Trail. Public meetings for scoping purposes were held in June 2010. A planning newsletter and a scoping report are available online at http://parkplanning.nps.gov/projectHome.cfm?projectID=30803. The reviewed statement of national significance has been posted as well. The draft study was released for a 60-day public review and comment period beginning January 5, 2015.
1979 Presidential Directive, Memorandum for the Heads of Departments and Agencies regarding Nationwide Rivers Inventory	National Park Service	The Nationwide Rivers Inventory (NRI) rivers are free-flowing river segments that are believed to possess one or more "outstandingly remarkable" natural or cultural values believed to be more than locally or regionally significant (NPS 2011d). A presidential directive requires each federal agency, as part of its normal planning and environmental review processes, to take care to avoid or mitigate adverse effects on rivers identified in the Nationwide Rivers Inventory compiled by NPS. Further, all agencies are required to consult with the National Park Service prior to taking actions

Table 3.12-1:
Recreation Laws and Regulations Applicable to the Project

Statute/Regulation	Agency	Applicability to the Project
		which could effectively foreclose wild, scenic or recreational status for rivers on the inventory (NPS 2011a). Guidance issued by CEQ on the NRI recommends that federal agencies should take care to avoid or mitigate adverse effects on rivers identified in the NRI and should consult with the National Park Service to ensure that a federal agency action does not adversely affect the natural, cultural and recreational values of the NRI river segment. Further, this guidance recommends that where a federal agency determines that its action may have adverse effects, the agency should incorporate avoidance/mitigation measures into the proposed action to maximum extent feasible within the agency's authority (NPS 2011d).
National Scenic Byways Program (23 USC § 162) Intermodal Surface Transportation Efficiency Act of 1991 (ISTEA; Public Law 102-240)	The Federal Highway Administration (FHA)	A scenic byway is a public road with special scenic, historic, recreational, cultural, archaeological, and/or natural qualities that have been recognized as such through legislation or official declaration. Easements associated with scenic byway ROWs may prohibit construction of transmission structures or other structures that degrade the scenic quality of the road. Federal regulations governing utility use/crossings of a highway ROW note that utilities provide “an essential public service to the general public. Traditionally, as a matter of sound economic public policy and law, utilities have used public road ROW for transmitting and distributing their services” (23 CFR 645.209a).
Historic Route 66 Corridor Preservation Program (Public Law 106-45)	National Park Service (NPS)	Historic Route 66 is a national scenic byway administered by the FHWA, but is also part of the Historic Route 66 Corridor Preservation Program (Pub. L. 106-45) administered by the National Park Service (NPS 2014a). The program collaborates with private property owners; non-profit organizations; and local, state, federal, and tribal governments to identify, prioritize, and address Historic Route 66 preservation needs.
State		
Intermodal Surface Transportation Efficiency Act of 1991 (ISTEA) (Public Law 102-240) Arkansas Code Annotated (ACA) 27-67-203	Arkansas State Highway Commission	The act created the National Scenic Byways program, but also encouraged states to develop their own scenic byway program. The Arkansas Highway Commission created criteria by which routes could be designated into the state program (AHTD 2007d). Arkansas has two designations for scenic roads within the state: Scenic Highway and Scenic Byways. Arkansas Scenic Highways are designated by the Arkansas General Assembly; however, there are no requirements or prerequisites to designation. Designated Arkansas Scenic Highways are codified and listed in Arkansas Code 27-67-203. Arkansas Scenic Byways are established by the Arkansas Highway Commission under the IS TEA. State Scenic Byway Designation is a prerequisite for nomination and designation as a National Scenic Byway. A roadway must first be designated as an Arkansas Scenic Highway by the Arkansas General Assembly before it can become an Arkansas Scenic Byway under IS TEA.
Local		
City and county zoning ordinances, development regulations, and general or comprehensive plans under Arkansas Code Title 14 Local Government; Oklahoma Statutes Title 19 Counties and County Officers, Section 863.1 City and County Planning and Zoning through Section 863.29 Exclusive Control	Local governments (cities and counties) in Arkansas, Oklahoma, and Tennessee	These resources are managed by the individual rules and regulations of cities, counties, and towns in which they occur, which may include zoning regulations, comprehensive plans, recreation plans, open space plans, trail plans, and similar land use planning documents.

Table 3.12-1:
Recreation Laws and Regulations Applicable to the Project

Statute/Regulation	Agency	Applicability to the Project
by Commission; Tennessee Statute Title 6 Cities and Towns, Municipal Government Generally, Chapter 54 Municipal Powers Generally and Chapter 58 Comprehensive Growth Plan		
Oklahoma Scenic Rivers Act (Oklahoma Statues Title 82-1451– 1471)	Oklahoma Water Resources Board (OWRB)	The OWRB is responsible for administration of the state Scenic Rivers Act to preserve the high quality and unique characteristics of outstanding water resources. There are five streams protected under the program in Oklahoma, including Lee Creek and Little Lee Creek. No other rivers designated under the Oklahoma Scenic Rivers Act occur within the ROI.

In addition to the regulations applicable to the project listed above, commenters requested a description of impacts to the America's Great Outdoors Initiative projects and the Arkansas Water Trail System.

The America's Great Outdoors Report (DOI 2013) is the Obama Administration's action plan under the America's Great Outdoors Initiative to achieve lasting conservation of the outdoor spaces that power our nation's economy, shape our culture, and build our outdoor traditions. To implement this initiative, individual projects are set up under the America's Great Outdoors 50 State Report and the All American Rivers Demonstration Projects. No current projects listed in the 50 State Report would be crossed by the Project. The Cache River, located in eastern Arkansas, is part of the All American Rivers Demonstration Projects. As the Cache River and surrounding landscape are restored, the landscape will be managed to benefit water quality, aquatic and wetland ecosystems, wildlife, local communities, and the public. The areas for improvement are located to the south and outside the ROI for the Project in the Cache River National Wildlife Refuge and surrounding private land. The Project in Region 6 are located far to the north of the Cache River National Wildlife Refuge boundaries. The portion of the All American Rivers Demonstration Projects performed along the Cache River National Wildlife Refuge was completed in 2013. Future project nomination and execution under both the America's Great Outdoors 50 State Report and the All American Rivers Demonstration Projects are chosen by local agencies and proposed to the America's Great Outdoors Initiative for inclusion in the program.

The Arkansas Water Trail System (AGFC 2011e), which is managed by the AGFC, develops public paddling trails throughout the state, creating well-mapped accessible day trips in a variety of settings and for all levels of paddling experience. None of the waterways established as water trails would be crossed by the proposed Project and alternatives. Landowners and communities nominate Water Trails for inclusion in the system.

3.12.2 Data Sources

Recreational resources identified through review of existing datasets for land ownership, and aerial imagery were used to determine the various recreation land uses within the ROI. GIS data sources include ESRI (2013). Ground and aerial reconnaissance by Clean Line and comments received during stakeholder outreach and the DOE scoping process supplemented the desktop information.

Jurisdiction and land ownership in Oklahoma and Arkansas were obtained from the Oklahoma Gap Analysis Project and Arkansas GeoStor (GIS Data Sources: USGS 2012; AHTD 2006a, 2006b, 2006c), respectively. Scenic byways data were obtained from the National Scenic Byways Program and Arkansas GeoStor (GIS Data Sources: FHWA 2013; AHTD 2006a). Scenic byways data were not available for Oklahoma.

NRI data and National Wild and Scenic Rivers data were obtained from the NPS and the USGS (GIS Data Sources: IWSRCC 1999; USGS 1996), respectively. Oklahoma and Arkansas scenic rivers data were obtained from the Oklahoma Scenic Rivers Program (Oklahoma Statutes 82-1451–1471), the ADEQ (*Arkansas Natural and Scenic Rivers System Act* [ACA 15-23-301–315]) and the National Hydrography Dataset (GIS Data Source: USGS 2014a).

3.12.3 Region of Influence

For recreation, the ROI for the Project and connected actions is the same as described in Section 3.1.1.

3.12.4 Affected Environment

The affected environment includes the recreation resources described for the ROI in Regions 1 through 7. A review of the existing recreational opportunities in the ROI provides the context for assessing potential effects to recreational resources and opportunities. Recreational areas include federal, state, and local parks; forests, lakes, rivers, museums, historic sites, and hunting grounds.

Recreation opportunities range from active pursuits such as hiking, water sports, hunting, and fishing, to sedentary recreation like sightseeing, car tours, and picnicking at many of the recreation areas throughout the ROI.

Several route variations to the Applicant Proposed Route in Regions 2–7 were developed in response to public comments on the Draft EIS and are described in Appendix M and summarized in Sections 2.4.2.1–2.4.2.7. Assessments of the impacts related to the route variations by Project region, including accompanying HVDC Alternative Route adjustments, are provided below. The variations are presented graphically in Exhibit 1 of Appendix M.

3.12.5 Regional Description

3.12.5.1 Region 1

Region 1 is referred to as the Oklahoma Panhandle Region and includes the Applicant Proposed Route, HVDC Alternative Routes I-A through I-D, and the AC collection system. The ROI for Region 1 HVDC would cross the Chisholm and Great Western Trail, which is being considered for addition to the National Historic Trail System. The Chisholm and Great Western Trail would cross Applicant Proposed Route Link 5 and HVDC Alternative Route 1-A in Region 1. The ROI for Region 1 HVDC would be located adjacent to and south of the Shorb WMA. The Shorb WMA, located southeast of Hardesty, is managed by the ODWC and offers hunting (GIS Data Source: ODWC 2014).

The ROI for the AC collection system would cross portions of the following recreational areas:

- The Optima NWR
- Optima WMA
- Schultz WMA and State Park
- Shorb WMA

The southern edges of the Optima NWR and WMA would be located within the ROI for AC Collection System Route E-1. The Optima NWR is managed by the USFWS and offers opportunities for public shotgun or archery hunting and wildlife watching. The Optima NWR is part of a larger complex of conservation lands near Hardesty, Oklahoma, that includes the Optima WMA. The Optima WMA includes land adjacent to the Optima NWR along the Beaver River and the Optima Reservoir. The Optima WMA is managed by the ODWC and is open to public hunting (USFWS 2014). The Optima WMA also offers two designated primitive camping areas and a rifle range (ODWC 2014a).

The ROIs associated with AC Collection System Routes E-3, SE-1, SE-3, and E-2 would cross the edges of the Schultz WMA and State Park. The Schultz WMA and State Park, located south of Hardesty, is managed by the ODWC and offers hunting (ODWC 2014b).

The ROI associated with AC Collection System Route SE-3 and E-2 would cross the Shorb WMA. The Shorb WMA located southeast of Hardesty, is managed by the ODWC and offers hunting (GIS Data Source: ODWC 2014).

There are no Texas-managed recreation areas or state designated recreational rivers in the AC collection system ROI in Texas (TPWD 2014a).

No route variations were proposed in Region 1.

3.12.5.2 Region 2

Region 2 is referred to as the Oklahoma Central Great Plains Region and includes the Applicant Proposed Route and HVDC Alternative Routes 2-A and 2-B. Facilities in Region 2 include the HVDC transmission line; the ROI would cross portions of the Major County WMA. The Chisholm and Great Western Trail crosses the ROI in Region 2. The trail which is being considered for addition to the National Historic Trail System. The Chisholm and Great Western Trail would cross Region 2 Applicant Proposed Route Link 3, and Alternative Route 2-B in Region 2.

The Major County WMA would be directly adjacent to the ROI for HVDC Alternative Route 2-A east of Woodward, Oklahoma, and north of Chester, Oklahoma, in Major County. Major County WMA is located in Major County in northwest Oklahoma. This WMA is managed by the ODWC. Hunting is allowed in this WMA, and fishing opportunities are very limited. Camping is not allowed in the WMA (ODWC 2011).

Two route variations to the Applicant Proposed Route were developed in Region 2 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.2. The variations are illustrated in Exhibit 1 of Appendix M. These variations represent minor adjustments to the Applicant Proposed Route and would not cross any additional designated recreation areas or remove crossing locations than those described for the original Applicant Proposed Route.

3.12.5.3 Region 3

Region 3 is referred to as the Oklahoma Cross Timbers Region and includes the Applicant Proposed Route and HVDC Alternative Routes 3-A through 3-E. Facilities in Region 3 include the HVDC transmission line. The ROI would cross portions of the following recreational areas:

- Robert S. Kerr Lake and Webbers Falls Reservoir
- Historic Route 66
- Lake Carl Blackwell

Robert S. Kerr Lake Recreation Area and Webbers Falls Reservoir are interconnected waterways and would be crossed by the ROI associated with the Applicant Proposed Route Link 6 near the Muskogee-Sequoyah county line, west of Gore, Oklahoma. Robert S. Kerr Lake is located on the McClellan-Kerr Arkansas River Navigation System. The lake features fishing, hunting, camping, picnicking, water sports, sightseeing, swimming, and hiking for recreation (USACE 2014a).

Historic Route 66 would be crossed by the ROI associated with Applicant Proposed Route Link 4 north of Bristow, Oklahoma and HVDC Alternative Route 3-C north of Depew, Oklahoma. Historic Route 66 is a national scenic byway administered by the FHWA but is also part of the Historic Route 66 Corridor Preservation Program (PL 106-45) administered by the NPS. The program collaborates with private property owners; non-profit organizations; and local, state, federal, and tribal governments to identify, prioritize, and address Historic Route 66 preservation needs (NPS 2014a; FHWA 2014d).

Lake Carl Blackwell would be crossed by the ROI associated with HVDC Alternative Routes 3-A and 3-B and Proposed Route Link 1, west of Stillwater, Oklahoma. Lake Carl Blackwell, managed by the Oklahoma State University, is located west of Stillwater and provides camping and cabins, horseback riding trails, fishing, water sports, hunting, and hiking (OSU 2014).

Five route variations to the Applicant Proposed Route were developed in Region 3 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.3. The variations are illustrated in Exhibit 1 of Appendix M. These variations represent minor adjustments to the Applicant Proposed Route, and they would not cross any additional designated recreation areas or remove crossing locations from those described for the original Applicant Proposed Route. It should be noted that a route adjustment was made for HVDC Alternative Route 3-A to maintain an end-to-end route with the Links 1 and 2 variations.

3.12.5.4 Region 4

Region 4 is referred to as the Arkansas River Valley Region and includes the Applicant Proposed Route and HVDC Alternative Routes 4-A through 4-E as well as the Lee Creek Variation. Facilities in Region 4 include the HVDC transmission line. The ROI would cross portions of several recreational areas including:

- Robert S. Kerr Lake and Webbers Falls Reservoir
- Ozark National Forest
- Ozark National Forest WMA
- Frog Bayou WMA
- Ozark Lake WMA
- Scenic Byways
- Portions of the Lee and Little Lee Creeks rivers managed by the Oklahoma Water Resources Board (OWRB) and listed on the NRI
- Arkansas Scenic Byways: State Highway 540/Boston Mountains Scenic Loop; State Highway 23/Pig Trail Byway; and State Highway 21/Ozark Highlands Scenic Byway
- Arkansas Scenic Highways: State Highway 220, State Highway 59, Interstate Highway 40, U.S. Highway 71
- The Trail of Tears National Historic Trail

Robert S. Kerr Lake and Webbers Falls Reservoir would be crossed by the ROI associated with the Applicant Proposed Route Link 1 of Region 4 west of Salisaw, Oklahoma. Robert S Kerr Lake and Webbers Falls Reservoir is located on the Oklahoma portion of the McClellan-Kerr Arkansas River Navigation System. Webbers Falls Reservoir features fishing, hunting, camping, picnicking, water sports, and sightseeing for recreation (USACE 2014b). Robert S. Kerr Lake features fishing, hunting, camping, picnicking, water sports, sightseeing, swimming, and hiking for recreation (USACE 2014a).

Ozark National Forest would be crossed by the ROI associated with HVDC Alternative Route 4-B. The crossing would take place along the southern end of the National Forest north of Fort Smith Arkansas. Many opportunities for recreation exist in the Ozark National Forest including biking, camping, climbing, fishing, hiking, horseback riding, hunting, nature and wildlife viewing, water sports (both motorized and non-motorized), and scenic driving (USFS 2014). No specific recreation areas, such as boat launches, campgrounds, or shooting ranges, are located within the ROI or crossed by the Applicant Proposed Route and HVDC alternative routes (USFS 2014). Within the Ozark National Forest there are public and private land holdings. The recreation opportunities are available only in the publicly held tracts of land. Impacts to private inholdings within the Ozark National Forest are addressed in Section 3.10 (Land Use).

The Ozark National Forest WMA, where it is crossed by the HVDC Alternative Route 4-B, shares the same boundaries as the Ozark National Forest (located in the Boston Mountain Ranger District). The Ozark National Forest WMA is located within the National Forest of the same name and is located in parts of Conway, Crawford, Franklin, Johnson, Madison, Newton, Pope, Searcy, Van Buren, and Washington counties in Oklahoma. Hunting is allowed in the WMA with the exception of alligator and elk hunting. All other species are allowed (AGFC 2011d). The Ozark National Forest WMA represents a zone where the AGFC manages the wildlife, but the USFS is the landowner. Each WMA is a separate zone for which the AGFC may establish and apply hunting regulations (AGFC 2014).

Frog Bayou WMA would be crossed by the ROI associated with the Applicant Proposed Route Link 6, west of Mulberry and south of Dyer, Arkansas. Frog Bayou WMA is managed by the AGFC and is located east of Van Buren along the Arkansas River. This WMA features hunting, with the exception of alligator and elk, and wildlife viewing, and it abuts USACE-managed land along the Arkansas River (AGFC 2011b).

Ozark Lake would be crossed by the ROI associated with the Applicant Proposed Route Link 6, west of Mulberry and east of Dyer, Arkansas. Ozark Lake WMA is managed by the AGFC and is located east of Van Buren along the Arkansas River on land managed by the USACE. The WMA features hunting with the exception of bear, alligator, and elk (AGFC 2011c).

Some segments of the Big Piney Creek are considered part of the NRI for Arkansas. The segments of the Big Piney Creek that are listed on the NRI are located from the upper Dardanelle Reservoir, to the headwaters near Fallsville, Arkansas. The Big Piney Creek segments on the NRI have the outstanding remarkable values of scenery, recreation, geology, fish, and wildlife (NPS 2004).

Lee Creek and Little Lee Creek NRI segments would be crossed by the ROI associated with HVDC Alternative Routes 4-A and 4-B and Applicant Proposed Route Link 3 north of Fort Smith, Arkansas. Lee Creek NRI segments would be crossed by the ROI associated with the Lee Creek Variation. Lee and Little Lee Creeks OWRB state natural and scenic river segments would be crossed by the ROI associated with HVDC Alternative Routes 4-A and 4-B north of Fort Smith in Sequoyah County, Oklahoma. Lee Creek is not considered a federally designated Wild and Scenic River, although it is included on the NRI for Oklahoma and Arkansas. The Lee Creek segments included on the NRI encompass 49 miles of river in Sequoyah County, Oklahoma, to the headwaters near Moffet, Arkansas, and have the outstanding remarkable values of scenery, recreation, fish, wildlife, and cultural (NPS 2011b, 2010). The OWRB manages the Lee and Little Lee Creeks state natural and scenic river segments in Sequoyah County, Oklahoma, and have the outstanding remarkable values of scenery, recreation, fish, wildlife, and cultural (NPS 2010). Review of available data shows that the Lee Creek and Little Lee Creek segments are part of the NRI and the OWRB Natural and Scenic Rivers System.

Oklahoma Highway 100, or the Cherokee Hills National Scenic Byway, would be crossed by the ROI associated with the Applicant Proposed Route Link 1 west of Sallisaw, Oklahoma. The Cherokee Hills National Scenic Byway is located on the western foothills of the Ozark Mountains and has scenic, cultural, and historic values (FHWA 2014a). Arkansas Highway 21, also known as the Ozark Highlands Scenic Byway, is crossed by Proposed Route Link 9 and Alternative Route 4-E north of Clarksville, Arkansas. The Ozark Highlands Scenic Byway is designated under the Arkansas State Scenic Byways program and is a scenic drive with recreational opportunities through the Boston Mountains region of the Ozark Mountains (AHTD 2007b).

The Boston Mountains Scenic Loop (Interstate 540 and US Highway 71) would be crossed by the ROI associated with HVDC Alternative Routes 4-A, 4-B, and 4-D north of Van Buren, Arkansas. This scenic loop, designated under the Arkansas State Scenic Byways program, has several high-span bridges and scenic and historic views (AHTD 2007a).

Pig Trail Scenic Byway would be crossed by the Applicant Proposed Route and HVDC Alternative Route 4B. The Pig Trail Scenic Byway is designated for 19 miles between the southern boundary of the Ozark National Forest to the intersection with Arkansas Highway 16 (Arkansas.com 2014).

State Scenic Highway 220 would be crossed by HVDC Alternative Routes 4-A and 4-B. State Scenic Highway 59 would be crossed by HVDC Alternative Routes 4-C, 4-D and the Applicant Proposed Route. Interstate-40 would be crossed twice by both HVDC Alterative Route 4-A and the Applicant Proposed Route. U.S. Highway 71 would be crossed by HVDC Alternative Route 4-D.

The Trail of Tears is located across eight states including Tennessee, Oklahoma, and Arkansas. Recreation is available along the trail itself in the form of driving or walking (NPS 2014c). There are no interpretive centers or sites along the Trail of Tears; the only park facility is the trail itself, which can be used for hiking (NPS 2014b). The Trail of Tears locations mapped by the NPS are representative of the historic location of the trail and the extent of the trail at each crossing location is not known. The historic significance of the Trail of Tears is addressed in detail in Section 3.9.

Seven route variations to the Applicant Proposed Route were developed in Region 4 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.4. The variations are illustrated in Exhibit 1 of Appendix M. These variations represent minor adjustments to the Applicant Proposed Route, and they would not cross any additional designated recreation areas or remove crossing locations from those described for the original Applicant Proposed Route. Link 6, Variation 3, would cross the Trail of Tears at a different location; however, recreational land uses are expected to be similar at the original Applicant Proposed Route location and at the route variation location.

3.12.5.5 Region 5

Region 5 is referred to as the Central Arkansas Region and includes the Applicant Proposed Route and HVDC Alternative Routes 5-A through 5-F. Facilities located in Region 5 include the HVDC transmission line, the Arkansas Converter Station Alternative Siting Area, and the Alternative AC Interconnection Siting Area. A new substation would be required at the point where the 500kV AC interconnection line taps the existing Arkansas Nuclear One-Pleasant Hill 500kV line. This new substation area would be located within the current Arkansas Converter Station Alternative AC Interconnection Siting Area; no recreational resources are located within these areas. Portions of the Cherokee WMA, segments of Cadron Creek listed on the NRI, and scenic byways would be crossed by Project features. Region 5 also crosses Arkansas Scenic 7 Byway, and Arkansas State Scenic Highways: State Highway 27, State Highway 9, U.S. Highway 65, State Highway 25, State Highway 5, and State Highway 16.

The Cherokee WMA is located in the ROI associated with the Applicant Proposed Routes Links 2 and 5. Portions of the Cherokee WMA are located in eight different counties in Arkansas (AGFC 2011a). Permitted game hunting on the overall WMA includes turkey, deer, bear, quail, rabbit, squirrel, and crow.

Cadron Creek segments listed on the NRI would be crossed by the ROI associated with HVDC Alternative Routes 5B, 5E, and 5F west of Guy, Arkansas. Cadron Creek is in the ROI associated with the Applicant Proposed Route Link 3 east of Damascus, Arkansas. Cadron Creek is crossed by the ROI associated with the Applicant Proposed Route Link 4 southeast of Quitman, Arkansas. Cadron Creek is not considered a federally designated Wild and Scenic River, although it is included on the NRI for Arkansas. The segments of Cadron Creek included on the NRI are located from the confluence of Cadron Creek with the Arkansas River near Gleason, Arkansas, to the headwaters, east of Pearson, Arkansas. The east fork of Cadron Creek also has segments included on the NRI that are located from the confluence of the East Fork and Cadron Creek north of Gleason, Arkansas, to the headwaters east of Rose Bud, Arkansas. The Cadron Creek and East Fork segments on the NRI have the outstanding remarkable values of scenery, recreation, geology, fish, and wildlife (NPS 2004).

The East Fork of Cadron Creek would be crossed by the ROI associated with HVDC Alternative Routes 5B, 5E, and 5F in Faulkner and White counties, Arkansas and is designated as part of the NRI system from the confluence of the East Fort and Cadron Creek north of Gleason upstream to the headwaters east of Rose Bud, Arkansas. The East Fork of Cadron Creek segments on the NRI have the following Outstanding and Remarkable Values (ORVs): scenic, recreational, geologic, fish and wildlife (NPS 2004).

Arkansas Scenic 7 Byway would be crossed by the ROI associated with the Applicant Proposed Route Link 1 and HVDC Alternative Route 5-A. The Arkansas Scenic 7 Byway travels almost 300 miles and provides views of several different regions of the state. The route is known for scenic views and proximity to recreation (AHTD 2007c).

Arkansas State Scenic Highway 27 would be crossed by HVDC Alternative Route 5-A, and the Applicant Proposed Route. Arkansas State Scenic Highway 9 would be crossed by HVDC Alternative Route 5-B and the Applicant Proposed Route. U.S. Highway 65 would be crossed by HVDC Alternative Route 5-B and the Applicant Proposed Route. Arkansas State Scenic Highway 25 would be crossed by HVDC Alternative Route 5-E and the Applicant Proposed Route. Arkansas State Scenic Highway 5 would be crossed by HVDC Alternative Route 5-B and the

Applicant Proposed Route. Arkansas State Scenic Highway 16 would be crossed by HVDC Alternative Route 5-B, 5-C and the Applicant Proposed Route.

Five route variations to the Applicant Proposed Route were developed in Region 5 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.5. The variations are illustrated in Exhibit 1 of Appendix M. These variations represent minor adjustments to the Applicant Proposed Route, and they would not cross any additional designated recreation areas or remove crossing locations from those is described for the original Applicant Proposed Route. Links 3 and 4, Variation 2, would cross the Cadron Creek at a different location; however, recreational land uses are expected to be similar at the original Applicant Proposed Route location and at the route variation location.

3.12.5.6 Region 6

Region 6 is referred to as the Cache River and Crowley's Ridge Region and includes the Applicant Proposed Route and HVDC Alternative Routes 6-A through 6-D. Facilities located in Region 6 include the HVDC transmission line. The ROI would cross portions of the following recreational areas: USFWS acquisition areas, the Singer Forest Natural Area/St. Francis Sunken Lands WMA, portions of the L'Anguille River on the NRI, and scenic byways/highway.

Portions of USFWS acquisition areas, associated with the Cache River NWR, would be crossed by the ROI associated with HVDC Alternative Route 6-B near Amagon, Arkansas, and by the ROIs associated with the Applicant Proposed Route Links 3 and 4, and HVDC Alternative Route 6-A north and west of Fisher, Arkansas. An acquisition area is an area that has been identified for purchase by the agency, should the opportunity arise. These areas are typically identified surrounding federally owned land in an attempt to expand the boundaries of the federal land holding. Acquisition areas are not owned, nor are they managed by the USFWS, although they have been identified for future purchase. No proposed or alternative routes or ROIs cross portions the Cache River NWR.

The Singer Forest Natural Area/St. Francis Sunken Lands WMA would be crossed by the ROI associated with the Applicant Proposed Route Link 7. The portion of the Singer Forest Natural Area/St. Francis Sunken Lands WMA that occurs within the Applicant Proposed Route is located in Pointsett County, Arkansas. This section of the lands encompasses a total of 520 acres in the Mississippi Alluvial Plain. The Natural Area consists of forested wetlands, bottomland forest, and overflow swamp. Hunting is allowed for turkey, deer, quail, rabbit, squirrel, and crow, and disallowed for alligator, elk, bear, and deer hunted with a muzzleloader (ANHC 2014b).

Portions of the L'Anguille River included in the NRI system would be crossed by the ROI associated with HVDC Alternative Route 6-C, and Applicant Proposed Route Link 6 west of Marked Tree, Arkansas. The L'Anguille River is not considered a federally designated Wild and Scenic River, although it is included on the NRI for Arkansas. The segments of L'Anguille River included on the NRI are located from the confluence of the L'Anguille River with the St. Francis Floodway near Marianna, Arkansas, to the Poinsett-Cross county line. The segments of the L'Anguille River included on the NRI have the outstanding remarkable values of scenic, recreation, fish, and wildlife (NPS 2004).

Crowley's Ridge Parkway National Scenic Byway would be crossed by the ROI associated with the Applicant Proposed Route Link 6 and HVDC Alternative Route 6-C south of Harrisburg, Arkansas. Recreational opportunities include wildlife and vegetation viewing, natural and historic sites, and Civil War battlefields along Crowley's Ridge

Parkway National Scenic Byway (FHWA 2014b). Arkansas State Scenic Highway 14 would be crossed by HVDC Alternative 6-C.

One route variation was developed in Region 6 in response to public comments on the Draft EIS to parallel more parcel boundaries to minimize impacts to agricultural operations and is shown in Exhibit 1 of Appendix M. This variation represents a minor adjustment to the Applicant Proposed Route, and it would not cross any additional designated recreation areas or remove crossing locations from those described for the original Applicant Proposed Route.

3.12.5.7 Region 7

Region 7 is referred to as the Arkansas Mississippi River Delta and Tennessee Region and includes the Applicant Proposed Route and HVDC Alternative Routes 7-A through 7-D. Facilities located in the ROIs for Region 7 include portions of the Trail of Tears National Historic Trail and the Great River Road National Scenic Byway and Arkansas State Scenic Highway 63. The ROIs associated with the HVDC transmission line also cross the Mississippi River in Region 7.

The Trail of Tears would be crossed by the ROI associated with the Applicant Proposed Route Link 1 and HVDC Alternative Route 7-A across the Mississippi River. The Trail of Tears locations mapped by the NPS are representative of the historic location of the trail, and the extent of the trail at each crossing location is not known.

The Great River Road National Scenic Byway would be crossed by the ROI associated with HVDC Alternative Route 7-A west of the Mississippi River crossing (west of Millington, Tennessee, in Arkansas). It is also crossed by the Applicant Proposed Route north of Birdsong, Arkansas, and the Mississippi River Crossing (west of Millington Tennessee in Arkansas). The Great River Road has many historic and cultural resources and scenic views into the River Valley (FHWA 2014c). The Arkansas State Scenic Highway 63 would be crossed by HVDC Alternative Route 7-A and the Applicant Proposed Route.

The Coon Valley Road Boat Launch area on the eastern bank of the Mississippi River in Tennessee would be crossed by the ROI associated with HVDC Alternative Route 7A. The Coon Valley Road Boat Launch appears to be a primitive ramp and parking lot for use by recreational watercraft. It is not clear whether this boat launch is maintained. The Mississippi River in this area is popular for recreational water sports, sightseeing, and fishing from the river even though the banks are steep and wooded and do not provide much access to the waterfront.

Three route variations to the Applicant Proposed Route were developed in Region 7 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.7. The variations are illustrated in Exhibit 1 of Appendix M. These variations represent minor adjustments to the Applicant Proposed Route, and they would not cross any additional designated recreation areas or remove crossing locations from those described for the original Applicant Proposed Route.

3.12.5.8 Connected Actions

3.12.5.8.1 Wind Energy Generation

There are several municipal parks within WDZ-A, including Leatherman Park, Stark Park, Murphy Park, Whippo Park, and Whighem Park that would be located in Perryton, Texas, in WDZ-A. The parks are located in the city limits of Perryton and have improved ball fields and running trails.

Palo Duro Reservoir is located in WDZ-B, 10 miles north of Spearman, Texas. The lake is a man-made reservoir used mainly for fishing and bird-watching. Palo Duro Reservoir is stocked with many fish species for recreational fishing (TPWD 2014b). Millers Lake and County Road 18 hunting areas in Hansford County, Texas, are used for hunting upland game birds. Hunting areas near Millers Lake are part of the Hansford County complex in the panhandle region of the Texas Parks and Wildlife public hunting lands. The Miller's Lake unit allows for teal, pheasant, sandhill crane, high plains mallard, and western zone goose hunting. The County Road 18 unit allows only pheasant hunting (TPWD 2012).

The Schultz WMA and Optima WMA would be located in WDZ-D. The Schultz WMA is located approximately 4.7 miles south of Hardesty, Oklahoma; 260 acres of the Schultz WMA would be located within the WDZ-D analysis area. The Schultz WMA is managed by the ODWC and offers hunting (ODWC 2014b). Parts of the Optima WMA are located in WDZ-D, 13.9 miles east of Guymon, Oklahoma. There are 256 acres of the Optima WMA located within WDZ-D. The Optima WMA is part of a larger complex of conservation lands near Hardesty, Oklahoma. The Optima WMA includes land adjacent to the Optima NWR along the Beaver River and the Optima Reservoir. The Optima WMA is managed by the ODWC and is open to public hunting (ODWC 2014a).

There are several municipal parks, including the City Park, Jaycee Park, and Womble Park in Spearman, Texas, that would be located in WDZ-L. The parks are located within the city limits of Spearman and have improved ball fields and a swimming pool.

Hunting may also take place in undesignated deciduous forest, evergreen forest, mixed forest, shrub/scrub, grassland/herbaceous, woody wetland, and emergent herbaceous wetland land cover types on both public and private land in all of the WDZs.

There are no recreational resources in WDZ-C, WDZ-E, WDZ-F, WDZ-G, WDZ-H, WDZ-I, WDZ-J, and WDZ-K.

3.12.5.8.2 Optima Substation

There are no recreation resources located within the future Optima Substation Siting Area.

3.12.5.8.3 TVA Upgrades

The ROI for the direct assignment facilities (which are included in the Applicant Proposed Project) would occur within the Tennessee Converter Station Siting Area and more specifically within the Shelby Substation. The ROI for the network upgrades, and in particular TVA's future 500kV transmission line, cannot be fully determined at this time. The new 500kV line would be constructed in western Tennessee. The upgrades to existing facilities would mostly be in western and central Tennessee. The upgrades to existing facilities would mostly be in western and central Tennessee. Upgrades to existing infrastructure would include upgrading terminal equipment at three existing 500kV substations and six existing 161kV substations, making appropriate upgrades to increase heights on 16 existing

161kV transmission lines to increase line ratings, and replacing the conductors on eight existing 161kV transmission lines. Where applicable, general impacts associated with the required TVA upgrades are discussed in the impact sections that follow.

3.12.6 Impacts to Recreation

Comments related to recreation received during the scoping period indicate that the public is concerned about impacts to public lands designated for recreation, including national forests and parks, state forests and parks, Scenic Byways and Highways, and Extraordinary Resource Waters specifically regarding fishing, hunting, hiking, camping, and canoeing opportunities within all regions of the Project. The public also expressed concern about impacts to recreation on private lands and requested that the EIS examine the use of the transmission line easement areas for recreational activities.

3.12.6.1 Methodology

To identify potential impacts that may result from construction and operations and maintenance of the Project, the Applicant Proposed Route, HVDC route alternatives, the Oklahoma and Arkansas AC interconnection areas, and the AC collection system were analyzed based on a desktop review of existing recreational uses within a representative 200-foot-wide corridor—100 feet on either side of a representative centerline. Quantitative data regarding the resources directly intersected by the 200-foot-wide corridor, the representative ROW for the purposes of this analysis, were used to analyze the likely effects of the Project on recreation. For the converter stations, it was assumed that 45 to 60 acres would be required within the Oklahoma and Tennessee Converter Station Siting Areas, and 40 to 50 acres would be affected within the Arkansas converter station, although the exact locations have not yet been determined. Because the exact location of access roads, 45 multi-use construction yards (approximately 25 acres each), and other anticipated temporary construction areas and access roads have not yet been determined, these impacts were evaluated in a general qualitative way.

Although exact access road locations have not yet been determined, it has been assumed each converter station would have an access road 20 feet wide by up to 1 mile long (2 acres), with temporary disturbance up to 35 feet wide (4 acres total, 2 acres temporary and 2 permanent).

The Applicant has developed a comprehensive list of EPMs that would avoid and minimize impacts to recreation resources. Implementation of these EPMs is assumed throughout the impact analysis that follows for both the Applicant Proposed Project and the DOE Alternatives. A complete list of EPMs for the Project is provided in Appendix F; those EPMs that would specifically avoid or minimize impacts on recreation resources are listed below:

- GE-1: Clean Line will train personnel on health, safety, and environmental matters. Training will include practices, techniques, and protocols required by federal and state regulations and applicable permits.
- GE-6: Clean Line will restrict vehicular travel to the ROW and other established areas within the construction, access, or maintenance easement(s).
- GE-7: Roads not otherwise needed for maintenance and operations will be restored to preconstruction conditions. Restoration practices may include decompacting, recontouring, and re-seeding. Roads needed for maintenance and operations will be retained.
- GE-8: Access controls (e.g., cattle guards, fences, gates) will be installed, maintained, repaired, replaced, or restored as required by regulation, road authority, or as agreed to by landowner.

- GE-23: Clean Line will maximize the distance between stationary equipment and sensitive noise receptors consistent with engineering design criteria.
- GE-24: Clean Line will minimize the number and distance of travel routes for construction equipment near sensitive noise receptors.
- GE-26: When needed, Clean Line will use guard structures, barriers, flaggers, and other traffic controls to minimize traffic delays and road closures.
- LU-1: Clean Line will work with landowners and operators to ensure that access is maintained as needed to existing operations (e.g., to oil/gas wells, private lands, agricultural areas, pastures, hunting leases).
- LU-2: Clean Line will minimize the frequency and duration of road closures.
- LU-4: Clean Line will coordinate with landowners to site access roads and temporary construction areas to avoid and/or minimize impacts to existing operations and structures
- LU-5: Clean Line will make reasonable efforts, consistent with design criteria, to accommodate requests from individual landowners to adjust the siting of the ROW on their properties. These adjustments may include consideration of routes along or parallel to existing divisions of land (e.g., agricultural fields and parcel boundaries) and existing compatible linear infrastructure (e.g., roads, transmission lines, and pipelines), with the intent of reducing the impact of the ROW on private properties.
- FVW-1: Clean Line will identify environmentally sensitive vegetation (e.g., wetlands, protected plant species, riparian areas, large contiguous tracts of native prairie) and avoid and/or minimize impacts to these areas.
- FVW-3: Clean Line will clearly demarcate boundaries of environmentally sensitive areas during construction to increase visibility to construction crews.
- W-2: Clean Line will identify, avoid, and/or minimize adverse effects to wetlands and waterbodies. Clean Line will not place structure foundations within the Ordinary High Water Mark of Waters of the United States.
- W-6: Clean Line will not construct counterpoise or fiber optic cable trenches across waterbodies.

Impacts to recreation on non-designated private property is not quantifiable because no land designations, regulations, or use data exist. In addition, any public recreation on private lands is likely either allowed or not allowed by the landowner and considered an unauthorized use. Dispersed recreation on private land by the landowners and their acquaintances is likely widespread in all regions of the Project and more prevalent among landowners who have large acreages. It is difficult to pinpoint these types of uses and frequencies, although general recreation use of private land is confirmed through the public comments on the Draft EIS.

In general, impacts to recreation use on private lands would be temporary in nature and limited to noise and heightened activity during construction. Users displaced as a result of construction of the Project may be able to recreate on another portion of their property. Once the Project is in operation, no impacts to recreation, including hunting and fishing, are expected from the Project. During construction, the Applicant will use EPMs listed above to help reduce impacts to recreation. In some cases, these EPMs may even benefit local recreational users of private lands.

For example, an access road may be used by landowners to better access portions of their property, which could open up new areas to recreation or improve access to existing areas. It is expected that the landowner and the Applicant would work together to site access roads, and the transmission line may be microsited to alleviate impacts to some recreational resources; however, these would occur on a case-by-case basis.

3.12.6.2 Impacts Associated with the Applicant Proposed Project

This section describes the potential impacts from the Project that would be common to the converter stations, AC interconnection siting areas, AC collection system, and Applicant Proposed Route that are a part of the Applicant Proposed Project. Impacts from the construction, operations and maintenance, and decommissioning of the Project are discussed separately by Project component.

3.12.6.2.1 Converter Stations and AC Interconnection Siting Areas

3.12.6.2.1.1 Construction Impacts

Impacts to recreation resources are not expected from construction of the Project converter stations, AC interconnection siting areas, and interconnection ties and would not impact any recreation resources because no recreational resources are located in these areas.

3.12.6.2.1.2 Operations and Maintenance Impacts

No impacts to recreation resources are expected from operations and maintenance of the Converter Stations or associated AC interconnections because no recreation resources are located within these areas.

3.12.6.2.1.3 Decommissioning Impacts

No impacts to recreation resources are expected from decommissioning of the converter stations or AC interconnections because no recreation resources are located within these areas.

3.12.6.2.2 AC Collection System

This section discusses the data reviewed within the 200-foot-wide representative ROWs of the AC collection system.

3.12.6.2.2.1 Construction Impacts

Construction of the AC collection system is not expected to permanently preclude the use of or access to any existing recreation areas or activities since no recreation resources have been identified within the representative ROW for any AC collection system routes. No impacts to recreation resources are anticipated from construction of AC Collection System Routes E-1, E-2, E-3, NE-1, NE-2, NW-1, NW-2, SE-1, SE-2, SW-1, SW-2, and W-1 because no recreation resources are located within the representative ROW.

Three of the AC Collection System Routes are located in close proximity to recreation resources. The southern boundaries of the Optima NWR and the Optima WMA are located to the north of AC Collection System Route E-1. At the closest point, the Optima NWR and the Optima WMA are approximately 1,500 feet from this route, and about 1.5 miles from the Optima lake shoreline, which is within the NWR and WMA areas. The boundaries of the Schultz Lake State Park and Schultz WMA are located to the north of AC Collection System Route SE-1. At the closest point, the Schultz Lake State Park and Schultz WMA are approximately 0.5 mile from the alternative. The boundary of Shorb WMA is located approximately 0.16 miles to the north of the AC Collection System Route SE-3 and E-2.

Long-term indirect impacts would result from vegetation clearing and structure erection and could have impacts on recreational visitors due to changes in the scenic landscapes provided by the Optima NWR and Optima WMR the Schultz Lake State Park and Schultz WMA, and Shorb WMA. Operations and Maintenance Impacts

No impacts to recreation resources are anticipated from operations and maintenance of any of the AC collection system routes because no recreation resources are located within the representative ROW.

3.12.6.2.2.2 Decommissioning Impacts

Potential impacts during decommissioning of the Project would be similar to those of the construction phase for all Project components. Once the decommissioning has been completed, all land would return to the preconstruction recreational land uses.

3.12.6.2.3 HVDC Applicant Proposed Route

This section identifies the potential impacts from the Applicant Proposed Route on recreation based on the three phases of the Project: construction, operations and maintenance, and decommissioning. The Applicant would conduct each phase in compliance with applicable state and federal laws, regulations, and permits related to environmental protection. Specific EPMs developed to avoid and minimize impacts are described in Section 3.12.6.1. Changes to impacts due to route variations and adjustments developed in response to public comments on the Draft EIS are described at the end of applicable sections.

3.12.6.2.3.1 Construction Impacts

This section describes the potential impacts to recreation during the construction phase of the Project within the 200-foot-wide representative ROWs of the Applicant Proposed Route.

Construction of the Project is not expected to permanently preclude the use of or access to any existing recreation areas or activities; however, some direct short-term impacts to these resources, such as noise, visual disturbance, or restricted access may diminish the quality of a recreational visit. The Applicant expects the duration of construction in each 140-mile segment to be approximately 24 months from mobilization of equipment to site restoration; however, construction at a discrete site would be shorter in duration. The duration of disturbance at any one location along a segment would be less, with the length of disturbance affected by the land use and progress of the individual work crews. Recreational areas are typically more popular on the weekends and during the summer, and since construction activities would be scheduled Monday through Saturday, recreationists would generally be most affected on Saturdays and during the summer months when the recreational lands in the Project regions commonly experience the most use. In most regions of the Project, alternate recreation areas can be found, including private or public land with similar habitat conditions, and hunting seasons vary depending upon each state department of wildlife.

Hunting and wildlife viewing opportunities could be temporarily impacted by the Project if wildlife species are displaced from areas near construction activities to suitable habitats adjacent to, but beyond the extent of, construction disturbances. Alternately, some wildlife may be temporarily attracted to cleared areas due to an increased availability of food. In such areas, food resources, such as nuts and seeds, left on the ground can be easily found by wildlife. Such displacement could improve hunting and wildlife viewing opportunities in some areas for a short period of time following clearing activities. These impacts would be limited to the immediate area of construction activity and would be short term in nature and, in some areas, may be mitigated by vegetation that is outside the ROW and not subject to clearing. Vegetation outside of the ROW may provide visual and noise screening to the affected areas within the ROW.

Direct long-term impacts would result from vegetation clearing and structure erection. The transmission structures could have impacts on scenic landscapes by reducing the quality of the natural or rural landscapes. The extent of these impacts would, however, depend on existing visual conditions in the affected areas, with impacts lower in those areas where high-voltage transmission lines and other types of development are already present. Impacts would also vary based on the distance of the recreation area from the proposed transmission line. Potential effects would tend to be greater in locations where the Project would be visible on the horizon. Site-specific visual impacts are evaluated in detail in Section 3.18.

The sections below describe the recreation resources that would be affected within each region of the Applicant Proposed Route.

3.12.6.2.3.1.1 Region 1 and Region 2

Applicant Proposed Route Link 5 in Region 1 near May, Oklahoma, and Link 3 in Region 2, near Enid, Oklahoma, would cross the Chisholm and Great Western Trail, which is proposed for inclusion in the National Historic Trail system. Applicant Proposed Route Link 2 in Region 1, southeast of Hardesty, Oklahoma would be located south and adjacent to the Shorb WMA. Locations mapped by the NPS are representative of the historical location of the trail, but the extent of the trail at each crossing location is not known. These impacts would be direct and temporary, similar to those described for construction in Section 3.12.6.

Construction of the Applicant Proposed Route is not expected to permanently preclude the use of or access to any existing recreation areas or activities related to the Chisholm and Great Western Trail and Shorb WMA; however, some direct short-term impacts to these resources, such as noise, visual disturbance, or restricted access, would likely diminish the quality of a recreational visit. These impacts would be limited to the immediate area of construction activity and would be short term in nature and, in some areas, may be mitigated by vegetation that is outside the ROW and not subject to clearing. Vegetation outside the ROW may provide visual and noise screening to the affected areas within the ROW.

No route variations were proposed in Region 1. Two route variations to the Applicant Proposed Route in Region 2 were developed in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.2. The variations are illustrated in Exhibit 1 of Appendix M. These variations represent minor adjustments to the Applicant Proposed Route, and they would not cross any additional designated recreation areas or remove crossing locations from those described for the original Applicant Proposed Route.

3.12.6.2.3.1.2 Region 3

The Applicant Proposed Route could potentially impact 4 acres of the Webbers Falls Lock and Dam Reservoir lands in Link 6 if the Project is routed on the representative centerline. The tensioning areas associated with the Applicant Proposed Route could potentially impact 1 acre of Webbers Falls Lock and Dam Reservoir lands and would have similar construction impacts. Short-term direct impacts during construction may include noise and visual disturbance, which could diminish the quality of a recreational visit.

The Webbers Falls Lock and Dam Reservoir is crossed by the Applicant Proposed Route in Region 3 and is also crossed by several existing transmission lines:

- Gore to Weleetka 161kV

- Gore to Webbers Falls 115kV
- Eufaula to Gore 138kV
- Muskogee to Pittsburg 345kV

Applicant Proposed Route Link 4 would cross Historic Route 66 near Bristow, Oklahoma. Tensioning areas associated with Applicant Proposed Route Links 3 and 4 would be located adjacent to the Historic Route 66 crossings, and construction equipment may be located next to the roadway during construction. Short-term direct impacts during construction may include visual disturbance, which could diminish the visual quality of driving along the historic route. It is not anticipated that traffic flow would be restricted during construction.

Five route variations to the Applicant Proposed Route were developed in Region 3 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.3. The variations are illustrated in Exhibit 1 of Appendix M. These variations represent minor adjustments to the Applicant Proposed Route, and they would not cross any additional designated recreation areas or remove crossing locations from those described for the original Applicant Proposed Route. It should be noted that a route adjustment was made for HVDC Alternative Route 3-A to maintain an end-to-end route with the Links 1 and 2 variations.

3.12.6.2.3.1.3 Region 4

The Applicant Proposed Route could potentially impact 2 acres of the Ozark Lake WMA, 4 acres of the Frog Bayou WMA, 2 acres of the Ozark National Forest, two Arkansas State Scenic Byways, and two Arkansas State Scenic Highways. The Applicant Proposed Route in Region 4, Link 1, could potentially impact 17 acres of the Webbers Falls Lock and Dam Reservoir lands. There is no HVDC alternative route to this link of the Applicant Proposed Route. The tensioning areas associated with the Applicant Proposed Route could potentially impact less than 0.1 acre of Webbers Falls Lock and Dam Reservoir lands and 4 acres of the Frog Bayou WMA.

The Mulberry River and Big Piney Creek are designated as an Arkansas Natural and Scenic Rivers where they are crossed by Applicant Proposed Route Link 6. Applicant Proposed Route Link 3 (the Lee Creek Variation) would cross a section of Lee Creek that is designated on the NRI. Applicant Proposed Route Link 9 would cross a section of the Piney Creek that is designated on the NRI. The rivers would likely be spanned.

Applicant Proposed Route Links 1, 5, 6, and 8 would cross the Trail of Tears National Historic Trail. Tensioning areas associated with the Applicant Proposed Route Links 6 and 8 would be located adjacent to the Trail of Tears crossing and construction equipment may be located near the trail during construction. Applicant Proposed Route Link 1 would cross the Cherokee Hills Scenic Byway. The Trail of Tears locations mapped by the NPS are representative of the historic location of the trail and the extent of the trail at each crossing location is not known. These impacts would be direct and temporary impacts as defined in Section 3.12.6.2.

The Applicant Proposed Route would cross Arkansas State Scenic Highway 59, Arkansas State Scenic Highway Interstate-40, Arkansas State Scenic Byway 23/Pig Trail Scenic Byway, and Arkansas State Scenic Byway 21/Ozark Highlands Scenic Byway.

Construction of the Applicant Proposed Route is not expected to permanently preclude the use of or access to any existing recreation areas or activities; however, some direct short-term impacts to these resources, such as noise, visual disturbance, or restricted access, would likely diminish the quality of a recreational visit. These impacts would be limited to the immediate area of construction activity and would be short term in nature and, in some areas, may be mitigated by vegetation that is outside the ROW and not subject to clearing. Vegetation outside of the ROW may provide visual and noise screening to the affected areas within the ROW.

Long-term direct impacts to Ozark Lake WMA, Frog Bayou WMA, the Mulberry River, and the Big Piney Creek would result from vegetation clearing and structure erection. The Webbers Falls Lock and Dam Reservoir is crossed by the Applicant Proposed Route in Region 3 and is also crossed by several existing transmission lines:

- Gore to Weleetka 161kV
- Gore to Webbers Falls 115kV
- Eufaula to Gore 138kV
- Muskogee to Pittsburg 345kV

Seven route variations to the Applicant Proposed Route were developed in Region 4 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.4. The variations are illustrated in Exhibit 1 of Appendix M. In general, these variations represent minor adjustments to the Applicant Proposed Route, and they would not cross any additional designated recreation areas or remove crossing locations from those described for the original Applicant Proposed Route. The only exception is Applicant Proposed Route Link 6, Variation 3, which would cross the Trail of Tears National Historic Trail at a new location. The potential impacts for this variation are expected to be the same as those described for the original Applicant Proposed Route.

3.12.6.2.3.1.4 Region 5

The Applicant Proposed Route could potentially impact 77 acres of the Cherokee WMA and cross several Arkansas Scenic Highways and Byways. The tensioning areas associated with the Applicant Proposed Route could potentially impact 6 acres of the Cherokee WMA. The boundary of the Rainey WMA would be approximately 0.25 miles northeast of the Applicant Proposed Route. Applicant Proposed Route Link 1 would cross the Arkansas Scenic 7 Byway and would span the road. Applicant Proposed Route Link 4 would cross a section of the Cadron Creek listed on the NRI. The rivers would likely be spanned and structures would not be placed within the riparian zones. The Applicant proposed Route would cross the following Arkansas Scenic Highways:

- State Scenic Highway 27
- State Scenic Highway 9
- State Scenic Highway 65
- State Scenic Highway 25
- State Scenic Highway 5
- State Scenic Highway 16

The Cherokee WMA in Region 5 is used for hunting. Hunting opportunities could be temporarily disturbed by the Applicant Proposed Route if wildlife species are displaced from areas near construction activities to suitable habitats adjacent to, but beyond the extent of, construction disturbances. These impacts would be limited to the immediate area of construction activity and would be short term in nature and, in some areas, may be mitigated by vegetation that is outside the ROW and not subject to clearing.

Five route variations to the Applicant Proposed Route were developed in Region 5 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.5. The variations are illustrated in Exhibit 1 of Appendix M. These variations represent minor adjustments to the Applicant Proposed Route, and they would not cross any additional designated recreation areas or remove crossing locations from those described for the original Applicant Proposed Route.

3.12.6.2.3.1.5 Region 6

The Applicant Proposed Route could potentially impact approximately 1 acre of the Singer Forest Natural Area/St. Francis Sunken Lands. The Applicant Proposed Route Link 6 would cross Crowley's Ridge Parkway National Scenic Byway. The Applicant Proposed Route Link 6 would also cross a section of the L'Anguille River listed on the NRI; the transmission line would likely span the river. No tensioning areas that are associated with the Applicant Proposed Route would affect any recreation resources.

The Singer Forest Natural Area/St. Francis Sunken Lands WMA is used for hunting. Hunting opportunities could be temporarily disturbed by the Applicant Proposed Route if wildlife species are displaced from areas near construction activities to suitable habitats adjacent to, but beyond the extent of, construction disturbances. These impacts would be limited to the immediate area of construction activity and would be short term in nature and, in some areas, may be mitigated by vegetation that is outside the ROW and not subject to clearing.

One route variation was developed in Region 6 in response to public comments on the Draft EIS and is shown in Exhibit 1 of Appendix M. This variation represents a minor adjustment to the Applicant Proposed Route, and it would not cross any additional designated recreation areas or remove crossing locations from those described for the original Applicant Proposed Route. It should be noted that a route adjustment was made for HVDC Alternative Route 6-A to maintain an end-to-end route with this variation.

3.12.6.2.3.1.6 Region 7

The Applicant Proposed Route would cross the Great River Road National Scenic Byway at two points, the Trail of Tears National Historic Trail, and Arkansas Scenic Highway 63. The Project is expected to span both the byway and the trail. No tensioning areas that are associated with the Applicant Proposed Route would affect any recreation resources.

Recreation opportunities could be temporarily impacted by the Applicant Proposed Route if construction was visible from the Great River Road and the Trail of Tears. The recreational experience for the Great River Road and Trail of Tears is based in part on the scenic views from these resources and may be impacted by visible construction activities and vegetation clearing. Visual resources are discussed in more detail in section 3.18. The Trail of Tears locations mapped by the NPS are representative of the historic location of the trail and the extent of the trail at each crossing location is not known. These impacts would be limited to the immediate area of construction activity and would be short term in nature and, in some areas, may be mitigated by vegetation that is outside the ROW and not subject to clearing. Long-term direct impacts to the Great River Road and the Trail of Tears would result from vegetation clearing and structure erection and may diminish the recreational experience if visible from the road or trail.

Three route variations to the Applicant Proposed Route were developed in Region 7 in response to public comments on the Draft EIS. The route variations are illustrated in Exhibit 1 of Appendix M and summarized in Section 2.4.2.7.

These variations represent minor adjustments to the Applicant Proposed Route, and they would not cross any additional designated recreation areas or remove crossing locations from those described for the original Applicant Proposed Route.

3.12.6.2.3.2 Operations and Maintenance Impacts

Operation and maintenance activities for facilities would be similar to activities during construction but generally smaller in scale, more localized, and shorter in duration.

The Applicant Proposed Route is not expected to permanently preclude the use of or access to any existing recreation areas or activities; however, some direct short-term impacts to these resources, such as noise, visual disturbance, or restricted access, would likely diminish the quality of a recreational visit.

3.12.6.2.3.3 Decommissioning Impacts

Potential impacts during decommissioning of the Project would be similar to those of the construction phase for all Project components, except they would last a shorter duration of time. Once the decommissioning is complete, all land would return to the preconstruction recreational land uses.

3.12.6.3 Impacts Associated with the DOE Alternatives

The impacts discussed in the sections below are common to all aspects of the DOE Alternatives, which include the Arkansas Converter Station Alternative Siting Area and AC Interconnection Siting Area, including the new substation at the interconnection point, the HVDC alternative routes, access roads, multi-use construction yards and other temporary construction areas, and communications sites.

3.12.6.3.1 Arkansas Converter Station Alternative Siting Area and AC Interconnection Siting Area

3.12.6.3.1.1 Construction Impacts

Impacts to recreation resources are not expected from construction of the Project converter station and AC interconnection siting areas, including the new substation at the interconnection point. Construction would not impact any recreation resources because no recreational resources exist in these areas.

3.12.6.3.1.2 Operations and Maintenance Impacts

Impacts to recreation resources are not expected from operations and maintenance of the Project converter station and AC interconnection siting areas, including the new substation at the interconnection point in Arkansas. Operations and maintenance would not impact any recreation resources because no recreational resources exist in these areas.

3.12.6.3.1.3 Decommissioning Impacts

Impacts to recreation resources are not expected from decommissioning of the Project converter station and AC interconnection siting areas, including the new substation at the interconnection point. Decommissioning would not impact any recreation resources because no recreational resources exist in these areas.

3.12.6.3.2 HVDC Alternative Routes

This section discusses the potential impacts within the 200-foot-wide representative ROWs of the HVDC alternative routes during the construction, operations and maintenance, and decommissioning phases of the Project.

3.12.6.3.2.1 Construction Impacts

Construction impacts from the HVDC alternative routes would be the same as impacts from the HVDC Applicant Proposed Route and are described in Section 3.12.6.2.3. The sections below describe the recreation resources that would be affected within each HVDC alternative route.

3.12.6.3.2.1.1 Region 1 and Region 2

HVDC Alternative Route 1-A in Region 1 near May, Oklahoma, and HVDC Alternative Route 2-B in Region 2, near Enid, Oklahoma, would cross the Chisholm and Great Western Trail, which is proposed to be part of the National Historic Trail system. Locations mapped by the NPS are representative of the historical location of the trails, but the extent of the trails at each crossing location is not known. These impacts would be direct and temporary similar to those described for construction in Section 3.12.6.

Construction of the HVDC alternative routes is not expected to permanently preclude the use of or access to any existing recreation areas or activities related to Chisholm and Great Western Trails; however, some direct short-term impacts to these resources, such as noise, visual disturbance, or restricted access, would likely diminish the quality of a recreational visit. These impacts are expected to be limited to the immediate area of construction activity and would be short term in nature and, in some areas, may be mitigated by vegetation that is outside the ROW and not subject to clearing. Vegetation outside of the ROW may provide visual and noise screening to the affected areas within the ROW.

3.12.6.3.2.1.2 Region 3

3.12.6.3.2.1.2.1 Alternative Route 3-A

HVDC Alternative Route 3-A could potentially impact 22 acres of the OSU-owned and -managed Lake Carl Blackwell if the Project is routed on the representative centerline. The tensioning areas associated with the HVDC Alternative Route 3-A could potentially impact 0.2 acre of Lake Carl Blackwell. HVDC Alternative Route 3-A and tensioning areas associated with HVDC Alternative Route 3-A crosses Historic Route 66 southwest of Bristow, Oklahoma. Corresponding Applicant Proposed Route Link 1 would not have impacts to recreation resources because no recreation resources are located in the representative ROW.

As described for the Applicant Proposed Route in Region 3, hunting opportunities could be temporarily impacted by construction of HVDC Alternative Route 3-A if wildlife species are displaced from areas near construction activities to suitable habitats adjacent to, but beyond the extent of, construction disturbances as described in Section 3.12.6.2.3.1. Views from Route 66 may also be affected from construction of the Project; however, Route 66 would likely be spanned.

As described in Appendix M and summarized in Section 2.4.2.3, a route adjustment was developed for HVDC Alternative Route 3-A to maintain an end-to-end route with Applicant Proposed Route Link 1, Variation 2, and Links 1 and 2, Variation 1. This route adjustment represents minor adjustments to the original HVDC alternative route, and it would not cross any additional designated recreation areas or remove crossing locations from those described for the original HVDC alternative route.

3.12.6.3.2.1.2.2 Alternative Route 3-B

HVDC Alternative Route 3-B could potentially impact 22 acres of the OSU-owned and -managed Lake Carl Blackwell if the Project is routed on the representative centerline. The tensioning areas associated with HVDC Alternative Route 3-B could potentially impact 0.2 acre of Lake Carl Blackwell and would have similar construction impacts as described for the HVDC Alternative Route 3-A. The corresponding Applicant Proposed Route Links 1, 2, and 3 have no impacts to recreation resources because no recreation resources are located in the representative ROW.

Hunting opportunities could be temporarily impacted by HVDC Alternative Route 3-B if wildlife species are displaced from areas near construction activities to suitable habitats adjacent to, but beyond the extent of, construction disturbances as described in Section 3.12.6.2.3. These impacts would be limited to the immediate area of construction activity and would be short term in nature and, in some areas, may be mitigated by vegetation that is outside the ROW and not subject to clearing.

3.12.6.3.2.1.2.3 Alternative Route 3-C

HVDC Alternative Route 3-C could potentially impact 1 acre of the Webbers Falls Lock and Dam Reservoir land, while corresponding Applicant Proposed Route Links 3, 4, 5, and 6 would impact 4 acres of Webbers Falls Lock and Dam. No tensioning areas are associated with HVDC Alternative Route 3-C. Short term impacts during construction may include noise and visual disturbance which could diminish the quality of a recreational visit.

3.12.6.3.2.1.2.4 Alternative Route 3-D

HVDC Alternative Route 3-D could potentially impact 1 acre of the Webbers Falls Lock and Dam Reservoir land if the Project is routed on the representative centerline, while corresponding Applicant Proposed Route Links 5 and 6 would affect 4 acres of Webbers Falls Lock and Dam. No tensioning areas are associated with the HVDC Alternative Route 3-D. Short term impacts during construction may include noise and visual disturbance which could diminish the quality of a recreational visit.

The Webbers Falls Lock and Dam Reservoir is crossed by Alternative Route 3-D in Region 3 and is also crossed by several existing transmission lines:

- Gore to Weleetka 161kV
- Gore to Webbers Falls 115kV
- Eufaula to Gore 138kV
- Muskogee to Pittsburg 345kV

3.12.6.3.2.1.2.5 Alternative Route 3-E

HVDC Alternative Route 3-E could potentially impact 1 acre of the Webbers Falls Lock and Dam Reservoir land if the Project is routed on the representative centerline, while corresponding Applicant Proposed Route Links 5 and 6 would affect 4 acres of Webbers Falls Lock and Dam. No tensioning areas are associated with HVDC Alternative Route 3-E; tensioning areas associated with Applicant Proposed Route Links 5 and 6 would affect 1 acre of Webbers Falls Lock and Dam. Short term impacts during construction may include noise and visual disturbance which could diminish the quality of a recreational visit.

3.12.6.3.2.1.3 Region 4

3.12.6.3.2.1.3.1 Alternative Route 4-A

HVDC Alternative Route 4-A would cross a section of the Mulberry River designated as Arkansas Natural and Scenic Rivers System by crossing the river near Clarksville, Arkansas. HVDC Alternative Route 4-A would cross a section of the Little Lee Creek designated as an Arkansas Natural and Scenic Rivers System by crossing the river near the Arkansas and Oklahoma state line. HVDC Alternative Route 4-A would cross a section of the Lee Creek designated on the NRI. The rivers would likely be spanned and structures would not be placed within the riparian zones.

HVDC Alternative Route 4-A would cross the Trail of Tears National Historic Trail in two places. HVDC Alternative Route 4-A would cross State Scenic Highway 220 and State Scenic Byway 540 (Boston Mountains Scenic Loop).

Corresponding Applicant Proposed Route Links 3, 4, 5, and 6 would affect 2 acres of the Ozark Lake WMA and 4 acres of the Frog Bayou WMA. Tensioning areas associated with Applicant Proposed Route Links 3, 4, 5, and 6 would affect 4 acres of the Frog Bayou WMA and cross the NRI segment of Lee Creek. Short term impacts during construction may include noise and visual disturbance which could diminish the quality of a recreational visit.

3.12.6.3.2.1.3.2 Alternative Route 4-B

HVDC Alternative Route 4-B could potentially impact 230 acres of the Ozark National Forest and Ozark National Forest WMA if HVDC Alternative Route 4-B is routed on the representative centerline. Within the Ozark National Forest, approximately 102 acres are federal (public) land and approximately 157 acres are private inholdings. Recreation is most likely to occur on the federal portion of the Ozark National Forest; however, private landowners may allow hunting or other recreation within their lands.

HVDC Alternative Route 4-B would cross a section of the Mulberry River designated as Arkansas Natural and Scenic Rivers System by crossing the river near Clarksville, Arkansas. HVDC Alternative Route 4-B could potentially impact the sections of the Little Lee Creek designated as Arkansas Natural and Scenic Rivers System by crossing the river near the Arkansas and Oklahoma state line. HVDC Alternative Route 4-B would cross three sections of the Lee Creek that are designated on the NRI. The rivers would be spanned and structures would not be placed within the riparian zones. Tensioning areas would be located adjacent to the Mulberry River crossing location for HVDC Alternative Route 4-B.

HVDC Alternative Route 4-B would cross the Trail of Tears National Historic Trail in two places. HVDC Alternative Route 4-B would cross State Scenic Highway 220, and State Scenic Byway 23 (Pig Trail Scenic Byway). The Trail of Tears locations mapped by the NPS are representative of the historic location of the trail and the extent of the trail at each crossing location is not known.

Short term impacts during construction may include noise and visual disturbance which could diminish the quality of a recreational visit.

Corresponding Applicant Proposed Route Links 2, 3, 4, 5, 6, 7 and 8 would affect 2 acres of the Ozark Lake WMA and 4 acres of the Frog Bayou WMA and would cross Lee Creek. Tensioning areas associated with Applicant Proposed Route Links 2, 3, 4, 5, 6, 7, and 8 would affect 4 acres of the Frog Bayou WMA. There are no specific recreation areas, such as boat launches, campgrounds, or shooting ranges, that are located in HVDC Alternative Route 4-B.

3.12.6.3.2.1.3.3 Alternative Route 4-C

HVDC Alternative Route 4-C would cross the Trail of Tears and would span the trail. The Trail of Tears locations mapped by the NPS are representative of the historic location of the trail and the extent of the trail at each crossing location is not known. Alternative Route 4-C would cross State Scenic Highway 59. Short term impacts during construction may include noise and visual disturbance which could diminish the quality of a recreational visit. No impacts to recreational lands or uses are anticipated from construction of corresponding Applicant Proposed Route Link 5 because no recreation resources are located within the representative ROW.

3.12.6.3.2.1.3.4 Alternative Route 4-D

HVDC Alternative Route 4-D could potentially impact the sections of the Mulberry River designated as Arkansas Natural and Scenic Rivers System by crossing the river near Clarksville, Arkansas. The river would likely be spanned and structures would not be placed within the riparian zones. HVDC Alternative Route 4-D would cross the Trail of Tears in two places and would span the trail. The Trail of Tears locations mapped by the NPS are representative of the historic location of the trail and the extent of the trail at each crossing location is not known. HVDC Alternative Route 4-D would cross State Scenic Highway 59 and State Scenic Highway U.S. Highway 71. Short term impacts during construction may include noise and visual disturbance which could diminish the quality of a recreational visit. The construction of corresponding Applicant Proposed Route Links 4, 5, and 6 would affect 2 acres of the Ozark Lake WMA and 4 acres of the Frog Bayou WMA, and tensioning areas associated with these same links would affect 4 acres of the Frog Bayou WMA.

3.12.6.3.2.1.3.5 Alternative Route 4-E

HVDC Alternative Route 4-E could potentially impact the Big Piney Creek listed on the NRI by crossing the river near Clarksville, Arkansas. The river would likely be spanned and structures would not be placed within the riparian zones. HVDC Alternative Route 4-E would cross the Trail of Tears and would span the trail. Tensioning areas associated with HVDC Alternative Route 4-E would be adjacent to the Trail of Tears crossing and construction equipment may be located adjacent to the trail. The Trail of Tears locations mapped by the NPS are representative of the historic location of the trail and the extent of the trail at each crossing location is not known.

HVDC Alternative Route 4-E would cross State Scenic Highway Interstate-40 and State Scenic Byway 21 (Ozark Highlands Scenic Byway). Short term impacts during construction may include noise and visual disturbance which could diminish the quality of a recreational visit. No impacts to recreational lands or uses are anticipated from construction of corresponding Applicant Proposed Route Link 5 because no recreation resources are located within the representative ROW.

3.12.6.3.2.1.4 Region 5

3.12.6.3.2.1.4.1 Alternative Route 5-A

HVDC Alternative Route 5-A and tensioning areas associated with HVDC Alternative Route 5-A would cross the Arkansas Scenic 7 Byway. HVDC Alternative 5-A would cross State Scenic Byway 7 (Arkansas Scenic 7 Byway) and State Scenic Highway 27. Short term impacts during construction may include noise and visual disturbance which could diminish the quality of a recreational visit. No impacts to recreational lands or uses are anticipated from construction of corresponding Applicant Proposed Route Link 1 because no recreation resources are located within the representative ROW.

3.12.6.3.2.1.4.2 Alternative Route 5-B

HVDC Alternative Route 5-B would cross two sections of the Cadron Creek listed on the NRI. HVDC Alternative Route 5-B would cross the following Arkansas State Scenic Highways: State Highway 9, U.S. Highway 65, State Highway 5 and State Highway 16. Short term impacts during construction may include noise and visual disturbance which could diminish the quality of a recreational visit. All features are expected to be spanned. No impacts to recreational lands or uses are anticipated from construction of corresponding Applicant Proposed Route Links 3, 4, 5, and 6 because no recreation resources are located within the representative ROWs.

As described in Appendix M and summarized in Section 2.4.2.4, a route adjustment was developed for HVDC Alternative Route 5-B to maintain an end-to-end route with Applicant Proposed Route Links 2 and 3, Variation 1. In general, these variations represent minor adjustments to the HVDC Alternative Route, and they would not cross any additional designated recreation areas or remove crossing locations from those described for the original HVDC alternative route. The only exception is Applicant Proposed Route Links 2 and 3, Variation 1, which would cross Cadron Creek at a new location. The potential impacts for this variation are expected to be the same as those described for the original HVDC alternative route.

3.12.6.3.2.1.4.3 Alternative Route 5-C

HVDC Alternative Route 5-C would cross State Scenic Highway 16 and would span the road. Short term impacts during construction may include noise and visual disturbance which could diminish the quality of a recreational visit. No impacts to recreational lands or uses are anticipated from construction of corresponding Applicant Proposed Route Links 6 and 7 because no recreation resources are located within the representative ROWs.

3.12.6.3.2.1.4.4 Alternative Route 5-D

No impacts to recreational lands or uses are anticipated from construction of HVDC Alternative Route 5-D because no recreational resources are located within the representative ROW. Likewise, no impacts to recreational lands or uses are anticipated from construction of corresponding Applicant Proposed Route Link 9 because no recreation resources are located within the representative ROW.

3.12.6.3.2.1.4.5 Alternative Route 5-E

HVDC Alternative Route 5-E would cross two sections of the Cadron Creek listed on the NRI, and State Scenic Highway 25, all are expected to be spanned. No impacts to recreational lands or uses are anticipated from construction of corresponding Applicant Proposed Route Links 4, 5, and 6 because no recreation resources are located within the representative ROWs.

As described in Appendix M and summarized in Section 2.4.2.5, a route adjustment was developed for HVDC Alternative Route 5-E in response to public comments on the Draft EIS to maintain continuity with Applicant Proposed Route Links 3 and 4, Variation 2. In general, these variations represent minor adjustments to the HVDC alternative route, and they would not cross any additional designated recreation areas or remove crossing locations from those described for the original HVDC alternative route. The only exception is Applicant Proposed Route Links 3 and 4, Variation 2, which would cross Cadron Creek at a new location. The potential impacts for this variation are expected to be the same as those described for the original HVDC alternative Route.

3.12.6.3.2.1.4.6 Alternative Route 5-F

HVDC Alternative Route 5-F would cross a section of the Cadron Creek listed on the NRI, and is expected to be spanned. Short term impacts during construction may include noise and visual disturbance which could diminish the quality of a recreational visit. No impacts to recreational lands or uses are anticipated from construction of corresponding Applicant Proposed Route Links 5 and 6 because no recreation resources are located within the representative ROWs.

3.12.6.3.2.1.5 Region 6

3.12.6.3.2.1.5.1 Alternative Route 6-A

No impacts to recreational lands or uses are anticipated from construction of HVDC Alternative Route 6-A because no recreation resources are located within the representative ROW. Likewise, no impacts to recreational lands or uses are anticipated from construction of corresponding Applicant Proposed Route Links 2, 3, and 4 because no recreation resources are located within the representative ROWs.

As described in Appendix M and summarized in Section 2.4.2.6, a route adjustment was developed for HVDC Alternative Route 6-A to maintain an end-to-end route with Applicant Proposed Route Link 2, Variation 1. The route adjustment would not cross any additional designated recreation areas, nor would it remove crossing locations from what is described for the original HVDC alternative route. The route adjustment is illustrated in Exhibit 1 of Appendix M.

3.12.6.3.2.1.5.2 Alternative Route 6-B

HVDC Alternative Route 6-B would cross Arkansas Scenic Highway 14 and is expected to span the road. Short-term impacts during construction may include noise and visual disturbance which could diminish the quality of a recreational visit. No impacts to recreational lands or uses are anticipated from construction of corresponding Applicant Proposed Route Link 3 because no recreation resources are located within the representative ROW.

3.12.6.3.2.1.5.3 Alternative Route 6-C

HVDC Alternative Route 6-C would cross the Crowley's Ridge Parkway National Scenic Byway and is expected to span the road. Short term impacts during construction may include noise and visual disturbance which could diminish the quality of a recreational visit. Corresponding Applicant Proposed Route Links 6 and 7 would affect 1 acre of the Singer Forest Natural Area/St. Francis Sunken

3.12.6.3.2.1.5.4 Alternative Route 6-D

No impacts to recreational lands or uses are anticipated from construction of HVDC Alternative Route 6-D because no recreational resources are located within the representative ROW. Likewise, no impacts to recreational lands or uses are anticipated from construction of corresponding Applicant Proposed Route Link 7 because no recreation resources are located within the representative ROW.

3.12.6.3.2.1.6 Region 7

3.12.6.3.2.1.6.1 Alternative Route 7-A

HVDC Alternative Route 7-A would cross State Scenic Highway 63 and Great River Road National Scenic Byway. Short term impacts during construction may include noise and visual disturbance which could diminish the quality of a recreational visit. No impacts to recreational lands or uses are anticipated from construction of corresponding Applicant Proposed Route Link 1 because no recreation resources are located within the representative ROW.

3.12.6.3.2.1.6.2 Alternative Route 7-B, 7-C, and 7-D

No impacts to recreational lands or uses are anticipated from construction of HVDC Alternative Routes 7-B, 7-C, and 7-D because no recreational resources are located within the representative ROW. Likewise, no impacts to recreational lands or uses are anticipated from construction of corresponding Applicant Proposed Route Links 3 and 4 (which correspond to Route 7-B) because no recreation resources are located within the representative ROWs. No impacts to recreational lands or uses are anticipated from construction of corresponding Applicant Proposed Route Links 3, 4, and 5 (which correspond to Route 7-C) because no recreation resources are located within the representative ROWs. No impacts to recreational lands or uses are anticipated from construction of corresponding Applicant Proposed Route Links 4 and 5 (which correspond to HVDC Alternative Route 7-D) because no recreation resources are located within the representative ROW.

3.12.6.3.2.2 Operations and Maintenance Impacts

Operation and maintenance impacts from the HVDC alternative routes are similar to those for construction; however, they would be shorter in duration and at a smaller scale as discussed in Section 3.12.6.2.3.

3.12.6.3.2.3 Decommissioning Impacts

Decommissioning of HVDC transmission lines, as with any of the HVDC alternative routes, would be expected to have impacts similar to those described in Section 3.12.6.1 for common construction activities.

3.12.6.4 Best Management Practices

The Applicant has developed a comprehensive list of EPMs as part of the Project to minimize impacts to recreation resources. No other BMPs are recommended; however, some of the impacts discussed in this section are unavoidable. A complete list of EPMs for the Project is provided in Appendix F; those EPMs that would specifically minimize the potential for impacts on recreation resources are summarized in Section 3.12.6.1.

3.12.6.5 Unavoidable Adverse Impacts

Unavoidable impacts include the potential loss or alteration of recreational land and recreational uses of public or private lands that are located within the transmission line ROW due to restriction of public access from structure locations. Following the completion of construction, access to the HVDC transmission line ROWs would resume consistent with access prior to construction; in some cases opening new areas within the ROW to recreational activities (e.g., hiking trails, hunting). Impacts to the setting of public recreational lands would be minimized by the EPMs, would be unavoidable and long-term, but would not be permanent in recreational areas that the Project crosses.

3.12.6.6 Irreversible and Irretrievable Commitment of Resources

All impacts related to recreational resources would cease with the end of the Project and would not be considered an irreversible or irretrievable commitment of resources.

3.12.6.7 Relationship between Local Short-term Uses and Long-term Productivity

Some direct short-term impacts to resources such as noise or visual disturbance, or restricted access to the recreation area during construction, would likely diminish the quality of a recreational visit. Long-term productivity of recreational areas could potentially decrease in recreational areas that were crossed by the Project.

3.12.6.8 Impacts from Connected Actions

3.12.6.8.1 Wind Energy Generation

The recreational lands within the WDZs may be affected by construction, operations and maintenance, and decommissioning of the Project. Indirect impacts to the visual setting would likely occur from construction, operations and maintenance, and decommissioning of wind facilities that would interconnect into the Project.

Recreational lands within the WDZs may experience short-term direct impacts during construction of wind projects. Noise, dust, and human activity, as well as vegetation clearing and turbine erection would cause short-term direct and indirect impacts to recreation. The quality of recreational activities such as sightseeing, fishing, hiking, bird watching, and wildlife viewing could be temporarily diminished due to construction noise and activity in the area and vegetation clearing. Recreation areas may also have long-term indirect visual impact from vegetation clearing (as needed) and the presence of turbines. The landscape in this region is flat with very few trees, which would make views of the wind turbines visible for a long distance.

Short-term direct impacts from construction-related noise and activity could be caused by the Project if wildlife species are displaced from areas near construction activities to suitable habitats adjacent to, but beyond the extent of, construction disturbances. Alternately, some wildlife may be temporarily attracted to cleared areas due to an increased availability of food. In such areas, food resources, such as nuts and seeds, left on the ground can be easily found by wildlife. Such displacement could improve hunting and wildlife viewing opportunities in some areas for a short period of time following clearing activities. After construction, operation of a wind project would not preclude hunting within the existing hunting boundaries or the wind farm boundary. Hunting is typically allowed on wind farms and public access is maintained. Access to hunting areas would likely not change as a result of developing a wind project; however, closures are possible during construction or maintenance for safety reasons. Noise and human activity could displace wildlife species from areas near construction activities to suitable habitats adjacent to, but beyond the extent of, construction disturbances. Such displacement could improve hunting and wildlife viewing opportunities in some areas while reducing or temporarily eliminating opportunities in other areas.

Local parks located in WDZ-A lie within municipal boundaries and are unlikely to experience impacts from wind development. Wind farms may be visible from local parks, causing long-term visual disturbance until after decommissioning of the wind farm.

Palo Duro Reservoir is popular for fishing, sight-seeing, and water sports and is located in WDZ-B. Direct impacts from construction, such as noise and activity, are unlikely to affect the Palo Duro Reservoir because wind facilities are typically located away from open water. The components of the wind farm could have long-term impacts on the quality of recreational visits to Palo Duro Reservoir by adding unnatural components to scenic landscapes. The extent of these impacts would, however, depend on existing visual conditions in the affected areas, with impacts lower in those areas where other types of development are already present. Impacts would also vary based on the distance of the recreation area from the components. The reservoir is used for camping, and it may experience an influx of construction workers to the area who would reside in campers or RVs for the duration of construction. Only a small permanent workforce would be required for operation of the wind facilities. If workers are expected to stay in campers or RVs near the wind facility site, the developer would notify local RV park and camp site owners.

Millers Lake and County Road 18 hunting areas are located in Hansford County, Texas, in WDZ-B. Hunting opportunities could be temporarily impacted by the wind farm if wildlife species are displaced from areas near construction activities to suitable habitats adjacent to, but beyond the extent of, construction disturbances.

No recreational areas are present in WDZ-C and WDZ-E through WDZ-K, so no impacts are expected.

Schultz WMA and Optima WMA are located in WDZ-D and are used primarily for hunting. Hunting opportunities could be temporarily impacted by the wind farm if wildlife species are displaced from areas near construction activities to suitable habitats adjacent to, but beyond the extent of, construction disturbances

Local parks located in WDZ-L lie within municipal boundaries and are unlikely to experience impacts from wind development because parks are unlikely to be targeted for development. Additionally, the wind industry has an established practice of avoiding local parks. It is assumed that wind energy developers would likely site wind farms to avoid direct impacts to parks and municipalities. Wind farms may be visible from local parks, causing long-term disturbance from potential views of the structures from these recreational resources until after decommissioning of the wind farm.

3.12.6.8.2 Optima Substation

No impacts to recreational lands or uses are anticipated from the future Optima Substation because no recreation resources are located within the substation siting area.

3.12.6.8.3 TVA Upgrades

The ROI for the direct assignment facilities cannot be fully determined at this time as described in Section 3.12.5.8.3.

Potential recreation impacts associated with the upgrades could include disruption of recreational activities from temporary closures of recreation lands or access needed for construction activities for new or upgraded facilities. Long-term impacts are not likely for the required upgrades to existing facilities. The new 37-mile-long transmission line could affect views from recreational areas, both from the structures and from the changes in vegetation within and adjacent to the ROW. Recreational activities could be interrupted periodically by maintenance activities. Recreational users could be affected by the new 37-mile-long transmission line if they opted for similar recreation areas without transmission lines or associated facilities, leading to increased visitation at other recreational sites in the area. Depending on its location, the new 37-mile-long transmission line could interfere with access to existing recreation areas.

3.12.6.9 Impacts Associated with the No Action Alternative

Under the No Action Alternative, DOE assumes for analytical purposes that the Project would not be constructed. No disturbances would occur due to the Project, including disturbances to recreation resources. No disturbances due to construction vehicles, equipment, or access roads would affect recreation resources.

Impacts to recreation resources would be consistent with present levels of disturbance already occurring locally.

3.13 Socioeconomics

3.13.1 Regulatory Background

Socioeconomic conditions and impacts are among “the effects on the human environment” to be discussed in an EIS. They are also commonly recognized and addressed as a concern under various federal, state, and local planning and management processes.

3.13.2 Data Sources

The socioeconomic analysis relies primarily on published information compiled by federal and state government agencies, supplemented by information from academic and private sources, as well as Project-specific data and information. Key federal and state data sources include the following:

- Federal agencies: U.S. Census Bureau, U.S. Bureau of Economic Analysis, U.S. Bureau of Labor Statistics, and USDA
- State agencies: economic, demographic, labor, and revenue/taxation departments

3.13.3 Region of Influence

3.13.3.1 Region of Influence for the Project

The ROI for the socioeconomic analysis consists of the 33 counties that could potentially be directly affected by the Project components. The ROI is divided into seven regions for the purposes of analysis (Table 3.13-1; Figure 2.1-2 in Appendix A). The counties crossed by the AC collection system that are not crossed by the HVDC transmission line—Hansford, Ochiltree, and Sherman counties, Texas, and Cimarron County, Oklahoma—are not identified in Table 3.13-1, but are included as part of Region 1. Faulkner County, Arkansas, is not crossed by the Applicant Proposed Route and is therefore not identified in Table 3.13-1, but is included as part of Region 5.

Table 3.13-1:
States and Counties Crossed by the Applicant Proposed HVDC Transmission Line by Region

Region	State	County[1]	Miles
1	Oklahoma[2]	Texas, Beaver, Harper	115.5
2	Oklahoma	Woodward, Major, Garfield[3]	106.0
3	Oklahoma	Garfield[3], Kingfisher, Logan, Payne, Lincoln, Creek, Okmulgee, Muskogee[3]	161.7
4	Oklahoma	Muskogee[3], Sequoyah	43.5
	Arkansas	Crawford, Franklin, Johnson, Pope[3]	82.8
5	Arkansas[4]	Pope, Conway, Van Buren, Cleburne, White, Jackson[3]	112.8
6	Arkansas	Jackson[3], Poinsett[3], Cross	54.3
7	Arkansas	Poinsett[3], Mississippi	26.4
	Tennessee	Tipton, Shelby	16.4
		Total	719.4

1 Counties are generally listed from west to east by region.
2 Region 1 also includes the following counties that would be potentially crossed by the AC collection system routes: Hansford, Ochiltree, and Sherman counties, Texas, and Texas and Cimarron counties, Oklahoma.
3 Counties located in more than one region.
4 Region 5 also includes Faulkner County because it would be crossed by HVDC Alternative Routes 5-B and 5-D.

Where possible, the socioeconomic assessment references the seven regions, but the available socioeconomic data are typically based on geopolitical boundaries, usually counties, that do not directly correspond with the regions. As indicated in Table 3.13-1, the regions typically break mid-county, which results in several counties being located in more than one region. In addition, the proposed HVDC transmission line, as currently proposed, would be constructed in five approximately 140-mile-long segments that do not directly coincide geographically with the seven regions.

The following counties are located in more than one region: Garfield and Muskogee counties, Oklahoma, and Pope, Jackson, and Poinsett counties, Arkansas. Counties are assigned to one region for the purposes of analysis. Garfield, Muskogee, and Pope counties are assigned to the region that includes the majority of the HVDC transmission line located in that county: Regions 2, 3, and 5, respectively. The length of transmission line in Jackson and Poinsett counties is fairly evenly divided between two regions. These counties are included in the easternmost area of the two regions, Regions 5 and 6, respectively.

The length of the HVDC transmission line ranges from 3.4 miles in Kingfisher County, Oklahoma, to 56 miles in Beaver County, Oklahoma (Table 3.13-2).

Table 3.13-2:
Miles Crossed by the Applicant Proposed HVDC Transmission Line by County and State

State/County[1]	Miles	State/County[1]	Miles	State/County[1]	Miles
Oklahoma		Arkansas		Tennessee	
Texas	23.8	Crawford	28.4	Shelby	5.0
Beaver	56.0	Franklin	19.8	Tipton	11.4
Harper	35.6	Johnson	27.8	Total	16.4
Woodward	32.4	Pope	27.1		
Major	52.2	Conway	21.6		
Garfield	22.2	Van Buren	13.2		
Kingfisher	3.4	Cleburne	23.5		
Logan	20.8	White	17.2		
Payne	35.7	Jackson	33.7		
Lincoln	10.0	Poinsett	31.5		
Creek	27.4	Cross	16.1		
Okmulgee	27.7	Mississippi	16.3		
Muskogee	39.5	Total	276.2		
Sequoyah	39.9				
Total	426.6				

1 Counties are generally listed from west to east by state.

Several route variations to the Applicant Proposed Route in Regions 2–7 were developed in response to public comments on the Draft EIS and are described in Appendix M and summarized in Sections 2.4.2.1–2.4.2.7. Assessments of the impacts related to the route variations by Project region, including accompanying HVDC alternative route adjustments, are noted below. The variations are presented graphically in Exhibit 1 of Appendix M.

Viewed at a county level, these variations would change the total length by county by less than 1 mile in all cases and would result in minor changes to the impact analyses presented in Section 3.13.6.

Potential socioeconomic impacts would occur in the counties where the proposed facilities would be located and these counties form the ROI for the following analysis. Some impacts would also likely occur outside these counties. This is especially likely to be the case where larger communities are located in adjacent or nearby counties. These communities are likely to provide some local workers and also provide temporary housing for workers temporarily relocating to the area. Larger communities where these types of impact may occur include Metropolitan Statistical Areas (MSAs) are part of or adjacent to the ROI. MSAs have at least one urbanized area with 50,000 or more residents, plus adjacent territory that has a high degree of social and economic integration with the core as measured by commuting ties (OMB 2013). These areas represent larger communities that form regional markets for labor, goods and services, and information. MSAs typically include an urbanized node and economically related surrounding counties. The potentially affected MSAs are identified in Table 3.13-3.

Table 3.13-3:
MSAs that are Part of or Adjacent to the ROI

Region[1]	MSA	Principal City	Counties
3	Oklahoma City, OK	Oklahoma City, OK	Canadian, OK; Cleveland, OK; Grady, OK; Lincoln, OK[2]; Logan, OK[2]; McClain, OK; Oklahoma, OK
3	Tulsa, OK	Tulsa, OK	Creek, OK[2]; Okmulgee, OK[2]; Osage, OK; Pawnee, OK; Rogers, OK; Tulsa, OK; Wagoner, OK
4	Fort Smith, AR-OK	Fort Smith, AR	Crawford, AR[2]; Sebastian, AR; Le Flore, OK; Sequoyah, OK[2]
5	Little Rock-North Little Rock-Conway, AR	Little Rock, North Little Rock, Conway	Faulkner, AR[2]; Grant, AR; Lonoke, AR; Perry, AR; Pulaski, AR; Saline, AR
6	Jonesboro, AR	Jonesboro, AR	Craighead, AR; Poinsett, AR[2]
7	Memphis, TN-MS-AR	Memphis, TN	Crittenden, AR; Benton, MS; DeSoto, MS; Marshall, MS; Tate, MS; Tunica, MS; Fayette, TN; Shelby, TN[2]; Tipton, TN[2]

1 Identifies the region that includes counties that are part of the identified MSA.
2 County included in the ROI.

3.13.3.2 Region of Influence for Connected Actions

The ROI for wind energy generation, the future Optima Substation, and TVA upgrades is described in Section 3.1.1.

3.13.4 Affected Environment

3.13.4.1 Population

The 33 counties in the ROI had a total combined population of slightly more than 2 million people (2,055,103) in 2012, with almost half this total (934,654) concentrated in Shelby County, Tennessee. This county, located at the eastern end of the ROI includes the city of Memphis, which had an estimated 2012 population of 655,155 (USCB 2014a). As a result, slightly more than half the total population of the counties in the ROI is concentrated in Region 7. Total population in the remaining six regions in 2012 ranged from 51,652 in Region 1 (2.5 percent of the ROI total) to 348,517 in Region 3 (17.0 percent of the ROI total), closely followed by Region 5 with 334,750 (16.3 percent of the ROI total) (Table 3.13-4).

The western portion of the ROI is sparsely populated. The seven counties that compose Region 1 had an average population density of 5.4 people per square mile in 2012 (compared to a national average of 88.9). The city of Guymon, the county seat of Texas County, Oklahoma, is the largest community in Region 1, with an estimated population of just 11,930 in 2012 (USCB 2014a). Woodward and Major counties in Oklahoma (Region 2) are also relatively sparsely populated with 2012 population densities of 16.3 and 7.9 people/square mile, respectively. Average population densities in the other regions ranged from 30.8 people/square mile in Region 6 to 491.2 people/square mile in Region 7 (Table 3.13-4). MSAs adjacent to the ROI are identified by region in Table 3.13-3. There are no larger communities or MSAs within commuting distance of Region 1.

Population increased from 1990 to 2000 in all four states that are crossed by the ROI, with increases ranging from 10 percent (Oklahoma) to 23 percent (Texas), compared to a nationwide increase of 13 percent (Table 3.13-5). As detailed in Table 3.13.4, viewed by region, changes in population in the ROI from 1990 to 2000 ranged from no change in Region 2 to 24 percent in Region 5. Population in Region 1 increased by 5 percent over this period, but this was mainly due to a 22 percent increase in Texas County, Oklahoma, the most populated of the seven Region 1 counties. Five of the remaining six counties actually lost population in the 1990s.

Population also increased from 2000 to 2012 in all four states, with increases ranging from 10 percent (Oklahoma and Arkansas) to 25 percent (Texas), compared to a nationwide increase of 11 percent (Table 3.13-5). Viewed by region, changes over this period ranged from a net decrease of 6 percent in Region 6 to a 17 percent increase in Region 5 (Table 3.13-4).

Population is projected to increase nationwide and in all four states from 2012 to 2020 and from 2020 to 2030. In all cases, projected increases are expected to be smaller than those experienced over the past two decades (Table 3.13-5). Population projections for 2012 to 2020 vary substantially by region, ranging from a 6 percent decrease in Region 6 to a 20 percent increase in Region 5. Most counties are anticipated to see increases in population from 2020 to 2030 in all regions (Table 3.13-4).

Table 3.13-4:
Population by County and Region

Region	County[1]	2012 Population	2012 Population Density (people/square mile)	Population Change (Percent)		Projected Population Change[2] (Percent)	
				1990 to 2000	2000 to 2012	2012 to 2020	2020 to 2030
1	Hansford, TX	5,521	6.0	-8	3	11	11
	Ochiltree, TX	10,728	11.7	-1	19	7	13
	Sherman, TX	3,073	3.3	11	-4	7	9

7	Mississippi, AR	46,388	51.5	-10	-11	-12	-9
	Shelby, TN	934,654	1224.7	9	4	2	1
	Tipton, TN	61,399	134.0	36	20	12	12
	Region 7 Total	1,042,441	491.2	9	4	2	1

1 Counties located in more than one region are assigned to one region for the purposes of analysis. Garfield and Muskogee counties, Oklahoma, and Pope County, Arkansas, are assigned to the region that includes the majority of the HVDC transmission line located in that county. Garfield County is assigned to Region 2, Muskogee County to Region 3, and Pope County to Region 5. The length of transmission line in Jackson and Poinsett counties, Arkansas, is fairly evenly divided between two regions. These counties are included in the first region from east to west. Jackson County is assigned to Region 5 and Poinsett County to Region 6. This distribution of counties by region is used throughout the following analysis.

2 Population projections for Texas, Oklahoma, and Tennessee counties are based on 2010 Census data. Projections for Arkansas for 2020 are based on 2010 Census data; 2030 Arkansas projections are based on 2000 Census data.

3.13.4.2 Economic Conditions

The USDA Economic Research Service (ERS) developed a set of county typology codes designed to capture differences in economic and social characteristics at the county level (USDA ERS 2008). These codes consist of six non-overlapping categories of economic dependence (farming, mining, manufacturing, federal/state government, services, and non-specialized) and seven overlapping categories of policy-relevant themes, including non-metropolitan recreation area and retirement destination. The economic dependence categories are assigned based on the share of average annual labor and proprietors' income and/or the share of total employment associated with the identified categories. The ERS assigned all counties to one of the economic dependence categories based on data from 1998 to 2000 (Table 3.13-6).

The ERS typology identified all seven counties in Region 1 as farming-dependent. The majority of the other counties were identified as non-specialized, with six counties identified as manufacturing-dependent, two counties identified as federal/state government-dependent, two counties identified as services-dependent, and one identified as mining-dependent (Table 3.13-6). In addition, three counties, all located in Region 5, were identified as retirement destination counties, and one other was identified as a non-metropolitan county.

Total employment increased from 2001 to 2011in all four states crossed by the ROI, as well as nationwide (Table 3.13-6). Viewed by region, changes in total employment from 2001 to 2011 ranged from a 7 percent decrease in Region 6 to a 14 percent increase in Region 1. Annual unemployment rates in 2012 by region ranged from 3.3 percent and 3.7 percent in Regions 2 and 1, respectively, to 9.1 percent in Region 7 (Table 3.13-6). The national unemployment rate in 2012 was 8.1 percent (Table 3.13-7). Average per capita income by region ranged from $28,698 (equivalent to 66 percent of the U.S. per capita income) in Region 4 to $44,558 in Region 1, which is slightly higher than the U.S. average per capita income (Table 3.13-6).

Table 3.13-6:
Economic Conditions by County and Region

Region	County	Economic Type	Employment[1]		Annual Unemployment Rate 2012	Per-Capita Income	
			2011	Percent Change 2001 to 2011		2012	Percent of U.S. Per Capita-Income
1	Hansford, TX	Farming	3,712	8	3.9	56,221	129%
	Ochiltree, TX	Farming	7,687	29	3.3	52,628	120%

1 Total employment includes self-employed individuals. Employment data are by place of work, not place of residence and, therefore, include people who work in the area but do not live there. Employment is measured as the average annual number of jobs, both full- and part-time, with each job that a person holds counted at full weight.
2 Retirement destination county
3 Non-metropolitan recreation county

One organization commenting on the Draft EIS expressed concern that the importance of natural gas operations on the Fayetteville shale in Arkansas was not adequately captured. According to a recent report (CBER 2012) commissioned by the Arkansas State Chamber of Commerce/Associated Industries of Arkansas, from 2008 to 2011, a total of $12.7 billion was invested in natural gas operations on the Fayetteville shale that supported a total statewide economic activity of more than $18.5 billion and annual employment of more than 22,000 people in 2011. Natural gas production from 2008 to 2011 occurred in nine counties, eight of which—Cleburne, Conway, Faulkner, Franklin, Jackson, Pope, Van Buren, and White counties—could be crossed by the Project. Major producers in the area of the Fayetteville shale play directly employed 1,092 full-time employees in these nine counties, with 335 employed elsewhere in the state. Total employment in the eight Fayetteville shale counties that could be crossed by the Project was 171,836 in 2011 (Table 3.13-6). In addition, it was estimated that from 2008 to 2011, Fayetteville shale activities resulted in the collection of almost $2.0 billion in state and local taxes from permit fees and severance, property, income, sales, and other taxes (CBER 2012).

Acres of shale play and the number of existing oil and gas wells within the ROI are identified by region in Section 3.6. The counties where drilling occurred from 2008 to 2011 are located in Regions 4 (Franklin County) and 5 (Cleburne, Conway, Faulkner, Jackson, Pope, Van Buren, and White counties). The ROI for identifying oil and gas wells is a 4,000-foot-wide corridor along the HVDC transmission lines and a 1,500-foot-wide buffer around converter station siting areas.

3.13.4.3 Agriculture

Land in farms accounted for 78 percent of the total land area in Texas in 2012 and 78 percent of total land area in Oklahoma. In Arkansas and Tennessee land in farms accounted for about 42 percent of each state's total land area (Table 3.13-8). Average farm size ranged from 160 acres in Tennessee to 523 acres in Texas. Livestock, poultry, and their products accounted for the majority of agricultural products sold by market value in three of the four states, ranging from 51 percent of the total in Arkansas to 74 percent in Oklahoma (Table 3.13-8). Tennessee was the exception, with crops accounting for 58 percent of agricultural products sold by market value in 2012.

Table 3.13-8:
Summary of Agriculture by State

County	Number of Farms	Land in Farms (acres)	Percent of Total Land Area	Average Farm Size (acres)	Market Value of Agriculture Products Sold ($ million)	Total Market Value of Agricultural Products Sold	
						Crops (%)	Livestock, Poultry, and Products (%)

Oklahoma	80,245	34,356,110	78%	428	7,130	26	74
Tennessee	68,050	10,867,812	42%	160	3,611	58	42
Texas	248,809	130,153,438	78%	523	25,376	29	71

Source: USDA (2014)

Viewed by region, land in farms ranged from 38 percent in Region 4 to 97 percent in Region 1. Land in farms also accounted for a large share (92 percent) of the total land area in Region 2 (Table 3.13-9). Average farm size by region ranged from 175 acres in Region 4 to 1,468 acres in Region 1. Average farm size by county ranged from 141 acres in Crawford County, Arkansas, to 2,155 acres in Hansford County, Texas. All seven counties in Region 1 had average farm sizes larger than 1,000 acres (Table 3.13-9).

Table 3.13-9:

(D) Data suppressed by the Census to prevent disclosure of an individual respondent's data.
Source: USDA (2014)

The market value of agricultural products sold in 2012 ranged from $374 million in Region 2 to $3,524 million in Region 1. Viewed by county, total market value in 2012 ranged from $20 million in Van Buren County, Arkansas, to $1,014 million in Texas County, Oklahoma (Table 3.13-9). Total market value and the relative distribution between crops and livestock, poultry, and their products are shown graphically by county in Figure 3.13-1. Livestock, poultry, and their products accounted for the majority of agricultural products sold by market value in the counties that compose Regions 1 through 4, and some of the counties in Region 5. Crops accounted for the vast majority of the value of agricultural products sold in the counties in Regions 6 and 7, as well as Jackson County in Region 5 (Figure 3.13-1).

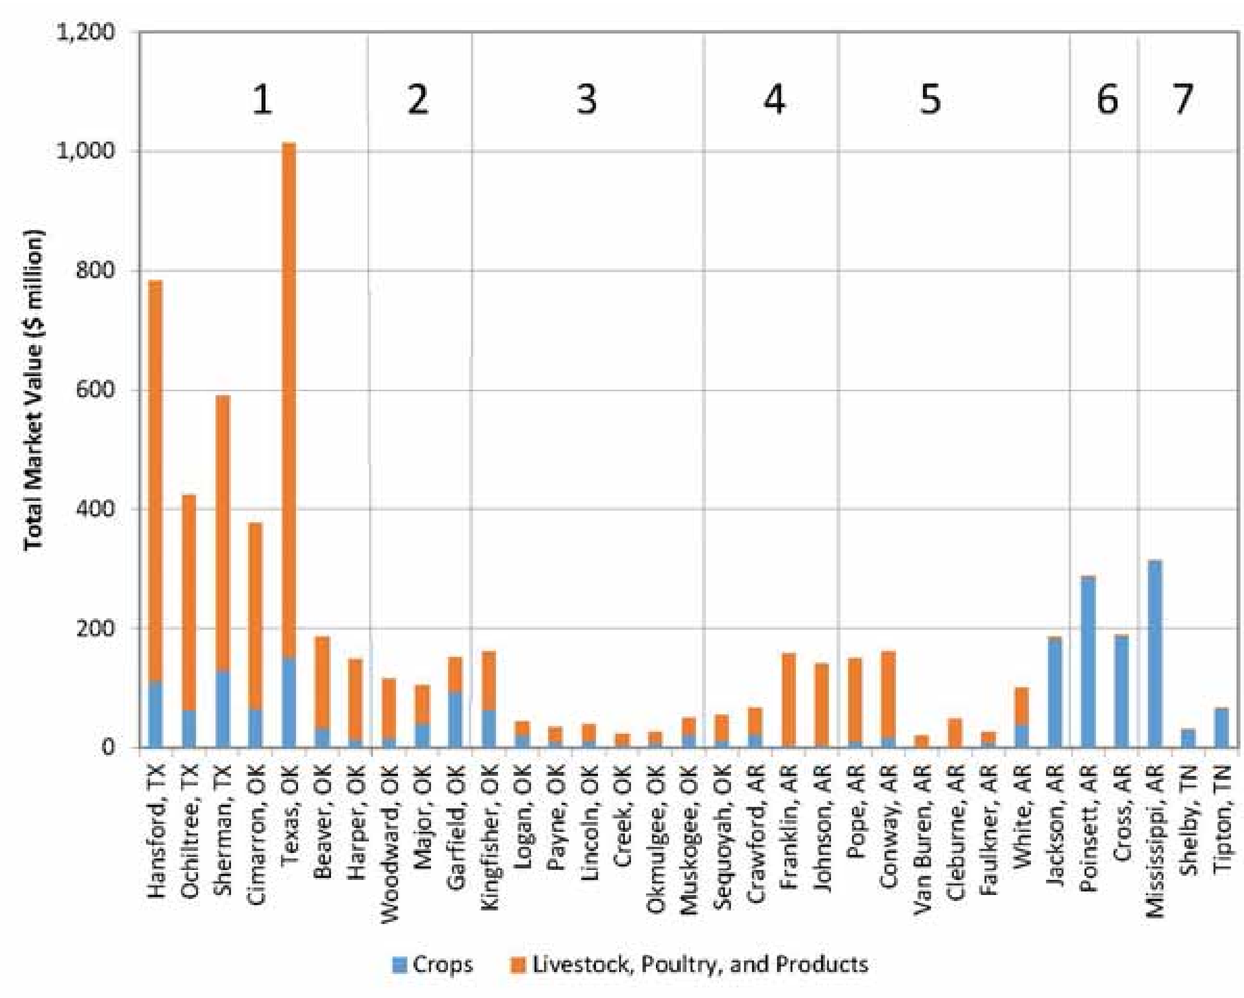

Figure 3.13-1: Total Market Value of Agricultural Products Sold, 2012

Source: USDA (2014)
The numbers (1 through 7) across the top of this figure represent the seven regions that compose the ROI.

Several people commenting on the Draft EIS stated that farmers and other rural landowners are unique in their ties to the land, with farms and land holdings often passed down through generations. Commenters also felt that rural landowners are unique because much of their income may be invested in their land and farming operations rather than banks. As shown in Table 3.13-9, land held as farms accounts for a large share of total land in many of the counties that would be crossed by the Project, especially those in Regions 1, 2, and 6, and all seven counties in Region 1 were identified by the ERS as farming-dependent (Table 3.13-8).

3.13.4.4 Housing

Construction of the HVDC transmission line is expected to draw local and workers from outside the region (import workers). The majority of import workers would likely temporarily relocate to the ROI and adjacent communities, especially the larger metropolitan areas that offer quality of life amenities and are within commuting distance to portions of the Project.

Housing resources are summarized for the ROI by county and region in Table 3.13-10. Data on housing units are estimates for 2012 prepared by the USCB (2014b). The Census Bureau defines a housing unit as a house, an apartment, a mobile home or trailer, a group of rooms, or a single room occupied or intended to be occupied as separate living quarters. Viewed by region, these estimates suggest that limited rental housing is available in Region 1, with less than 100 units available in six of the seven counties that compose the region for a combined estimated total of 370 units (Table 3.13-10). Rental housing is also relatively limited in Regions 2 and 6, with 862 and 908 units available, respectively. The relatively low number of units available in Region 6 is largely due to the small size of the region, which consists of just two counties.

Table 3.13-10:
Housing Resources by County and Region

County	Housing Units 2012[1]			Hotel and Motel Rooms[2]	RV Spaces[3]
	Total	Rental Vacancy Rate	Units Available for Rent

N/A —Number of units not available

1 Data on housing units were compiled from USCB (2014b).

2 Data for hotel and motel rooms were compiled by Clean Line (2013) from the following sources:
Texas—Source Strategies, Inc.
Oklahoma—Oklahoma Tourism and Recreation Department
Arkansas—Arkansas Department of Parks and Tourism
Tennessee—Memphis Convention and Visitors Bureau

3 Data for RV spaces were compiled by Clean Line (2013) from the following sources:
Texas—Texas Office of Economic Development and Tourism
Oklahoma—Oklahoma Tourism and Recreation Department
Arkansas—Arkansas Department of Parks and Tourism
Tennessee—Memphis Convention and Visitors Bureau

Data on hotel and motel rooms and recreational vehicle (RV) spaces were compiled by Clean Line (2013) from various state resources (identified in Table 3.13-10). These data are partial estimates and likely underestimate the number of hotel and motel rooms and RV spaces present. Numbers of hotel and motel rooms estimated by Clean Line range from 238 in Region 5 to 11,827 in Region 7. Other regions with relatively low estimates of hotel and motel rooms include Region 1 (1,093 rooms), Region 2 (1,604 rooms), and Region 4 (1,868 rooms).

Comprehensive data on hotel and motel rooms are available for the three Texas counties in Region 1. These data indicate that the supply of rooms is extremely limited in these counties. Number of rooms varied from just 22 and 29 rooms located in Hansford and Sherman counties, respectively, and 252 rooms located in Ochiltree County while occupancy rates varied by season in 2013, with rates generally higher in the third quarter than in the earlier part of the year (Source Strategies 2013b). Occupancy rates in the third quarter (July, August, and September) were 75.0 percent, 74.1 percent, and 49.4 percent in Hansford, Ochiltree, and Sherman counties, respectively (Source Strategies 2013a, 2013b).

Estimates of RV spaces range from 51 in Region 6 to 679 in Region 3 (Table 3.13-10). Comprehensive data are not available on these types of resources, and the estimates presented in Table 3.13-10, while representing the best available information, likely understate the number of RV spaces in many cases. However, information from various state resources suggests that RV facilities are more likely to be available in the vicinity of the more populated parts of the ROI and adjacent communities.

The data presented in Table 3.13-10 are for those counties within the ROI only. Additional housing resources within daily commuting distance are available in adjacent larger communities along parts of the ROI. This is the case for Regions 3 through 7 where communities within commuting distance generally include Oklahoma City and Tulsa in Oklahoma, Fort Smith, Little Rock, and Jonesboro in Arkansas, and Memphis in Tennessee. Located in Shelby County, Memphis is part of Region 7, but is also within daily commuting distance of parts of Region 6.

3.13.4.5 Community Services

3.13.4.5.1 Police and Fire Services

Summary data for law enforcement and fire departments are presented by county and region in Table 3.13-11. These data compiled by Clean Line (2013) provide a partial overview of resources available in each county. In general, the number of police and fire departments is directly related to the overall size and population of the county, as well as the number of communities. Multiple law enforcement agencies and providers exist in the potentially affected counties, including state patrol, county sheriffs, and local police departments. In many cases, mutual aid agreements allow agencies to support one another in emergency situations. Multiple fire departments and districts also provide fire protection and suppression services in the ROI. Many of these fire departments and districts are at least partially staffed by volunteers and tend to be housed in stations and fire houses in the larger communities.

3.13.4.5.2 Medical Facilities

Medical facilities in the ROI are identified in Table 3.13-12. Minor Project-related injuries would be treated at local medical facilities or emergency rooms. Workers with more serious injuries would be taken to one of the major hospitals in the general vicinity.

Table 3.13-12:
Medical Facilities by County and Region

Region	Hospital	County[1]	Beds	Services
1	Hansford County Hospital	Hansford	4	Emergency Services
	Ochiltree General Hospital	Ochiltree, TX	25	Emergency Services
	Stratford Hospital District	Sherman	42	Emergency Services
	Cimarron Memorial Hospital	Cimarron	25	Emergency Room Services
	Memorial Hospital of Texas County	Texas	47	Emergency Room Services
	Beaver County Memorial Hospital	Beaver	24	Emergency Room Services

N/A—not applicable
1 No hospitals were identified in Major County, Oklahoma, or Poinsett County, Arkansas.
2 Okeene Municipal Hospital is located in Blaine County, Oklahoma, approximately 7 miles south of Major County.
3 River Valley Medical Center is located in Yell County, Arkansas, across the Arkansas River from Pope County.
Source: Clean Line (2013)

Medical facilities are limited in the Texas counties located in Region 1. The Ochiltree General Hospital, a Level IV trauma center, provides emergency services in Ochiltree County. Emergency medical services are provided in Sherman County by the Stratford EMS, which is part of the Stratford Hospital District. Additional hospitals are located in neighboring counties, including the Moore County Hospital, south of Sherman County, which provides 24-hour emergency services.

Most counties in Oklahoma within the ROI have at least one hospital that provides emergency services. Major County is the one exception. Emergency room services are, however, available at the Okeene Municipal Hospital in neighboring Blaine County, about 7 miles south of the county line. All but one of the counties in Arkansas has at least one hospital with emergency services. Poinsett County is the exception. Medical services are available in nearby counties. At least six hospitals serve the Memphis area in Tennessee and provide emergency services and a substantial number of beds (Table 3.13-12).

3.13.4.5.3 Education

The total number of school districts, schools, students, and teachers are summarized by county in Table 3.13-13. Student/teacher ratios are also summarized by county and region. Student/teacher ratios, calculated by dividing the total number of students by the total number of full-time equivalent teachers, are a common measure used to assess the overall quality of a school. The national average student teacher ratio for the 2011 school year (the most recent available data) was 16.0. The statewide average ratios in Texas, Oklahoma, Arkansas, and Tennessee were 15.4, 16.1, 15.1, and 14.8, respectively (NEA 2012).

All three Texas counties in Region 1 had student/teacher ratios below the state and national average (fewer students per teacher). This was also the case with Oklahoma counties in Regions 1 through 4, all of which had student/teacher ratios below the corresponding state and national averages, ranging from 6.9 in Beaver County (Region 1) to 11.8 in Logan and Payne counties (Region 3). Average student/teacher ratios in the Arkansas counties in the ROI range from 9.7 in Van Buren County to 15.0 in Faulkner County (both in Region 5), below the corresponding and state averages. Student/teacher ratios in the two Tennessee counties (Region 7) were higher than the statewide and national averages (Table 3.13-13). The numbers, presented here by county and region, are averages. Student/teacher ratios vary by school district and by school in each county, as well as by grade within each school.

Table 3.13-13:
Schools by County and Region

Region	County	Number of School Districts	Total Number of Schools	Total Number of Students	Total Number of Teachers	Student/Teacher Ratio (Average)[1]

3.13.4.6 Tax Revenues

3.13.4.6.1 Sales, Use, and Lodging Taxes

The state of Texas levies a 6.25 percent sales and use tax on all retail and rental sales. In addition, counties and cities have the option to levy additional combined sales and use taxes of up to 2 percent within their jurisdictions. Most counties in the state of Texas levy an additional 0.5 percent sales and use tax. None of the counties in the ROI currently levies a sales and use tax, and no sales tax receipts were received in these counties in July 2013 (Table 3.13-14).

Table 3.13-14:
Sales and Use Tax by Texas County, 2013

Region	State/County	Sales Tax (Percent)	Monthly Sales Tax Receipts (July 2013)
	Texas	6.25	N/A
1	Hansford	0.00	$0
	Ochiltree	0.00	$0
	Sherman	0.00	$0

Source: Texas Comptroller of Public Accounts (2013a)

The state of Oklahoma levies a sales, use, and lodging tax of 4.5 percent. Sales tax is levied on goods and services purchased within the state. Use tax is imposed on goods purchased tax-free outside Oklahoma for use in Oklahoma (see Oklahoma Administrative Code Title 710, Chapter 65). County and other local jurisdictions are allowed to levy additional sales, use, and lodging taxes within their jurisdictions. Additional sales, use, and lodging taxes levied by counties in Oklahoma in the ROI range from 0.25 percent in Major County (Region 2) to 2 percent in Beaver and Harper counties (Region 1) (Table 3.13-15).

Table 3.13-15:
Sales and Use Tax by Oklahoma County, 2013

The state of Arkansas levies a sales and use tax of 6.5 percent. Counties and other local jurisdictions are also able to levy additional sales and use taxes within their jurisdictions. Current county rates range from 0.5 percent in Faulkner County (Region 5) to 2.25 percent in Jackson County (Region 5) (Table 3.13-16).

Table 3.13-16:
Sales and Use Tax by Arkansas County, 2013

3.13.4.6.2 Property and Ad Valorem Taxes

Texas has no state property tax. Property taxes are local taxes levied by local governments and used to pay for schools, streets, police, fire protection, and other services. Counties, cities, school districts, and various special districts collect and spend property taxes. The governing body of each of these local governments determines the amount of property taxes it wants to raise and sets its own tax rate. Most local governments contract with their county's tax assessor-collector to collect the tax on their behalf (Texas Comptroller of Public Accounts 2014). Utility property in Texas is assessed by each county using a unitary method that can include one or more of the cost, income, or market approach to valuation. These approaches are briefly summarized below.

Each county is served by an appraisal district responsible for determining the value of the county's taxable property. Property taxes are calculated by applying a millage rate to the assessed value of the property. One mill equals one-thousandth of a dollar. If the assessed value of a property is $1,000 and the millage rate is 1.00, then the tax on that property is $1.00. Millage rates for the three Texas counties in Region 1 are shown in Table 3.13-18.

Table 3.13-18:
Millage Tax Rate by Texas County, 2012

Region	County	Millage Rate[1]
1	Hansford	4.131
	Ochiltree	4.200
	Sherman	4.392

1. Property tax rates are presented per $100 of assessed value in Texas. The applicable rates have been adjusted here so they are per $1,000 of assessed value.

Source: Texas Comptroller of Public Accounts (2013b)

Property or ad valorem taxes in Oklahoma are local taxes. County officials typically value property, set tax rates, and collect tax revenues. Oklahoma uses a fractional assessment system, which means the assessed value is less than 100 percent of the property's fair cash value. Once an assessed value has been determined, the various taxing entities apply their tax rate or millage rate to this assessed value to determine the total amount of ad valorem tax.

Special rules apply to the valuation of public service corporations in Oklahoma. Public service corporations, which include electric companies, are valued at the state level by the Oklahoma Tax Division. Fair cash value of public service corporation property may be determined by any combination of three possible approaches: an income approach, which converts projected future income or cash flow into an estimate of present value; the stock and debt or market approach, which estimates the price obtainable from the sale of all outstanding capital stock and funded debt; or the cost approach, which uses either the original cost or historical cost less depreciation. Assessed values are determined for public service corporation property by applying an assessment rate of 22.85 percent to the fair cash value (Oklahoma SBE 2006).

Property taxes are then calculated by applying a millage rate to the assessed value of the property. Millage rates vary within a county based on location and the corresponding jurisdictions levying a property tax. Table 3.13-19 presents a range of potential millage rates for each of the Oklahoma counties within the ROI.

Table 3.13-19:
Millage Tax Rates by Oklahoma County, 2012

Region	State/County	Low Millage[1]	High Millage[1]
1	Cimarron	61.74	67.29
	Texas	55.60	80.73
	Beaver	52.19	67.94
	Harper	57.00	86.36
2	Woodward	63.64	93.10
	Major	78.89	100.12
	Garfield	80.29	103.61
3	Kingfisher	77.99	105.94
	Logan	76.29	119.76
	Payne	73.67	102.61
	Lincoln	73.75	99.11
	Creek	73.98	120.55
	Okmulgee	80.68	97.29
	Muskogee	74.96	100.40
4	Sequoyah	68.50	84.33

1. Millage rates are presented as a range. Actual rates vary by district.
Source: OK Assessor (2012)

In Arkansas, local government entities, such as county and city governments, school districts, fire and emergency medical districts, sewer districts, and other special taxing districts, are allowed to levy *ad valorem* property taxes on real and personal property within their jurisdictions. The Arkansas Public Service Commission's Tax Division determines ad valorem assessments for transmission lines throughout the state. The Division uses a unitary appraisal method that considers the value of the company as a whole to determine assessed values (APSC 2010). An assessment rate of 20 percent is applied to the fair cash value to determine the total assessed value of the property (Arkansas Assessment Coordination Department 2012).

The average overall millage rates for Arkansas counties within the ROI are presented in Table 3.13-20. These rates consist of the combined total of the average school district, average city, and average county millage rate for each county. The combined rate for Cleburne County (41.94), for example, consists of an average school district millage of 34.86 plus the average city millage of 1.98 plus the average county millage of 5.10 (Arkansas Assessment Coordination Department 2013).

Table 3.13-20:
Millage Tax Rates by Arkansas County, 2012

Region	State/County	Millage Rate
4	Crawford, AR	49.11
	Franklin, AR	46.79
5	Johnson, AR	47.96
	Pope, AR	45.98
	Conway, AR	46.53
	Van Buren, AR	43.90
	Cleburne, AR	41.94
	Faulkner, AR	48.70
	White, AR	43.01
	Jackson, AR	46.65
6	Poinsett, AR	44.47
	Cross, AR	49.89
7	Mississippi, AR	49.70

Source: Arkansas Assessment Coordination Department (2013)

The Tennessee Comptroller of the Treasury is responsible for assessing public utility property throughout the state for property tax purposes, employing a unitary method to assess the value of the company as a whole. Utility property is assessed at 55 percent of fair market value with an appraisal ratio applied for each county to equalize values throughout the state (Tennessee SBE 2013, 2014). Average millage rates in Shelby and Tipton counties in Tennessee in 2012 were 4.06 and 2.34, respectively (Tennessee Comptroller of the Treasury 2013). These tax rates are expressed as an amount per $100 of assessed value and set by the governing body of the county (Tennessee SBE 2013). Adjusted to be per $1,000 of assessed value, the average millage rates in Shelby and Tipton counties in Tennessee in 2012 were 40.6 and 23.4, respectively.

3.13.5 Connected Actions

3.13.5.1 Wind Energy Generation

The Applicant has identified a total of 12 WDZs within a 40 mile radius of the Oklahoma Converter Station Siting Area spread over six counties, three in Oklahoma (Beaver, Cimarron, and Texas) and three in Texas (Hansford, Ochiltree, and Sherman (Table 3.13-21). These counties are the ROI for Region 1 and baseline information is presented for each of these counties in Section 3.13.4.

Table 3.13-21:
Total WDZ Acres by State and County

Wind Development Zone	Oklahoma[1]			Texas[1]			Total[2]
	Beaver	Cimarron	Texas	Hansford	Ochiltree	Sherman	
A				14	95		109
B				125			125
C				52		109	161
D			69				69
E			47				47

Table 3.13-21:
Total WDZ Acres by State and County

Wind Development Zone	Oklahoma[1]			Texas[1]			Total[2]
	Beaver	Cimarron	Texas	Hansford	Ochiltree	Sherman	
F			110			2	112
G		125	62				187
H			116				116
I			105				105
J	70		22				92
K	92				1		93
L				39	127		166
Total	162	125	531	230	223	111	1,382

1 WDZ areas are summarized in thousands of acres.
2 Totals may not sum due to rounding.

3.13.5.2 Optima Substation

The ROI for the future Optima Substation for socioeconomics is Texas County, Oklahoma. This county is part of the ROI for Region 1; baseline information is presented for this county in Section 3.13.4.

3.13.5.3 TVA Upgrades

The ROI for the direct assignment facilities (which are included in the Applicant Proposed Project) would occur within the Tennessee Converter Station Siting Area and more specifically within the Shelby Substation. The ROI for the network upgrades, and in particular TVA's future 500kV transmission line, cannot be fully determined at this time. The new 500kV line would be constructed in western Tennessee. The upgrades to existing facilities would mostly be in western and central Tennessee. Upgrades to existing infrastructure would include upgrading terminal equipment at three existing 500kV substations and six existing 161kV substations, making appropriate upgrades to increase heights on 16 existing 161kV transmission lines to increase line ratings, and replacing the conductors on eight existing 161kV transmission lines. Where possible, general impacts associated with the required TVA upgrades are discussed in the impact sections that follow.

3.13.6 Socioeconomic Impacts

3.13.6.1 Methodology

The socioeconomic analysis is based primarily on secondary data compiled from federal, state, and local government agencies. Key sources of data include the U.S. Census Bureau, the U.S. Bureau of Economic Analysis, the U.S. Bureau of Labor Statistics, USDA, and various state agencies.

The potential effects of the converter stations, AC collection system, Applicant Proposed Route, and the DOE Alternatives, including the Arkansas Converter Station Alternative and DOE alternative routes, were evaluated with respect to the key aspects of the socioeconomic environment, including demographic characteristics, economic conditions, housing, property values, community services, and tax revenues. These evaluations employ different resource-specific analysis methods that are described in their respective sections.

Key Project-related variables used in the socioeconomic analysis include projected construction employment and expenditures. Operations-related employment and expenditures are also used. Construction employment and spending estimates are disaggregated by county where appropriate, primarily based on the share of overall construction that would occur in that county. Information is primarily presented by region (Figure 2.1-2 in Appendix A) consistent with other resources and with consideration given to an ROI more consistent with socioeconomic analysis of linear facilities. These estimates represent the best available information and a reasonable approximation of the likely distribution of potential impacts, but should not be considered precise forecasts. In most cases, estimated impacts may be compared with the existing conditions data presented in the preceding part of this section.

Total regional economic impacts are estimated at the state level using direct-effect multipliers for earnings and for employment from the U.S. Bureau of Economic Analysis' RIMS II regional modeling system (BEA 2013b). The multipliers from this model are based on regional information derived from databases analyzing commercial, industrial, and household spending patterns and relationships. Multipliers are provided for different sectors of the economy. Multipliers for the construction and utilities sectors are used in this analysis. Total economic impacts consist of direct, indirect, and induced impacts.

Direct impacts represent the change in economic activity resulting from the initial round of inputs purchased by the project. In this case, direct impacts consist of the employment and related earnings directly associated with construction, operations and maintenance, and decommissioning phases of the Project. These direct impacts generate economic activity elsewhere in the local economy through the multiplier effect, as initial changes in demand "ripple" through the economy and generate indirect and induced impacts. *Indirect* impacts are generated by the expenditures by suppliers who provide goods and services to the construction project or for project operations. *Induced* impacts are generated by the spending of households benefiting from the additional wages and business income earned through related direct or indirect activities.

Economic impacts to agriculture in eastern Arkansas are assessed using information from the Arkansas Delta Agricultural Economic Impact Study prepared for this project. This agricultural economic impact study, which focuses on four counties in eastern Arkansas: Jackson (Regions 5 and 6), Cross (Region 6), Poinsett (Regions 6 and 7), and Mississippi (Region 7), is included as Appendix J to this EIS.

Clean Line will implement the EPMs listed in Appendix F to avoid or minimize potential impacts from construction of the Project. Those EPMs that would help avoid or minimize potential socioeconomic impacts include the following:

- GE-6: Clean Line will restrict vehicular travel to the ROW and other established areas within the construction, access, or maintenance easement(s).
- GE-8: Access controls (e.g., cattle guards, fences, gates) will be installed, maintained, repaired, replaced, or restored as required by regulation, road authority, or as agreed to by landowner.
- GE-11: Clean Line will conduct construction, operation, and maintenance activities to minimize the creation of dust. This may include measures such as limitations on equipment, speed, and/or travel routes utilized. Water, dust palliative, gravel, combinations of these, or similar control measures may be used. The Applicant will implement measures to minimize the transfer of mud onto public roads.
- GE-12: Clean Line will avoid remedial structures (e.g., capped areas, monitoring equipment, or treatment wells) on contaminated sites, Superfund sites, CERCLA remediation areas, and other similar areas. Workers will use

appropriate protective equipment and appropriate safe working techniques when working at or near contaminated sites.

- GE-15: Waste generated during construction or maintenance, including solid waste, petroleum waste, and any potentially hazardous materials will be removed and taken to an authorized disposal facility.
- GE-20: Clean Line will conduct construction and scheduled maintenance activities on the facilities during daylight hours, except in rare circumstances that may include, for example, to address emergency or unsafe situations, to avoid adverse environmental effects, to minimize traffic disruptions, or to comply with regulatory or permit requirements.
- GE-21: Clean Line will maintain construction equipment in good working order. Equipment and vehicles that show excessive emissions of exhaust gasses and particulates due to poor engine adjustments or other inefficient operating conditions will be repaired or adjusted.
- GE-22: Clean Line will impose speed limits during construction for access roads (e.g., to reduce dust emissions, for safety reasons, and for protection of wildlife).
- GE-23: Clean Line will maximize the distance between stationary equipment and sensitive noise receptors consistent with engineering design criteria.
- GE-24: Clean Line will minimize the number and distance of travel routes for construction equipment near sensitive noise receptors.
- GE-25: Clean Line will turn off idling equipment when not in use.
- GE-27: Clean Line will minimize compaction of soils and rutting through appropriate use of construction equipment (e.g., low ground pressure equipment and temporary equipment mats).
- GE-28: Hazardous materials and chemicals will be transported, stored, and disposed of according to federal, state, or local regulations or permit requirements.
- AG-1: Clean Line will avoid or minimize adverse effects to surface and subsurface irrigation and drainage systems (e.g., tiles). The Applicant will work with landowners to minimize the placement of structures in locations that would interfere with the operation of irrigation systems.
- AG-2: Agricultural soils temporarily impacted by construction, operation, or maintenance activities will be restored to pre-activity conditions. For example, soil remediation efforts may include decompaction, recontouring, liming, tillage, fertilization, or use of other soil amendments.
- AG-4: Clean Line will work with landowners and/or tenants to identify specialty agricultural crops or lands (e.g., certified organic crops or products that require special practices, techniques, or standards) that may require protection during construction, operation, or maintenance. The Applicant will avoid and/or minimize impacts that could jeopardize standards or certifications that support specialty croplands or farms.
- AG-5: Clean Line will work with landowners and/or tenants to consider potential impacts to current aerial spraying or application (i.e., crop dusting) of herbicides, fungicides, pesticides, and fertilizers within or near the transmission ROW. The Applicant will avoid or minimize impacts to aerial spraying practices when routing and siting the transmission line and related infrastructure.
- AG-6: Clean Line will work with landowners to develop compensation for lost crop value caused by construction and/or maintenance.
- LU-1: Clean Line will work with landowners and operators to ensure that access is maintained as needed to existing operations (e.g., to oil/gas wells, private lands, agricultural areas, pastures, hunting leases).
- LU-2: Clean Line will minimize the frequency and duration of road closures.
- LU-3: Clean Line will work with landowners to avoid and minimize impacts to residential landscaping.

- LU-4: Clean Line will coordinate with landowners to site access roads and temporary work areas to avoid and/or minimize impacts to existing operations and structures.
- W-15: Clean Line will seek to procure water from municipal water systems where such water supplies are within a reasonable haul distance; any other water required will be obtained through permitted sources or through supply agreements with landowners.

Additionally, Clean Line proposes to implement the following plans that would help minimize other potential socioeconomic impacts:

- Transportation and Traffic Management Plan. This plan will describe measures designed to avoid and/or minimize adverse effects associated with the existing transportation system.
- Spill Prevention, Control and Countermeasures Plan. This plan will describe the measures designed to prevent, control, and clean up spills of hazardous materials.
- Construction Security Plan. This plan will describe measures designed to avoid and/or minimize adverse effects associated with breaches in Project security during construction including terrorism, sabotage, vandalism, and theft. The plan will include provisions describing how the Project construction team will coordinate with state and local law enforcement agencies during construction to improve Project security and facilitate security incident response, if required.
- Communications Plan. This plan will incorporate all forms of communication with the public, with elements implemented as appropriate during different phases of the Project. Elements of this plan are described in Section 3.1.2.

3.13.6.2 Impacts Associated with the Applicant Proposed Project

3.13.6.2.1 Population

3.13.6.2.1.1 Converter Stations and AC Interconnection Siting Areas

3.13.6.2.1.1.1 Construction Impacts

The Applicant proposes to locate new AC/DC converter stations in Texas County, Oklahoma, and Shelby County, Tennessee. The Oklahoma converter station would be located in Region 1. The Tennessee converter station would be located in Region 7.

Employment during construction of each converter station is expected to follow a bell-shaped pattern, with an average of 138 workers over a 32-month construction period and a peak of 232 to 242 workers from months 12 to 17 (Figure 3.13-2). An estimated 26 percent of the workers who would be employed on the Project are expected to be hired locally (i.e., workers who normally reside within daily commuting distance of the applicable converter station site). Daily commuting distance is assumed to be up to a 2-hour drive each way for the purposes of this analysis (Clean Line 2014a). Some workers would be employed for the full duration of construction, but many workers would be employed for shorter periods based on their trades. Local hires would include surveyors and workers employed in site development, fence installation, and traffic control. Local hires would compose a smaller share of the workforce for more specialized tasks, such as equipment footings and cable trenching, conduits, and grounding and steel structure erection and electrical equipment installation. The proportion of non-local workers on site at any one time would vary over the construction period as the mix of labor categories and skills varies.

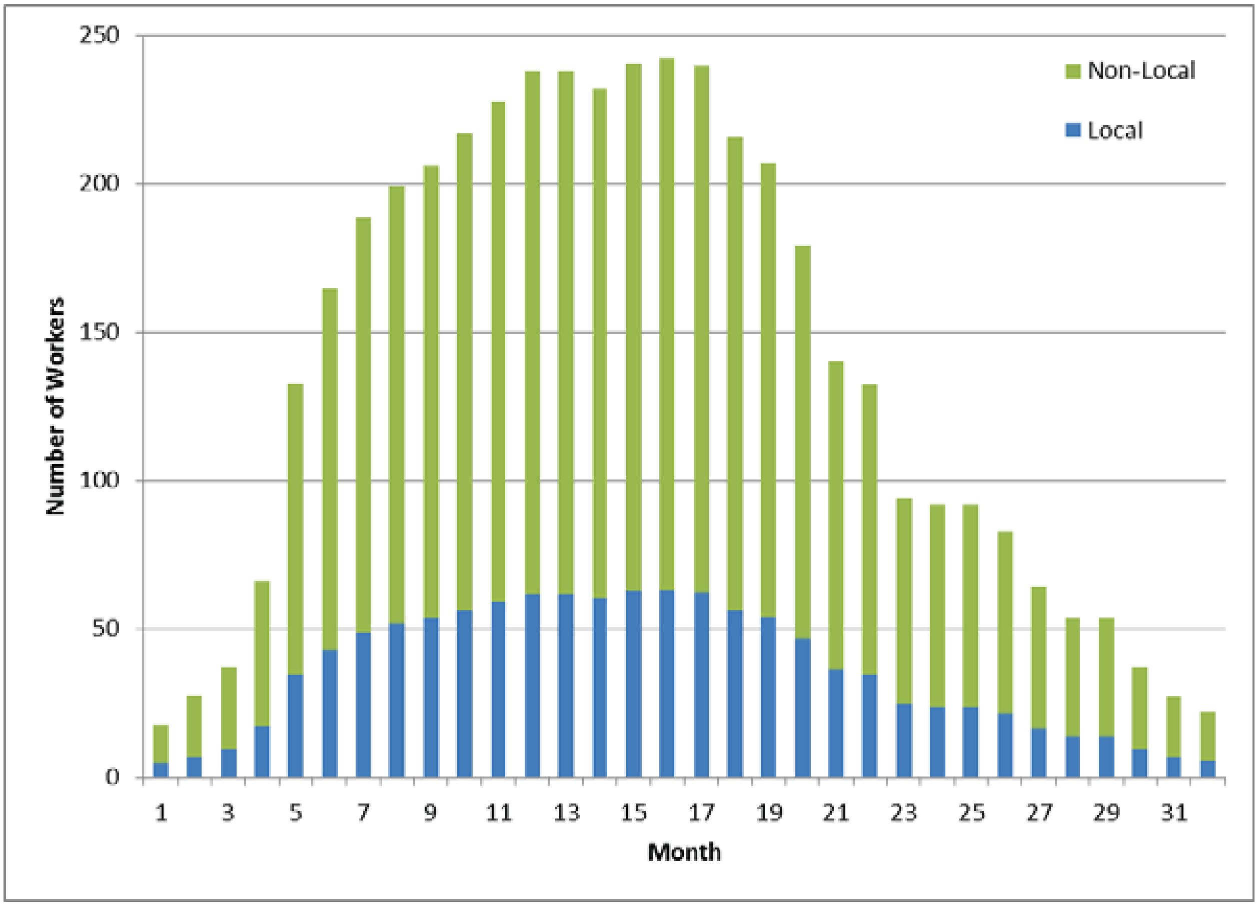

Figure 3.13-2: Estimated Construction Workforce per Converter Station by Month and Local/Non-Local Workers

Source: Clean Line (2014a)

For the purposes of analysis, the share of non-local workers is assumed to be 74 percent for the full duration of convertor station construction, resulting in an average of 102 non-local workers employed over the 32-month construction period, with an estimated peak of 171 to 179 non-local workers employed during months 12 to 17. In addition, 10 percent of non-local workers temporarily relocating to the Project sites are assumed to be accompanied by family members; the average size of a family that is relocating is assumed to be two adults and one school-age child (Clean Line 2013).

Based on these assumptions, an estimated average of 123 people would be expected to temporarily relocate to the vicinity of each converter station for the full duration of the 32-month construction period, with the number of people who would relocate increasing to 215 during the peak construction period (months 12 to 17). The average increase would be equivalent to approximately 0.6 percent and less than 0.1 percent of the existing (2012) population in Texas and Shelby counties, respectively. The peak increase would be equivalent to approximately 1 percent and less than 0.1 percent of the respective existing (2012) populations in Texas and Shelby counties. Very few, if any, of the non-local workers employed during the construction phase of the converter stations would be expected to permanently relocate to the affected areas, so it is unlikely that construction of the converter stations would result in any long-term changes in population.

3.13.6.2.1.1.2 Operations and Maintenance Impacts

Operations and maintenance of each of the converter stations is expected to employ up to 15 workers. These estimated staffing levels would have no noticeable impact on existing population levels in the potentially affected counties.

3.13.6.2.1.1.3 Decommissioning Impacts

The labor force required to decommission each converter station would be similar to that required for construction. Impacts to population from decommissioning are, therefore, expected to be similar to those from construction.

3.13.6.2.1.2 AC Collection System

3.13.6.2.1.2.1 Construction Impacts

The counties crossed by the AC collection system routes and mileage of each route within each county are provided in Table 2.1-5. The AC collection system routes are all located in Region 1 (Figure 2.1-2 in Appendix A).

Assuming that workforce requirements are similar to those estimated for the HVDC transmission line on a per-mile basis, the average length of an AC collection system route, 34.4 miles, would require an average of 51 workers over a 24-month construction period, with an estimated peak of 71 workers. Adjusted to reflect the length of each alternative, the respective average and peak number of workers would range from 20 and 28 for AC Collection System Routes SE-2 and SW-1 (13.4 miles) to 83 and 116 for AC Collection System Route NW-2 (56.0 miles).

Estimated temporary increases in population are shown by alternative and county in Table 3.13-22. These estimates assume that 74 percent of the workforce would be non-local for the duration of the Project. In addition, approximately 10 percent of non-local workers are assumed to be accompanied by family members; the average size of a family that is relocating is assumed to be three, two adults and one school-age child. Population is distributed for the purposes of analysis based on the length of the line in each county.

Table 3.13-22:
Estimated Temporary Change in Population During Construction by AC Collection System Routes and County

County/Route	E-1	E-2	E-3	NE-1	NE-2	NW-1	NW-2	SE-1	SE-2	SE-3	SW-1	SW-2	W-1
Temporary Change in Population Based on Average Employment Forecast[1]													
Beaver, OK	5	20	21	0	0	0	0	0	0	4	0	0	0
Texas, OK	33	32	31	39	35	66	71	25	5	32	5	20	27
Cimarron, OK	0	0	0	0	0	2	3	0	0	0	0	0	0
Hansford, TX	0	0	0	0	0	0	0	3	13	0	13	4	0
Ochiltree, TX	0	0	0	0	0	0	0	26	0	28	0	0	0
Sherman, TX	0	0	0	0	0	0	0	0	0	0	0	25	0
Total	38	52	52	39	35	68	74	53	18	64	18	49	27

Table 3.13-22:
Estimated Temporary Change in Population During Construction by AC Collection System Routes and County

County/Route	E-1	E-2	E-3	NE-1	NE-2	NW-1	NW-2	SE-1	SE-2	SE-3	SW-1	SW-2	W-1
Temporary Change in Population Based on Peak Employment Forecast[1]													
Beaver, OK	7	28	30	0	0	0	0	0	0	6	0	0	0
Texas, OK	46	45	44	55	48	93	99	34	7	45	7	28	38
Cimarron, OK	0	0	0	0	0	3	4	0	0	0	0	0	0
Hansford, TX	0	0	0	0	0	0	0	4	18	0	18	6	0
Ochiltree, TX	0	0	0	0	0	0	0	36	0	40	0	0	0
Sherman, TX	0	0	0	0	0	0	0	0	0	0	0	35	0
Total	53	73	73	55	48	95	103	74	25	90	25	68	38

1 Totals may not sum due to rounding.

Viewed by AC collection system route, projected changes in population during peak construction would range from about 25 (AC Collection System Routes SE-2 and SW-1) to about 103 (AC Collection System Route NW-1) (Table 3.13-22). The largest expected temporary increase (103) is equivalent to about 0.2 percent of the total existing (2012) population in Region 1 (51,652) (Table 3.13-4). The largest expected gain for an individual county would be a temporary increase of 99 in Texas County, Oklahoma, under AC Collection System Route NW-2. This estimated increase of 99 people is equivalent to about 0.5 percent of Texas County's total 2012 population (20,620) (Table 3.13-4).

Four to six AC transmission lines are expected to be built. Assuming that six alternatives with an average length of 34.4 miles are constructed, average and peak population increases of about 271 and 379 people, respectively, approximately 0.5 percent and 0.7 percent of the total 2012 population in Region 1, would result.

Very few, if any, of the non-local workers employed during the construction phase of the AC collection system routes would be expected to permanently relocate to the affected areas, so it is unlikely that construction of the AC collection system would result in any long-term changes in population.

3.13.6.2.1.2.2 Operations and Maintenance Impacts

Combined operation of the HVDC and AC transmission lines in Region 1 is expected to employ 15 workers based in Guymon, Oklahoma (Texas County). This number is not expected to vary based on which AC collection system routes are selected. This estimated staffing level would have no noticeable impact on existing population levels in Texas County, which had a total estimated population of 20,620 in 2012 (Table 3.13-4).

3.13.6.2.1.2.3 Decommissioning Impacts

Decommissioning of the AC transmission lines would require a labor force approximately equal to that needed for its construction. Impacts to population from decommissioning are, therefore, expected to be similar to those from construction.

3.13.6.2.1.3 HVDC Applicant Proposed Route

3.13.6.2.1.3.1 Construction Impacts

Overall construction of the 720-mile-long HVDC transmission line is expected to take 36 months. Total employment by month is expected to range from 83 in month 1 to a peak of 1,277 in month 16, with an average monthly employment of 690 (Appendix F). The transmission line would be constructed in five 140-mile-long segments, each taking 24 months to complete. The estimated workforce is shown by month and task for a representative 140-mile segment in Figure 3.13-3. Total employment by month for each 140-mile segment is expected to range from 55 workers in month 24 to a peak of 290 workers in months 4, 5, and 6, with an average monthly employment of 207.

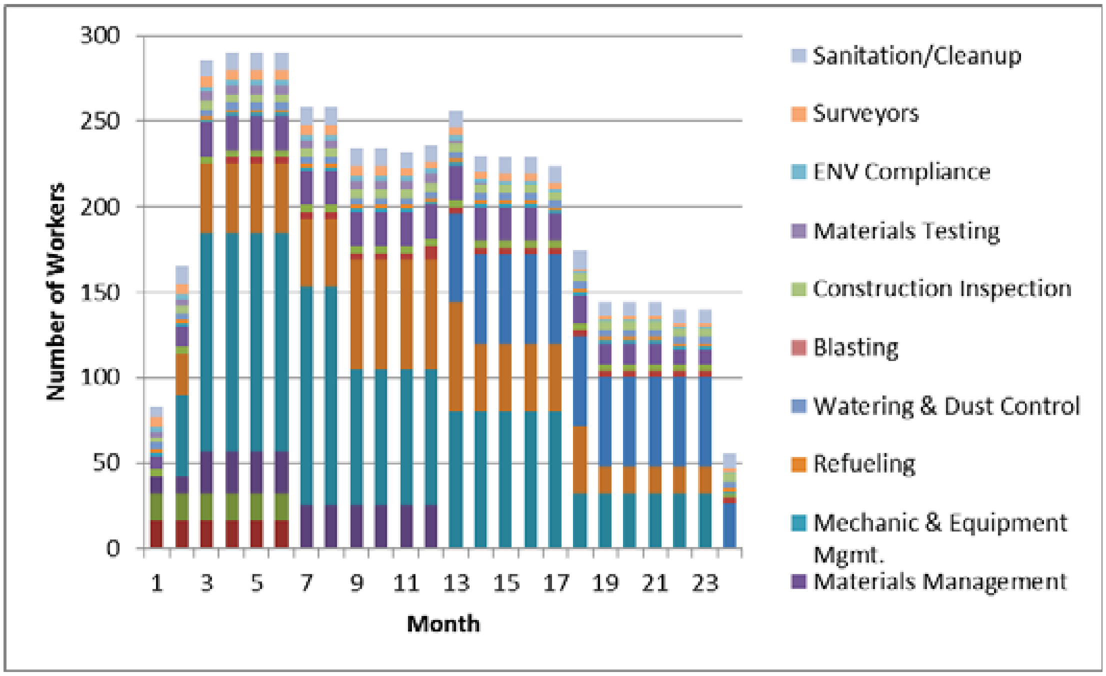

Figure 3.13-3: Estimated Construction Workforce per 140-mile Segment of HVDC Transmission Line by Month and Task

Source: Clean Line (2013)

Figure 3.13-4 identifies the expected local/non-local breakdown for an average 140-mile segment by month. Local workers are those who normally reside within commuting distance of the work sites. Non-local workers would temporarily relocate to the ROI or immediate vicinity for the duration of their employment; some workers would possibly commute home on weekends, depending on the location of their primary residence. Individual non-local workers may also relocate along the ROI and between segments depending on their assignment.

Tasks expected to mainly employ local workers include ROW clearing, access road and pad construction, foundation construction, restoration, and materials management. Tasks expected to be dominated by non-local workers are related to specialty trades and include tower lacing (assembly), tower setting (erection), wire stringing, supervision, blasting, and construction inspection. The distribution of local/non-local workers shown in Figure 3.13-4 assumes that non-local workers would account for 74 percent of the total workforce for the duration of the Project. Local employment by month for each 140-mile segment is expected to range from 14 workers per month in month 24 to 75 workers per month in months 4, 5, and 6, with an average monthly employment of 54.

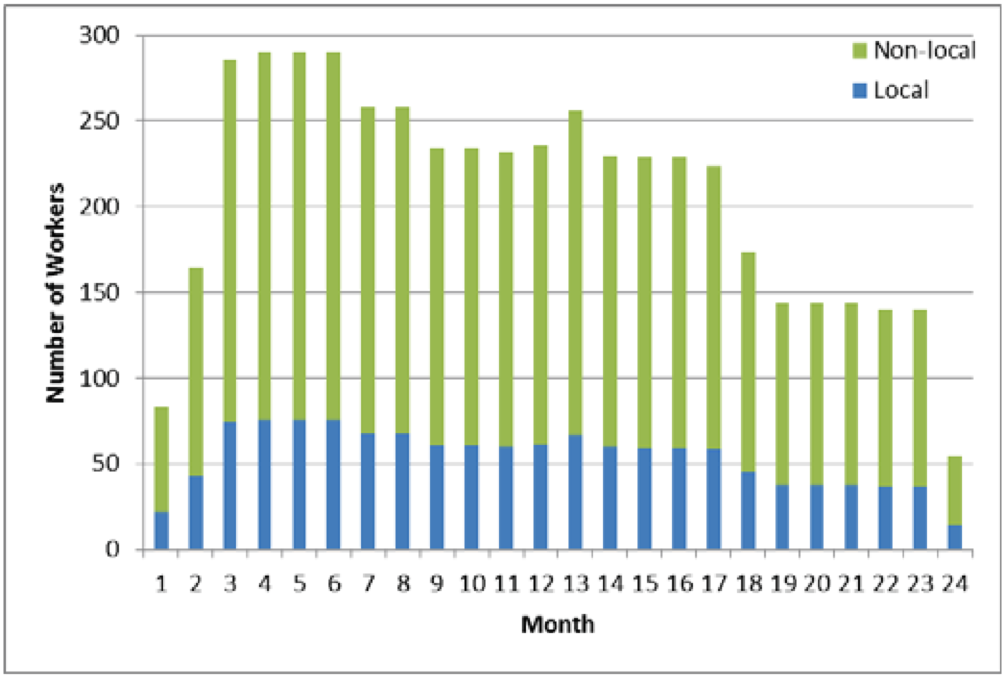

Figure 3.13-4: Estimated Construction Workforce per 140-mile Segment of HVDC Transmission Line by Month and Local/Non-Local Workers

Source: Clean Line (2013, 2014a)

Non-local employment is expected to range from 41 workers per month in month 24 to 215 workers per month in months 4 to 6, with an average monthly employment of 153 (Figure 3.13-4). Very few, if any, of the non-local workers employed during the construction phase of each segment would be expected to permanently relocate to the affected areas. For the purposes of analysis, 10 percent of non-local workers temporarily relocating to the Project sites are assumed to be accompanied by family members; the average size of a family that is relocating is assumed to be three, two adults and one school-age child (Clean Line 2013).

Table 3.13-23 compares the projected average and peak numbers of people relocating by region with the corresponding 2012 population totals. Estimates of people by region are based on the estimated workforce per 140-mile segment, adjusted to account for the miles of HVDC transmission line that would be located in each region. Projected temporary peak increases in population range from less than 0.1 percent of total existing (2012) population in Region 7 to 0.4 percent in Region 1.

Table 3.13-23:
Projected Temporary Change in Population During Construction of the Applicant Proposed Route by Region

Region	2012 Population[1]	Average Employment Forecast		Peak Employment Forecast	
		Number of People Temporarily Relocating[2, 3]	Percent of 2012 Population	Number of People Temporarily Relocating[2, 3]	Percent of 2012 Population
1	51,652	151	0.3	212	0.4
2	88,067	139	0.2	195	0.2
3	348,517	212	0.1	297	0.1
4	147,279	166	0.1	232	0.2
5	334,750	148	0.0	207	0.1
6	42,397	71	0.2	100	0.2
7	1,042,441	56	0.0	79	0.0

1 Existing population data are estimates prepared by the USCB (2014a). These estimates are presented by county in Table 3.13-4.
2 The estimated numbers of people temporarily relocating are based on the projected workforce requirements shown in Figure 3.13-4. An estimated 10 percent of workers temporarily relocating are assumed to be accompanied by their families; the average size of a family that is relocating is assumed to be three, two adults and one school-age child. Workers and their families are allocated by region based on the total miles of transmission line proposed for each region.
3 The values in this table would not change as a result of the minor route variations and adjustments to the HVDC Applicant Proposed Route.

Construction of the HVDC transmission line, converters stations, and AC collection system routes could potentially occur at the same time, with associated temporary population increases also taking place at the same time. If this were to occur, the largest overall temporary population increases would occur in Region 1, with the concurrent construction of the HVDC transmission line, Oklahoma converter station, and four to six AC transmission lines. The combined peak increase in population in Region 1 would be equivalent to 1.6 percent of the 2012 population total. In Region 7, the combined peak (HVDC transmission line plus the Tennessee converter station) would be equivalent to 0.03 percent of the 2012 population (Table 3.13-24).

Table 3.13-24:
Projected Temporary Change in Population During Construction of the Applicant Proposed Route, Converter Stations, and AC Collection System Routes by Region

Region[1]	2012 Population	Average Employment Forecast[1, 2]		Peak Employment Forecast[1, 2]	
		Number of People Temporarily Relocating	Percent of 2012 Population	Number of People Temporarily Relocating	Percent of 2012 Population
1	51,652	545	1.1	807	1.6
7	1,042,441	179	0.0	294	0.0

1 Average and peak employment forecasts by region include the following Project components:
Region 1: 115.5 miles of HVDC transmission line, the Oklahoma converter station, and six AC collection system routes with an average length of 34.4 miles (total length 206 miles)
Region 7: 42.8 miles HVDC transmission line and the Tennessee converter station
2 The values in this table would not change as a result of the minor route variations and adjustments to the HVDC Applicant Proposed Route.

3.13.6.2.1.3.2 Operations and Maintenance Impacts

Operations and maintenance of the HVDC and AC transmission lines would employ 32 workers in Oklahoma, including 15 in Guymon, Oklahoma (Texas County) (Region 1), seven in Woodward, Oklahoma (Region 2), and 10 in Muskogee, Oklahoma (Region 3). An additional 10 workers would be employed in Newport, Arkansas (Jackson County) (Region 6). These workers would be responsible for operations and maintenance of all of the HVDC and AC transmission lines, including those located in Regions 4, 5, and 7. These estimated staffing levels would have no noticeable impact on existing population levels in the potentially affected counties or regions.

Operations and maintenance of the Oklahoma converter station would employ up to 15 workers. If these workers and those required to operate and maintain the HVDC and AC transmission lines in Texas County all permanently relocated to the area from elsewhere, these combined staffing levels (30 workers) would not be expected to have a noticeable impact on existing population levels. Assuming an average family size of three people, a permanent increase in population of 90 people, about 0.4 percent of the estimated 2012 total of 20,620 would result (Table 3.13-4). The operations and maintenance employees associated with the Tennessee converter station would not be expected to reside in the same counties as the HVDC transmission line staff.

3.13.6.2.1.3.3 Decommissioning Impacts

Decommissioning of the HVDC transmission line would require a labor force approximately equal to that needed for its construction. Impacts to population from decommissioning are, therefore, expected to be similar to those from construction.

3.13.6.2.2 Economic Conditions

3.13.6.2.2.1 Converter Stations and AC Interconnection Siting Areas

3.13.6.2.2.1.1 Construction Impacts

Construction of the Oklahoma and Tennessee converter stations would each result in a temporary increase in employment and income in the surrounding area. Construction of each converter station is expected to cost approximately $250 million and employ an average of 138 workers over a 32-month construction period, resulting in estimated total employee earnings of $16.2 million.

Viewed in terms of annualized jobs, each converter station would provide approximately 367 years of employment, with 143 of these job-years in the first 12 months (Year 1), 188 job-years in Year 2, and 36 job-years in Year 3 (Table 3.13-25). Annualized jobs are employment estimates adjusted to be based on 12 months of employment. These estimates do not directly translate into numbers of individual workers, who may be employed for shorter periods. Construction of the Oklahoma converter station would support an estimated total (direct, indirect, and induced) of 266 jobs in Year 1, 348 jobs in Year 2, and 67 jobs in Year 3 (Table 3.13-25). Construction of the Project would also support an estimated total (direct, indirect, and induced) earnings of about $11.3 million in Year 1, $14.8 million in Year 2, and $2.8 million in Year 3 (Table 3.13-26).

Construction of the Tennessee converter station would support an estimated total (direct, indirect, and induced) of 285 jobs in Year 1, 373 jobs in Year 2, and 72 jobs in Year 3 (Table 3.13-25). Construction of the Project would also support an estimated total (direct, indirect, and induced) earnings of about $12.2 million in Year 1, $16.0 million in Year 2, and $3.1 million in Year 3 (Table 3.13-26).

Table 3.13-25:
Estimated Total Employment Associated with Construction of the Converter Stations, AC Collection System Routes, and Applicant Proposed Route by Region and Year

Region	Year 1[1]			Year 2[1]			Year 3[1]		
	Direct Employment	Indirect and Induced Employment[2]	Total Employment[3]	Direct Employment	Indirect and Induced Employment[2]	Total Employment[3]	Direct Employment	Indirect and Induced Employment[2]	Total Employment[3]
Converter Stations[4 5]									
1	143	123	266	188	160	348	36	31	67
7	143	142	285	188	185	373	36	36	72
AC Collection System[6]									
1				305	284	589	305	284	589
Applicant Proposed Route[7]									
1	196	168	364	145	124	269			
2	180	154	334	133	114	247			
3	275	235	510	203	174	377			
4	215	183	398	159	136	294			
5	192	164	355	142	121	263			
6	92	79	171	68	58	127			
7	73	66	139	54	46	100			
Converter Stations, AC Collection System, and Applicant Proposed Route[8]									
1	340	290	630	638	568	1,206	341	314	655
7	216	207	424	242	231	473	36	36	72

1 The direct, indirect, and induced employment estimates presented here by year are slightly different than those in the corresponding table in the Draft EIS because the Applicant adjusted the proposed scheduling of some of the Project components between the Draft and Final EIS. There were no changes to projected employment per component.

2 Indirect and induced effects are estimated using the applicable state multipliers for the construction sector. Regions 4 and 7 include counties from more than one state (see Table 3.13-1). For these regions, the projected construction workforce is divided by state with the appropriate state multipliers used to estimate indirect and induced effects.

2 Total employment consists of direct, indirect, and induced employment.

3 Construction of each converter station is expected to take place over a 32-month period (Figure 3.13-2).

4 The Oklahoma converter station would be located in Region 1; the Tennessee converter station would be located in Region 7.

5 The AC collection system routes assume that six routes with an average length of 34.4 miles would be built. Construction of all six average routes would take place over a 24-month construction period with the workforce assumed to be divided equally between Year 2 and Year 3 for the purposes of analysis.

6 The Applicant Proposed Route would be constructed in five 140-mile-long segments, each taking 24 months to complete. These segments are assumed to be constructed concurrently for the purposes of analysis. The values in this table would not change as a result of the minor route variations and adjustments to the HVDC Applicant Proposed Route.

7 Data are presented for those regions with two or more Project components only. Region 1 includes the proposed Oklahoma converter station, approximately 206 miles of AC collection system routes, and 115.5 miles of HVDC transmission line. Region 7 includes the proposed Tennessee converter station and approximately 42.8 miles of HVDC transmission line.

This page intentionally left blank.

Table 3.13-26:
Estimated Total Earnings Associated with Construction of the Converter Stations, AC Collection System Routes, and Applicant Proposed Route by Region and Year ($ million)

Region	Year 1[1]			Year 2[1]			Year 3[1]		
	Direct Earnings[2]	Indirect and Induced Earnings[2 3]	Total Earnings[2 4]	Direct Earnings[2]	Indirect and Induced Earnings[2 3]	Total Earnings[2 4]	Direct Earnings[2]	Indirect and Induced Earnings[2 3]	Total Earnings[2 4]
Converter Stations[5 6]

Converter Stations, AC Collection System, and Applicant Proposed Route[9]									
1	$15.0	$11.8	$26.8	$28.1	$22.8	$50.9	$15.0	$12.5	$27.5
7	$9.5	$8.4	$17.9	$10.6	$9.5	$20.2	$1.6	$1.5	$3.1

1 The direct, indirect, and induced earnings estimates presented here by year are slightly different than those in the corresponding table in the Draft EIS because the Applicant adjusted the proposed scheduling of some of the Project components between the Draft and Final EIS. There were no changes to projected employment or earnings per component.
2 Direct earnings estimates are based on an average annual construction salary of $44,050 (BLS 2012). Earnings estimates are presented in millions of dollars ($ million).
3 Indirect and induced effects are estimated using the applicable state multipliers for the construction sector. Regions 4 and 7 include counties from more than one state (see Table 3.13-1). Indirect and induced earnings are estimated based on the share of construction in each state.
4 Total earnings consist of direct, indirect, and induced earnings.
5 Construction of each converter station is expected to take place over a 32-month period (Figure 3.13-2).
6 The Oklahoma converter station would be located in Region 1; the Tennessee converter station would be located in Region 7.
7 The AC collection system routes assume that six routes with an average length of 34.4 miles would be built. Construction of all six average routes would take place over a 24-month construction period with the workforce assumed to be divided equally between Year 2 and Year 3 for the purposes of analysis.
8 The Applicant Proposed Route would be constructed in five 140-mile-long segments, each taking 24 months to complete. These segments are assumed to be constructed concurrently for the purposes of analysis. The values in this table would not change as a result of the minor route variations and adjustments to the HVDC Applicant Proposed Route.
9 Data are presented for those regions with two or more Project components only. Region 1 includes the proposed Oklahoma converter station, approximately 206 miles of AC collection system routes, and 115.5 miles of HVDC transmission line. Region 7 includes the proposed Tennessee converter station and approximately 42.8 miles of HVDC transmission line.

This page intentionally left blank.

Total regional economic impacts are estimated at the state level using direct-effect multipliers for earnings and for employment from the U.S. Bureau of Economic Analysis' RIMS II regional modeling system (BEA 2013b). The multipliers for the construction sector in Tennessee are slightly higher than those for the corresponding sector in Oklahoma and, as a result, *total* estimates for the Tennessee converter station are higher than those for the Oklahoma converter station.

3.13.6.2.2.1.2 Operations and Maintenance Impacts

Operations and maintenance of each of the converter stations is expected to support up to 15 workers, with total estimated annual earnings of approximately $1 million. Operations and maintenance activities associated with the Oklahoma converter station would support an estimated total (direct, indirect, and induced) of 54 jobs and $2.1 million in annual earnings (Table 3.13-27). Statewide multipliers for the utilities sector are lower in Tennessee than in Oklahoma. The corresponding total annual impacts for the Tennessee converter station are estimated to be 39 jobs and $1.74 million in total annual earnings (Table 3.13-28).

Table 3.13-27:
Total Annual Economic Impacts from Operations and Maintenance of the Oklahoma Converter Station

Impacts	Employment (Jobs)	Annual Earnings ($ million)[1]
Direct Impact	15	$1.02
Indirect and Induced Impacts[2]	39	$1.11
Total Impact	54	$2.13

1 Total earnings were estimated based on the 2012 estimate of $67,950 for the annual average wage across the United States for all occupations in the electric power generation, transmission, and distribution industry (BLS 2012).
2 Indirect and induced impacts are estimated using the U.S. Bureau of Economic Analysis RIMS II direct-effect multipliers for the state of Oklahoma (BEA 2013b).

Table 3.13-28:
Total Annual Economic Impacts from Operations and Maintenance of the Tennessee Converter Station

Impacts	Employment (Jobs)	Annual Earnings ($ million)[1]
Direct Impact	15	$1.02
Indirect and Induced Impacts[2]	24	$0.72
Total Impact	39	$1.74

1 Total earnings were estimated based on the 2012 estimate of $67,950 for the annual average wage across the United States for all occupations in the electric power generation, transmission, and distribution industry (BLS 2012).
2 Indirect and induced impacts are estimated using the U.S. Bureau of Economic Analysis RIMS II direct-effect multipliers for the state of Tennessee (BEA 2013b).

3.13.6.2.2.1.3 Decommissioning Impacts

Decommissioning of the each converter station would require a labor force approximately equal to that needed for its construction. Local expenditures on materials and supplies and payments to workers would likely be similar, resulting in broadly similar economic impacts to those from construction.

3.13.6.2.2.2 AC Collection System

3.13.6.2.2.2.1 Construction Impacts

Estimates of direct employment and earnings are presented by alternative in Table 3.13-29. These estimates assume similar workforce requirements to those estimated for the HVDC transmission line, with direct earnings estimates based on an average annual construction worker salary of $44,050 (BLS 2012). Total (direct, indirect, and induced) employment and earnings are estimated using the applicable multipliers for Oklahoma and Texas. The resulting annual total employment estimates range from 43 for AC Collection System Route SW-1 to 154 for AC Collection System Route NW-2; respective total earnings are estimated to be $1.7 million and $6.5 million.

Table 3.13-29:
Total Economic Impacts from Construction by AC Collection System Route

Route[1]	Direct Employment	Indirect and Induced Employment[2]	Total Employment	Direct Earnings ($ million)	Indirect and Induced Earnings ($ million)	Total Earnings ($ million)
E-1	43	37	80	$1.9	$1.5	$3.4
E-2	59	50	109	$2.6	$2.0	$4.6
E-3	59	50	109	$2.6	$2.0	$4.6
NE-1	44	38	82	$2.0	$1.5	$3.5
NE-2	39	33	72	$1.7	$1.3	$3.0
NW-1	77	65	142	$3.4	$2.7	$6.1
NW-2	83	71	154	$3.6	$2.9	$6.5
SE-1	60	64	124	$2.6	$2.4	$5.0
SE-2	20	23	43	$0.9	$0.8	$1.7
SE-3	73	75	148	$3.2	$2.9	$6.1
SW-1	20	23	43	$0.9	$0.8	$1.7
SW-2	55	60	115	$2.4	$2.3	$4.7
W-1	31	26	57	$1.4	$1.1	$2.5
Average	51	47	98	$2.2	$1.9	$4.1

1 Construction is expected to take place over a 24-month period.
2 Indirect and induced impacts are estimated using the BEA RIMS II direct effect multipliers for the states of Oklahoma and Texas (BEA 2013b).

Assuming that six routes with an average length of 34.4 miles are constructed would result in direct annual employment of 305, with total (direct, indirect, and induced) employment of about 589 jobs (Table 3.13-25). Direct employment would support $13.4 million in employee earnings, with total employment supporting $24.6 million. These direct and total employment estimates are equivalent to approximately 0.9 percent and 1.7 percent of total employment in Region 1 (35,599) in 2011, respectively (Table 3.13-6).

3.13.6.2.2.2.2 Operations and Maintenance Impacts

Operations and maintenance of the HVDC and AC transmission lines would employ 32 workers in Oklahoma, including 15 in Guymon, Oklahoma (Texas County) (Region 1). The potential economic impacts of this employment are discussed below in the Applicant Proposed Route section.

3.13.6.2.2.2.3 Decommissioning Impacts

Decommissioning of the AC transmission lines would require a labor force approximately equal to that needed for its construction. Local expenditures on materials and supplies and payments to workers would likely be similar, resulting in broadly similar economic impacts to those from construction.

3.13.6.2.2.3 HVDC Applicant Proposed Route

3.13.6.2.2.3.1 Construction Impacts

The transmission line would be constructed in five 140-mile-long segments, each taking 24 months to complete. The estimated workforce is shown by month for a representative 140-mile segment in Figures 3.13-3 and 3.13-4. Total employment by month is expected to range from 55 workers in month 24 to a peak of 290 workers in months 4, 5, and 6, with an average monthly employment of 207. Viewed in terms of annualized jobs, each 140-mile segment would provide approximately 414 years of employment, with approximately 58 percent or 238 of these job-years in the first 12 months (Year 1) and the remaining 176 job-years in Year 2.

Table 3.13-30 compares the projected number of job-years for each region with the corresponding 2011 employment totals. Projected job-years are presented by 12-month period (Year 1 and 2) based on the estimated workforce per 140-mile segment, adjusted to account for the miles of HVDC transmission line that would be located in each region. Viewed as a share of total employment in 2011, projected construction employment ranges from 0.01 percent in Region 7 (Years 1 and 2) to 0.6 percent in Region 1 (Year 1).

Table 3.13-30:
Estimated Direct Construction Employment for the Applicant Proposed Route by Region and Year

Region[2]	2011 Employment[3]	Year 1[1]		Year 2[1]	
		Direct Jobs	Percent of 2011 Employment	Direct Jobs	Percent of 2011 Employment
1	35,599	196	0.6	145	0.4
2	55,875	180	0.3	133	0.2
3	177,897	275	0.2	203	0.1
4	60,648	215	0.4	159	0.3
5	164,835	192	0.1	142	0.1
6	16,439	92	0.6	68	0.3
7	663,979	73	0.01	54	0.01

1 The Applicant Proposed Route would be constructed in five 140-mile-long segments, each taking 24 months to complete. These segments are assumed to be constructed concurrently for the purposes of analysis.
2 Estimated employment by region is based on the projected workforce requirements shown in Figure 3.13-4. Workers are allocated by region based on the total miles of transmission line proposed for each region. The values in this table would not change as a result of the minor route variations and adjustments to the HVDC Applicant Proposed Route.
3 Existing employment data are from the BEA (2013b) and presented by county in Table 3.13-6.

Total (direct, indirect, and induced) employment and earnings estimates for the construction phase of the Project are presented by region and year in Tables 3.13-25 and 3.13-26, respectively. These estimates were developed using an average annual construction worker salary of $44,050 and direct-effect multipliers for the corresponding states. Total employment divided into direct and indirect/induced components is shown graphically for Years 1 and 2 in Figures 3.13-5 and 3.13-6, respectively.

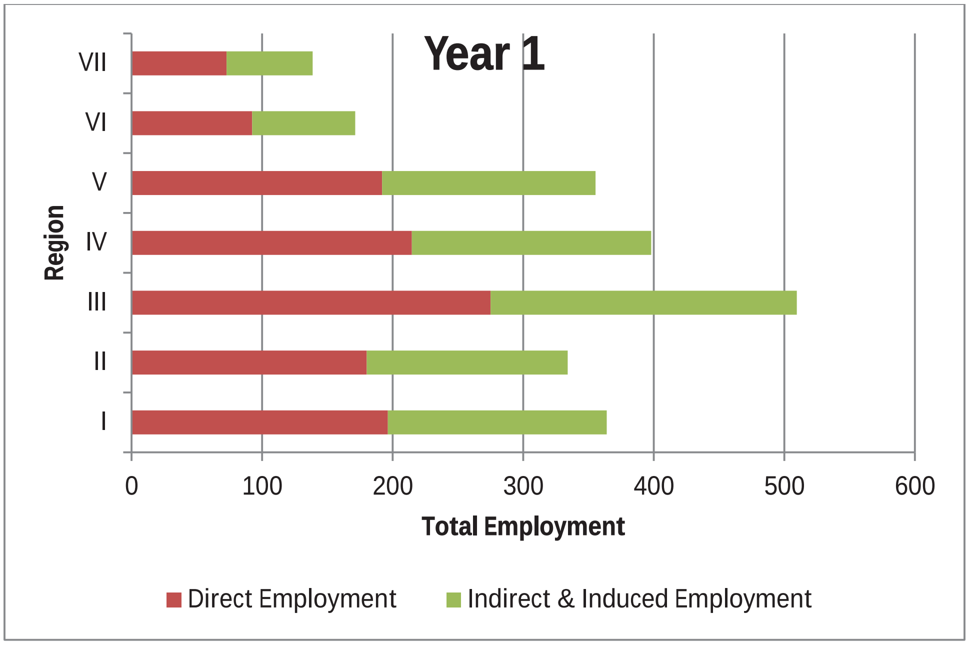

Figure 3.13-5: Total Projected HVDC Construction-Associated Employment by Region, Year 1

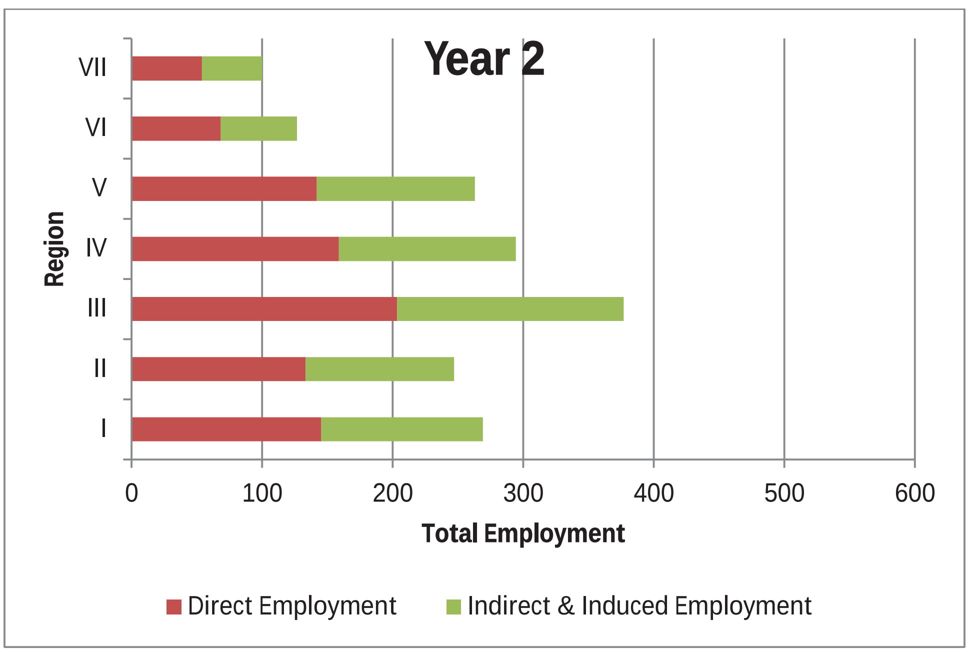

Figure 3.13-6: Total Projected HVDC Construction-Associated Employment by Region, Year 2

As noted above, an estimated 57 percent of the total construction employment (viewed in terms of job-years) would occur in Year 1 (as shown in Figures 3.13-3 and 3.13-4). Viewed by region, total HVDC construction-related employment in Year 1 would range from 139 jobs in Region 7 to 510 jobs in Region 3, reflecting the relative length of transmission line proposed for each region (Table 3.13-25). Viewed as a share of total employment in 2011, total projected construction employment in Year 1 would range from less than 0.1 percent of total employment in Region 7 to 1.0 percent in Regions 1 and 6. Estimated direct earnings for construction activities in Year 1 would range from $3.2 million in Region 7 to $12.1 million in Region 3. Estimated total (direct, indirect, and induced) earnings in Year 1 range from about $5.7 million in Region 7 to $21.6 million in Region 3 (Table 3.13-26).

Table 3.13-25 also summarizes the direct and total (direct, indirect, and induced) employment that would be supported if construction of the converter stations, AC collection system routes, and Applicant Proposed Route were to occur at the same time. Data are presented by year and region. The largest combined employment totals would occur in Region 1, with the concurrent construction of about 116 miles of HVDC transmission line, the Oklahoma converter station, and an estimated 206 miles of AC collection system transmission line. The estimated miles for the AC collection system routes assume that six routes with an average length of 34.4 miles would be built in Years 2 and 3. The combined estimated total employment in Region 1 would be 630 jobs in Year 1, and 1,206 jobs and 655 jobs in Years 2 and 3, respectively, equivalent to about 1.8 percent, 3.4 percent, and 1.8 percent of total employment in the region in 2011, respectively. Combined total employment in Region 7 would be approximately 424 jobs in Year 1, and 473 jobs and 72 jobs in Years 2 and 3, respectively, equivalent to about 0.1 percent and less of total employment in the region in 2011 (Table 3.13-25).

Total combined employment in Region 1 would support an estimated $26.8 million in earnings in Year 1 and $50.9 million and $27.5 million in Years 2 and 3, respectively (Table 3.13-26). In Region 7, combined converter station- and transmission line-related construction employment would support estimated total (direct, indirect, and induced) earnings of $17.9 million in Year 1 and $20.2 million and $3.1 million in Years 2 and 3, respectively (Table 3.13-26).

3.13.6.2.2.3.1.1 *Fayetteville Shale*

One organization commenting on the Draft EIS expressed concern that the potential economic impact of the Project on the development of the Fayetteville shale in Arkansas was not adequately captured. Potential impacts identified by the commenter were possible difficulties siting new well pads, accessing existing well pads, developing gathering pipelines, and using related electronic equipment. Viewed in the context of the overall Fayetteville shale play, the representative ROW that would be occupied by the Project constitutes a small share of the area and is not expected to result in overall reductions to future shale play development.

Potential adverse impacts to mineral resources and supporting infrastructure would be minimized through the implementation of EPMs GE-29, LU-1, and LU-4. These measures state that Clean Line will work with landowners and operators of active oil and gas wells, utilities, and other infrastructure to identify and verity the location of facilities and to minimize adverse impacts (GE-29); the Project would be designed to avoid crossing existing operations (such as the well pads of any active oil and gas wells or impeding access to these resources) (LU-1); and that Clean Line will work with landowners and operators to ensure that access is maintained as needed to existing operations (e.g., to oil/gas wells, private land, agricultural areas, pasture, hunting leases) (LU-4). Micrositing of the lines and towers can be employed when necessary to allow adequate access to existing infrastructure.

3.13.6.2.2.3.2 Operations and Maintenance Impacts

Operations and maintenance of the HVDC and AC transmission lines would employ 32 workers in Oklahoma: 15 in Guymon, Oklahoma (Texas County) (Region 1), seven in Woodward, Oklahoma (Region 2), and 10 in Muskogee, Oklahoma (Region 3). An additional 10 workers would be employed in Newport, Arkansas (Jackson County) (Region 6). Using the annual average wage for installation, maintenance, and repair occupations in the electric power generation, transmission, and distribution industry ($67,950), these jobs would support an estimated direct total of $2.07 million in salary and wages in Oklahoma and $0.65 million in Arkansas. Total (direct, indirect, and induced) estimated employment and earnings are presented by affected region in Table 3.13-31.

Table 3.13-31:
Estimated Total Employment Associated with Operations and Maintenance of the Applicant Proposed Route by Region and Year

Region[2]	Employment[1]		Earnings[1]	
	Direct	Total (Direct, Indirect, and Induced)[3]	Direct[4] ($ million)	Total (Direct, Indirect, and Induced)[3] ($ million)
1	15	54	$1.0	$2.1
2	7	25	$0.5	$1.0
3	10	36	$0.7	$1.4
6	10	25	$0.7	$1.1

1 The values in this table would not change as a result of the minor route variations and adjustments to the HVDC Applicant Proposed Route.
2 Data are presented for the regions where operations and maintenance staff would be based. No operations and maintenance staff are proposed for locations in Regions 4, 5, or 7.
3 Total impacts (employment and earnings) are estimated using statewide multipliers for the utilities sector for Oklahoma (Regions 1, 2, and 3) and Arkansas (6) from the BEA (2013b).
4 Total direct earnings are estimated using an annual average wage of $67,950 (BLS 2012)

Operations and maintenance of the Oklahoma converter station is expected to support up to 15 workers, with estimated annual earnings of approximately $1 million. This employment would support approximately 54 total (direct, indirect, and induced) jobs and $2.1 million in annual earnings (Table 3.13-27). Operations and maintenance of this converter station and HVDC and AC transmission line operations and maintenance in Region 1 would support a combined annual total of 108 jobs and $4.3 million in earnings. The operation and maintenance employees associated with the Tennessee converter station would not be expected to reside in the same counties as the HVDC transmission line staff.

3.13.6.2.2.3.3 Decommissioning Impacts

Decommissioning of the HVDC transmission line would require a labor force approximately equal to that needed for its construction. Local expenditures on materials and supplies and payments to workers would likely be similar, resulting in broadly similar economic impacts to those from construction.

3.13.6.2.3 Agriculture

3.13.6.2.3.1 Converter Stations and AC Interconnection Siting Areas

3.13.6.2.3.1.1 Construction and Operations and Maintenance

Both of the converter stations would affect agricultural land use. The Oklahoma converter station is located on rangeland and would involve the conversion of 45 to 60 acres to industrial use. Construction of the Tennessee converter station would involve the conversion of approximately 45 to 60 acres of land to industrial land use. Potentially affected land uses would likely include cultivated crops and pasture/hay. Construction of both converter stations would also temporarily disturb an additional 5 to 10 acres. Other related short- and long-term land use impacts are described in Section 3.2.6.2.1. These land use conversions would affect a very small share of the total agricultural land use in the Texas County, Oklahoma, and Shelby County, Tennessee, which included about 1.3 million and 81,860 acres in 2012, respectively (see Table 3.13-9).

3.13.6.2.3.1.2 Decommissioning Impacts

Decommissioning of the converter stations would involve restoring the affected sites to their preconstruction condition to the extent possible and a return to their preconstruction use. Some of the affected areas could be used for agriculture again at some point in the future.

3.13.6.2.3.2 AC Collection System and HVDC Applicant Proposed Route

3.13.6.2.3.2.1 Construction and Operations and Maintenance

The majority of the land in the ROI used to assess land use impacts is used for agriculture, with cultivated crops, grassland/herbaceous, and pasture/hay land covers together ranging from 38 percent of the land use ROI in Region 5 to 90 percent in Region 1 (see Tables 3.10-3 through 3.10-11). Livestock dominates the agricultural sectors in Regions 1 through 4 in terms of total market value of agricultural products sold (Table 3.13-9; Figure 3.13-1). Cultivated crops make up a large share of the land use in the land use ROI for Regions 6 and 7, accounting for 78 percent and 69 percent of their respective totals. Crops also account for the vast majority of the value of agricultural products sold in these regions (Table 3.13-9; Figure 3.13-1).

Several people commenting on the Draft EIS stated that farmers and other rural landowners are unique in their ties to the land, with farms and land holdings often passed down through generations, and that if displaced, these landowners would have difficulty finding another property with similar attributes. Commenters also felt that rural landowners are unique because much of their income may be invested in their land and farming operations rather than banks. No farmers and rural landowners are expected to be displaced as a result of the Project.

The introduction of a new transmission line can have an impact on agricultural production by reducing the acreage available for cultivation and, in some cases, disrupting existing harvest patterns, with new transmission line structures affecting the farmer’s ability to maneuver equipment in the vicinity of the immediately affected area. A new transmission line also has the potential to negatively affect farm operations that employ pivot irrigation systems by potentially disrupting the “sweep area.” Potential impacts to agricultural land are discussed in Section 3.2 and include the potential impacts to livestock grazing, crop production, irrigation, global navigation satellite systems (GNSS), and aerial spraying. Impacts addressed include those associated with construction, operations and maintenance, and decommissioning of the Project.

Viewed in terms of agricultural operations in the socioeconomic ROI, total estimated disturbance based on the land use ROI represents a very small share of the 14 million acres of land in farms in the 33 potentially affected counties and is unlikely to noticeably affect overall agricultural production and employment in any of the affected counties. Impacts could, however, be potentially significant to the individual operations affected.

3.13.6.2.3.2.1.1 *Livestock*

Construction and operations and maintenance of the transmission lines could affect the economic value of livestock production in the ROI by increasing ranchers’ costs and decreasing available forage. Potential impacts during construction could result from road construction providing increased access and related disturbance to livestock grazing patterns, temporary reductions in available forage, and reductions in the palatability of forage due to construction-related dust.

The Project could affect net earnings from livestock production in the following ways:

- Decreased forage from land taken out of production.
- Increased management costs associated with controlling additional noxious and invasive vegetation species introduced by Project construction equipment.
- Increased management costs associated with moving livestock around Project-related structures and easements.

Total construction- and operations and maintenance-related disturbance to rangeland and pasture is discussed by Region in Section 3.2. This analysis evaluates impacts in terms of acres of forage that would be temporarily (construction) or permanently (operations) unavailable for use.

The value of the grazing land that would be affected can be approximated using data compiled by the USDA. The average land value for pasture in the affected states ranged from $1,330 per acre in Oklahoma to $3,600 per acre in Tennessee (Table 3.13-32). Average cash rents for pasture ranged from $6.5 per acre in Texas to $20 per acre in Tennessee (Table 3.13-33).

Table 3.13-32:
Average Agricultural Land Value per acre by State, 2013

State	Pasture	Cropland		
		Irrigated[1]	Non-Irrigated[1]	Overall Average[1, 2]
Texas	1,560	1,830	1,610	1,640
Oklahoma	1,330	N/A	1,500	1,520
Arkansas	2,400	3,100	1,950	2,560
Tennessee	3,600	N/A	N/A	3,550
U.S. Total	1,200	N/A	N/A	4,000

N/A = Not available; separate irrigated and non-irrigated values are only provided for states with significant irrigated acreage
1 Values are expressed in dollars per acre.
2 This represents the average land value per acre for all cropland (irrigated and non-irrigated).
Source: USDA (2013b)

Table 3.13-33:
Average Agricultural Cash Rent per Acre by State, 2013

State	Pasture[1]	Cropland		
		Irrigated[1]	Non-Irrigated[1]	Overall Average[1, 2]
Texas	6.5	82	24	35.5
Oklahoma	12	70	32	33.5
Arkansas	18	122	50	95.5
Tennessee	20	160	89	92
U.S. Total	12	202	125	136

1 Values are expressed in dollars per acre.
2 This represents the average land value per acre for all cropland (irrigated and non-irrigated).
Source: USDA (2013a)

3.13.6.2.3.2.1.2 *Cropland*

Construction of the transmission lines could affect net earnings from cropland in the following ways:

- Reduce acreage available for cultivation and use due to the placement of transmission structures, access roads, and other proposed Project uses.
- Increase irrigation costs due to limitations placed with respect to pivot irrigation systems.
- Increase costs due to the need to maneuver farming equipment around transmission structures.
- Increase management costs associated with controlling additional noxious and invasive vegetation species introduced by Project construction equipment.
- Reduce productivity as a result of construction-related soil compaction and erosion and damage to drainage tiles.

Potential impacts to cropland would vary based on the design and location of the transmission line structures and access roads relative to existing agricultural operations.

The value of the cropland that would be affected can be approximated using average land value and cash rent data compiled by the USDA (2013a, 2013b). The average land value for cropland in the affected states ranged from $1,520 per acre in Oklahoma to $3,550 per acre in Tennessee (Table 3.13-32). Average land values for irrigated and non-irrigated cropland are only available for those states with substantial irrigated acreage. Values are typically higher for irrigated land as illustrated in Table 3.13-32. Average cash rents for cropland ranged from $33.5 per acre in Oklahoma to $95.5 per acre in Arkansas (Table 3.13-33). Average cash rents were higher for irrigated than non-irrigated cropland, with average cash rents for irrigated cropland ranging from $70 per acre in Oklahoma to $160 per acre in Tennessee.

The Arkansas Delta Agricultural Economic Impact Study (Arkansas Delta study) commissioned by the Applicant assesses the potential economic impact of the Project on agricultural resources in Jackson, Poinsett, Cross, and Mississippi counties, Arkansas (see Appendix J). These counties are spread over two regions, Regions 6 and 7 (Table 3.13-1). Much of the cropland in these counties has a higher land value than the Arkansas average of $2,560 per acre in 2013 (Table 3.13-32), with prices ranging up to $5,000 per acre. These high values reflect local conditions (soil and topography) that allow farmers to precision level their fields and the ready availability of irrigation water from shallow aquifers.

The Arkansas Delta study estimated the following potential Project-related monetary impacts: one-time impacts expected to occur during construction and operation and annual impacts expected to occur for the life of the project.

3.13.6.2.3.2.1.2.1 One-Time Impacts

Using a “with and without Project” framework, the Arkansas Delta study estimated one-time impacts to agricultural production using data from the University of Arkansas crop budgets and a weighted average of net returns for six crops (corn, soybeans, rice, cotton, wheat, and sorghum). Net returns are estimated by subtracting production and capital costs from gross revenues (average yield per crop × price per unit). Values for the six major crops were weighted based on their share of total cropland in the four study-area counties resulting in a “without Project” average net return of $331 per acre based on a full year of costs and returns (Table 3.13-34).

Net returns estimated for the same average or “composite” acre “with Project” assume no revenues and vary depending on the time year that Project construction begins and the production costs that have been incurred up to that point. If construction begins in March, estimated cumulative production costs per disturbed composite acre would be $60, increasing as the season progresses and peaking at $407 per acre in August. Capital recovery costs are assumed to be constant at $47 per composite acre. Table 3.13-34 shows estimated with Project net returns per composite acre by month.

Table 3.13-34:
Estimated Monetary Impact per Composite Acre by Month

Month	Value per Composite Acre[1]					
	Net Return Without Project	Gross Revenues With Project	Cumulative Production Cost With Project[2]	Capital Cost With Project	Net Return With Project[3]	Estimated Monetary Impact[4]
March	$331	$0	$60	$47	-$107	-$438
April	$331	$0	$161	$47	-$208	-$539
May	$331	$0	$289	$47	-$336	-$667
June	$331	$0	$344	$47	-$391	-$722
July	$331	$0	$369	$47	-$416	-$747
August	$331	$0	$407	$47	-$454	-$785
September	$331	$0	$264	$47	-$311	-$642

1 Values for an average or composite acre were estimated using data from University of Arkansas crop budgets, with values for six major crops (corn, soybeans, rice, cotton, wheat, and sorghum) weighted based on their share of total cropland in the four study area counties. Corresponding estimates of net returns are presented by crop in Appendix 7.7 to the Arkansas Delta study (see Appendix J to this EIS).
2 Production costs consist of operating and post-harvest costs. Operating costs were estimated based on seasonal investments in crop production, which increase as the season progresses up until harvest. For summer crops, production expenditures are lowest from October through February when investments mainly consist of field work completed in fall in preparation for the next crop. Field expenses start to increase in March as farmers till, fertilize, and implement weed control measures in advance of planting, and they continue to increase until the crop is harvested in the fall.
3 The net return with Project equals gross revenues with Project minus cumulative production and capital costs.
4 Estimated monetary impacts per composite acre consist of the net return with Project minus the net return without Project.
Source: Appendix J

3.13.6.2.3.2.1.2.2 Annual Impacts

The Arkansas Delta study (Appendix J of this EIS) considered potential annual impacts to agricultural water management systems, aerial application (crop dusting), crop production logistics, and crop insurance and commodity programs.

Agricultural Water Management Systems

According to Arkansas Delta study, the proposed transmission line structures could potentially affect both center-pivot and furrow irrigation systems. Where sprinkler (center-pivot) irrigation is used, depending on its location, the presence of a new transmission line structure could prevent the pivot from being able to traverse the entire circle, with the area affected increasing the closer the structure is located to the pivot point. For fields with furrow irrigation systems, placement of a new transmission line structure could block the flow of water downstream of the structure, with the area affected increasing the closer the structure is to the upper end of the furrow.

The Arkansas Delta study estimated potential monetary impacts based on the net return for a composite acre that is a weighted average of net returns for irrigated corn, soybean, cotton, and sorghum. Impacts may be estimated by assuming that land that is no longer irrigated will be converted to dryland production, with a commensurate reduction in yield per acre and net returns. The estimated change in net return would involve a reduction from $276 per composite acre to $104 per acre, a 62 percent reduction in net returns. Annual impacts may subsequently be estimated by adjusting estimated net returns based on the number of acres expected to be converted from irrigated to dryland farming.

Aerial Applications (Aerial Spraying)

The Arkansas Delta study assumes that the presence of a transmission line would impede the ability of applicators to apply fertilizers and chemicals resulting in a reduction in yields, which the study authors assumed would be equivalent to 50 percent of the without Project yield. Reducing yields by 50 percent would reduce net returns per composite acre from $331 to -$19 per acre. Impacts may subsequently be estimated by adjusted based on the number of acres where aerial application would be affected.

Crop Production Logistics

The placement of transmission line structures could potentially affect crop production logistics by requiring a farmer to spend additional time maneuvering around the structures. The Arkansas Delta study did not quantify these potential impacts, but it should be noted that with large equipment, the additional time required to maneuver could add to crop production costs in affected areas, especially when combined with associated damage to crops.

Crop Insurance and Commodity Programs

The Arkansas Delta study discusses potential impacts to crop insurance and commodity payment programs in qualitative terms. The crop insurance program uses a 10-year crop yield history to determine losses and payments. Any potential reduction in yield, therefore, has the potential to affect crop insurance damage assessments and payments should a crop be damaged from a storm. Further, changes in yield over time could potentially affect payments a farmer might receive from the new Agricultural Risk Coverage (Individual option) program in the 2014 Farm Bill.

3.13.6.2.3.2.2 Decommissioning Impacts

Potential impacts to agriculture during decommissioning would be similar to those experienced during construction. Decommissioning could involve restoring the affected sites to their preconstruction condition to the extent possible and a return to their preconstruction use. Some of the affected areas could be used for agriculture again at some point in the future.

3.13.6.2.4 Housing

An estimated 26 percent of the construction workforce would be hired and/or contracted locally (i.e., within commuting distance) and would likely commute to and from their homes to work each day. The remaining 74 percent of the construction workforce is assumed to permanently reside further than commuting distance from the Project sites and would be expected to temporarily relocate to the ROI or immediate vicinity for the duration of their employment, possibly commuting home on weekends, depending on the location of their primary residence (Clean Line 2014a). Approximately 10 percent of workers temporarily relocating are assumed for the purposes of analysis to be accompanied by their families (see Section 3.13.9.3).

Almost half (45 percent) of the workers temporarily relocating are expected to require motel or hotel rooms, with the remaining non-local workers expected to require rental housing (apartments, houses, or mobile homes) (20 percent), or provide their own housing in the form of RVs or pop-up trailers (35 percent). Construction workers, particularly those working in less populated areas, often commute relatively long distances to job sites depending on cost and availability of housing and community amenities/services within the vicinity. The Applicant estimates that workers could commute up to 2 hours or approximately 100 miles each way.

Housing availability within the vicinity of the Project would be influenced by a number of factors outside Project demand. Other sources of temporary housing demand could include other construction projects, community-sponsored events, and hunting and other recreational activities.

3.13.6.2.4.1 Converter Stations and AC Interconnection Siting Areas

3.13.6.2.4.1.1 Construction Impacts

Construction of each of the converter stations is expected to employ an average of 138 workers over a 32-month construction period. The share of non-local workers is assumed to be 74 percent for the full duration of construction for each converter station, resulting in an average of 102 non-local workers employed over the 32-month construction period, with an estimated peak of 179 non-local workers employed during months 12 to 17 (Figure 3.13-2). The Oklahoma converter station would be located in Region 1; the Tennessee converter station would be located in Region 7.

Table 3.13-35 compares projected peak housing demand with estimated supply in the two affected regions. These data suggest that adequate temporary housing resources likely exist within each of the affected regions, a situation that is especially likely to be the case for the Tennessee converter station, which is located within commuting distance of the city of Memphis. Existing housing resources are substantially more limited in Region 1, within the counties that make up the region and also elsewhere within a commuting distance of up to 2 hours. Unlike Regions 3 through 7, there are no large communities within 2 hours commuting distance of Region 1. Economic development organizations in the Oklahoma Panhandle region have identified a potential shortage in permanent housing in and around the city of Guymon in Texas County, with these problems expected to be further exacerbated by future wind energy development (Fleming 2013).

3.13.6.2.4.1.2 Operations and Maintenance Impacts

Operations and maintenance of each of the converter stations is expected to employ up to 15 workers. These estimated staffing levels would have a minor impact on existing demand for housing in the potentially affected areas.

3.13.6.2.4.1.3 Decommissioning Impacts

Decommissioning each of the converter stations would require a labor force approximately equal to that needed for its construction. Impacts to housing from decommissioning are, therefore, expected to be similar to those from construction.

3.13.6.2.4.2 AC Collection System

3.13.6.2.4.2.1 Construction Impacts

Assuming six routes with an average length of 34.4 miles are constructed at the same time would result in a combined average of 226 non-local workers and an estimated combined peak of 316 non-local workers temporarily relocating to Region 1. A comparison of expected peak housing demand with existing temporary housing resources suggests that this demand would be equivalent to 52 percent of the hotel and motel rooms assumed to be available and 47 percent of all identified RV spaces (Table 3.13-35).

Table 3.13-35:
Estimated Construction-Related Housing Demand by Project Component, Housing Type, and Region

Region	Projected Non-Local Employment[1]		Projected Peak Housing Demand[2]			Estimated Available Housing Units[3]			Projected Demand as a Share of Existing Resources		
	Average Employment (Jobs/Week)	Peak Employment (Jobs/Week)	Rental Housing	Hotel and Motel Rooms	RV Spaces	Rental Housing[4]	Hotel and Motel Rooms[5]	RV Spaces	Rental Housing	Hotel and Motel Rooms	RV Spaces
Converter Stations											
1	102	179	36	81	63	370	273	235	10	29	27
7	102	179	36	81	63	23,358	2,957	393	0	3	16
AC Collection System[6]											
1	226	316	63	142	111	370	273	235	17	52	47
Applicant Proposed Route[7]											
1	119	168	34	76	59	370	273	235	9	28	25
2	112	158	32	71	55	862	401	94	4	18	59
3	182	255	51	115	89	3,193	718	679	2	16	13
4	130	182	36	82	64	1,335	467	440	3	18	14

Converter Stations, AC Collection System Routes, and Applicant Proposed Route											
1	447	663	133	298	232	370	273	235	36	109	99
7	134	225	45	101	79	23,358	2,957	393	0	3	20

1 An estimated 74 percent of the total construction workforce is assumed to be non-local for the duration of the Project.
2 Projected housing demand is assumed to be divided as follows: rental housing (apartments, houses, or mobile homes) (20 percent), hotel and motel rooms (45 percent), and RV spaces (35 percent) (Clean Line 2013).
3 Estimated available housing units are presented by county in Table 3.13-10. Data are presented for those counties within the ROI only.
4 Many of these available units include more than one bedroom and, if rented, could be occupied by more than one worker. A large number of in-migrating workers on similar projects typically rent a room in a house or live five in a rented house (BLM 2013).
5 Assumes an average occupancy rate of 75 percent for the purposes of analysis, with 25 percent of total units assumed to be potentially available.
6 Assumes six AC collection system routes with an average length of 34.4 miles.
7 The values in this table would not change as a result of the minor route variations and adjustments to the HVDC Applicant Proposed Route.

This page intentionally left blank.

3.13.6.2.4.2.2 Operations and Maintenance Impacts

Combined operation of the HVDC and AC transmission lines in Region 1 is expected to employ 15 workers based in Guymon, Oklahoma (Texas County). This number is not expected to vary based on the selected AC collection system routes or affect existing trends in housing demand in Texas County.

3.13.6.2.4.2.3 Decommissioning Impacts

Decommissioning of the AC transmission lines would require a labor force approximately equal to that needed during construction. Impacts to housing from decommissioning are, therefore, expected to be similar to those from construction.

3.13.6.2.4.3 HVDC Applicant Proposed Route

3.13.6.2.4.3.1 Construction Impacts

The HVDC transmission line would be constructed in five 140-mile-long segments, each taking 24 months to complete. Total employment by month is expected to range from 55 workers in month 24 to a peak of 290 workers in months 4, 5, and 6, with an average monthly employment of 207. The share of non-local workers is assumed to be 74 percent for the full duration of the Project. Non-local employment is expected to range from 41 workers per month in month 24 to 215 workers per month in months 4 to 6, with an average monthly employment of 153 (Figure 3.13-4).

Projected peak housing demand is compared with estimated supply by region in Table 3.13-35. The distribution of non-local workers is based on the miles of transmission line for each region and an average 140-mile-long segment. Demand for rental housing would range from less than 0.1 percent of the estimated available units in Region 7 to 9 percent in Region 1. Estimated peak demand for hotel and motel rooms as a share of existing available units would range from 1 percent in Region 7 to 50 percent in Region 6. Demand as a share of available hotel and motel rooms would also be relatively high in Region 1, accounting for about 28 percent of the available supply (Table 3.13-35).

Estimated peak demand for RV spaces as a share of total identified spaces would range from 4 percent in Region 7 to 59 percent in Region 2. Demand as a share of identified spaces would also be relatively high in Region 6, accounting for about 45 percent of the identified spaces (Table 3.13-35).

Table 3.13-35 also summarizes the estimated demand for housing if construction of the converter stations, AC collection system routes, and Applicant Proposed Route were to all peak at the same time. If construction of the Oklahoma converter station, six AC collection system routes, and the portion of the HVDC transmission line for Region 1 all occurred at the same time, demand for hotel and motel rooms would exceed the estimated available supply by 7 percent and demand for RV spaces would almost be equal to the total number of identified spaces (Table 3.13-35).

If the Tennessee converter station and the portion of the HVDC transmission line for Region 7 were built at the same time, demand for rental housing would be less than 1 percent of the estimated available properties, demand for hotel and motel rooms would be equivalent to 3 percent of the available supply, and demand for RV spaces would be equal to 20 percent of the total identified spaces (Table 3.13-35).

3.13.6.2.4.3.2 Operations and Maintenance Impacts

Operations and maintenance of the HVDC and AC transmission lines would employ 32 workers in Oklahoma: 15 in Guymon, Oklahoma (Texas County) (Region 1), seven in Woodward, Oklahoma (Region 2), and 10 in Muskogee, Oklahoma (Region 2). An additional 10 workers would be employed in Newport, Arkansas (Jackson County) (Region 6). These estimated staffing levels would not be expected to affect existing trends in housing demand in the potentially affected counties or regions.

Operations and maintenance of the converter station in Texas County, Oklahoma, would employ up to 15 workers. If these workers and those required to operate and maintain the HVDC and AC transmission lines in Texas County all permanently relocated to the area from elsewhere, these combined staffing levels would still not be expected to have more than a minor impact on existing housing demand. The operations and maintenance employees associated with Tennessee converter station would not be expected to reside in the same counties as the HVDC transmission line staff.

3.13.6.2.4.3.3 Decommissioning Impacts

Decommissioning of the HVDC transmission line would require a labor force approximately equal to that needed for its construction. Impacts to housing from decommissioning are, therefore, expected to be similar to those from construction.

3.13.6.2.5 Property Values

The HVDC transmission line would require a new ROW. The effect that a transmission line may have on property value is a damage-related issue that would be part of the negotiation between the Applicant and the affected landowner during the easement acquisition process. In theory, the value of each easement should be equal to the difference in value of the affected property before and after easement acquisition and construction of the facilities.

Changes in land use often raise concerns about the potential effect these changes may have on nearby property values. Research into the relationship between electric transmission facilities and local property values has tended to focus on residential properties, employing research methods that can, for the most part, be divided into surveys and opinion-based studies on one hand and quantitative studies largely based on comparisons of market data on the other.

Research conducted since the 1980s has tended to support the idea that proximity to transmission lines may affect the desirability and, therefore, the value of residential property (Bottemiller et al. 2000; Colwell 1990; Cowger et al. 1996; Delaney and Timmons 1992; Des Rosiers 2002; Hamilton and Schwann 1995). Some observers linked this general finding to increased concerns regarding potential EMF-related health effects, but a nationwide survey of real estate appraisers suggests that, for the most part, potential negative effects on property values tend to be related to the visual impact of transmission line facilities (Delaney and Timmons 1992).

The results of the studies cited above suggest that proximity to electric transmission lines can have negative effects on residential property values, with average impacts ranging from less than 1 percent to about 10 percent. The findings of these studies also suggest that this impact decreases with distance and tends to decline over time. A detailed literature review conducted by Chalmers and Voorvaart (2009) supported these conclusions, finding that in studies where depreciation was found, the typical change ranged from 3 percent to 6 percent within a few hundred feet and tended to decrease with distance and over time.

Studies of property-value impacts during periods of physical change, such as new transmission line construction or structural rebuilds, have generally revealed greater short-term impacts than long-term effects. Most studies have concluded that other factors, such as the general location, the size of property, improvements, conditions, amenities, and supply and demand factors in a specific market area are more important criteria than the presence or absence of transmission lines in determining the value of residential real estate.

Some short-term adverse impacts on residential property values (and marketability) might occur on an individual basis as a result of the Project. However, these impacts would be highly variable, individualized, and are difficult to predict. Unique Project characteristics that need to be taken into consideration when assessing the potential effects of transmission line structures on residential property values include the type and height of the structures, the distance and view from the potentially affected property, intervening topography and vegetation, and the property market and type of landscape involved. Chalmers (2012) evaluated the impacts of a 500kV transmission line on rural residential subdivisions in Montana using a case-study approach and a limited number of sales. Finding some evidence of impacts to sales price and the time it took for a property to sell, Chalmers notes that effects vary depending on the characteristics of the affected property and placement of the transmission line.

Few studies have addressed the impacts of transmission lines on the value of commercial and industrial properties. Those that have done so generally find the impacts are less than the impacts on residential properties. In interviews with appraisers, real-estate brokers, and owners and managers of commercial and industrial parks, Chapman (2005) found that, for the most part, the presence of a transmission line had little effect on market prices for commercial and industrial properties.

A review of studies of the impacts on agricultural land found that overhead transmission lines have the potential to reduce the sales price and the effect can vary widely, ranging from no effect to a decrease of 20 percent or more depending on the productivity of the land and the amount of disruption to farm operations (Kroll and Priestly 1992). Priestley (2015) noted that the cited decrease of 20 percent was based on a single appraiser study and was not consistent with the findings of other research on the effects of transmission lines on agricultural properties. More recently, Jackson (2010) assessed the impact of transmission lines on rural land used for agricultural or recreational purposes in Wisconsin. Using multivariate statistical analysis, Jackson found that prices for properties sold with a transmission line easement were 1.1 percent to 2.4 percent less than otherwise comparable properties sold at least 0.25 mile from a transmission line. These differences were not statistically significant (Jackson 2010). Chalmers (2012) evaluated the impacts of a 500kV transmission line on rural property values in Montana. Using a case-study approach and a range of techniques, including paired sales comparison and interviews, Chalmers considered the impacts to a range of rural land uses, broadly comparable to those that would be affected by the Project. Evaluating transactions for production agricultural lands, agricultural lands with recreational influence, and agricultural lands with high amenity recreation and natural features, Chalmers found no evidence that the presence of a transmission line affected sales price.

3.13.6.2.6 Community Services

3.13.6.2.6.1 Converter Stations and AC Interconnection Siting Areas

3.13.6.2.6.1.1 Construction Impacts

Projected peak employment and the number of workers and family members expected to temporarily relocate during construction of the converter stations is discussed in Section 3.13.9.3. The peak increase for each station, estimated to be about 213 people during months 12 to 17, would be equivalent to approximately 1 percent and less than 0.1 percent of the respective existing (2012) populations in Texas County, Oklahoma, and Shelby County, Tennessee.

The temporary addition of these workers to local communities is not expected to affect the levels of service provided by existing law and fire protection personnel. The number of law enforcement and fire departments per county are identified in Table 3.13-11. Increased demands for local services that could occur from construction workers and family members temporarily relocating to the affected areas would be short term. It is anticipated that community commercial and retail services would experience an economic benefit from additional spending from relocating workers and their families.

The closest major medical facility to the Oklahoma converter station is the Memorial Hospital of Texas County, located 10.3 miles northwest of the site in Guymon, Oklahoma. This 47-certified-bed facility has a staff that includes 17 licensed practical nurses, 45 registered practical nurses, and two full-time physicians. This hospital provides emergency room services and would be capable of treating most construction-related injuries. At least six hospitals serve the Memphis area in Tennessee and would be capable of treating construction-related injuries were they to occur (Table 3.3-12). The temporary relocation of workers and family members to the affected areas is not expected to affect existing levels of health care and medical services. Minor increases in demands for local services that could occur from workers and family members temporarily relocating to the area would be short term.

An average and peak of 10 and 18 school-age children are expected to temporarily relocate to the affected counties during construction of each converter station. This potential increase in the number of students would not be expected to affect existing average student/teacher ratios in either affected area (Table 3.13-13).

3.13.6.2.6.1.2 Operations and Maintenance Impacts

Operations and maintenance of each of the converter stations is expected to employ up to 15 workers. If these workers and their families were to relocate from elsewhere, the resulting very small increase in population would not be expected to noticeably affect the provision of community services.

3.13.6.2.6.1.3 Decommissioning Impacts

Decommissioning of each converter stations would require a labor force approximately equal to that needed for its construction. Impacts to community services from decommissioning are, therefore, expected to be similar to those from construction.

3.13.6.2.6.2 AC Collection System

3.13.6.2.6.2.1 Construction Impacts

Projected peak employment and the number of workers and family members expected to temporarily relocate during construction of the AC collection system routes are discussed in Section 3.13.9.3. Assuming that six routes with an average length of 34.4 miles are constructed would result in average and peak population increases of about 271 and 379 people, respectively, approximately 0.5 percent and 0.7 percent of the total 2012 population in Region 1. The temporary addition of these workers to local communities is not expected to affect the levels of service provided by existing law and fire protection personnel. The number of law enforcement and fire departments per county are identified in Table 3.13-11. Increased demands for local services that could occur from construction workers and family members temporarily relocating to the area would be short term. It is anticipated that community commercial and retail services would experience an economic benefit from additional spending from relocating workers and their families.

Construction of the AC collection system routes could result in increased demand for emergency services. Local police assistance would likely be required to facilitate traffic flows during construction at some road crossings and permits may be required for vehicle load and width limits for some of the vehicles delivering Project materials and supplies.

Medical facilities located in Region 1 are identified in Table 3.3-12. Medical facilities are limited in the Texas counties in the region. The Ochiltree General Hospital, a Level IV trauma center, provides emergency services in Ochiltree County. Emergency medical services are provided in Sherman County by the Stratford EMS. Additional hospitals are located in neighboring counties, including the Moore County Hospital, south of Sherman County, which provides 24-hour emergency services. The Oklahoma counties in Region 1—Cimarron, Texas, Beaver, and Harper counties—each have a hospital that provides 24-hour emergency services. These facilities would be capable of treating most construction-related injuries. The temporary relocation of workers and family members to the counties in the region is not expected to affect existing levels of health care and medical services. Minor increases in demands for local services that could occur from workers and family members temporarily relocating to the area would be short term.

The estimated number of children expected to temporarily relocate to Region 1 during peak construction ranges from about 2 (AC Collection System Routes SE-2 and SW-1) to 8 (AC Collection System Route Alternative NW-1). If six routes with an average length of 34.4 miles are constructed, an estimated peak increase of 38 school-age children would result. These children would likely be located in a number of different school districts throughout Region 1 and would not be expected to affect existing average student/teacher ratios (Table 3.13-13).

3.13.6.2.6.2.2 Operations and Maintenance Impacts

Combined operation of the HVDC and AC transmission lines in Region 1 is expected to employ 15 workers based in Guymon, Oklahoma (Texas County). This number is not expected to vary based on the selected AC collection system routes. If these workers and their families were to relocate from elsewhere, the resulting very small increase in population would not be expected to noticeably affect the provision of community services.

3.13.6.2.6.2.3 Decommissioning Impacts

Decommissioning of the transmission lines would require a labor force approximately equal to that needed for their construction. Impacts to community services from decommissioning are, therefore, expected to be similar to those from construction.

3.13.6.2.6.3 HVDC Applicant Proposed Route

3.13.6.2.6.3.1 Construction Impacts

Projected peak employment and the number of workers and family members expected to temporarily relocate during construction of the Applicant Proposed Route are identified by Region in Table 3.13-23, with peak increases in populations ranging from less than 0.1 percent (Region 7) to 0.4 percent (Region 1) of 2012 population totals. The temporary addition of these workers to local communities is not expected to affect the levels of service provided by existing law and fire protection personnel. Law enforcement and fire departments within each region are identified by county in Table 3.13-11. Increased demands for local services that could occur from construction workers and family members temporarily relocating to the affected Regions would be short term. It is anticipated community commercial and retail services would experience an economic benefit from additional spending from relocating workers and their families.

Construction of the HVDC transmission line could result in increased demand for emergency services. Local police assistance would likely be required to facilitate traffic flows during construction at some road crossings and permits may be required for vehicle load and width limits for some of the vehicles delivering Project materials and supplies.

Medical facilities located near the transmission line are identified by location in Table 3.13-12. Construction of the Applicant Proposed Route should not have significant adverse impacts on local and regional medical facilities and services. The temporary relocation of workers and family members to the counties in the ROI is not expected to affect existing levels of health care and medical services. Minor increases in demands for local services that could occur from workers and family members temporarily relocating to the area would be short term.

The numbers of workers expected to temporarily relocate with their families during construction of the Applicant Proposed Route are identified by Region in Table 3.13-36. Table 3.13-36 also identifies the projected peak and average number of school-age children expected to temporarily relocate to each Region, and compares the peak estimates with the existing number of students in each Region. The projected peak number of school children temporarily relocating to the area would be equivalent to approximately 0.01 percent (Region 7) to 0.14 percent (Region 1) of the existing enrollment in school districts in the regions and would have no noticeable effect on existing average student/teacher ratios (Table 3.13-36).

Table 3.13-36 also summarizes the estimated temporary increase in school-age children if construction of the converter stations, AC collection system routes, and Applicant Proposed Route were to all peak at the same time. This increase would affect Regions 1 and 7 and result in increases in school-age children equivalent to 0.58 percent and 0.04 percent of existing enrollment, respectively (Table 3.13-36). These increases would not be expected to affect existing average student/teacher ratios in these regions.

Table 3.13-36:
Projected Construction-Related Demand for Education Resources by Region

Region	1	2	3	4	5	6	7
Applicant Proposed Route[1]							
Projected Non-Local Employment[2]							
Average Employment (Jobs/Week)	126	116	177	138	123	59	47
Peak Employment (Jobs/Week)	177	162	248	194	173	83	66
Projected Number of School Age Children[3]							
Average	13	12	18	14	12	6	5
Peak	18	16	25	19	17	8	7
Estimated Education Resources							
Number of Schools	66	52	177	68	119	21	87
Number of Students	12,701	16,012	57,993	27,456	51,455	7,673	65,177
Number of Teachers	1,312	1,455	5,294	2,112	3,875	611	4,117
Student/Teacher Ratio (average)	9.7	11.0	11.0	13.0	13.3	12.6	15.8
Peak Comparison with Existing Student Numbers							
Percent of Existing Students	0.14	0.10	0.04	0.07	0.03	0.11	0.01

Table 3.13-36:
Projected Construction-Related Demand for Education Resources by Region

Region	1	2	3	4	5	6	7
Applicant Proposed Route, Converter Stations, and AC Collection System Routes[1]							
Projected Number of School Age Children[3]							
Peak	74	16	25	19	17	8	25
Peak Comparison with Existing Student Numbers							
Percent of Existing Students	0.58	0.10	0.04	0.07	0.03	0.11	0.04

1 The values in this table would not change as a result of the minor route variations and adjustments to the HVDC Applicant Proposed Route.
2 An estimated 74 percent of the total construction workforce is assumed to be non-local for the duration of the Project.
3 Projected numbers of school children are based on the assumptions that 10 percent of workers would be accompanied by their families; the average family household includes 1.0 child under the age of 18 years; and all children relocating to the area would be of school age.

3.13.6.2.6.3.2 Operations and Maintenance Impacts

Operations and maintenance of the HVDC and AC transmission lines would employ 32 workers in Oklahoma, including 15 in Guymon, Oklahoma (Texas County) (Region 1), seven in Woodward, Oklahoma (Region 2), and 10 in Muskogee, Oklahoma (Region 3). An additional 10 workers would be employed in Newport, Arkansas (Jackson County) (Region 6). Even if these workers were to relocate to the affected counties from outside the respective region, the associated increase in population would not be expected to noticeably affect the provision of community services.

Operations and maintenance of the converter station in Texas County, Oklahoma, would employ up to 15 workers. If these workers and those required to operate and maintain the HVDC and AC transmission lines in Texas County were all to relocate to the area permanently from elsewhere, these combined staffing levels would still not be expected to have a noticeable impact on community services. The operations and maintenance employees associated with Tennessee converter station would not be expected to reside in the same counties as the HVDC transmission line staff.

3.13.6.2.6.3.3 Decommissioning Impacts

Decommissioning the HVDC transmission line would require a labor force approximately equal to that needed for its construction. Impacts to community services from decommissioning are, therefore, expected to be similar to those from construction.

3.13.6.2.7 Tax Revenues

3.13.6.2.7.1 Converter Stations and AC Interconnection Siting Areas

3.13.6.2.7.1.1 Construction Impacts

Construction of the converter stations would generate sales, use, and lodging tax revenue during the construction period. According to the Applicant, approximately 90 percent of the total estimated construction costs of $250 million for each station would be for materials subject to sales and use tax in Oklahoma and Tennessee, respectively. Estimated sales and use tax revenues are summarized for the two converter stations in Table 3.13-37. Estimated state and county revenues are higher for the Tennessee converter station because the sales and use tax rates are higher in Tennessee and Shelby County (see Tables 3.13-14 and 3.13-17). These revenues would be generated over the 32-month construction period projected for each converter station. The Oklahoma and Tennessee converter stations would be located in Regions 1 and 7, respectively. Local spending by construction workers would also generate sales and lodging tax revenues, but the amount and distribution of this type of spending is difficult to accurately forecast. These potential revenues are not estimated here.

Table 3.13-37:
Estimated Sales and Use Tax Revenues from Converter Station Construction ($ million)

Converter Station	Total Estimated Cost[1]	Estimated State Revenues	Estimated County Revenues
Oklahoma	$250	$10.1	$2.3
Tennessee[1]	$250	$15.8	$5.1

1 Total estimated costs are from Clean Line (2013).

3.13.6.2.7.1.2 Operations and Maintenance Impacts

Operations of the converter stations would generate annual property or ad valorem tax revenues in the counties where they would be located. Using a simplified cost approach and an assumed value of $250 million (Clean Line 2013), annual ad valorem or property tax revenues generated by the Oklahoma converter station would range from $3.2 million to $4.6 million. These estimates are based on Oklahoma's assessment ratio (the share of assessed value subject to taxation) of 22.85 percent and the low and high millage rates identified for Texas County in 2012 (Table 3.13-19). These estimates are for payments that would be made in the first year of operation. Thereafter, ad valorem taxes would be paid annually based on an annual assessment by the responsible taxing agency.

Clean Line has entered into a payment in lieu of taxes (or "PILOT") arrangement with the Economic Development Growth Engine Industrial Development Board of City of Memphis and Shelby County, Tennessee ("EDGE"), with respect to the Tennessee converter station. Plains & Eastern was awarded a 41 percent 11-year PILOT incentive on the real and tangible personal property at the converter station. According to the terms of the agreement, after the construction of the Project, Shelby County would receive an estimated $3.19 million annually for the term of the PILOT and $5.4 million thereafter. Plains & Eastern would pay 59 percent of the assessed value for all real and tangible personal property during the term of the PILOT lease.

3.13.6.2.7.1.3 Decommissioning Impacts

Decommissioning the Project would involve local expenditures for supplies and services and would likely require the temporary influx of construction workers to remove the Project components. This spending would be expected to generate local sales and use tax. It is not possible to estimate approximate values, but adjusted for inflation, tax revenues would likely be generally equivalent to those estimated for construction, other conditions remaining equal. Removal of the Project would reduce the value of the affected property and result in a net reduction in ad valorem and property taxes, generally equivalent to the estimates developed for Project operations.

3.13.6.2.7.2 AC Collection System

3.13.6.2.7.2.1 Construction Impacts

The Applicant estimates that the AC transmission lines would cost $1 million to build per mile with 90 percent of this cost expected to be subject to sales and use tax in the affected states and counties (Clean Line 2014a). Estimated state sales and use tax revenues in Oklahoma range from $0.2 million for AC Collection System Routes SE-2 and SW-1 to $2.5 million for AC Collection System Route Alternative NW-2 (Table 3.13-38). Five of the alternatives are located in Texas counties. Estimated state sales and use tax for those alternatives ranges from $0.6 million (AC Collection System Routes SE-2 and SW-1) to $1.4 million (AC Collection System Routes SE-1 and SW-2). These revenues would be generated over the construction period for each alternative.

Table 3.13-38:
Estimated State Sales and Use Tax Revenues by AC Collection System Route ($ million)

County/ Alternative	Oklahoma[1]				Texas[1]			
	Beaver	Texas	Cimarron	Total	Hansford	Ochiltree	Sherman	Total
E-1	0.2	1.1		1.3				
E-2	0.7	1.1		1.8				
E-3	0.7	1.1		1.8				
NE-1		1.4		1.4				
NE-2		1.2		1.2				
NW-1		2.3	0.1	2.3				
NW-2		2.4	0.1	2.5				
SE-1		0.8		0.8	0.1	1.2		1.4
SE-2		0.2		0.2	0.6			0.6
SE-3	0.1	1.1		1.2		1.3		1.3
SW-1		0.2		0.2	0.6			0.6
SW-2		0.7		0.7	0.2		1.2	1.4
W-1		0.9		0.9				

1 Estimates in this table are for sales and use tax revenues that would be paid to the state. The affected counties in Oklahoma also levy additional sales, use, and lodging taxes (see Table 3.13-15). Estimated county sales and use revenues are not included in this table.

Counties and other local jurisdictions in Texas and Oklahoma are allowed to levy additional sales, use, and lodging taxes within their jurisdictions. Although most counties in Texas levy an additional 0.5 percent sales and use tax, none of the Texas counties in Region 1 currently levy a local sales and use tax (Table 3.13-14). As a result, the AC collection system routes that cross counties in Texas would not generate sales and use tax revenues for those counties.

Sales and use taxes levied by Oklahoma counties are identified in Table 3.13-15 and range from 1 percent to 2 percent in the Oklahoma counties in Region 1. Estimated sales and use tax revenues generated for Texas County would range from less than $0.1 million (AC Collection System Routes SE-2 and SW-1) to $0.5 million (AC Collection System Route NW-1). Four routes cross Beaver County. Sales and use tax revenues generated for that county would range from $0.1 million (AC Collection System Route SE-3) to about $0.7 million (AC Collection System Routes E-2 and E-3). Two routes cross Cimarron County (AC Collection System Routes NW-1 and NW-2) and would each generate less than $0.1 million in county sales and use tax revenues.

Local spending by construction workers would also generate sales and lodging tax revenues, but the amount of spending and distribution by county is difficult to accurately forecast, so these potential revenues are not estimated here.

3.13.6.2.7.2.2 Operations and Maintenance Impacts

Operations and maintenance of the AC collection transmission lines would generate annual property or ad valorem tax revenues in the counties where they would be located. Using a simplified cost approach and an assumed value of $1 million per mile (Clean Line 2014a), annual ad valorem or property tax revenues estimates are presented by alternative and county in Table 3.13-39. In all cases, these estimates are for payments that would be made in the first year of operation. Thereafter, ad valorem taxes would be paid annually based on an annual assessment by the responsible taxing agency.

Estimates for the affected Oklahoma counties (Beaver, Texas, and Cimarron counties) are based on the state assessment ratio (the share of assessed value subject to taxation) of 22.85 percent and the low and high millage rates identified for each county in 2012 (Table 3.13-19). Estimated low ad valorem tax revenues generated for Texas County range from less than $0.1 million (AC Collection System Routes SE-2 and SW-1) to $0.6 million (AC Collection System Route NW-1). Estimated high revenues would range from less than $0.1 million (AC Collection System Routes SE-2 and SW-1) to about $1 million (AC Collection System Route NW-2) (Table 3.13-39).

Low ad valorem tax revenues estimated for Beaver County range from less than $0.1 million (AC Collection System Routes E-1 and SE-3) to about $0.2 million (AC Collection System Routes E-2 and E-3). High estimates range from less than $0.1 million (AC Collection System Route E-1) to about $0.25 million (AC Collection System Route E-3). Two routes cross Cimarron County (AC Collection System Routes NW-1 and NW-2) and would each generate less than $0.1 million in ad valorem tax revenues under the low and high tax scenarios (Table 3.13-39).

Table 3.13-39:
Estimated Ad Valorem Tax Revenues by AC Collection System Route and County in Oklahoma ($ million)

County/Alternative	Low Ad Valorem Tax Estimate[1]			High Ad Valorem Tax Estimate[1]		
	Beaver	Texas	Cimarron	Beaver	Texas	Cimarron
E-1	0.05	0.32		0.06	0.46	
E-2	0.18	0.31		0.24	0.45	
E-3	0.19	0.30		0.25	0.44	
NE-1		0.38			0.55	
NE-2		0.33			0.48	
NW-1		0.64	0.02		0.93	0.02
NW-2		0.47	0.03		0.68	0.03
SE-1		0.24			0.35	
SE-2		0.05			0.07	
SE-3	0.04	0.31		0.05	0.45	
SW-1		0.05			0.07	
SW-2		0.19			0.28	
W-1		0.26			0.38	

1 Low and high ad valorem tax revenues are estimated based on an assumed value of $1 million per mile (Clean Line 2014a), the state assessment ratio, and county specific low and high millage rates.

Estimated ad valorem revenues for the potentially affected counties in Texas are presented in Table 3.13-40. Estimated values range from less than $0.1 million in Hansford and Ochiltree counties to $0.1 million in Ochiltree County (AC Collection System Route SE-3). Values are estimated using the average county millage rates for 2012 (see Table 3.13-18).

Table 3.13-40:
Estimated Ad Valorem Tax Revenues by AC Collection System Route and County in Texas ($ million)

County/Alternative	SE-1	SE-2	SE-3	SW-1	SW-2
Hansford, TX	0.01	0.04		0.04	0.01
Ochiltree, TX	0.08		0.09		
Sherman, TX					0.1

3.13.6.2.7.2.3 Decommissioning Impacts

The general tax implications of decommissioning the AC collection system routes would be similar to those discussed above with respect to the converter stations.

3.13.6.2.7.3 HVDC Applicant Proposed Route

3.13.6.2.7.3.1 Construction Impacts

Construction of the transmission line would generate sales and use tax during the construction period. The Applicant estimates that the transmission line would cost $2 million to build per mile with 90 percent of this cost expected to be subject to sales and use tax in the affected states and counties (Clean Line 2013). Estimated sales and tax revenues are presented by county in Table 3.13-41. These estimates are based on the miles of transmission line proposed for each county and the applicable state and county sales and use tax rates (see Tables 3.13-15, 3.13-16, and 3.13-17).

Total estimated state sales and use tax revenues range from $2.1 million in Tennessee to $34.6 million in Oklahoma; the estimated total for Arkansas would be $32.3 million. Estimated county sales and use tax revenues generated for the affected counties in Oklahoma range from $0.05 million in Kingfisher County to $2.0 million in Beaver County. In Arkansas, estimated sales and use tax revenues generated for the affected counties range from $0.5 million in several different counties to $1.4 million in Jackson County. The transmission line would generate an estimated $0.2 million in county sales and use tax revenues in Shelby County and $0.5 million in Tipton County (Table 3.13-41). These revenues would be generated over the construction period for each transmission line segment.

Table 3.13-41:
Estimated Sales and Use Tax Revenues from HVDC Transmission Line Construction ($ million)

County	Total Estimated Cost[1]	Estimated State Revenues[1]	Estimated County Revenues[1]
Region 1			
Texas, OK	$47.6	$1.9	$0.4
Beaver, OK	$112.0	$4.5	$2.0
Harper, OK	$71.3	$2.9	$1.3
Region 2			
Woodward, OK	$64.8	$2.6	$0.8
Major, OK	$104.3	$4.2	$0.2
Garfield, OK	$44.3	$1.8	$0.1
Region 3			
Kingfisher, OK	$6.7	$0.3	$0.0
Logan, OK	$41.6	$1.7	$0.4
Payne, OK	$71.5	$2.9	$0.5
Lincoln, OK	$19.9	$0.8	$0.2
Creek, OK	$54.9	$2.2	$0.5

Table 3.13-41:
Estimated Sales and Use Tax Revenues from HVDC Transmission Line Construction ($ million)

County	Total Estimated Cost[1]	Estimated State Revenues[1]	Estimated County Revenues[1]
Okmulgee, OK	$55.4	$2.2	$0.6
Muskogee, OK	$79.0	$3.2	$0.5
Region 4			
Sequoyah, OK	$79.9	$3.2	$1.0
Crawford, AR	$56.9	$3.3	$0.5
Franklin, AR	$39.7	$2.3	$0.5
Johnson, AR	$55.6	$3.3	$0.5
Region 5			
Pope, AR	$54.3	$3.2	$0.5
Conway, AR	$43.2	$2.5	$0.7
Van Buren, AR	$26.5	$1.5	$0.5
Cleburne, AR	$47.0	$2.7	$0.7
White, AR	$34.4	$2.0	$0.5
Jackson, AR	$67.3	$3.9	$1.4
Region 6			
Poinsett, AR	$63.0	$3.7	$0.7
Cross, AR	$32.2	$1.9	$0.6
Region 7			
Mississippi, AR	$32.7	$1.9	$0.6
Shelby, TN	$10.0	$0.6	$0.2
Tipton, TN	$22.8	$1.4	$0.5

1 The values in this table do not reflect the small changes that would result from application of the minor route variations and adjustments.

Local spending by construction workers would also generate sales and lodging tax revenues, but the amount of spending and distribution by county is difficult to accurately forecast, so these potential revenues are not estimated here. If construction of all three Project components—converter stations, AC transmission lines, and the HVDC transmission line—were to occur at the same time, combined sales and use totals in Beaver and Texas counties, Oklahoma, and Shelby County, Tennessee, would result. Combined sales and use tax revenue estimates are presented in Table 3.13-42. These estimates are based on a number of assumptions (see the table footnotes) and provide an illustration of the potential combined impacts.

Table 3.13-42:
Estimated Combined Sales and Use Tax Revenues from Converter Stations, AC Collection System, and HVDC Transmission Line Construction ($ million)

County	Estimated County Revenues[1]			
	Converter Stations	AC Collection System[2]	HVDC Transmission Line[3]	Total
Texas, OK	$2.3	$1.4	$0.4	$4.1
Beaver, OK		$0.8	$2.0	$2.8
Shelby, TN	$5.1		$0.2	$5.3

1 Data are combined estimates of the sales and use tax revenues that would accrue to each county and do not include sales and use tax that would be paid to the state (see the above tables).
2 The combined totals for Beaver and Texas counties would vary depending on the selected AC collection system routes. Estimates are based on six alternative AC transmission lines of average length, with four assumed to be partially located in Beaver County.
3 The values in this table do not reflect the small changes that would result from application of the minor route variations and adjustments.

3.13.6.2.7.3.2 Operations and Maintenance Impacts

Operations and maintenance of the HVDC transmission line would generate annual property or ad valorem tax revenues in the counties where it would be located. Using a simplified cost approach and an assumed value of $2 million per mile (Clean Line 2013), annual ad valorem or property tax revenues estimates are presented by county in Tables 3.13-43. In all cases, these estimates are for payments that would be made in the first year of operation. Thereafter, ad valorem taxes would be paid annually based on an annual assessment by the responsible taxing agency.

Estimates for the affected Oklahoma counties are based on the state assessment ratio (the share of assessed value subject to taxation) of 22.85 percent and the low and high millage rates identified for each county in 2012. The low estimates range from about $0.1 million in Kingfisher County (Region 3) to $1.9 million in Major County (Region 2). High estimates range from $0.2 million in Kingfisher County to $2.4 million in Major County (Table 3.13-43).

Table 3.13-43:
Estimated Ad Valorem Tax Revenues for the HVDC Transmission Line by County in Oklahoma ($ million)

Region/County	Total Estimated Cost	Low Millage (2012)	High Millage (2012)	Low Estimate[1]	High Estimate[1]
Region 1					
Texas, OK	$47.6	55.60	80.73	$0.6	$0.9
Beaver, OK	$112.0	52.19	67.94	$1.3	$1.7
Harper, OK	$71.3	57.00	86.36	$0.9	$1.4
Region 2					
Woodward, OK	$64.8	63.64	93.10	$0.9	$1.4
Major, OK	$104.3	78.89	100.12	$1.9	$2.4
Garfield, OK	$44.3	80.29	103.61	$0.8	$1.0
Region 3					
Kingfisher, OK	$6.7	77.99	105.94	$0.1	$0.2
Logan, OK	$41.6	76.29	119.76	$0.7	$1.1
Payne, OK	$71.5	73.67	102.61	$1.2	$1.7
Lincoln, OK	$19.9	73.75	99.11	$0.3	$0.5
Creek, OK	$54.9	73.98	120.55	$0.9	$1.5

Table 3.13-43:
Estimated Ad Valorem Tax Revenues for the HVDC Transmission Line by County in Oklahoma ($ million)

Region/County	Total Estimated Cost	Low Millage (2012)	High Millage (2012)	Low Estimate[1]	High Estimate[1]
Okmulgee, OK	$55.4	80.68	97.29	$1.0	$1.2
Muskogee, OK	$79.0	74.96	100.40	$1.4	$1.8
Region 4					
Sequoyah, OK	$79.9	68.50	84.33	$1.2	$1.5

1 The values in this table do not reflect the small changes that would result from application of the minor route variations and adjustments.
2 Low and high ad valorem tax revenues are estimated based on an assumed value of $2 million per mile (Clean Line 2014a), the state assessment ratio, and county-specific low and high millage rates.

Estimated annual ad valorem tax revenues are presented for the affected counties in Arkansas and Tennessee in Table 3.13-44. Estimates for Arkansas counties are based on the state assessment ratio (the share of assessed value subject to taxation) of 20 percent and the average millage rates identified for each county in 2012. Estimates range from $0.2 million in Van Buren County to about $0.6 million in Crawford, Jackson, and Poinsett counties (Table 3.13-44).

Table 3.13-44:
Estimated Ad Valorem Tax Revenues for the HVDC Transmission Line by County in Arkansas and Tennessee ($ million)

Region/County/State[1, 2, 3]	Total Estimated Cost	Average Millage Rates (2012)	Estimated Ad Valorem Tax Revenues
Region 4			
Crawford, AR	$56.9	49.11	$0.6
Franklin, AR	$39.7	46.79	$0.4
Johnson, AR	$55.6	47.96	$0.5
Region 5			
Pope, AR	$54.3	45.98	$0.5
Conway, AR	$43.2	46.53	$0.4
Van Buren, AR	$26.5	43.90	$0.2
Cleburne, AR	$47.0	41.94	$0.4
White, AR	$34.4	43.01	$0.3
Jackson, AR	$67.3	46.65	$0.6
Region 6			
Poinsett, AR	$63.0	44.47	$0.6
Cross, AR	$32.2	49.89	$0.3
Region 7			
Mississippi, AR	$32.7	49.70	$0.3
Shelby, TN	$10.0	4.06	$0.2
Tipton, TN	$22.8	2.34	$0.3

1 Estimates for Arkansas counties are based on the state assessment ratio (the share of assessed value subject to taxation) of 20 percent and the average millage rates identified for each county.
2 Estimates for Tennessee are based on the state's assessment ratio for utility property (55 percent), the applicable county appraisal ratios, and the average millage rates identified for each county.
3 The values in this table do not reflect the small changes that would result from application of the minor route variations and adjustments.

Annual ad valorem or property taxes are estimated for Shelby and Tipton counties, Tennessee, using the state's assessment ratio for utility property (55 percent), the applicable county appraisal ratios, and the average millage rates identified for each county in 2012. The transmission line would generate about $0.2 million and $0.3 million in annual ad valorem tax revenues in Shelby and Tipton counties, respectively (Table 3.13-44).

The proposed locations of the three Project components—converter stations, AC transmission lines, and the HVDC transmission line—would result in combined ad valorem tax estimates for Beaver and Texas counties, Oklahoma, and Shelby County, Tennessee. Based on the preceding analyses, combined ad valorem tax revenues would range from $4.5 million to $6.5 million in Texas County and from $1.8 million to $2.3 million in Beaver County, with an estimated combined total of $5.8 million in Shelby County.

3.13.6.2.7.3.3 Decommissioning Impacts

The general tax implications of decommissioning the HVDC transmission line would be similar to those discussed above with respect to the converter stations.

3.13.6.3 Impacts Associated with the DOE Alternatives

3.13.6.3.1 Arkansas Converter Station Alternative and AC Interconnection Siting Area

3.13.6.3.1.1 Construction Impacts

The Applicant has indicated that the Arkansas Converter Station Alternative, which would include construction of an associated switching station and transmission line, would cost an estimated $135 million to construct. The proposed converter station would be located in Region 5 in Pope County and require a similar labor force to that required to build the Oklahoma and Tennessee converter stations (Figure 3.13-2).

3.13.6.3.1.1.1 Population

Based on the assumptions outlined in 3.11.5.2.1.1.1, an estimated average of 123 people would temporarily relocate to the vicinity of the Arkansas converter station over the 32-month construction period, with an estimated total of 213 people relocating during the peak construction period (months 12 to 17). The average increase in population would be equivalent to approximately 0.2 percent of the existing (2012) population in Pope County, with the peak increase equivalent to approximately 0.3 percent. Very few, if any, of the non-local workers employed during the construction phase of the converter station projects would be expected to permanently relocate to the affected areas, so it is unlikely that construction of the converter stations would result in any long-term changes in population.

3.13.6.3.1.1.2 Economic Conditions

Construction of the Arkansas converter station would result in a temporary increase in employment and earnings in the local area. This construction is expected to cost approximately $135 million and employ an average of 138 workers over the 32-month construction period, with total estimated employee earnings of $16.2 million. Construction of the converter station would support an estimated average of 244 total (direct, indirect, and induced) jobs and generate a total of $27.1 million in earnings over the course of the 32-month construction period (Table 3.13-45). Indirect and induced jobs and earnings are estimated at the state level using multipliers for the state of Arkansas.

Table 3.13-45:
Total Economic Impacts from Construction of the Arkansas Converter Station Alternative

Impacts	Employment (Jobs)	Annual Earnings	Earnings Over the Construction Period[1]
Direct Impact	138	$6.1	$16.2
Indirect and Induced Impacts[2]	106	$4.1	$10.9
Total Impacts	244	$10.2	$27.1

1 Construction is expected to take place over a 32-month period.
2 Indirect and induced impacts are estimated using the U.S. Bureau of Economic Analysis RIMS II direct effect multipliers for the state of Arkansas (BEA 2013b).

Potential economic impacts related to mineral development and the Fayetteville shale play are addressed in Section 3.13.6.2.2.3.1.1.

3.13.6.3.1.1.3 Housing

Projected peak housing demand for the Arkansas converter station is compared with estimated supply in Region 5 and Pope County in Table 3.13-46. The data presented in Table 3.13-46 suggest that adequate temporary housing would be available to accommodate Project demand in Region 5, and this would also likely be the case for Pope County alone. Rooms are also available in adjacent counties in Region 5, as well as the cities of Little Rock and North Little Rock to the south.

Table 3.13-46:
Projected Construction-Related Housing Demand for the Arkansas Converter Station Alternative

Housing Demand and Supply	Region 5	Pope County
Projected Peak Housing Demand[1]		
Rental Housing	36	36
Hotel and Motel Rooms	81	81
RV Spaces	63	63
Estimated Available Housing Units[2]		
Rental Housing[3]	4,207	878
Hotel and Motel Rooms[4]	1,137	269
RV Spaces	633	177
Projected Demand as Share of Existing Resources		
Rental Housing	1	4
Hotel and Motel Rooms	7	30
RV Spaces	10	35

1 Projected housing demand is assumed to be divided as follows: rental housing (apartments, houses, or mobile homes) (20 percent), hotel and motel rooms (45 percent), and RV spaces (35 percent).
2 Estimated available housing units are presented by county in Table 3.13-10.
3 Many of these available units include more than one bedroom and, if rented, could be occupied by more than one worker. A large number of in-migrating workers on similar projects typically rent a room in a house or live five in a rented house (BLM 2013).
4 Assumes an average occupancy rate of 75 percent for the purposes of analysis, with 25 percent of total units assumed to be potentially available.

3.13.6.3.1.1.4 Community Services

The potential temporary addition of non-local workers to Pope County, which would be equivalent to 0.3 percent of the existing (2012) population, is not expected to affect the levels of service provided by existing law and fire protection personnel. The number of law enforcement and fire departments per county are identified in Table 3.13-11. Increased demands for local services that could occur from construction workers and family members temporarily relocating to the area would be short term.

The closest medical center to the Arkansas converter station siting location is St. Mary's Regional Medical Center. St. Mary's provides emergency room services and has a medical helicopter pad (Table 3.13-12). The temporary relocation of workers and family members to Pope County is not expected to affect existing levels of health care and medical services. Minor increases in demands for local services that could occur from workers and family members temporarily relocating to the area would be short term.

An average and peak of 10 and 18 school-age children, respectively, are expected to temporarily relocate to the affected county during construction the converter station alternative. This minor potential increase in the number of students is not expected to affect existing average student/teacher ratios in Pope County (Table 3.13-13).

3.13.6.3.1.1.5 Tax Revenues

Construction of the Arkansas Converter Station Alternative would generate sales, use, and lodging tax revenue during the construction period. According to the Applicant, approximately 90 percent of the total estimated construction costs of $135 million would be for materials subject to sales and use tax in Arkansas (Clean Line 2013). Estimated state sales and use tax revenues would be $7.9 million, with estimated county revenues of $1.2 million (Table 3.13-47).

Table 3.13-47:
Estimated Sales and Use Tax Revenues from Construction of the Arkansas Converter Station Alternative ($ million)

County	Total Estimated Cost	Estimated State Revenues	Estimated County Revenues
Pope	$135	$7.9	$1.2

3.13.6.3.1.2 Operations and Maintenance Impacts

3.13.6.3.1.2.1 Population

Operations and maintenance of the Arkansas converter station is expected to employ up to 15 workers. These estimated staffing levels would have no noticeable impact on existing population levels in Pope County.

3.13.6.3.1.2.2 Economic Conditions

Operations and maintenance of the Arkansas converter station would support up to 15 workers, with estimated annual earnings of approximately $1 million. Operations and maintenance activities would support an estimated total (direct, indirect, and induced) of 37 jobs and $1.7 million in annual earnings (Table 3.13-48). Indirect and induced jobs and earnings are estimated at the state level using multipliers for the state of Arkansas.

Table 3.13-48:
Total Annual Economic Impacts from Operations and Maintenance of the Arkansas Converter Station Alternative

Impacts	Employment (Jobs)	Annual Earnings ($ million)[1]
Direct Impact	15	$1.02
Indirect and Induced Impacts[2]	22	$0.63
Total Impacts	37	$1.65

1 Total earnings were estimated based on the 2012 estimate of $67,950 for the annual average wage across the United States for all occupations in the electric power generation, transmission, and distribution industry (BLS 2012).
2 Indirect and induced impacts are estimated using the U.S. Bureau of Economic Analysis RIMS II direct-effect multipliers for the state of Oklahoma (BEA 2013b).

3.13.6.3.1.2.3 Housing

The potential relocation of up to 15 workers to Pope County would have no noticeable impact on existing demand for housing in the potentially affected counties.

3.13.6.3.1.2.4 Community Services

If up to 15 workers and their families were to relocate from elsewhere, the resulting very small increase in population would not be expected to noticeably affect the provision of community services.

3.13.6.3.1.2.5 Tax Revenues

Operations and maintenance of the Arkansas converter station would generate annual property or ad valorem tax revenues in Pope County. Using a simplified cost approach and an assumed value of $135 million, annual ad valorem or property tax revenues generated by the converter station would be about $1.2 million in the first year of operation. These estimates are based on Arkansas' assessment ratio of 20 percent and the 2012 millage rate for Pope County (Table 3.13-20). After the first year of operation, ad valorem taxes would be paid annually and would be based on an annual assessment by the responsible taxing agency.

3.13.6.3.1.3 Decommissioning Impacts

Decommissioning the converter station would require a labor force approximately equal to that needed for its construction. Impacts to population, economic conditions, housing, and community services from decommissioning are, therefore, expected to be similar to those from construction. Decommissioning of the Arkansas converter station and associated transmission line would be expected to generate local sales and use tax, which, adjusted for inflation, would likely be generally equivalent to those estimated for construction, other conditions remaining equal. Removal of the converter station would reduce the value of the affected property and result in a net reduction in ad valorem and property taxes, generally equivalent to the estimates developed for Project operations and maintenance.

3.13.6.3.2 HVDC Alternative Routes

The HVDC alternative routes and their net change in length relative to the Applicant Proposed Route are presented in Table 3.13-49. These alternatives are mainly alternatives to sections of the Applicant Proposed Route in each region, not complete alternative routes.

As described in Appendix M and summarized in Section 2.4.2.2, route adjustments were developed for HVDC Alternative Routes 3-A, 5-B, 5-E, and 6-A to maintain an end-to-end route with Applicant Proposed Route Links that were affected by minor route variations and adjustments. Viewed at a county level, these variations would change the total length by county by less than 1 mile in all cases and would have minor effects on the impact analyses presented in the following subsections.

Table 3.13-49:
HVDC Alternative Routes by Region

Region	Miles by Region[2]	Net Change in Length (miles)[2]	Percent Change in Length[3]	Estimated Change Relative to Applicant Proposed Route During Construction[1]			
				Peak Employment (Local and Non-Local Workers)	Non-Local Workers Temporarily Relocating	Total Number of People Temporarily Relocating	Number of School Age Children
Region 1	115.5						
AR 1-A		9.4	8	19	14	16	1
AR 1-B		-2.0	-2	-4	-3	-3	0
AR 1-C		-1.8	-2	-4	-3	-3	0
AR 1-D		-0.1	0	0	0	0	0
Region 2	106.0						
AR 2-A		2.7	3	5	4	5	0
AR 2-B		-1.5	-1	-3	-2	-3	0
Region 3	161.7						
AR 3-A		-2.4	-1	-5	-4	-5	0
AR 3-B		-2.2	-1	-5	-3	-4	0
AR 3-C		3.1	2	7	5	6	0
AR 3-D		4.2	3	9	7	8	1
AR 3-E		0.8	0	2	1	1	0
Region 4	126.3						
AR 4-A		-2.0	-2	-4	-3	-3	0
AR 4-B		-2.7	-2	-5	-4	-5	0
AR 4-C		1.2	1	2	2	2	0
AR 4-D		0.0	0	0	0	0	0
AR 4-E		-2.0	-2	-4	-3	-3	0
Region 5	112.8						
AR 5-A		0.4	0	1	1	1	0
AR 5-B		3.9	3	9	7	8	1
AR 5-C		4.7	4	11	8	10	1
AR 5-D		1.2	1	3	2	3	0
AR 5-E		3.2	3	8	6	7	1
AR 5-F		3.6	3	9	6	8	1
Region 6	54.3						
AR 6-A		-1.5	-3	-2	-2	-2	0
AR 6-B		4.5	8	7	5	7	1
AR 6-C		-1.7	-3	-3	-2	-2	0
AR 6-D		0.6	1	1	1	1	0

Table 3.13-49:
HVDC Alternative Routes by Region

Region	Miles by Region[2]	Net Change in Length (miles)[2]	Percent Change in Length[3]	Estimated Change Relative to Applicant Proposed Route During Construction[1]			
				Peak Employment (Local and Non-Local Workers)	Non-Local Workers Temporarily Relocating	Total Number of People Temporarily Relocating	Number of School Age Children
Region 7	42.8						
AR 7-A		14.7	34	21	16	19	2
AR 7-B		0.2	1	0	0	0	0
AR 7-C		10.6	25	15	11	14	1
AR 7-D		0.1	0	0	0	0	0

1 Estimated changes relative to the Applicant Proposed Route are based on the per-mile values of the affected resource category by region.
2 The values in this table do not reflect the minor changes that would result from application of the minor route variations and adjustments.
3 Percent change is the net change in length as a percent of the total miles per region.

3.13.6.3.2.1 Construction Impacts

3.13.6.3.2.1.1 Population

Viewed by region, proposed changes in length range from a decrease of 2.7 miles in Region 4 (HVDC Alternative Route 4-B) to an increase of 10.6 miles and 14.7 miles in Region 7 (HVDC Alternative Routes 7-C and 7-A, respectively) (Table 3.13-49). HVDC Alternative Route 1-A would also result in a relative large increase, a net gain of 9.4 miles. Net changes to the projected temporary peak increases in population summarized in Table 3.13-23, range from decreases of about 5 people in Region 3 (HVDC Alternative Route 3-A) and Region 4 (HVDC Alternative Route 4-B) to increases of 16 people in Region 1 (HVDC Alternative Route 1-A) and 19 people in Region 7 (HVDC Alternative Route 7-A) (Table 3.13-49). These changes would have very small to no effect on the estimated changes in population summarized Table 3.13-23.

3.13.6.3.2.1.2 Economic Conditions

Substituting one or more of the HVDC alternative routes for the corresponding links of the Applicant Proposed Route would not substantially affect the regional economic impact estimates presented by region in Tables 3.13-25 and 3.13-26. Estimated changes in peak direct employment (local and non-local workers) by HVDC alternative route would range from -5 workers in Region 3 (HVDC Alternatives 3-A and 3-B) to 21 workers in Region 7 (HVDC Alternative Route 7-A) and 19 workers in Region 1 (HVDC Alternative Route 1-A) (Table 3.13-49).

3.13.6.3.2.1.3 Housing

The net change in the number of people who would temporarily relocate to each region, relative to the Applicant Proposed Route, is identified by HVDC alternative route in Table 3.13-49. The largest net increases would occur in Region 1 with the addition of 16 people (HVDC Alternative Route 1-A) and Region 7 where 14 and 19 more people could be added (HVDC Alternative Routes 7-C and 7-A, respectively). Substituting one of more of the HVDC alternative routes for the corresponding section of the Applicant Proposed Route would not substantially affect the findings of the housing analysis summarized in Section 3.13.5.2.4.

3.13.6.3.2.1.4 Community Services

The estimated net changes in workers and family members temporarily relocating to the affected regions identified in Table 3.13-49 are not expected to alter the conclusions presented with respect to the Applicant Proposed Route and community services in Section 3.13.5.2.6. The majority of the HVDC alternative routes would not affect the peak number of school age children temporarily relocating to the affected regions. In other cases, there would be a potential increase of one to two school-age children relative to the Applicant Proposed Route for that region (Table 3.13-49).

3.13.6.3.2.1.5 Tax Revenues

Changes in the projected length of the transmission line by county would result in corresponding changes in construction-related sales and use tax revenues expected to accrue to the affected counties and states. Net changes in estimated sales and use tax revenues, relative to the Applicant Proposed Route, are identified by county in Table 3.13-50. In most cases, the miles of transmission line in each county are affected by more than one alternative. The largest estimated change (positive or negative) relative to the Applicant Proposed Route is identified by county in Table 3.13-50 to ensure that the largest potential variation is considered in the following assessment.

Table 3.13-50:
Estimated Tax Revenues by HVDC Alternative Route and County

County[1]	Total Crossed by Applicant Proposed Route	Largest Net Change (miles)[2]	Percent Change in Miles	Estimated Change Relative to the Applicant Proposed Route		
				Construction Phase Sales and Use Tax Revenues ($ million)		Ad Valorem and Property Tax Revenues ($ million)[3]
				State	County	
Region 1						
Texas, OK	23.8	1.4	6	$0.11	$0.03	$0.04
Beaver, OK	56.0	4.3	8	$0.35	$0.15	$0.12
Harper, OK	35.6	3.8	11	$0.31	$0.14	$0.12
Region 2						
Woodward, OK	32.4	-0.9	-3	-$0.07	-$0.02	-$0.03
Major, OK	52.2	3.6	7	$0.29	$0.02	$0.15
Garfield, OK	22.2	1.6	7	$0.13	$0.01	$0.07
Region 3						
Garfield, OK	22.2	7.0	32	$0.6	$0.0	$0.29
Kingfisher, OK	3.4	-3.4	-100	-$0.28	-$0.05	-$0.14
Logan, OK	20.8	-7.0	-34	-$0.57	-$0.13	-$0.31

Region 4						
Sequoyah, OK	39.9	-1.1	-3	-$0.09	-$0.03	-$0.04
Crawford, AR	28.4	-3.5	-12	-$0.41	-$0.06	-$0.07
Franklin, AR	19.8	1.9	10	$0.22	$0.05	$0.04
Johnson, AR	27.8	1.0	4	$0.12	$0.02	$0.02

Table 3.13-50:
Estimated Tax Revenues by HVDC Alternative Route and County

County[1]	Total Crossed by Applicant Proposed Route	Largest Net Change (miles)[2]	Percent Change in Miles	Estimated Change Relative to the Applicant Proposed Route: Construction Phase Sales and Use Tax Revenues ($ million) — State	Construction Phase Sales and Use Tax Revenues ($ million) — County	Ad Valorem and Property Tax Revenues ($ million)[3]
Pope, AR	27.1	-3.1	-11	-$0.36	-$0.06	-$0.06
Region 5						
Pope, AR	27.1	1.1	4	$0.13	$0.02	$0.02
Conway, AR	21.6	0.1	0	$0.01	$0.00	$0.00
Van Buren, AR	13.2	-13.2	-100	-$1.54	-$0.48	-$0.23
Cleburne, AR	23.5	-23.5	-100	-$2.75	-$0.69	-$0.39
Faulkner, AR	0.0	21.8	100	$2.55	$0.20	$0.34
White, AR	17.2	17.6	102	$2.06	$0.48	$0.59
Jackson, AR	33.7	-0.5	-1	-$0.06	-$0.02	$0.00
Region 6						
Jackson, AR	33.7	4.4	13	$0.51	$0.18	$0.00
Poinsett, AR	31.5	14.4	46	$1.68	$0.32	$0.13
Cross, AR	16.1	-16.1	-100	-$1.88	-$0.58	$0.00
Region 7						
Mississippi, AR	16.3	12.2	75	$1.43	$0.44	$0.00
Shelby, TN	5.0	12.9	257	$1.63	$0.52	$0.58
Tipton, TN	11.4	4.1	36	$0.52	$0.17	$0.11

1 The values in this table do not reflect the minor changes that would result from application of the minor route variations and adjustments.
2 The miles of transmission line in some counties would be affected under more than one alternative. This column presents the largest change (positive or negative) relative to the Applicant Proposed Route that could occur in each county.
3 Estimated as valorem tax revenues for the Applicant Proposed Route in Oklahoma counties are based on average low and high millage rates (Table 3.13-43). This sensitivity analysis is based on the average of this range of estimates for each county.

Viewed as a relative share of the Applicant Proposed Route, estimated changes in miles of HVDC transmission line by county would range from less than 1 percent to 257 percent. In four counties the largest change relative to the Applicant Proposed Route would be a 100 percent decrease because the corresponding HVDC alternative route would no longer cross that county. The four counties that would no longer be crossed are Kingfisher County, Oklahoma (Region 3), Van Buren and Cleburne counties, Arkansas (Region 5), and Cross County, Arkansas (Region 6). Two of the alternative routes for Region 5 (HVDC Alternative Routes 5-B and 5-E) would cross Faulkner County, Arkansas, which is not crossed by the Applicant Proposed Route. The largest change for Faulkner County would occur under HVDC Alternative 5-E, which would involve construction of 21.8 miles of HVDC transmission line across the county (Table 3.13-50).

Relative to the Applicant Proposed Route, the largest changes in estimated sales and use tax revenue that would accrue to the respective state would occur in counties in Region 5 and range from a decrease of $2.75 million (-100 percent) in Cleburne County to an increase of $2.55 million (100 percent) in Faulkner County. Changes in estimated sales and use tax that would be paid to each county would range from a decrease of about $0.7 million in Cleburne County, Arkansas (Region 5) to an estimated increase of $0.5 million in Shelby County, Tennessee (Region 7) (Table 3.13-50).

3.13.6.3.2.2 Operations and Maintenance Impacts

3.13.6.3.2.2.1 Population, Economic Conditions, Housing, and Community Services

Substituting one of more of the HVDC alternative routes for the corresponding link of the Applicant Proposed Route would not affect estimated operations and maintenance employment for the HVDC and AC transmission lines. Potential impacts to population, economic conditions, housing, and community services from operations and maintenance related to estimated operations and maintenance employment would be the same or very similar to those described above for the Applicant Proposed Route.

3.13.6.3.2.2.2 Property Values

The discussion of property value impacts in Section 3.13.6.2.5 would also apply to the HVDC alternative routes.

3.13.6.3.2.2.3 Tax Revenues

Changes in the projected length of the transmission line by county would result in corresponding changes in the property and ad valorem tax revenues expected to accrue to the affected counties. Net changes in estimated property and ad valorem tax revenues, relative to the Applicant Proposed Route, are identified by county in Table 3.13-50. These changes would be less than $1 million in all cases, ranging from a decrease of about $0.4 million in Cleburne County, Arkansas (Region 5), which would not be crossed by HVDC Alternative Routes 5-B and 5-E, to a relative increase of $0.6 million in Shelby County, Tennessee (Region 7) (Table 3.13-50).

3.13.6.3.2.3 Decommissioning Impacts

3.13.6.3.2.3.1 Population, Economic Conditions, Housing, and Community Services

Decommissioning of the proposed HVDC transmission line would require a labor force approximately equal to that needed for its construction. This would be the case for the Applicant Proposed Route and all the HVDC alternative routes. Impacts to population, economic conditions, housing, and community services from decommissioning are, therefore, expected to be similar to those from construction.

3.13.6.3.2.3.2 Tax Revenues

The general tax implications of decommissioning the HVDC transmission line would be similar to those discussed with respect to the converter stations in Section 3.13.5.2.7 for the Applicant Proposed Route and all the HVDC alternative routes.

3.13.6.4 Best Management Practices

A potential impact related to housing demand exists specifically in Region 1: there is a projected shortage of hotel and motel rooms and RV spaces in this region that would be further exacerbated if the construction schedules for the Oklahoma converter station, AC collection system, and HVDC transmission line were to overlap. The analysis assumes that 25 percent of total hotel and motel units would typically be available. This availability could be further reduced by other outside activities in the ROI such as other construction projects, community-sponsored events, and hunting and other recreational activities.

The Applicant has developed a comprehensive list of EPMs that will help avoid and minimize impacts to socioeconomic resources. A complete list of EPMs for the Project is provided in Appendix F; EPMs that pertain to socioeconomic resources are identified in Section 3.13.6.1. Additionally, the Applicant will prepare and implement a workforce housing strategy that would minimize potential impacts to housing availability. This strategy would consider Project component construction schedules, workforce required, and other outside influences.

3.13.6.5 Unavoidable Adverse Impacts

No unavoidable adverse impacts to socioeconomic resources were identified.

3.13.6.6 Irreversible and Irretrievable Commitment of Resources

No irreversible or irretrievable commitments of socioeconomic resources were identified. Construction and operation of the Project would involve the use of capital and labor resources. Construction of the Project would also involve the use of temporary housing resources in the Project vicinity. These types of short-term resource use have opportunity costs (resources used for the Project cannot be used for other concurrent projects), but they are not irreversible or irretrievable.

3.13.6.7 Relationship between Local Short-term Uses and Long-term Productivity

Potential short-term impacts to socioeconomic resources are not expected to outweigh the long-term benefits of the Project. In the long term, the Project would be expected to increase economic productivity through the delivery of renewable energy generated in the Oklahoma Panhandle region to load-serving entities in the mid-south and southeast regions of the United States.

3.13.6.8 Impacts from Connected Actions

3.13.6.8.1 Wind Energy Generation

For the purposes of analysis, the Applicant assumed that 90 percent of this capacity would be constructed over a 2-year timeframe leading up to the commercial operation date of the Project, with the remaining 10 percent expected to be built within a year following this date (Clean Line 2014b). Individual wind farms could range in capacity from 50MW to 1,000MW in a single phase; multiple-phased projects are possible. Future nameplate capacities for a single turbine are assumed to range from 1.5MW to 3.5MW (Clean Line 2014b).

The potential socioeconomic impacts of the development of approximately 4,000MW of wind generating capacity in the 12 identified WDZs (Table 3.13-21) are assessed using data derived from the DOE National Renewable Energy Laboratory's Jobs and Economic Development Impacts (JEDI) Wind model (NREL 2014). The JEDI Wind model allows the user to identify potential impacts assuming general wind industry averages.

The following analysis assesses two potential scenarios based on the range of potential capacity for individual wind farms (50MW to 1,000MW per facility). These scenarios recognize that there are labor-related economies of scale associated with larger facilities, during both construction and operation. The two scenarios are as follows: (1) 74 facilities with a nameplate capacity of 53MW, for a total capacity of 3,885MW; and (2) four facilities with a nameplate capacity of 975MW, for a total capacity of 3,900MW. The first scenario assumes an average facility (wind farm) consists of sixteen 3.5MW turbines. The second scenario assumes an average facility (wind farm) consists of six hundred fifty 1.5MW turbines. In both scenarios, the proposed generating capacity is assumed to be divided equally between Oklahoma and Texas, with the same total capacity and number of facilities located in the WDZs in each state. Construction is also assumed to spread evenly over the 2 years prior to the transmission line Project's commercial operation date.

3.13.6.8.1.1 Population

3.13.6.8.1.1.1 Construction Impacts

Total annual employment estimates are presented by wind development scenario and stated in Table 3.13-51. Viewed in FTEs, total direct employment under Scenario 1 would be equivalent to 2,080 FTEs. Total direct employment under Scenario 2 would be less than half this total (1,012 FTEs), reflecting the labor economies of scale involved in constructing four 975MW facilities (Scenario 2) versus seventy-four 53MW facilities (Scenario 1). FTEs are employment estimates based on 12 months (2,080 hours) employment. These numbers do not translate into individual workers who may be employed for shorter periods.

Table 3.13-51:
Estimated Annual Change in Population During Construction by Potential Wind Development Scenario

Workers/Population[1]	Scenario 1[2]			Scenario 2[2]		
	Oklahoma	Texas	Region 1 Total	Oklahoma	Texas	Region 1 Total
Workers[3]						
Commute to Job Site Daily[4]	589	589	1,179	276	270	547
Move to the Affected Region alone[5]	414	397	812	215	204	419
Move to the Affected Region with family[5]	46	44	90	24	23	47
Total	1,050	1,031	2,080	515	497	1,012
Population						
2012 Population[6]	28,658	19,322	51,652	28,658	19,322	51,652
Number of People Temporarily Relocating[7]	552	530	1,082	287	272	558
Percent of 2012 Population	1.9	2.7	2.1	1.0	1.4	1.1

1 Data are annual estimates and assume that construction would be spread evenly over 2 years.
2 Scenario 1 consists of 74 wind generation facilities with a nameplate capacity of 53MW, for a total capacity of 3,885MW; Scenario 2 consists of four facilities with a nameplate capacity of 975MW, for a total capacity of 3,900MW.
3 The JEDI Wind model was used to estimate construction workforce requirements by scenario and state. Jobs are FTEs for a period of one year (1 FTE = 2,080 hours).
4 The share of the annual construction workforce expected to be hired locally was estimated using the JEDI Wind model and varies slightly by state and scenario.
5 An estimated 90 percent of workers temporarily relocating to the region are assumed to do so alone. The remaining 10 percent are assumed to be accompanied by their families for the purposes of analysis.
6 2012 population totals are as follows:
Oklahoma = Cimarron, Texas, and Beaver counties
Texas = Hansford, Ochiltree, and Sherman counties
Region 1 Total = The above six counties plus Harper County, Oklahoma (see Table 3.13-4).
7 Number of people temporarily relocating assumes an average family size of 3 (two adults and one school-age child).

The share of the annual construction workforce expected to be hired or contracted locally was estimated using the JEDI Wind model and varies slightly by state and scenario. According to the JEDI Wind model, an estimated 56 percent (Oklahoma) and 57 percent (Texas) of workers under Scenario 1 would be hired locally; 54 percent (Oklahoma and Texas) of the annual construction workforce would be expected to be hired locally under Scenario 2. The remaining workforce would be expected to temporarily relocate to Region 1 for the duration of their employment, possibly commuting home on weekends, depending on the location of their primary residence.

Very few, if any, of the non-local workers employed during the construction phase of the potential wind facilities would be expected to permanently relocate to the affected areas. For the purposes of analysis, 10 percent of non-local workers temporarily relocating to the area are assumed to be accompanied by family members; the average size of a family that is relocating is assumed to be three, two adults and one school-age child (Clean Line 2013). The estimated annual change in population would be equivalent to approximately 2.l percent of the total Region 1 population in 2012 under Scenario 1 and approximately 1.1 percent under Scenario 2 (Table 3.13-51).

3.13.6.8.1.1.2 Operations and Maintenance Impacts

Operations and maintenance of the potential wind facilities would employ an estimated total of 140 full-time employees in Oklahoma and 140 full-time employees in Texas under Scenario 1 and 88 full-time employees in each state under Scenario 2, reflecting the labor economies of scale associated with operating a substantially smaller number (4 versus 74) of much larger (975MW versus 53MW) facilities (Table 3.13-52). These estimates were developed using the JEDI Wind model and general wind industry averages. Assuming these employees would all permanently relocate to the area from elsewhere with an average family size of three (two adults and one school-age child), estimated total population increases in Region 1 would be 840 and 530 under Scenarios 1 and 2, respectively, which would be equivalent to 1.6 percent and 1.0 percent of the total population in Region 1 in 2012 (Table 3.13-52).

Table 3.13-52:
Estimated Annual Change in Population During Operations and Maintenance by Potential Wind Development Scenario

Workers/Population[1]	Scenario 1[2]			Scenario 2[2]		
	Oklahoma	Texas	Region 1 Total	Oklahoma	Texas	Region 1 Total
2012 Population[3]	28,658	19,322	51,652	28,658	19,322	51,652
Number of Workers[4]	140	140	280	88	88	177
Number of People Permanently Relocating[5]	420	420	840	265	265	530
Percent of 2012 Population	1.5	2.2	1.6	0.9	1.4	1.0

1 Data are annual estimates and assumed to continue for the operating lives of the potential facilities.
2 Scenario 1 consists of 74 wind generation facilities with a nameplate capacity of 53MW, for a total capacity of 3,885MW; Scenario 2 consists of four facilities with a nameplate capacity of 975MW, for a total capacity of 3,900MW.
3 2012 population totals are as follows:
Oklahoma = Cimarron, Texas, and Beaver counties
Texas = Hansford, Ochiltree, and Sherman counties
Region 1 Total = The above six counties plus Harper County, Oklahoma (see Table 3.13-4).
4 The JEDI Wind model was used to estimate annual operations and maintenance workforce requirements by scenario and state. Jobs are FTEs for a period of one year (1 FTE = 2,080 hours).
5 Number of people permanently relocating assumes that all the onsite workers would relocate from elsewhere and represent an average family size of three (two adults and one school-age child).

3.13.6.8.1.1.3 Decommissioning Impacts

Decommissioning of the potential wind generation facilities would require a labor force approximately equal to that needed for their construction. Impacts to population from decommissioning are, therefore, expected to be similar to those from construction.

3.13.6.8.1.2 Economic Conditions

3.13.6.8.1.2.1 Construction Impacts

Construction of the two potential wind development scenarios would result in a temporary increase in employment and earnings in the surrounding area. Annual estimates are presented by scenario and state in Table 3.13-53. Construction would support an estimated total (direct, indirect, and induced) of 9,910 jobs in Region 1 under Scenario 1 and 8,762 jobs under Scenario 2. Construction would also support estimated total (direct, indirect, and induced) earnings of $494 million and $435 million under Scenarios 1 and 2, respectively (Table 3.13-53). These annual impacts would occur each year for 2 years leading up to the commercial operation date of the Project.

Table 3.13-53:
Total Annual Economic Impacts During Construction by Potential Wind Development Scenario

Impacts[1]	Scenario 1[2]			Scenario 2[2]		
	Oklahoma	Texas	Region 1 Total	Oklahoma	Texas	Region 1 Total
Employment (Jobs)[3]						
Direct Impact	1,050	1,031	2,080	515	497	1,012
Indirect and Induced Impacts	3,986	3,843	7,830	3,962	3,789	7,750
Total Impacts	5,036	4,874	9,910	4,477	4,285	8,762
Annual Earnings ($ million)[4]						
Direct Impact	$48.34	$63.24	$111.58	$24.83	$31.71	$56.53
Indirect and Induced Impacts	$170.72	$211.61	$382.33	$169.60	$208.60	$378.20
Total Impacts	$219.05	$274.85	$493.90	$194.43	$240.31	$434.73

1 The JEDI Wind model was used to estimate direct, indirect, and induced impacts. Indirect impacts during construction are identified in the model as turbine and supply chain impacts. Data are annual estimates and assume that construction would be spread evenly over 2 years. Indirect and induced impacts are estimated at the state level.
2 Scenario 1 consists of 74 wind generation facilities with a nameplate capacity of 53MW, for a total capacity of 3,885MW; Scenario 2 consists of four facilities with a nameplate capacity of 975MW, for a total capacity of 3,900MW.
3 Jobs are FTEs for a period of one year (1 FTE = 2,080 hours).
4 Annual earnings are expressed in millions of dollars in year 2014 dollars.

3.13.6.8.1.2.2 Operations and Maintenance Impacts

Operations and maintenance of the potential wind facilities would employ an estimated total of 140 full-time employees in Oklahoma and 140 full-time employees in Texas under Scenario 1 and 88 full-time employees in each state under Scenario 2 (Table 3.13-54).

Operations and maintenance would support an estimated total (direct, indirect, and induced) of 798 jobs under Scenario 1 and 665 jobs under Scenario 2. Operations and maintenance would also support estimated total (direct, indirect, and induced) earnings of $41.2 million and $32.9 million under Scenarios 1 and 2, respectively (Table 3.13-54). These annual impacts would occur each year for the operating life of the potential facilities.

Table 3.13-54:
Total Annual Economic Impacts During Operations and Maintenance by Potential Wind Development Scenario

Impacts[1]	Scenario 1[2]			Scenario 2[2]		
	Oklahoma	Texas	Region 1 Total	Oklahoma	Texas	Region 1 Total
Employment (Jobs)[3]						
Direct Impact	140	140	280	88	88	177
Indirect and Induced Impacts	237	281	518	224	264	488
Total Impacts	377	421	798	312	352	665
Annual Earnings ($ million)[4]						
Direct Impact	$7.12	$9.56	$16.68	$4.17	$5.60	$9.77
Indirect and Induced Impacts	$9.87	$14.65	$24.52	$9.41	$13.72	$23.13
Total Impacts	$17.00	$24.21	$41.20	$13.58	$19.32	$32.90

1 The JEDI Wind model was used to estimate direct, indirect, and induced impacts. Indirect impacts during construction are identified in the model as local revenue and supply chain impacts. Data are annual estimates and assumed to continue for the operating lives of the potential facilities. Indirect and induced impacts are estimated at the state level.
2 Scenario 1 consists of 74 wind generation facilities with a nameplate capacity of 53MW, for a total capacity of 3,885MW; Scenario 2 consists of four facilities with a nameplate capacity of 975MW, for a total capacity of 3,900MW.
3 Jobs are FTEs for a period of one year (1 FTE = 2,080 hours).
4 Annual earnings are expressed in millions of dollars in year 2014 dollars.

3.13.6.8.1.2.3 Decommissioning Impacts

Decommissioning of the HVDC transmission line would require a labor force approximately equal to that needed for its construction. Local expenditures on materials and supplies and payments to workers would likely be similar, resulting in broadly similar economic impacts to those from construction.

3.13.6.8.1.3 Agriculture

Agriculture is the primary existing land use in the 12 WDZs. An estimated 3 to 5 percent of the land within the boundaries of each potential wind energy facility is expected to be affected during construction, with 1 percent or less expected to be affected during the operations and maintenance phase of each facility. Assuming full build-out, 20 to 30 percent of the area within the WDZs would involve an estimated total of 6,492 to 16,230 acres of primarily agricultural land would be affected during construction, with 2,164 to 3,246 acres affected during operations and maintenance (see Section 3.2). This potential disturbance represents a very small share of the 5.9 million acres of land in farms in Region 1 (Table 3.13-9) and is unlikely to noticeably affect overall agricultural production and employment in the affected counties.

In cases where turbines are located on agricultural land, land owners typically receive lease payments. Wind lease agreements usually include provisions to minimize construction-related losses, including minimizing soil compaction and revegetating temporary work areas. In addition, these types of agreement typically stipulate compensation for landowners for other potential losses, such as damage to or loss of crops, gates, fences, landscaping and trees, irrigation, and livestock.

3.13.6.8.1.4 Housing

3.13.6.8.1.4.1 Construction Impacts

Using the same assumptions employed in the above transmission line Project analysis, an estimated 45 percent of the workers temporarily relocating during construction are expected to require motel or hotel rooms, with the remaining non-local workers expected to require rental housing (apartments, houses, or mobile homes) (20 percent), or provide their own housing in the form of RVs or pop-up trailers (35 percent). Projected average annual housing demand based on the number of FTE workers for the anticipated 2-year construction period is compared with estimated supply in Table 3.13-55.

Table 3.13-55:
Estimated Construction-Related Housing Demand by Potential Wind Development Scenario

Housing/Geographic Area	Scenario 1[1]			Scenario 2[1]		
	Oklahoma	Texas	Region 1 Total	Oklahoma	Texas	Region 1 Total
Projected Non-Local Employment[2]	460	442	902	239	226	465
Projected Peak Housing Demand						
Rental Housing	92	88	180	48	45	93
Hotel and Motel Rooms	207	199	406	108	102	209
RV Spaces	161	155	316	84	79	163
Estimated Available Housing Units[3]						
Rental Housing	279	38	370	279	38	370
Hotel and Motel Rooms[4]	194	76	273	194	76	273
RV Spaces	48	161	235	48	161	235
Projected Demand as a Share of Existing Resources						
Rental Housing	33	232	49	17	119	25
Hotel and Motel Rooms	107	262	149	55	134	77
RV Spaces	336	96	134	174	49	69

1 Scenario 1 consists of 74 wind generation facilities with a nameplate capacity of 53MW, for a total capacity of 3,885MW; Scenario 2 consists of four facilities with a nameplate capacity of 975MW, for a total capacity of 3,900MW.

2 The JEDI Wind model was used to estimate construction workforce requirements by scenario and state. Jobs are FTEs for a period of one year (1 FTE = 2,080 hours). According to the JEDI Wind model analysis, an estimated 44 percent (Oklahoma) and 43 percent (Texas) of workers under Scenario 1 would be hired locally, with 46 percent (Oklahoma and Texas) of the annual construction workforce expected to be hired locally under Scenario 2.

3 Estimated housing unit totals are for the following counties:
Oklahoma = Cimarron, Texas, and Beaver counties
Texas = Hansford, Ochiltree, and Sherman counties
Region 1 Total = The above six counties plus Harper County, Oklahoma (see Table 3.13-10).

4 Assumes an average occupancy rate of 75 percent for the purposes of analysis, with 25 percent of total units assumed to be available.

This comparison indicates that temporary housing demand under Scenario 1 (74, 53MW facilities built over 2 years) would be more than double (232 percent) of the supply of rental housing in the three Texas counties. Demand under Scenario 1 would also exceed the estimated supply of available hotel and motel rooms in the counties in both states and Region 1 as a whole. Demand for RV spaces would exceed the total identified spaces in the three Oklahoma counties and Region 1 as a whole, and be almost equal to the number of identified spaces in the three Texas counties (Table 3.13-55).

Projected housing demand would be lower under Scenario 2 (four 975MW facilities) due to labor economies of scale. This scenario represents the low end of the range of potential effects on housing; Scenario 1 represents the high end of this range. Under this scenario, demand would exceed supply for rental housing in the three Texas counties. Demand would also exceed the estimated supply of available hotel and motel rooms in the three Texas counties, as well as the total number of identified RV spaces in the three Oklahoma counties (Table 3.13-55).

3.13.6.8.1.4.2 Operations and Maintenance Impacts

Operations and maintenance of the potential wind facilities would employ an estimated total of 140 full-time employees in Oklahoma and 140 full-time employees in Texas under Scenario 1, and 88 full-time employees in each state under Scenario 2. If all these employees permanently relocated to the area, a corresponding demand for permanent housing would be created. This potential demand is compared with housing data in Table 3.13-56. In the short-term, workers relocating would likely stay in hotels or motels while looking for a more permanent residence to rent or purchase.

Table 3.13-56:
Estimated Housing Demand by Potential Wind Development Scenario under Operations and Maintenance

Housing/Geographic Area[2]	Scenario 1[1]			Scenario 2[1]		
	Oklahoma	Texas	Region 1 Total	Oklahoma	Texas	Region 1 Total
Number of Households Permanently Relocating[3]	140	140	280	88	88	177
Vacant Housing Units						
For Rent or Sale	450	79	597	450	79	597
Rented or Sold, Not Occupied	242	113	365	242	113	365
Seasonal, Recreational, or Occasional use	158	192	409	158	192	409
Other Vacant4	1,349	544	2,153	1,349	544	2,153
Total	2,199	928	3,524	2,199	928	3,524

1 Scenario 1 consists of 74 wind generation facilities with a nameplate capacity of 53MW, for a total capacity of 3,885MW; Scenario 2 consists of four facilities with a nameplate capacity of 975MW, for a total capacity of 3,900MW.

2 Estimated housing unit totals are for the following counties:
Oklahoma = Cimarron, Texas, and Beaver counties
Texas = Hansford, Ochiltree, and Sherman counties
Region 1 Total = The above six counties plus Harper County, Oklahoma

3 Number of households relocating is based on estimated total annual employment and assumes that all workers would permanently relocate to the area from elsewhere.

4 According to the U.S. Census Bureau, a housing unit is classified as “other vacant” when it is unoccupied and does not fit into one of the other categories identified in the above table. Common reasons a housing unit is labeled as “other vacant” are that nobody lives in the unit and the owner is making repairs or renovating, does not want to rent or sell, or the unit is being held for settlement of an estate or in foreclosure (Kresin 2013).

Economic development organizations in the Oklahoma Panhandle region have identified a potential shortage in permanent housing in and around the city of Guymon in Texas County, with these problems expected to be further exacerbated by this type of wind energy development (Fleming 2013). Estimated demand under Scenario 1 in the three Oklahoma counties would be equivalent to 31 percent of the housing units available for rent or sale in 2012 (140 versus 450). Demand in the three Texas counties would be almost 1.8 times the number of housing units available for rent or sale under Scenario 1 (140 versus 79), and 1.1 times under Scenario 2 (88 versus 79) (Table 3.13-56). This imbalance may be partially offset by some of the housing units currently identified as “other vacant" coming on the market for rent or sale. "Other vacant" housing units comprised 59 percent of the vacant housing in the three Texas counties in 2012.

3.13.6.8.1.4.3 Decommissioning Impacts

Decommissioning of the wind facilities would require a labor force approximately equal to that needed for their construction. Impacts to housing from decommissioning are, therefore, expected to be similar to those from construction.

3.13.6.8.1.5 Community Services

3.13.6.8.1.5.1 Construction Impacts

Increased demands for local services that would likely occur from wind facility construction workers and family members temporarily relocating to the affected areas would be short term. The estimated number of workers and family members expected to temporarily relocate to Region 1 during construction ranges from 558 (Scenario 2) to 1,082 (Scenario 1) (Table 3.13-51). This estimated increase in population would be equivalent to approximately 1.1 percent to 2.1 percent of total Region 1 population in 2012 (Table 3.13-51). The temporary addition of these workers and family members to local communities is not expected to affect the levels of service provided by existing law and fire protection personnel.

Medical facilities located in Region 1 are identified in Table 3.3-12 and discussed with respect to the AC collection system routes in Section 3.13.2.4.2. The temporary relocation of workers and family members to the counties in the region is not expected to affect existing levels of health care and medical services.

The estimated number of children expected to temporarily relocate to Region 1 during peak construction ranges from about 47 (Scenario 2) to 90 (Scenario 1) (Table 3.13-51). These children would likely be located in a number of different school districts throughout Region 1 and would not be expected to affect existing average student/teacher ratios (Table 3.13-13).

Spending by relocating workers and their families would likely generate economic benefits for community commercial and retail services, as would be the case with other local construction-related expenditures.

3.13.6.8.1.5.2 Operations and Maintenance Impacts

Operations and maintenance of the potential wind facilities would employ between 177 (Scenario 2) and 280 (Scenario 1) workers. If these workers and their families were all to relocate from elsewhere, the estimated increase in population would be equivalent to approximately 1.0 percent to 1.6 percent of total Region 1 population in 2012 (Table 3.13-52). The permanent addition of these workers and family members would not be expected to affect the provision of community services in the affected areas.

3.13.6.8.1.5.3 Decommissioning Impacts

Decommissioning of the transmission lines would require a labor force approximately equal to that needed for their construction. Impacts to community services from decommissioning are, therefore, expected to be similar to those from construction.

3.13.6.8.1.6 Tax Revenues

3.13.6.8.1.6.1 Construction Impacts

Construction of the potential wind facilities would generate sales, use, and lodging tax during the construction period. All equipment and material costs are assumed for the purposes of analysis to be subject to sales and use tax. Wind facility equipment would include turbines, blades, and towers. Materials would include transformers, electrical equipment, and construction materials (concrete, rebar, and construction equipment). Estimated equipment and material costs are approximately $95 million for a single 50MW wind facility and $1.79 billion for a single 1,000MW facility. These costs were estimated using the JEDI Wind model and general wind energy averages. The use of these averages results in total estimated equipment and material costs of $6,981 million and $7,159 million for Scenarios 1 and 2, respectively.

State sales and use tax rates are 4.5 percent in Oklahoma and 6.25 percent in Texas (Tables 3.13-15 and 3.13-14, respectively). Estimated state sales and use tax revenues would range from $158 million to $161 million in Oklahoma and from $217 million to $223 million in Texas, with the higher end of the range in each case estimated for Scenario 2.

None of the potentially affected Texas counties levy local sales and use tax. In the three Oklahoma counties, local county sales and use tax rates are either 1 percent (Texas County) or 2 percent (Cimarron and Beaver counties) (Table 3.13-15). Based on these rates, estimated county sales and use tax revenues per facility would range from $0.9 million to $1.9 million for a 50MW facility and from $17.9 million to $35.7 million for a 1,000MW facility.

3.13.6.8.1.6.2 Operations and Maintenance Impacts

Operations and maintenance of the potential wind facilities would generate annual property or ad valorem tax revenues in the counties where they would be located. Estimated installed costs are approximately $105 million for a single 50MW wind facility and $1.95 billion for a single 1,000MW facility. These costs were estimated using the JEDI Wind model and general wind energy averages. The use of these averages results in total estimated installed costs of $7,774 million and $7,798 million for Scenarios 1 and 2, respectively.

Millage rates for the potentially affected Oklahoma counties range from 52.19 to 80.73 (Table 3.13-19). Adjusting the range of estimated installed costs for a single wind facility by the state assessment ratio (the state share of assessed value subject to taxation) of 22.85, the application of these millage rates would result in ad valorem tax revenues ranging from $1.9 million (for a 50MW facility in Beaver County) to $36 million (for a 1,000MW facility in Texas County).

Average millage rates (expressed per $1,000 of assessed value) in the three potentially affected Texas counties range from 4.131 (Hansford County) to 4.392 (Sherman County) (Table 3.13-18). Using a simplified cost approach, property tax revenues for a single wind facility could range from $4.3 million (for a 50MW facility in Hansford County) to $85.6 million (for a 1,000MW facility in Sherman County).

3.13.6.8.1.6.3 Decommissioning Impacts

The general tax implications of decommissioning the potential wind generation facilities would be similar to those discussed with respect to the converter stations, above (see Section 3.13.5.2.7.1).

3.13.6.8.2 Optima Substation

Employment during construction of the substation would follow a similar bell-shaped pattern as construction of the proposed converter stations (see Figure 3.13-2) but would likely involve fewer workers. Impacts would be similar to those discussed for the Oklahoma converter station, but smaller. Some workers would likely temporarily relocate to the Texas County area for the duration of their employment. Adequate temporary housing likely exists to accommodate this demand, but a potential shortage in temporary housing could occur if construction of the future Optima Substation were to coincide with construction of the Oklahoma converter station, AC collection system routes, or HVDC transmission line in this area. The Applicant proposes to prepare and implement a workforce housing strategy for the Project designed to minimize potential impacts to housing availability.

3.13.6.8.3 TVA Upgrades

The required TVA upgrades could result in potential impacts to population, economic conditions, housing, property values, community services, and tax revenues. A short-term increase in the influx of temporary workers and increased demand for temporary housing resources and goods and services would be expected during construction activities, particularly construction of the new 500kV electric transmission line. The temporary relocation of construction workers to the affected areas could create increased demand for community services such as education, medical facilities, municipal services, police, and fire in addition to retail services. These potential effects would be short term and temporary. New permanent employment associated with the operation of the upgraded and new facilities would not likely have a noticeable effect on existing short- or long-term population trends or demand for housing and goods and services.

Local expenditures, employment, and construction-related earnings would have a positive impact on the local economy and employment for the duration of construction. Construction of the required TVA upgrades would generate sales and use tax revenues through expenditures on construction supplies and equipment. Long-term economic impacts from the required TVA upgrades would be primarily associated with operation and maintenance-related expenditures for materials and supplies. As a federal agency, TVA does not pay property taxes. Instead, it returns 5 percent of its power sales revenues as in-lieu tax payments to the states and local governments where it sells electricity or has power properties. These tax equivalent payments are allocated among the states according to the power sales and value of TVA power properties within each state. The new 500kV transmission line could result in a small increase in tax equivalent payments to affected counties. Overall, economic impacts would be expected to be small.

3.13.6.9 Impacts Associated with the No Action Alternative

Under the No Action Alternative, DOE assumes for analytical purposes that the Project would not be constructed. There would be no Project-related impacts to socioeconomics.

3.14 Special Status Wildlife, Fish, Aquatic Invertebrate, and Amphibian Species

3.14.1 Special Status Terrestrial Wildlife Species

3.14.1.1 Regulatory Background

Regulations that directly influence the evaluation of wildlife resources within the region of influence are primarily implemented by the USFWS and state wildlife agencies. The applicable state agencies in this area include the ODWC, the AGFC, Tennessee Wildlife Resources Agency (TWRA), and Texas Parks and Wildlife Department (TPWD). The wildlife regulations relevant to the Project are presented in Table 3.14.1-1.

Table 3.14.1-1:
Relevant Laws and Regulations for Wildlife Species

Regulation	Regulatory Agency	Summary
Endangered Species Act (ESA) (16 USC § 1531 et seq.; 50 CFR Part 402)	USFWS	Establishes lists of threatened or endangered species and their designated critical habitats; requires federal agencies to ensure that actions they authorize, fund, or carry out are not likely to jeopardize the continued existence of listed species or result in adverse modification to designated critical habitat.
Migratory Bird Treaty Act (MBTA) (16 USC §§ 703–712)	USFWS	Prohibits take, possess, import, export, transport, sell, purchase, barter, or offer for sale, purchase, or barter, any migratory bird, or the parts, nests, or eggs of such a bird unless expressly permitted by federal regulations or authorized under a MBTA permit.
Executive Order 13186, "Responsibilities of Federal Agencies to Protect Migratory Birds"	USFWS	Directs executive departments and agencies to take certain actions to protect and conserve migratory birds. The Executive Order provides broad guidelines on conservation responsibilities and requires the development of more detailed guidance in Memoranda of Understanding (MOUs).
Bald and Golden Eagle Protection Act (BGEPA) (16 USC §§ 668-668d; 50 CFR Part 22)	USFWS	Prohibits the "take" of bald and golden eagles as defined: pursue, shoot, shoot at, poison, wound, kill, capture, trap, collect, molest, or disturb without a BGEPA Permit.
Oklahoma Statutes 29-5-412.1	ODWC	Establishes list of threatened or endangered species within Oklahoma.
Texas Administrative Code 31-65.171–65.177	TPWD	Establishes list of threatened or endangered wildlife within Texas; prohibits the taking, possession, transportation, or sale of threatened or endangered species within the issuance of a permit.
Arkansas Code Annotated 15-45-301–306	AGFC[1]	Prohibits imports, transportation, sale, purchase, hunting, harassment, or possession of threatened or endangered wildlife or their parts.
Tennessee Administrative Code 70-1-101 et seq.	TWRA	Establishes a list of threatened or endangered wildlife within Tennessee; prohibits the take, attempt to take, possession, transportation, export, processing, selling, offering to sell, shipment of, or knowing receipt of shipment of threatened or endangered wildlife.

1 Arkansas does not have an endangered species law, but does maintain a list of Species of Special Concern.

3.14.1.2 Data Sources

Data sources included a desktop analysis of relevant information, research findings, reports available to the public, a database that includes GIS data from government agencies as well as non-governmental organizations, and information received from both regulatory agencies and stakeholders during the DOE scoping process. Data sources used for this analysis were open source and readily available to the public (i.e., the public may assess them without restrictions). Some specific state wildlife data is considered sensitive information and may not be disclosed at the discretion of wildlife agencies to prevent potential disturbances to specific wildlife species and their habitat. Examples include locations of wildlife breeding sites (e.g., LEPC leks), nesting areas (e.g., eagle nests or interior least tern colonies), and roosting sites (e.g., bald eagles and bats). If available, more general information on distribution and location of special status wildlife species and their habitat was used in this assessment. For example, location data on LEPC leks consisted of approximately 5-square-mile circular areas with no information on the exact location of the lek within that area. General locations of interior least tern colonies were available in published reports. For species where no site specific information was available or was not disclosed to protect the species, it was assumed that the species were present if suitable habitats were present (i.e., a conservative estimate of species use was used). For example, information on bat roost trees or caves used for roosting or hibernation were either not available, were not disclosed to protect the resource, or only regional locations where caves are located were provided. Under CEQ regulations 40 CFR 1502.22 the lack of such information could be considered incomplete and unavailable. However, using available general distributional data and the conservative approach of assuming that species are present if suitable habitat exists in the ROI would assure that potential impacts to those species are considered and evaluated. Data sources are described in more detail in Table 3.14.1-2.

Table 3.14.1-2:
Summary of Data Sources Wildlife

Resource	Data Source	Exception within the ROI
Federal Special Status Terrestrial Wildlife		
Lesser Prairie-Chicken (LEPC)	LEPC Habitat—Southern Great Plains Crucial Habitat Assessment Tool (CHAT) Agency Consultation[1] GIS Data Sources: KBS (2013a, 2013b, 2014)	A 3-mile buffer from each edge of the 1,000-foot-wide corridor was added to the ROI within or in proximity to the Estimated Occupied Range of the LEPC and the general location of LEPC leks, as identified through CHAT data.
Whooping crane	USFWS Cooperative Whooping Crane Tracking Project GIS Data Sources: USFWS (2014b, 2014e, 2014f)	A 15-mile buffer from each edge of the 1,000-foot-wide corridor was added to the ROI within the whooping crane migration corridor.
American burying beetle	USFWS (2008a); GIS Data Source: Jin et al. (2013)[2] Agency Consultation[1]	N/A
Ozark big-eared bat	Ozark Big-Eared Bat *(Corynorhinus townsendii ingens),* 5-Year Review: Summary and Evaluation (USFWS 2008b) Agency Consultation[1]	A 2-mile buffer from each edge of the 1,000-foot-wide corridor was added to the ROI in proximity to known occurrences of the species.
Indiana bat	Indiana Bat *(Myotis sodalis)* Draft Recovery Plan: First Revision, USFWS (2007a) Agency Consultation[1]	A 2-mile buffer from each edge of the 1,000-foot-wide corridor was added to the ROI in proximity to known occurrences of the species
Gray bat	Gray Bat *(Myotis grisescens)* 5-Year Review: Summary and Evaluation (USFWS 2009a) Agency Consultation[1]	A 2-mile buffer from each edge of the 1,000-foot-wide corridor was added to the ROI in proximity to known occurrences of the species
Northern long-eared bat	80 FR 17973, "Endangered and Threatened Wildlife and Plants; Threatened Species Status for the Northern Long-Eared Bat With 4(d) Rule; Final Rule and Interim Rule."	A 2-mile buffer from each edge of the 1,000-foot-wide corridor was added to the ROI in proximity to known occurrences of the species
Interior least tern	Interior Population of the Least Tern (*Stemula antillarum athalassos*) Recovery Plan (USFWS 1990)	A 5-mile buffer from each edge of the 1,000-foot-wide corridor was added to the ROI based on potential foraging distance from nest colonies.

Table 3.14.1-2:
Summary of Data Sources Wildlife

Resource	Data Source	Exception within the ROI
Other terrestrial species protected by the Endangered Species Act (ESA), including: Florida panther Piping plover Red knot Sprague's pipit	USFWS Endangered Species Program Threatened and Endangered Species Range Maps (http://www.fws.gov/endangered/map/index.html) USFWS Recovery Plans USFWS Critical Habitat Portal (http://ecos.fws.gov/crithab/) Agency Consultation[1]	N/A. The Florida panther is not known to occur within the ROI but areas in Arkansas within the ROI are under review by the USFWS for possible re-introduction. No variation from the standard ROI was defined for the piping plover, red knot, and Sprague's pipit.
Bald and Golden Eagle Protection Act (BGEPA)	Agency Consultation1	A 1-mile buffer from each edge of the 1,000-foot-wide corridor was added to the ROI for known occurrences of bald eagle nests or bald and golden eagle roosting areas.
State Special Status Terrestrial Wildlife		
State protected species with potential habitat in the ROI	ODWC Threatened Endangered, and Rare Species List (ODWC 2013) AGFC Endangered Species List (http://www.agfc.com/species/Pages/SpeciesEndangered.aspx) Tennessee Natural Heritage Inventory Program Element Occurrence Polygons2 (http://www.tn.gov/environment/natural-areas/natural-heritage-inventory-program.shtml) TPWD Texas Natural Diversity Database (http://www.tpwd.state.tx.us/huntwild/wild/wildlife_diversity/txndd/) Agency Consultation[1]	N/A

1 Federal and state agencies often maintain non-public data files on species presence and occurrence. The Applicant consulted with federal and state resource agencies to identify and collect such non-public data. Non-public data were included in the analysis to the extent that the data were not confidential, available, and complete.

2 Clean Line created an American burying beetle potential occurrence area data layer by selecting certain categories from the NLCD 2006 data within the counties of occurrence based on habitat requirements identified by USFWS (2008a). Areas considered as potential occurrence areas included the following NLCD 2006 categories: Deciduous Forest, Evergreen Forest, Mixed Forest, Barren Land, Shrub/Scrub, Grassland/Herbaceous, and Pasture/Hay.

3.14.1.3 Region of Influence

3.14.1.3.1 Region of Influence for the Project

The general ROI considered for this Project is described in Section 3.1.1. The following subsection describes where the ROI used for special status wildlife species was expanded beyond the area described in Section 3.1.1. Many avian and bat species can range over a considerable distance, particularly migratory species. The expansion of the ROI does not mean that impacts would necessarily occur at that distance, but instead, it identifies whether species are in the vicinity and could possibly be affected by the Project.

3.14.1.3.2 Variations of the Region of Influence for Special Status Wildlife

The ROI for the following special status wildlife species was expanded to account for potential occurrence of each species and to assess the potential direct and indirect effects to the species as follows:

- LEPC: Winder et al. (2013) found that the strongest predictor of female greater prairie chicken space use for nesting was distance from leks. The Lesser Prairie Chicken Range-wide Conservation Plan recommends avoiding leks by 1.25 miles (Van Pelt et al. 2013). Hagen et al. (2004) state that most female LEPC select nest sites within approximately 2 miles of a lek. However, because of variation among individual prairie chickens and possibly the limited availability of suitable nesting habitat in the vicinity of some leks, a buffer distance of 1.25 miles probably represents an area containing only about 85 percent of the LEPC nests in the vicinity of a lek (Van Pelt et al. 2013). Therefore, to more fully account for potential LEPC in the vicinity of the APR to account for breeding, nesting, and brood rearing habitat, a 3-mile ROI was selected from each edge of the 1,000-foot-wide corridor for the Applicant Proposed Route and HVDC Alternative Routes (Pitman et al. 2005, Hagen et al. 2004).
- Whooping crane: Within the 200-mile-wide whooping crane migration corridor where approximately 95 percent of migrating whooping cranes are observed (95 percent migration corridor), the ROI was expanded to encompass a 15-mile buffer from each edge of the 1,000-foot-wide corridor (Applicant Proposed Route and HVDC alternative routes) to identify any known or potential whooping crane stopover locations in the vicinity of the Project. This distance was based on the known foraging distance from stopover locations and recommended BMPs for transmission lines within the whooping crane migratory corridor (USFWS 2009d).
- Protected bat species: The ROI was expanded for bat species designated as candidate, threatened, or endangered under the Endangered Species Act (ESA) to encompass a 1.5-mile buffer from each edge of the 1,000-foot-wide corridor (Applicant Proposed Route and HVDC alternative routes) in proximity of known occurrences of such species to evaluate potential roosting and hibernacula habitat[1], including the potential for karst or cave features that may serve as habitat for the species. This distance was based upon the recommended review distance for protected bat species habitats (USFWS 2014b, 2014c).
- Interior least tern: The ROI was expanded in proximity to known occurrences of interior least tern nesting to encompass a 5-mile buffer from each edge of the 1,000-foot-wide corridor so that potential impacts to interior least tern within the ROI could be identified and assessed. This distance was based on the known foraging distance for nesting interior least terns (USFWS 1990).

A summary of the data sources used is provided in Table 3.14.1-2.

3.14.1.3.3 Region of Influence for Connected Actions

The ROI for wind energy generation, the future Optima Substation, and TVA upgrades is described in Section 3.1.1.

3.14.1.4 Affected Environment for Terrestrial Special Status Wildlife Species

As discussed in Section 3.17, the ROI crosses multiple ecoregions that support diverse vegetation communities. Overall, the ROI is within the Great Plains and Eastern Temperate Forests Level I Ecoregions (EPA 2012). From the western edge of the ROI in the Oklahoma Panhandle and moving eastward across Oklahoma, Arkansas, and western Tennessee, the vegetation changes from arid to semi-arid grasslands to forests and river valleys as precipitation increases from west to east and elevation changes. Additional information regarding climate may be found in Section 3.3. As such, a variety of wildlife species, both terrestrial and aquatic, is expected to occur within the

[1] A bat hibernaculum is a site where bats hibernate over the winter. These sites are most often caves or abandoned mines.

habitats found within the ROI. The highest species diversity can be expected to occur in areas of greater habitat diversity such as transitional zones between forests and grasslands, wetlands, riparian zones, and open waters.

The following sections provide regional descriptions of special status species known to occur within the ROI or that have the potential to occur within the ROI based on habitat associations and known range information. Detailed descriptions of special status wildlife species in the ROI in Regions 1 through 7 are provided below. Twenty-three route variations to the Applicant Proposed Route in Regions 2–7 were developed in response to public comments on the Draft EIS and are described in Appendix M and summarized in Sections 2.3.1 and 2.4.2.1–2.4.2.7. The route variations are discussed in relation to the terrestrial special status species in the regional descriptions in Section 3.14.1.5. Potential impacts to these species in the route variations are discussed in Section 3.14.1.7.

Thirty federal candidate or listed animal species have been identified within the ROI, including both terrestrial and aquatic species (USFWS 2014a). Of these, 14 of the species are considered terrestrial species. Twelve are either candidates or listed as threatened or endangered under the ESA (Table 3.14.1-3), and two species, the golden and bald eagle, are protected by the BGEPA. Species discussions are presented below by species type (e.g., mammals, birds, etc.) and in increasing order of protection (e.g., candidate, threatened, endangered, etc.). Of the 12 federal candidate or listed terrestrial wildlife species, the whooping crane and Interior least tern are also state protected species. An additional nine species of terrestrial wildlife are protected by state law or regulation, but are not federally protected under the ESA or BGEPA.

Table 3.14.1-3:
Federally Designated Threatened and Endangered Terrestrial Wildlife Potentially Occurring in the ROI

Common Name	Scientific Name	Federal Status	County[2]	Region

1 Although counties were identified by the USFWS (2014a) for potential reintroduction, the species is considered extinct in Arkansas.
2 No designated critical habitats are found within the Project's ROI or the various counties crossed by the Project for listed terrestrial species or those species proposed for listing.

3 The USFWS listed the LEPC (Tympanuchus pallidicinctus) as a threatened species under the ESA in a final rule published in 2014 (79 FR 19974, April 10, 2014). USFWS also issued a special take rule for the LEPC under Section 4(d) of the ESA (79 FR 20074, April 10, 2014). On September 1, 2015, a federal court in Texas vacated the final rule listing the LEPC as a threatened species. *Permian Basin Petroleum Ass'n v. Dep't of Interior*, No. MO–14–CV–50, 2015 WL 5192526 (W.D. Tex. Sept. 1, 2015). Given that appeals are possible in this matter, the legal status of the LEPC will continue to be considered as threatened for the purposes of this EIS.

Source: USFWS (2014a)

3.14.1.4.1 Federally Listed Terrestrial Mammals

3.14.1.4.1.1 Northern Long-eared Bat

The northern long-eared bat *(Myotis septentrionalis)* is a federally threatened species (80 FR 17974, April 2, 2015). The northern long-eared bat ranges throughout much of the eastern and north-central United States (USFWS 2014a). Within this species' range in the ROI, it has been documented or has the potential to occur in the following counties within or near the ROI: Muskogee, Okmulgee, and Sequoyah counties in east-central Oklahoma (Regions 3 and 4); Crawford, Conway, Franklin, Johnson, Pope, Van Buren, Cleburne, White, Jackson, Poinsett, Mississippi, and Cross counties in northern Arkansas (Regions 4–5); and Tipton and Shelby counties in southwestern Tennessee near the Arkansas border (Regions 6–7; 78 FR 61045).

The northern long-eared bat is a migratory bat that uses two habitat types during different seasons of the year: caves for hibernacula in winter and dense forest stands that contain trees with exfoliating bark or cavities for maternity roosts in spring, summer, and fall. The northern long-eared bat does not appear dependent on a particular tree species but opportunistically uses those species that form cavities, crevices, or retain bark such as oaks, maples, black locust, American beech, and shortleaf pine (78 FR 61045). Hibernacula may occur within suitable caves and/or abandoned mines throughout its range, generally the eastern and north-central United States, and are established in October and begin to break up in March or April. This species has shown fidelity to particular hibernation caves from year to year; however, some bats may not use the same hibernacula in successive years (Caceres and Barclay 2000). Northern long-eared bats emerge from hibernacula in the spring and migrate to summer foraging areas. Movements between summer roosts and winter hibernacula in the late fall are typically short (35 to 55 miles); however, movements from hibernacula to summer maternity colonies have ranged up to 168 miles (78 FR 61045). Seven caves in the Ozark Plateau National Wildlife Refuge located in Adair County, Oklahoma, north of Sequoyah County, are known to be inhabited by northern long-eared bats (80 FR 17974, April 2, 2015).

Northern long-eared bats are nocturnal insectivores and have a diverse diet including moths, flies, leafhoppers, caddisflies, and beetles (78 FR 61045, October 2, 2013). As insectivores, preferred forage habitat includes the forest interior in areas below the canopy but above the shrub layer where insects are most commonly found. This species also may occasionally forage in open areas, such as forest clearings, along waterways, and roads (78 FR 61045).

Historically, this species has been documented as common throughout its range and has not been considered at risk in the United States. The USFWS listed the northern long-eared bat as threatened in April 2015 based on the species' risk of extinction, which is predominately related to the threat of white-nose syndrome, a fungal infection that has reduced some bat populations in the eastern United States by 30 to 99 percent (USFWS 2014d). Additional threats to the northern long-eared bat include destruction or degradation of habitat through deforestation and loss of forest connectivity (i.e., habitat fragmentation) and disturbance (e.g., recreational caving and vandalism) of bat hibernacula (78 FR 61045).

3.14.1.4.1.2 Ozark Big-eared Bat

The Ozark big-eared bat *(Corynorhinus townsendii ingens)* is a federally endangered species. The range of the Ozark big-eared bat is limited to a small number of counties in Oklahoma and Arkansas, including documented occurrences in the following counties in Region 4 and 5: Sequoyah County in east-central Oklahoma near the Arkansas border and Crawford, Franklin, Johnson, and Pope counties in northern Arkansas near the Oklahoma border (78 FR 61045). Oklahoma has 10 caves of known use by Ozark big-eared bats in Adair County, one cave in Sequoyah County, and one in Cherokee County identified as essential to the species. Fifty other caves in Oklahoma are known to be infrequently used by the Ozark big-eared bat. These caves may be used by small groups or solitary males during the maternity season. Arkansas has seven caves considered essential sites, of which none occurs in counties within the ROI (USFWS 2008b). In January 2015, Ozark big-eared bats were found in two caves in the vicinity of Lee Creek Reservoir within the ROI. It is not known whether the species also uses these caves during the summer for roosting.

Ozark big-eared bats are a cave obligate species that rely on limestone and sandstone talus caves associated with karst topography for roosting and hibernation (USFWS 2008b). This species has shown fidelity to particular hibernation caves from year to year, but may occasionally move between caves (USFWS 2008b). Hibernation generally is initiated in October, when Ozark big-eared bats typically seek out the coldest regions of selected caves with temperatures ranging from 46 to 50 Fahrenheit (°F) and 86 to 93 percent humidity (USFWS 2008b). When bats come out of hibernation in April, maternity colonies begin forming in late April and early May with births occurring in May or June (USFWS 2008b).

This species forages over forests and grasslands for moths, their primary prey, but it also glean beetles and other flying insects (USFWS 2008b). Open areas allow for easy foraging because bats are not obstructed by branches while pursuing prey and are able to discriminate insects at greater distances. Ozark big-eared bats have smaller home ranges compared to other bats and generally have a foraging distance of approximately 1.2 miles to a maximum of 5 miles and exhibit an avoidance of areas of human development and cropland (Graening et al. 2011). Current threats to the Ozark big-eared bat consist of human disturbance of occupied caves (i.e., recreational caving); loss and fragmentation of foraging habitat; and disturbance of talus slopes, abandoned buildings, and bridges that may be used by solitary roosting bats.

3.14.1.4.1.3 Gray Bat

The gray bat *(Myotis grisescens)* is a federally endangered species. The range of the gray bat includes the southeastern United States (USFWS 2014a). Within this species' range in the ROI, it has been documented or has the potential to occur in the following counties within, or near, the ROI: Muskogee and Sequoyah counties in east-central Oklahoma near the Arkansas border (Region 3 and 4), and Crawford, Franklin, Johnson, Pope, Van Buren, Cleburne, White, and Johnson counties in northern Arkansas (Regions 4 and 5) (USFWS 2013b). Gray bats are cave obligate species using different caves for winter hibernation and summer roosting. Oklahoma is home to nine summer colonies of gray bats, though none stay through hibernation (Martin 2007). Two summer colonies are located in Adair County, Oklahoma. Six active gray bat hibernacula are in Arkansas counties crossed by, or near, the Project (Martin 2007).

Gray bats emerge from hibernacula in late March or early April and select summer caves near water sources for prime insect foraging locations. Gray bats are strictly insectivorous, feeding only on insects, especially aquatic insects such as mayflies, caddisflies, and stoneflies (USFWS 2009a). River edges and reservoirs provide abundant supplies of insects for gray bats (Tuttle 1976). Colonies reside in multiple caves during different times of the year; however, the unifying factor is that gray bats are only found in limestone karst areas in the southeastern United States (Tuttle 1975). Hibernacula caves are typically deep vertical caves selected in early October with females arriving prior to males (Martin 2007). No hibernation colonies are known from Oklahoma (USFWS 2011b). Gray bats have specific cave requirements, selecting cold caves in winter and warm caves near water in summer, resulting in 95 percent of gray bats using only nine caves (USFWS 2009a).

Historically, threats to gray bats have included pollutants that impact insect populations; alterations to caves that change temperature, airflow, humidity, or light, and cave flooding (USFWS 1997; Fremling and Johnson 1989). However, current threats have expanded to include white-nose syndrome that causes hibernation disruptions that, in turn, can deplete energy stores and may result in mortality from starvation (USFWS 2009a). Disturbance of caves, both those used for winter hibernation and for maternity roosts, are potential threats to the species.

3.14.1.4.1.4 Indiana Bat

The Indiana bat *(Myotis sodalis)* is a federally endangered species. The Indiana bat range includes the northeastern east-central, and Midwestern United States (USFWS 2014a). Within this species' range in the ROI, it has been documented or has the potential to occur in the following counties within the ROI: Sequoyah County in east-central Oklahoma near the Arkansas border; Crawford, Franklin, Johnson, Pope, Van Buren, Cleburne, and Jackson counties in northern Arkansas; and Shelby County in southwestern Tennessee near the Arkansas border (USFWS 2014a). An inhabited hibernaculum, known as Rosson Hollow Crevices, is located in Franklin County, Arkansas. Portions of the ROI pass through USFWS-recognized Karst Conservation Zones in which Indiana bat habitat may occur (USFWS 2013b). The Ozark Plateau Wildlife Refuge in Adair County, north of Sequoyah County in east-central Oklahoma, has been identified by the USFWS as important to the Indiana bat because of the availability of cave hibernacula.

The Indiana bat is a migratory bat that uses caves for hibernacula in winter and is found in dense forest stands using exfoliating bark or tree cavities for maternity roosts in spring, summer, and fall. Hibernacula may occur in suitable caves and/or abandoned mines throughout its range and are usually established by November, earlier in more northern regions, and begin to break up in April. This species has shown fidelity to particular hibernation caves from year to year.

Indiana bats emerge from hibernacula in spring from late March to mid-May and migrate to summer foraging areas that can be up to 350 miles from hibernacula (USFWS 2007a). This species will use the sloughing bark of dead/dying trees, tree cavities, and exfoliating bark of live trees for maternity colonies and summer roosts. Primary roost trees are usually larger than the surrounding forest trees and are located in forest canopy openings, fence lines, or along wooded edges (USFWS 2007a). Common roost tree species used include ash, elm, oak, hickory, maple, and poplar. Maternity roost habitat includes riparian areas, bottomland hardwood forests, and other forested wetlands, as well as upland forests. Indiana bats are nocturnal insectivores that feed almost exclusively on flying insects. Preferred foraging areas include sites around water sources (e.g., rivers, streams, ponds, etc.) or open woodlands (USFWS 2007a). Foraging usually occurs within 2 miles of a primary roost tree but may occur up to 5 miles from the roost (USFWS 2007a).

Current threats to the Indiana bat include loss of habitat (i.e., roost sites and foraging areas) from deforestation and loss of forest connectivity (i.e., habitat fragmentation), degradation of hibernacula by human activities (recreational caving, vandalism, etc.), and white-nose syndrome (USFWS 2012b, 2009b).

3.14.1.4.1.5 Florida Panther

The Florida panther (*Puma concolor coryi*) is a federally endangered species. This species' range is limited to southern and south-central Florida and it is considered extinct in Arkansas (USFWS 2008c), and therefore is not present in the ROI. However, the USFWS has considered reintroducing the Florida panther into Arkansas. Areas being considered for reintroduction in proximity to the ROI include the Ozark National Forest and the Ouachita National Forest (USFWS 2008c).

The preferred habitat of the Florida panther includes cypress swamps, pinelands, hardwood swamps, and upland hardwood forests. Threats to the Florida panther in its current range include loss of habitat, urbanization encroachment, disease, intraspecific aggression, and collisions with vehicles (USFWS 2008c).

3.14.1.4.2 Federal Candidate or Listed Birds

3.14.1.4.2.1 Sprague’s Pipit

Sprague's pipit *(Anthus spragueii)* is a candidate for federal ESA listing (79 FR 72449, December 5, 2014). The listing priority number (scale of 1 to 12) of Sprague’s pipit is 11, indicating that threats to the species are medium to low and non-imminent (79 FR 72449). Sprague’s pipit is documented to occur in the ROI in Region 1 (Beaver County in the Oklahoma Panhandle), in Region 3 (Payne County in north-central Oklahoma), in Region 4 (Sequoyah County in east-central Oklahoma near the Arkansas border, and Franklin County in northern Arkansas near the Oklahoma border [USFWS 2014a]). Sprague’s pipit occurs as an uncommon migrant and rare winter resident in Oklahoma and Arkansas. Sprague’s pipit is a small grassland bird noted for its distinct high flights and secretive behaviors. The species is strongly tied to unplowed native prairie throughout its life cycle. Native prairie habitat used by Sprague’s pipit includes short-grass prairie, mixed-grass prairie, alkaline meadows, and wet meadows. Its current breeding distribution includes portions of Montana, North Dakota, South Dakota, and Canada, and its current wintering distribution includes south-central and southeast Arizona, southern New Mexico, Texas, southern Oklahoma, southern Arkansas, northwestern Mississippi, southern Louisiana, and northern Mexico. The majority of sightings occur in Texas (78 FR 70103, November 22, 2013) but Sprague’s pipit is assumed to pass through the states of Oklahoma and Arkansas. Sprague’s pipit also may use stubble and fallow alfalfa, soybean, and wheat fields in the fall and winter.

Current threats to Sprague's pipit include loss, degradation, and fragmentation of native grassland habitat, energy development (i.e., oil, gas, and wind), climate change, and drought (78 FR 70103).

3.14.1.4.2.2 Red Knot

The *rufa* subspecies of the red knot *(Calidris canutus rufa)* is a federally threatened subspecies. This subspecies is a potential migrant in the interior United States and does not breed or winter in the vicinity of the ROI; however, the overall range of the red knot overlaps the vicinity of the ROI. Most *rufa* subspecies of the red knot migrate along the Atlantic Coast during spring and fall; however, every interior state has multiple documented migration records and recent research has shown that birds wintering along the Gulf of Mexico fly to and from breeding grounds via the Central Flyway (78 FR 60023, September 30, 2013). The ROI traverses both the Central and Mississippi Flyways, and potentially lies in the migratory path of the relatively small number of red knots that migrate through the interior United States. No critical habitat has been designated for the red knot.

The red knot is a medium-sized shorebird largely dependent upon high quality habitats that serve as staging areas for their long-distance migration (78 FR 60023). The conditions at these staging areas factor heavily in the annual cycle and survival of red knots. These staging areas, or stopover sites, are primarily along the Atlantic Coast; however, relatively small numbers occur annually across the interior United States (Harrington 2001; 78 FR 60023). Red knots use aquatic habitats with exposed sediments and abundant, readily accessible invertebrates. There are no known primary stopover sites in the vicinity of the ROI, and red knots migrating through the Central Flyway are believed to depart the Texas coast and stopover in the Northern Great Plains and Hudson Bay areas before reaching their Arctic breeding grounds (78 FR 60023). Red knots stopping over in the vicinity of the ROI are expected to be a rare occurrence with relatively few individuals.

Threats to the red knot include climate change, habitat loss, declining food availability at stopover sites, human disturbances at migration and wintering areas, wind energy development, pollution, and predation pressures. Climate change may be one of the more critical threats to red knots (Harrington 2001; 78 FR 60023). Habitat loss and modification also are a major threat to red knots.

3.14.1.4.2.3 Lesser Prairie-Chicken

The LEPC *(Tympanuchus pallidicinctus)* was listed as a federally threatened species (79 FR 19974 and 79 FR 20074, April 10, 2014). The USFWS listed the LEPC (*Tympanuchus pallidicinctus*) as a threatened species under the ESA in a final rule published in 2014 (79 FR 19974, April 10, 2014). USFWS also issued a special take rule for the LEPC under Section 4(d) of the ESA (79 FR 20074, April 10, 2014). On September 1, 2015, a federal court in Texas vacated the final rule listing the LEPC as a threatened species. *Permian Basin Petroleum Ass'n v. Dep't of Interior*, No. MO–14–CV–50, 2015 WL 5192526 (W.D. Tex. Sept. 1, 2015). Given that appeals are possible in this matter, the legal status of the LEPC will continue to be considered as threatened for the purposes of this EIS. The range for the LEPC overlaps with the ROI in Region 1 in Texas, Beaver, and Harper counties, and Woodward County in Region 2 in the Oklahoma Panhandle, and with the AC collection system routes in Ochiltree County, Texas, in the Texas Panhandle (USFWS 2014a) (Figures 3.14-1a and 3.14-1b (located in Appendix A). No critical habitat had been proposed or designated for the LEPC at the time of the final listing rule (USFWS 2014a; 79 FR 19974; 79 FR 20074).

In Oklahoma and Texas, the LEPC occupies sand sagebrush habitat in the western and eastern Panhandle and mixed-grass habitat in the northwest region (Van Pelt et al. 2013). Courtship and breeding occurs on leks formed by groups of male birds, similar to other grouse or prairie-chicken groups. Leks typically occur on knolls or ridges with relatively short and/or sparse vegetation. Developed or manipulated areas may also be used for lek sites and include oil well pads, roads, reverted cropland, cultivated fields, areas treated with herbicides, and recently burned areas (Van Pelt et al. 2013). However, LEPC cannot survive solely in landscapes with greater than 30 percent cultivated or disturbed land (Bidwell et al. 2003). Preferred nesting sites are in sand sagebrush or shinnery oak grasslands with high canopy cover and moderate vertical and horizontal cover (Elmore et al. 2009; ODWC 2012). Brood rearing habitat is generally close to nesting habitat but may contain more structural diversity with shorter grasses and more forbs mixed with taller shrubs and grasses that allow easy travel for broods, insects and seeds for food, and escape cover (Elmore et al. 2009). The LEPC requires large contiguous blocks of habitat to maintain sustainable populations. The minimum size of contiguous grassland required is uncertain but may range from 1,200 to 25,000 acres (Van Pelt et al. 2013).

Through the Western Governors Association CHAT, crucial habitats and important corridors for the LEPC have been mapped in Region 1 and 2 (Figure 3.14-1 in Appendix A). CHAT category 1 habitat (CHAT-1) is considered focal habitat areas for LEPC conservation and represents the best remaining areas of LEPC habitat. CHAT-2 areas comprise habitat connectivity areas that have been identified as those areas important for maintaining large-scale habitat connections between crucial LEPC habitats. Areas mapped as CHAT-3 include those sites modeled as LEPC habitat based on data such as locations of leks and nests, land in the Conservation Reserve Program, land cover type, and abiotic site conditions. CHAT-4 areas are estimated occupied LEPC range based on expert opinion. CHAT categories 1 through 4 represent the best known current potential range of the LEPC.

The primary threats to LEPC include habitat loss through conversion of preferred grassland/shrub land habitat to agricultural uses, degradation and fragmentation, and the subsequent displacement from or avoidance of remaining habitat patches. Threats to this species' sustainability are exacerbated by conservation challenges such as incompatible grazing management, tree encroachment, conversions of rangeland to crop and non-native forage production, energy development, and increased disturbance, particularly of breeding leks and nesting areas (79 FR 19974 and 79 FR 20074, April 10, 2014). Because LEPC prefer relatively large areas of undisturbed habitat, degradation of LEPC habitat occurs through conversion of smaller land areas to agricultural uses and placement of human infrastructure such as windbreaks, communication and transmission towers, wind turbines, and oil and gas wellheads that fragment larger habitat areas (79 FR 19974). Research indicates that LEPC will avoid certain human structures such as roads, wellheads, and vertical structures such as buildings and transmission structures and lines even if suitable habitat occurs in the immediate surroundings (79 FR 19974; Pruett et al. 2009; Robel et al. 2004). Transmission lines and structures may impact this species use of otherwise suitable habitats due to increased predation rates that can result from avian predators perching and roosting along the structures and line. Fragmentation of habitat reduces potential movement (i.e., emigration and immigration) between areas of suitable habitat, thereby reducing the potential augmentation of isolated populations.

3.14.1.4.2.4 Piping Plover

The piping plover *(Charadrius melodus)* is a federally threatened species that has a large range across the Great Plains and East Coast of the United States (USFWS 2014a). The piping plover is a wide-ranging small shorebird typically observed as a migratory species within the ROI. The breeding range for piping plovers that migrate through the Project area is primarily the Northern Great Plains population (USFWS 2009e). Records of nesting piping plovers within the ROI and its vicinity are rare; only two nests are documented at Optima Lake in Texas County, Oklahoma (78 FR 61045, October 2, 2013). In relation to Optima Lake, the ROI for the Applicant Proposed Route is about 7 miles south, HVDC alternative routes are approximately 3 to 5 miles south, and AC Collection System Routes E-1 and NE-2 are approximately 1.5 miles south and 5 miles west, respectively. Documented or potential occurrence of the piping plover include the following counties within the ROI in Regions 1 through 7: Texas, Beaver, Harper in the Oklahoma Panhandle; Woodward County in northwestern Oklahoma; Garfield, Kingfisher, Logan, Payne, Lincoln counties in north-central Oklahoma; Okmulgee and Muskogee counties in east-central Oklahoma near the Arkansas border; Crawford County, Arkansas, in northern Arkansas near the border with Oklahoma; Johnson, Pope, Conway, Faulkner, and White counties in north-central Arkansas and Mississippi County in northeastern Arkansas near the border with Tennessee (USFWS 2014a). No federally designated critical habitat is within the ROI.

The piping plovers within the ROI are individuals of the northern Great Lakes population of piping plovers that breed along open, sparsely vegetated sand or gravel beaches adjacent to alkali wetlands, and on beaches, sand bars, and dredged material islands of major river systems (USFWS 2009c). During migration, typically April and August, the species can be documented throughout Oklahoma at rivers, wetlands, and reservoirs using sandbars, beaches, and sparsely vegetated areas on their way to wintering grounds along the Gulf of Mexico. However, inland populations appear to migrate nonstop from northern breeding areas to winter grounds along the Gulf of Mexico contributing to fewer observations within the ROI (USFWS 2014d).

The primary threat to the piping plover is destruction and degradation of summer and winter habitat. The major threats in the northern Great Plains breeding range include predation, habitat alteration due to impoundments, river channelization and manipulation of water flows, sand and gravel mining, oil and gas production, and invasive species encroachment. All piping plover populations face increasing human disturbance during their coastal migration and in their wintering range. Human presence may inhibit courtship, incubation, and brooding, and impact nesting and foraging activities (USFWS 2009c). Because piping plovers occur primarily along rivers and wetlands, collisions with transmission lines and structures near crossings of rivers appear to be the greatest potential Project impact to the piping plover.

3.14.1.4.2.5 Whooping Crane

The whooping crane *(Grus americana)* is a federally endangered species with a range that extends from Canada through the Great Plains to the Texas Gulf Coast. The Project would cross the migration corridor for the Aransas-Wood Buffalo population of the whooping crane (Tacha et al. 2010; USFWS 2012d, 2014d). The migration corridor range, based on where approximately 95 percent of the documented occurrences of migrating whooping cranes, includes the following Oklahoma counties within the ROI: Beaver County in the Oklahoma Panhandle (Region 1); Woodward and Major counties in northwestern Oklahoma (Region 1 through 2); and Garfield, Kingfisher, Logan, Payne, and Lincoln counties in north-central Oklahoma (Region 3) (USFWS 2014a). The migration corridor is approximately 200 miles wide. Other counties in Oklahoma where whooping cranes could occur during migration but are less likely include Texas County in the Oklahoma Panhandle and Okmulgee and Muskogee counties in east-central Oklahoma (Region 4; USFWS 2014a). No federally designated critical habitat for this species is currently located within the ROI.

The whooping crane is a large migratory crane that overwinters along the Gulf of Mexico at the Aransas National Wildlife Refuge. The Aransas-Wood Buffalo population of whooping cranes migrates through the central United States and breeds in central Canada at Wood Buffalo National Park. Autumn migration normally begins in mid-September, with most birds arriving on the Gulf of Mexico wintering grounds between late October and mid-November. Spring migration departure dates are normally between late March and mid-April, with the last birds usually leaving by May 1 (USFWS 2014a). During the annual migration, whooping cranes use stopover areas for resting and foraging. Whooping cranes will feed in shallow waters along the margin of wetlands, harvested grain fields, pastures, grasslands, and burned upland fields (USFWS 2014d). Roosting habitat is usually shallow, seasonally, and semi-permanent flooded wetlands or wide, sandy rivers. Generally, this species prefers wetlands with less vegetation (USFWS 2009d). The USFWS Cooperative Whooping Crane Tracking Project maps observations of whooping cranes during migration and has identified a primary migration corridor within the central United States (Figure 3.14-2 in Appendix A) (Tacha et al. 2010). This migration corridor is further delineated into sections based upon the percentage of observations from the centerline. Approximately 95 percent of all whooping crane observations during migration occur within 200 miles of the centerline of the migration corridor. Known migration and stopover observations of whooping crane may occur outside the delineated migration corridor, but the migration corridor is indicative of 95 percent of the known migration and stopover observations reported to the USFWS Cooperative Whooping Crane Tracking Project. No whooping crane critical habitat has been designated in the ROI, but the Salt Plains National Wildlife Refuge approximately 35 miles north of the Applicant Proposed Route in north-central Oklahoma in Alfalfa County has been designated critical habitat and is an important migration stopover area (Figure 3.14.-3 in Appendix A).

Current threats to recovery of whooping cranes include ongoing loss and degradation of migratory stopover and coastal wintering habitats, and collisions with structures (e.g., fences, power lines, and communication towers) (Stehn and Wassenich 2006; USFWS 2009d, 2014d). Climate change also may threaten this species' continued existence, reducing inflows of freshwater in wintering, migration, and breeding grounds (USFWS 2009d). Additionally, whooping cranes are sensitive to human disturbance, particularly to the presence of humans on foot (USFWS 2009d, 2014a). Transmission lines and structures bordering fields and wetlands where cranes forage and roost pose a greater collision risk and are of concern (USFWS 2009d).

3.14.1.4.2.6 Interior Least Tern

The interior least tern (*Sternula antillarum athalassos*) is a federally endangered species that ranges from the northern Great Plains through the Texas Gulf Coast in the United States (USFWS 2014a). The breeding range for the interior population of the least tern based on documented occurrences and potential for occurrences includes all counties traversed within the ROI: Texas, Beaver and Harper counties in the Oklahoma Panhandle (Region 1); Woodward and Major counties in northwestern Oklahoma (Region 1 through 2); Kingfisher, Logan, Payne, Lincoln, and Creek counties in central Oklahoma (Region 3); Okmulgee, Muskogee, and Sequoyah counties in east-central Oklahoma (Region 3 through 4); Crawford, Franklin, Pope, Conway, Faulkner, Cross, and Mississippi counties in northern Arkansas (Regions 4 through 6); and Shelby County in southwestern Tennessee near the border with Arkansas (Region 7: USFWS 2014a). No critical habitat has been designated for the interior least tern (USFWS 2014a).

The least tern is the smallest member of the gull family. The interior population of the least tern presently breeds in the Mississippi, Missouri, and Rio Grande River systems from Montana south to Texas and from eastern New Mexico and Colorado to Indiana and Louisiana. Nesting habitat for interior least tern occurs along the Cimarron (Major County in Oklahoma), Arkansas (Muskogee County in Oklahoma), and Mississippi rivers (Mississippi County in Arkansas) (Lott et al. 2013). A nesting colony is known to occur 7 miles north of where the Project would cross suitable foraging and nesting habitat on the Arkansas River near the Robert S. Kerr Lock and Dam (USFWS 2014d). On the Mississippi River, the interior least tern nests on large sandbars primarily from the confluence with the Ohio River south to Louisiana. Nesting interior least terns have been observed along the Mississippi River in Shelby, and Lauderdale counties in Tennessee (Lott et al. 2013). In 2012, interior least tern colonies were documented about 3 miles and 2.5 miles to the north and south of the Mississippi River crossing, respectively (Jones 2012). Arriving on breeding grounds from early April through early June, interior least terns breed colonially on bare or sparsely vegetated sandy or dried mud substrates often along rivers, but also on shores of impoundments, saline flats in salt marshes, and shell beaches. Colonies are typically situated near (less than 7.5 miles) a water resource (e.g., rivers, lakes, reservoirs) with a viable food supply of small fishes and crustaceans (Thompson et al. 1997; USFWS 2014a). Colonies disperse in late August when terns begin migration to wintering grounds along coastlines in Central and South America. Although migration routes are not well understood for the interior least tern, the least tern appears to follow major river basins to the confluence of the Mississippi River (USFWS 2014d). Least terns forage in shallow water and rest on sandbars, beaches, and docks during migration.

The primary threat to this species is loss of sandbar and island habitat from dam construction and river channelization on major rivers throughout the Mississippi, Missouri, and Rio Grande river systems. Dams alter river flows in a way that is not conducive to the creation and maintenance of sandbars with sparse vegetation. Other threats include human disturbance (e.g., degradation of habitat, disturbance at nest and roost sites) and cold-water temperatures in reservoirs, which affect biological activity and growth and, in turn, the quantity of forage fish available (USFWS 2014a; Thompson et al. 1997). Interior least terns may avoid nesting in the vicinity of structures that could serve as perches for avian predators (USFWS 2013a).

3.14.1.4.3 Federally Listed Terrestrial Invertebrates

3.14.1.4.3.1 American Burying Beetle

The American burying beetle *(Nicrophorus americanus)* is a federally endangered species with a range that is generally restricted to the southeastern Great Plains (USFWS 2014a). The American burying beetle range within the ROI is based on documented occurrences and potential for occurrences and includes Payne, Lincoln, Creek, Okmulgee, Muskogee, and Sequoyah counties in east-central Oklahoma (Regions 3-4); and Crawford, Franklin, and Johnson counties in northern Arkansas near the border with Oklahoma (Region 4; USFWS 2014a). No critical habitat has been designated for the American burying beetle (USFWS 2014a). The USFWS has identified conservation priority areas for the American burying beetle in Okmulgee, Muskogee, and Sequoyah counties in east-central Oklahoma that are crossed by the ROI of the Applicant Proposed Route and HVDC alternative routes (USFWS 2014e). There are two publicly identified American burying beetle populations in the vicinity of the Project. Camp Gruber sits approximately 7 miles north of the Project in Muskogee County, Oklahoma, and Fort Chaffee is approximately 15 miles south of the Project in Crawford County, Arkansas (USFWS 2008). The USFWS' Oklahoma Ecological Services Field Office has published American burying beetle location data resulting from presence/absence surveys conducted in Kansas, Oklahoma, and Texas from 2012 to 2014. A single survey location, which is located approximately 0.48 mile north of the 200-foot-wide HVDC ROW in Okmulgee County, Oklahoma, yielded positive detection of American burying beetles in 2013 within the ROI (USFWS 2015).

The American burying beetle is a habitat generalist that prefers areas that exhibit a high biomass of small mammals and birds suitable for scavenging (Holloway and Schnell 1997); however, American burying beetles do exhibit habitat selectivity with regard to areas conducive for carcass burial and breeding activities (Lomolino et al. 1995). During carcass burial and breeding, studies have suggested that American burying beetles have a preference for forested sites, likely due to an increase in leaf litter and deeper, less compacted soils found in forested sites (Lomolino and Creighton 1996). However, the distribution of burying beetles is limited more by the availability of properly sized carrion (i.e., presence of small bird/mammal carrion), the number of competing scavengers (e.g., ants), and the soil characteristics conducive to carcass burial rather than vegetation structure and plant species composition as burying beetles are also found in shrublands, grasslands, and forest edges (Lomolino et al. 1995; Holloway and Schnell 1997; USFWS 2012a).

The USFWS has published impact assessment guidelines for the American burying beetle (USFWS 2014e). Sites considered unfavorable for the burying beetle exhibit the following characteristics:

- Land that has already been developed and no longer exhibits surficial topsoil, leaf litter, or vegetation.
- Land that is tilled on a regular basis, planted in monoculture, and does not contain native vegetation.
- Pasture or grassland that is maintained through frequent mowing or herbicide application at a height of 8 inches or less.
- Urban areas with maintained lawns, paved surfaces, or roadways.
- Stockpiled soil without vegetation.
- Wetlands with standing water or saturated soils (defined as sites exhibiting hydric soils and vegetation and/or wetland hydrology (USFWS 2014e). It should be noted that areas adjacent to wetlands and/or riparian areas may be used by the burying beetle and not considered unfavorable. These areas may be important for burying beetles seeking moist soil during dry conditions.

The USFWS lists the majority of threats to the American burying beetle as related to habitat loss, modification, and fragmentation. Fragmentation alters habitat by changing species composition and lowering the reproductive success of the beetles' targeted prey. Fragmentation also increases edge habitat that, in turn, supports a greater density of vertebrate predators and scavengers (e.g., ants, crows, raccoons, foxes, opossums, etc.) that compete with American burying beetles for carrion. Other potential threats or hypotheses for declines in populations include artificial lighting, although the evidence is largely circumstantial, and disease and pesticides (Sikes and Raithel 2002; USFWS 2012b).

3.14.1.4.4 Other Federally Protected Wildlife

3.14.1.4.4.1 Bald Eagles

Bald eagles (*Haliaeetus leucocephalus)* are federally protected under the BGEPA. Bald eagles can occur throughout the ROI as year-round residents, breeders, winter residents, or migrants (Buehler 2000). Bald eagles are opportunistic foragers that prey primarily on fish, but also feed on other aquatic and terrestrial vertebrates as well as on carrion (Buehler 2000). Bald eagles nest in large trees or cliffs. Breeding areas are closely associated with aquatic habitats with forested shorelines or cliffs (Buehler 2000). Within the ROI, nesting generally occurs from April through July, although nest building can occur during the winter and spring (USFWS 2007b). Wintering locations are typically associated with open water areas (i.e., lakes, reservoirs, and rivers) used for foraging on fish. Wintering bald eagles roost (often communally) anywhere between 6 miles and 20 miles from foraging sites depending on abundance of prey.

The ODWC estimates that the statewide overwinter population of bald eagles in Oklahoma is between 800 and 2,000 (ODWC 2011a). The nesting range of the bald eagle has expanded and now includes western Oklahoma. However, the primary nesting area in Oklahoma is the Arkansas River and its main tributaries (USFWS 2014d). Typically, the population of bald eagles within the ROI will increase during the winter as migrants from more northern breeding grounds migrate to overwinter. Migrating bald eagles from more northern regions begin arriving in late November and December. In proximity to the ROI in eastern Oklahoma in Regions 4, known wintering concentrations of bald eagles can be located at Sequoyah State Park and Greenleaf State Park (ODWC 2011b). In Oklahoma, wintering bald eagle concentrations are highest at the following lakes: Kaw, Keystone, Texoma, Tenkiller, Ft. Gibson, Grand, Canton, Great Salt Plains Lakes, Tishomingo, and Spavinaw (ODWC 2011a).Village Creek State Park, Mt. Magazine State Park, and Lake Dardanelle in western Arkansas in Regions 4 and 5 have known wintering concentrations of bald eagles (Arkansas State Parks 2014). Greers Ferry Lake in central Arkansas and the Mississippi River between Arkansas and Tennessee also have populations of wintering bald eagles.

Current threats include collisions with transmission lines that can occur when the birds are distracted (i.e., actively engaged in territorial displays and fights or pursuing prey), during low visibility (i.e., dawn, dusk, or bad weather), and when fledglings have poorly developed flight skills. Electrocution from electric transmission lines is a possibility depending on the spacing of conductors and electrical grounding practices. Disturbances to nests or nesting territories may cause eagles to abandoned their nests and decrease annual productivity. Illegal shooting and lead poisoning are also known causes of bald eagle mortality.

3.14.1.4.4.2 Golden Eagles

Golden eagles (*Aquila chrysaetos)* are most common in the semi-arid western portions of the ROI in Regions 1 and 2, where they can occur as year-round residents, breeders, winter residents, or migrants (Kochert et al. 2002). In Oklahoma, only two to four pairs of golden eagles are known to nest in the state, typically in the far western panhandle in the vicinity of the Black Mesa (ODWC 2011c), outside the ROI; however, golden eagles may occur outside the nesting season as residents throughout the year. Golden eagles in the western United States are most commonly associated with open and semi-open habitats such as shrublands, grasslands, woodland-brushlands, and coniferous forests as well as in cropland and riparian habitats (Kochert et al. 2002). Golden eagles nest on cliff faces or in large trees and breeding areas vary by region, but are generally associated with mountainous canyon land, rimrock terrain of open desert, grassland areas, riparian habitats, and occasionally in forested areas (Kochert et al. 2002). Wintering habitat includes open areas with native vegetation such as sagebrush communities, riparian areas, grasslands, and rolling oak savanna (Kochert et al. 2002).

Golden eagles feed primarily on small mammals such as rabbits, ground squirrels, and prairie dogs, but they will consume birds, reptiles, and carrion. These food items are typically more abundant and accessible in open grasslands and shrub/scrub habitats found in semi-arid habitats in Region 1 and 2.

Golden eagles are more sensitive to human occupation than bald eagles, and disturbance impacts are a potential concern (USFWS 2014d). Current threats to golden eagles include mortality from collisions with transmission lines, wires, wind turbines, structures, and other vertical structures. Trapping and poisoning incidental to mammal control programs and lead poisoning from ammunition remain hazards for this species. Electrocution from electric transmission lines is a hazard, but generally from smaller distribution lines where the spacing of conductors is closer together compared to transmission lines and the eagles' wings can more easily contact more than one conductor. Disturbance to nests or nesting territories can also cause eagles to abandon nests and lower productivity.

3.14.1.4.5 State Designations for Wildlife

In addition to federal designations, there are 11 species of terrestrial wildlife with state level designations that occur within the ROI. Oklahoma and Arkansas do not maintain a state-level threatened or endangered terrestrial wildlife list. The state-designated wildlife of Tennessee and Texas that could potentially occur in the ROI are listed in Table 3.14.1-4.

Table 3.14.1-4:
State Designated Threatened and Endangered Terrestrial Wildlife Potentially Occurring in the ROI

Common Name	Scientific Name	State Status	County
Oklahoma			
The ODWC recognizes the federally designated threatened or endangered terrestrial wildlife. No additional state threatened or endangered terrestrial wildlife are found within the ROI.			
Arkansas			
The AGFC recognizes the federally designated threatened or endangered terrestrial wildlife. No additional state threatened or endangered terrestrial wildlife are found within the ROI.			
Tennessee			
Reptiles			
Northern pinesnake	*Pituophis melanoleucus melanoleucus*	State Threatened	Shelby
Birds			
Bewick's wren	*Thryomanes bewickii*	State Endangered	Shelby
Interior least tern[1]	*Sterna antillarum athalassos*	State Endangered	Tipton and Shelby
Lark sparrow	*Chondestes grammacus*	State Threatened	Shelby
Texas			
Mammals			
Black bear	*Ursus americanus*	State Threatened	Sherman
Gray wolf	*Canis lupus*	State Endangered	Sherman, Hansford, Ochiltree
Reptiles			
Texas horned lizard	*Phrynosoma cornutum*	State Threatened	Sherman, Hansford, Ochiltree
Birds			
American peregrine falcon	*Falco peregrinus anatum*	State Threatened	Sherman, Hansford, Ochiltree
Bald eagle	*Haliaeetus leucocephalus*	State Threatened	Sherman, Hansford, Ochiltree
Peregrine falcon	*Falco peregrinus*	State Threatened	Sherman, Hansford, Ochiltree
Whooping crane[1]	*Grus americana*	State Endangered	Sherman, Hansford, Ochiltree

1 Federally designated species (see Table 3.14.1-3).
Sources: ODWC (2013), ANHC (2013), TDEC (2014), TPWD (2013)

3.14.1.5 Regional Description

As discussed above, 12 terrestrial special status wildlife species are known to occur or have the potential to occur within the ROI. A summary of the terrestrial special status wildlife species and habitat occurrence by Project region is provided in the sections below. The highest diversity of special status wildlife species occurs in Regions 4 and 5, because the variability of habitats is high within these two regions. The special status species that could occur in the 23 route variations developed in response to public comments on the Draft EIS are discussed for each region. The route variations are minor adjustments. The new route variations are relatively short, usually several miles or less and typically within 0.5 mile or less of the original route. The habitats within the route variations are similar to the original routes with only minor differences and typically include a subset of the regional habitats because the route variations are relatively short. Some special status species, therefore, would not be affected because suitable habitat does not occur in the route variations.

3.14.1.5.1 Region 1

The ROI in Region 1 is referred to as the Oklahoma Panhandle Region and includes the Applicant Proposed Route, HVDC Alternative Routes I-A through I-D, Oklahoma converter station and AC interconnection, and the AC collection system. None of the 23 route variations of the Applicant Proposed Route occurs in Region 1.

No federally listed bat species are known to occur within the Region 1 ROI in Oklahoma.

Of the five federally listed bird species and one federal candidate bird species, four of the species are known to occur or to have the potential to occur within the ROI in Region 1. The piping plover has two historical nests at Optima Lake in Texas County, Oklahoma (USFWS 2014d). In relation to Optima Lake, the Applicant Proposed Route would be approximately 7 miles south at its nearest point to the lake, and the Oklahoma Converter Station Siting Area would be located approximately 10 miles southwest. As described in Section 3.10, the predominant land cover in the Region 1 ROI is grassland/herbaceous. Piping plovers are unlikely to use the grassland/herbaceous habitat that dominate the ROI in Region 1 for nesting habitat; however, the proximity to Optima Lake, and known nesting occurrences, near the western terminus of the Applicant Proposed Route suggests that piping plovers may occur during the nesting and breeding session. Although the interior least tern has been documented in counties traversed by the Project in Region 1, no known breeding colonies are known to occur in the region. There are no known stopover locations of whooping crane within the overall ROI. The nearest known stopover location would be approximately 4 miles from HVDC Alternative Route 1-A; however, portions of the eastern edge of Region 1 ROI are within the 95 percent corridor of known whooping crane observations (USFWS 2009d) indicating that whooping cranes may occur within the overall ROI during migration (Figure 3.14-2 in Appendix A). In contrast to the piping plover, the whooping crane may use the grassland/herbaceous habitat that dominate the ROI in Region 1. Further, limited areas of open water, and woody wetlands occur along portions of the ROI in Region 1 (see Section 3.19 for additional discussion). The LEPC has the potential to occur throughout the ROI in Region1 based on documented occurrences within the Applicant Proposed Route and HVDC Alternative 1-A through 1-D (Van Pelt et al. 2013) (Figure 3.14-1a in Appendix A). The LEPC may occur within the grassland/herbaceous habitat that dominate the ROI; however, specific habitat use within the ROI is dependent upon the quality of habitats (Hagen et al. 2013).

Bald and golden eagles are known to winter around Optima Lake WMA in Texas County, Oklahoma, approximately 7 miles north of the Applicant Proposed Route and 10 miles northeast of the Oklahoma Converter Station Siting Area (ODWC 2014a). Bald eagles are less likely to occur within the ROI in Region 1 due to lack of suitable habitat within the ROI; however, proximity to known winter occurrences at Optima Lake WMA suggests that some occurrence during migration and during winter may occur. In contrast, golden eagles are more likely to occur year-round within the ROI of Region 1, due to suitability of habitat, namely grassland/herbaceous land cover suitable for foraging, and the proximity to both known wintering and nesting occurrences.

3.14.1.5.1.1 AC Collection System

The AC collection system routes are located entirely within Region 1. The four primary land cover types that compose the AC collection system routes are cultivated crops, grassland/herbaceous, shrub/scrub, and developed open space (see Section 3.10.6.2.2, Table 3.10-13).

No federally listed bat species are known to occur within the ROI for the AC collection system routes.

Of the five federally listed bird species and one federal candidate bird species, three are known to occur or to have the potential to occur within the ROI in Region 1. The piping plover has two historical nests at Optima Lake in Texas County, Oklahoma (USFWS 2014d). In relation to Optima Lake, the ROI for the AC collection system routes NE-1 and E-1 would be approximately 1.5 miles south and 3.8 miles west, respectively. As described in Section 3.10, the predominant land cover in the ROI for the AC collection system routes is grassland/herbaceous. Piping plovers are unlikely to use the primary habitat (land cover types) that dominate the ROI of the AC collection system routes for nesting habitat; however, the proximity to Optima Lake and known nesting occurrences in the vicinity of the AC collection system routes suggests that piping plovers may occur in the area during the nesting and breeding session. Riverine habitat used by the least tern is limited to Region 1, where the bird has been documented. There are no known stopover locations of whooping crane within the ROI for the AC collection system routes. The nearest known migratory and stopover locations are approximately 2.5 miles from AC Collection System Route E-1. Further, the AC collection system routes are outside the 95 percent corridor of known whooping crane observations (USFWS 2009d), indicating that whooping cranes are unlikely to occur within the ROI for the AC collection system routes during migration (Figure 3.14-2 in Appendix A). Any whooping cranes that do migrate through the area may infrequently use the grassland/herbaceous habitat and occasionally use the cultivated cropland that dominates the ROI for the AC collection system routes. Further, limited areas of open water and woody wetlands occur along portions of the AC collection system routes (see Section 3.19 for additional discussion). The LEPC occurs within eight of the counties in the ROI for the AC collection system routes, including focal area habitat mapped within AC Collection System Route E-1 in Beaver County, Oklahoma (Kansas Biological Survey 2013; Van Pelt et al. 2013). The LEPC is likely to occur within the grassland/herbaceous habitat that dominates the ROI for the AC collection system routes; however, specific habitat use within the ROI is dependent upon the quality of habitats (Figure 3.14-1 in Appendix A). The ROI associated with AC Collection System Routes E-3, SE-1, SE-3, and E-2 would cross the edges of the Schultz WMA and State Park while Routes SE-3 and E-2 would cross the Shorb WMA. Both areas are managed by the ODWC for wildlife habitat and hunting.

The ODWC indicated that bald and golden eagles are known to winter around Optima Lake WMA in Texas County, Oklahoma (ODWC 2014a). The southern edges of the Optima NWR and WMA would be located within the ROI for AC Collection System Route E-1. Bald eagles have a low likelihood of occurring within the AC collection system routes during the breeding season given the lack of suitable habitat within the ROI; however, proximity to known winter occurrences at Optima Lake WMA suggests that some occurrence during migration and during winter may occur. In contrast, golden eagles are more likely to occur year-round within the AC collection system routes given the suitability of the habitat, namely grassland/herbaceous land cover suitable for foraging, and the proximity to both known wintering and nesting occurrences.

3.14.1.5.2 Region 2

The ROI in Region 2 is referred to as the Oklahoma Central Great Plains Region and includes the Applicant Proposed Route and HVDC Alternative Routes 2-A through 2-B.

No federally listed bat species are known to occur within the ROI in Region 2 in Oklahoma.

Of the five federally listed bird species and one federal candidate bird species, four have known occurrences or potential for occurrences within the ROI. The dominant land cover within the ROI in Region 2 is grassland/herbaceous followed by cropland (i.e., cultivated crops) (see Section 3.10). There are no known stopover locations of whooping crane within the ROI. As discussed above, whooping cranes will use grassland/herbaceous land cover when in proximity to wetlands. Limited wetlands occur within the ROI. Portions of the ROI are within the 95 percent to 75 percent corridor of known whooping crane observations (USFWS 2009c), which suggests that whooping cranes may occur within the ROI during migration even in limited habitats (Figure 3.14-2 in Appendix A). Furthermore, the nearest known migration and stopover location for migratory whooping cranes is approximately 1.8 miles from the Applicant Proposed Route. Interior least terns are known to nest along the Cimarron River, the closest occurrence (1 to 3 miles) of which is located near HVDC Alternative Route 2-A in Major County (Lott 2006, Lott et al. 2013). Although limited suitable nesting habitats for interior least terns occur within the ROI, the known nesting occurrences of interior least terns suggest that the species may occur during migration generally from April through June. The piping plover is a potential migrant through Region 2 and uses habitat along rivers, lakes, and reservoirs, but it does not concentrate in large numbers at inland locations and seems to stop opportunistically; single individuals of the species are often reported (USFWS 2009e). Many piping plovers are believed to fly directly to and from breeding and wintering grounds. The LEPC has the potential to occur within Woodward County within Region 2 (Van Pelt et al. 2013); however, specific habitat use within the ROI is dependent upon the quality of habitats (Figure 3.14-1b in Appendix A) (Hagen et al. 2013). The red knot is considered an occasional transient migrant through the state of Oklahoma.

The ODWC indicates that bald eagles are known to winter around Canton Lake WMA in Blaine County, Oklahoma (ODWC 2014b), which is located approximately 3.5 miles south of the Applicant Proposed Route. Bald eagles are less likely to occur within the ROI in Region 2, given a lack of suitable habitat within the ROI; however, proximity to known winter occurrences at Canton Lake WMA suggests that some occurrence during migration and during winter may occur. Two route variations to the Applicant Proposed Route were developed in Region 2 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.2. The variations are illustrated in Exhibit 1 of Appendix M. These variations represent minor adjustments to the Applicant Proposed Route. The only special status species that would possibly occur in the vicinity of Link 1, Variation 1, would be the LEPC. The whooping crane would be a potential migrant through Link 2, Variation 2, but the route variation does not contain any potential stopover habitat similar to the original route. Both route variations in Region 2 would cross through the same types of vegetation and habitat as the original Applicant Proposed Route Links 1 and 2.

3.14.1.5.3 Region 3

Region 3 is referred to as the Oklahoma Cross Timbers Region and includes the Applicant Proposed Route and HVDC Alternative Routes 3-A through 3-E.

As discussed in Section 3.10, the ROI in Region 3 is more varied than in Regions 1 and 2. It primarily consists of grassland/herbaceous (33.9 percent), deciduous forest (27.7 percent), and pasture/hay (23.4 percent). Because of this increased variation in habitats, the diversity of special status wildlife species increases as well.

Two of the four federally listed bat species occur within Region 3. The gray bats have been documented to occur within Muskogee County in Oklahoma (USFWS 2014d). Gray bats are cave obligate species (i.e., use caves for both summer roosting and winter hibernation) and are limited in occurrence to cave and karst features within Region 3. The northern long-eared bat is known or believed to occur in Okmulgee and Muskogee counties, Oklahoma. Unlike the gray, the northern long-eared bat uses forested areas as summer roosting sites and caves for winter hibernation.

Of the five federally listed bird species and one federal candidate bird species, four have known occurrences or potential for occurrences within the ROI. The red knot is an occasional transient migrant through Region 3. The Sprague's pipit has been documented in Payne County, Oklahoma; however, the exact location of the documented occurrence is not provided by the USFWS (USFWS 2014d). Sprague's pipit is a grassland species, and occurrences are likely to be limited to portions of the ROI with the highest percentage of grasslands. The piping plover has been documented in numerous counties in the ROI (USFWS 2014d). However, piping plovers are limited to open areas, sparsely vegetated sand or gravel beaches adjacent to alkali wetlands, and on beaches, sand bars, and dredged material islands of major river systems. Within Region 3, these areas are limited to the Canadian and Cimarron rivers (see Section 3.20). The western edge of the ROI in Region 3 is within the 75 percent to 95 percent corridor of known whooping crane observations (USFWS 2009d) (Figure 3.14-2 in Appendix A). However, the nearest known migration or stopover observation is approximately 2.3 miles from the HVDC Alternative Route 3-A. As discussed above, whooping cranes will use grassland/herbaceous land cover when wetlands are nearby. Limited grassland/ herbaceous land cover or wetlands occur within the ROI, suggesting that although no stopover locations were documented within the ROI, there is the potential for whooping crane to occur. Interior least terns have been documented along the Cimarron River within 1 to 2 miles of the proposed HVDC transmission line in Payne County, Oklahoma; and along the Arkansas River (within 3 to 4 miles) in Muskogee County, Oklahoma (Lott 2006, Lott et al. 2013). Although limited suitable nesting habitats for interior least terns occur within the ROI, the known nesting occurrences of interior least terns suggest that the species may occur during migration, which generally occurs from April through June.

The American burying beetle has the potential to occur in the ROI (USFWS 2014d). However, based on habitat characteristics considered unfavorable for the American burying beetle (USFWS 2014e), the American burying beetle is expected to most likely occur within undisturbed native vegetation types within the ROI (Section 3.17.5.3). It is most likely to occur within deciduous and coniferous forests and also possibly native grasslands, but not in cultivated, maintained pasture or grassland, or developed areas (USFWS 2014e).

Bald eagles are likely to occur within the ROI given the proximity to suitable habitat, specifically habitat along the Arkansas River, suggesting that some occurrence during migration and during winter may occur. The Tulsa Audubon Society has numerous documented occurrences of bald eagles at Greenleaf State Park, which is located approximately 3 miles north of the Applicant Proposed Route in Muskogee County, Oklahoma (Tulsa Audubon Society 2009).

Five route variations to the Applicant Proposed Route were developed in Region 3 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.3. The variations are illustrated in Exhibit 1 of Appendix M. These variations represent minor adjustments to the Applicant Proposed Route. The Sprague's pipit is the only terrestrial special status species that would possibly occur in Links 1 and 2, Variation 1, and Link 1, Variation 2, similar to the original Applicant Proposed Route Links 1 and 2. However, Link 1, Variation 2, would increase the amount of forest and native prairie within the ROI. The American burying beetle is the only special status species that would possibly occur in Link 4, Variation 1, and Link 4, Variation 2. The northern long-eared bat, gray bat and American burying beetle are the only terrestrial special status species that would possibly occur in Link 5, Variation 2, in Muskogee County, Oklahoma.

3.14.1.5.4 Region 4

Region 4 is referred to as the Arkansas River Valley Region and includes the Applicant Proposed Route, including the Lee Creek Variation, and HVDC Alternative Routes 4-A through 4-E.

Publically available USFWS information shows documented occurrences of the four protected bat species in Region 4 (USFWS 2014d). All four bat species potentially occur at the Ozark Plateau NWR, which is located approximately 15.5 miles north of the Applicant Proposed Route. In addition, portions of the Area of Potential Bat Caves, as indicated by the USFWS (2014d), overlap portions of the ROI in Region 4 in Sequoyah County, Oklahoma. Rosson Hollow Crevices, a hibernacula of Indiana bats, is located in Franklin County, Arkansas; however, the exact location of the entrance of the hibernacula is protected by the USFWS (USFWS 2007a). Protected bats may use suitable cave and karst features located within Region 4 ROI during winter hibernation. Ozark big-eared bats and gray bats also use caves for summer roosting. During the spring and summer, northern long-eared and Indiana bats may use suitable deciduous and evergreen forest that can be found throughout the region (see Section 3.10). Evergreen forests are predominantly found along the eastern portions of the region. However, the Indiana bat and northern long-eared bat could occupy forested areas of the ROI that contain suitable maternity roost trees. In January 2015, staff of the city of Fort Smith and AGFC confirmed the presence of hibernating Ozark big-eared bats in two new caves in Crawford County, Arkansas. It is not known whether the Ozark big-eared bat also uses these caves as summer roosts.

Of the five federally listed bird species and one federal candidate bird species, four have known occurrences or potential for occurrences within the ROI in Region 4. The Sprague’s pipit has been documented in Franklin County, Arkansas; however, exact location of the occurrence in Franklin County is not provided by the USFWS. Sprague’s pipit is a grassland species, and occurrences are likely to be limited because grasslands comprise a relatively small proportion of the ROI in Region 4. Interior least terns and piping plovers have been documented within three counties in the ROI in Region 4 in Arkansas (Lott 2006; USFWS 2014a; Lott et al. 2013). Interior least terns and piping plovers are likely to use suitable habitat along the Arkansas River, which would be crossed by the Applicant Proposed Route (USFWS 2014d). Although limited suitable nesting habitats for interior least terns and piping plover occur within the ROI, which is dominated by pasture/hay land cover, the known nesting occurrences of interior least terns and piping plover suggest that the species may occur during migration, which generally occurs from April to June. The red knot is a potential transient migrant through Region 4 and would likely only occur where aquatic habitats with exposed sediments and abundant aquatic invertebrates are present.

The American burying beetle has the potential for occurrence along the ROI (USFWS 2014d). However, based on habitat characteristics considered unfavorable for the American burying beetle (USFWS 2014e), the American burying beetle is expected to most likely occur within undisturbed, native vegetation types within the ROI (Section 3.17.5.4) such as deciduous and coniferous forests and also possibly native grasslands, but not in cultivated, maintained pasture or grassland, or developed areas (USFWS 2014e).

There are documented occurrences of bald eagles along the Arkansas River in Sequoyah County, Oklahoma (Lish and Sherrod 1986). Bald eagles are likely to occur within the ROI in Region 4, due to the proximity of suitable habitat, specifically habitat along the Arkansas River and at Lake Dardanelle, suggesting that some occurrence during migration and during winter may occur. Furthermore, Lake Dardanelle (which is located approximately 6 to 10 miles south of Alternative Route 4-E and 7 to 14 miles south of the Applicant Proposed Route in Johnson and Pope counties, Arkansas) has documented high wintering concentrations of bald eagles (ANHC 2013). In contrast, golden eagles are not likely to occur within the ROI of Region 4 given a lack of suitable habitat, namely grassland/herbaceous land cover suitable for foraging. Although the OBS (2013, as cited in USFWS 2014d) has a documented occurrence of golden eagle in Sequoyah County, Oklahoma, the observation is limited and suggests that golden eagle occurrence may be limited to migration within the region.

Seven route variations to the Applicant Proposed Route were developed in Region 4 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.4. The variations are illustrated in Exhibit 1 of Appendix M. These variations represent minor adjustments to the Applicant Proposed Route. The northern long-eared bat, gray bat, Indiana bat, Ozark big-eared bat, and American burying beetle are the only terrestrial special status species that would possibly occur in Applicant Proposed Route Link 3, Variation 1, and Link 3, Variation 2, in Sequoyah County, Oklahoma. The original Applicant Proposed Route associated with Link 3, Variation 2, is also being carried forward for continued consideration. The new Variation 2 contains more forested land and karst features than the original Applicant Proposed Route Link 3 but also parallels more existing infrastructure. The northern long-eared bat, gray bat, Indiana bat, Ozark big-eared bat, and American burying beetle are the only terrestrial special status species that would possibly occur in Link 3, Variation 3; Link 6, Variation 1; Link 6, Variation 2; and Link 6, Variation 3, in Crawford County, Arkansas. Link 3, Variation 3, was developed to avoid two recently found cave hibernacula for the Ozark big-eared bat. The new route variation also reduces forested land in the route. Link 9, Variation 1, is in Pope County, Arkansas, and the northern long-eared bat, gray bat, Indiana bat, and Ozark big-eared bat would possibly occur in the vicinity.

3.14.1.5.5 Region 5

Region 5 is referred to as the Central Arkansas Region and includes the Applicant Proposed Route and HVDC Alternative Routes 5-A through 5-F.

All four protected bat species have documented occurrences in Region 5 based on publically available information on known occurrence from the USFWS (2014d). There are documented occurrences of northern long-eared bats, Ozark big-eared bats, gray bat, and Indiana bat occur in Pope County (USFWS 2014d). A hibernaculum for gray bat is documented in Pope County, which is located south-southwest of the proposed HVDC transmission line, as well as Independence County which is located north of the proposed HVDC transmission line (Martin 2007). Protected bats may use suitable cave and karst features located within Region 5 ROI during winter hibernation. Ozark big-eared bats and gray bats also use caves for summer roosting. During the spring and summer, northern long-eared and Indiana bats may use suitable deciduous and evergreen forest that can be found throughout the Region. Evergreen forests are predominantly found along the eastern portions of the Region. No studies to document the occurrence of protected bat species within the ROI in Region 5 have been completed; however, the BISON database did contain two occurrences of gray bats within the ROI of Region 5.

Conway County has historical occurrences of Florida panther (USFWS 2014d); however, as discussed above, the Florida panther is currently considered extirpated in Arkansas.

Of the five federally listed bird species and one federal candidate bird species, two have known occurrences or potential for occurrences within the ROI in Region 5. Interior least terns and piping plovers have been documented within three counties in Region 5 in Arkansas. Interior least terns and piping plovers are likely to use suitable habitat along the Arkansas River located approximately 7 miles south from the Applicant Proposed Route at its nearest point (Lott 2006; Lott et al. 2013; USFWS 2014d). Although limited suitable nesting habitats for interior least terns occur within the ROI, which is dominated by deciduous forest and pasture/hay land cover, the known nesting occurrences of interior least terns suggest that the species may occur during migration, which generally occurs from April through June. Sprague's pipit and the red knot are unlikely migrants in the region.

Bald eagles are likely to occur within the ROI in Region 5 given the proximity to suitable habitat, specifically habitat at Greers Ferry Lake, suggesting that some occurrence during migration and during winter may occur. Greers Ferry Lake (which is located approximately 6 to 10 miles north of the Applicant Proposed Route in Van Buren and Cleburne County, Arkansas) has documented high wintering concentrations of bald eagles (ANHC 2013). Bald eagles may migrate through the ROI for the HVDC transmission line routes to reach the Arkansas River approximately 10 to 18 miles to the south in Pope and Conway counties.

Five route variations to the Applicant Proposed Route were developed in Region 5 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.5. The variations are illustrated in Exhibit 1 of Appendix M. These variations represent minor adjustments to the Applicant Proposed Route. The northern long-eared bat, gray bat, Indiana bat, and Ozark big-eared bat are the only terrestrial special status species that would possibly occur in Link 1, Variation 2; Link 2, Variation 2; and Links 2 and 3, Variation 1, in Pope County, Arkansas, and they would cross through the same types of vegetation and habitats as the original Applicant Proposed Route. The northern long-eared bat, gray bat, and Indiana bat are the only terrestrial special status species that would possibly occur in Links 3 and 4, Variation 2, in Van Buren County, and Link 7, Variation 1, in White County, Arkansas.

3.14.1.5.6 Region 6

Region 6 is referred to as the Cache River and Crowley's Ridge Region and includes the Applicant Proposed Route and HVDC Alternative Routes 6-A through 6-D.

Of the four protected bat species, the northern long-eared bat, gray bat, and Indiana bat have may occur in Jackson County, Arkansas, in Region 6 based on publically available information on known occurrence from the USFWS (USFWS 2014d, 2014a). Protected bats are limited in occurrence to cave and karst features (see Section 3.6) within Region 6 during winter hibernation; however, occurrence during the spring through fall is likely to be limited given a lack of suitable foraging and roosting habitat. Region 6 is dominated by croplands, and little to no forested habitat occurs within the ROI except for about 3 miles that crosses Crowley's Ridge. No studies to document the occurrence of protected bat species within the ROI in Region 6 have been completed, and the BISON database did not contain any documented occurrences of these listed bat species within the ROI of Region 6 (USGS 2014).

Of the five federally listed bird species and one federal candidate bird species, two have known occurrences or potential for occurrences in the Region 6 ROI. However, because of limited preferred habitat in the ROI for both species, the presence of either species is likely to be limited. Piping plovers have documented occurrences in Jackson County, Arkansas based on publically available information on known occurrences from the USFWS (2014a). Interior least terns and piping plovers have been documented within Cross and Crittenden counties in the ROI in Region 6 in Arkansas based on publically available information from the USFWS and published scientific studies (Lott 2006; Lott et al. 2013; USFWS 2014a). Piping plovers are limited to open sparsely vegetated sand or gravel beaches adjacent to alkali wetlands, and on beaches, sand bars, and dredged material islands of major river systems that do not occur in Region 6. Neither the piping plovers nor interior least terns are likely to use the croplands habitat that dominates Region 6 for nesting habitat. The Mississippi River is about 25 miles east of Region

6 where known nesting occurs and both piping plovers and interior least terns may occasionally occur in Region 6 during the nesting and breeding session.

Bald eagles have been documented throughout Region 6 in Jackson, Poinsett, Cross and Crittenden counties, Arkansas (ANHC 2013), and the Mississippi River in Region 7 is known to have a high wintering concentration of bald eagles. However, the ANHC (2013) does not indicate whether bald eagles are known to occur within the ROI in Region 6, rather the occurrences are provided on a county-level. Nevertheless, the available evidence indicates that bald eagles are likely to occasionally occur within the ROI in Region 6 because of nearby suitable habitat and known winter concentrations, specifically habitat along the Mississippi River, suggesting that some occurrence during migration and during winter may occur.

One route variation to the Applicant Proposed Route in Region 6 (i.e., Applicant Proposed Route Link 2, Variation 1) was developed in response to public comments on the Draft EIS. This route variation is described in Appendix M and summarized in Section 2.4.2.6. The variation is illustrated in Exhibit 1 of Appendix M. This variation represents a minor adjustment to the Applicant Proposed Route. The route variation crosses cultivated cropland. None of the terrestrial special status species would likely occur in Link 2, Variation 1, except as an occasional migrant through the area.

3.14.1.5.7 Region 7

Region 7 is referred to as the Arkansas Mississippi River Delta and Tennessee Region and includes the Applicant Proposed Route and HVDC Alternative Routes 7-A through 7-D.

Of the four protected bat species, the northern long-eared bat and Indiana bat potentially occur in Region 7 (USFWS 2014d, 2014a) based on publically available information on known occurrence from the USFWS. These two species of bats are limited in occurrence to cave and karst features (see Section 3.6) within Region 7 during winter hibernation; however, occurrence during the spring through fall is likely to be limited given a lack of suitable foraging and roosting habitat. Region 7 is dominated by croplands, and little forested habitat, except in the vicinity of the Mississippi River, occurs within the ROI. The BISON database did not contain any documented occurrences of these listed bat species within the ROI of Region 7 (USGS 2014). However, forested areas in Tipton County, Tennessee, and bottomland forest in Mississippi County in Arkansas could potentially contain maternity roost habitat for the northern long-eared bat and Indiana bat.

Of the five federally listed bird species and one federal candidate bird species, two have known occurrences or potential for occurrences within in the ROI in Region 7. Interior least terns nest along the Mississippi River in Region 7 (TDEC 2014; Lott et al. 2013), and have been documented in Crittenden and Mississippi counties in Arkansas and Tipton and Shelby counties in Tennessee (Lott 2006). Interior least terns are unlikely to use the croplands habitat that dominates Region 7 for nesting habitat; however, the Mississippi River provides known nesting habitat in the ROI of the proposed HVDC transmission line (Lott et al. 2013). Piping plovers could potentially use sandbars and sparsely vegetated shore habitats along the Mississippi River and have been documented in Mississippi County in Arkansas.

Bald eagles are likely to occur within the ROI in Region 7 given the proximity of suitable habitat and known winter concentrations along the Mississippi River.

Three route variations to the Applicant Proposed Route were developed in Region 7 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.7. The variations are illustrated in Exhibit 1 of Appendix M. None of the terrestrial special status species would likely occur in Link 1, Variation 1, because it crosses cultivated cropland. The northern long-eared bat would possibly occur in Link 1, Variation 2, but it is unlikely because the route is predominately cropland. The northern long-eared bat and Indiana bat are the only terrestrial special status species that would possibly occur in Link 5, Variation 1, in Tennessee.

3.14.1.6 Connected Actions

3.14.1.6.1 Wind Energy Generation

Wind energy generation would likely occur within WDZs. The potential WDZs are identified in Section 3.1.1 and occur in the Oklahoma and Texas panhandles within a 40-mile radius of the Oklahoma converter station. The special status wildlife species that could potentially occur in the WDZs include Sprague's pipit, red knot, golden eagle, LEPC, and whooping crane. Within all of the WDZs there is a lack of suitable riverine habitat for piping plovers and the interior least tern and both species are unlikely to occur in the WDZs; however, there is the potential for piping plover and interior least tern to occur within the WDZs during migration, especially those near Optima Lake. Migration generally occurs from April to June. Sprague's pipit could occur but is uncommon and likely migrates through the area. The red knot is a rare migrant and is unlikely to occur in the WDZs. The golden eagle is a wide-ranging species and could occur throughout the region, but would most likely occur in areas with native grasslands and shrub lands that support small mammal prey species.

The LEPC is a resident species in the vicinity of the WDZs. Most of the occupied LEPC habitat occurs north and east of WDZs (Figure 3.14-1a, Appendix A). Although LEPC will occasionally use developed or disturbed areas such as oil well pads, roads, and croplands for lek sites because they provide open visible areas for courtship displays, LEPC require large contiguous blocks of grassland or shrub/grasslands. Areas that contain 30 percent or more of cropland typically do not provide adequate habitat to sustain populations of LEPC (see Section 3.14.1.4.2.3). Croplands are predominant throughout the region of the WDZs, which would limit potential habitat for LEPC. However, larger contiguous tracts of undeveloped grassland would provide suitable habitat for the LEPC. Throughout the region, private property may be enrolled in the Candidate Conservation Agreement with Assurances program, the goal of which is to implement habitat management practices for the LEPC on private lands.

Individual or small groups of whooping cranes could possibly migrate through the WDZs even though the WDZs are west of the primary migration corridor (Figure 3.14-2, Appendix A). Suitable whooping crane roosting habitats (i.e., semi-permanent shallow wetlands or open, sandy riverine habitat) have limited acreage in the region of the WDZs. However, whooping cranes will use any available habitat such as croplands if forced to descend unexpectedly during migration by inclement weather. Wetland areas that may potentially be used by special status wildlife species are described in more detail in Section 3.19. The dominant land cover for each WDZ is described in Section 3.10.5.8.

3.14.1.6.1.1 WDZ-A

The dominant land cover in WDZ-A is croplands. Other land cover types potentially used by special status wildlife species include grassland/herbaceous, and shrub/scrub. LEPC and whooping crane may use the croplands that are predominant within WDZ-A; however, whooping crane occurrence within WDZ-A is likely to be limited to infrequent migratory and stopover occurrences (e.g., Optima Lake). LEPC occurrence within WDZ-A is likely to be limited to more suitable grassland/herbaceous and shrub/scrub cover types that are limited to the northwestern side of WDZ-A.

3.14.1.6.1.2 WDZ-B

The dominant land cover in WDZ-B is croplands. Other land cover types potentially used by special status wildlife species include grassland/herbaceous, and shrub/scrub. LEPC and whooping crane may use the croplands that are predominant within the WDZ-B; however, whooping crane occurrence within the WDZ-B is likely to be limited to infrequent migratory and stopover occurrences while LEPC occurrence within WDZ-B is likely to be limited based on lack of more suitable grassland/herbaceous and shrub/scrub habitats.

3.14.1.6.1.3 WDZ-C

The dominant land cover in WDZ-C is grassland/herbaceous. Other land cover types potentially used by special status wildlife species include croplands (primarily center-pivot irrigated with some dryland areas), and shrub/scrub. LEPC and whooping crane may use the grassland/herbaceous land cover that is predominant within WDZ-C; however, whooping crane occurrence within WDZ-C is likely to be limited to infrequent migratory and stopover occurrences. Occurrence of the LEPC is most likely in native grasslands.

3.14.1.6.1.4 WDZ-D

The dominant land cover in WDZ-D is grassland/herbaceous. Other land cover types potentially used by special status wildlife species include croplands (primarily center-pivot irrigated with some dryland areas), and shrub/scrub. LEPC and whooping crane may use the grassland/herbaceous land cover that is predominant within WDZ-D; however, whooping crane occurrence within WDZ-D is likely to be limited to migratory and stopover occurrences in the adjacent Optima Lake area. WDZ-D contains the Schultz ODWC WMAs, and the eastern end of the WDZ is within the estimated occupied range of the LEPC.

3.14.1.6.1.5 WDZ-E

The dominant land cover in WDZ-E is croplands (primarily center-pivot irrigated with some dryland areas). Other land cover types potentially used by special status wildlife species include grassland/herbaceous, and shrub/scrub. LEPC and whooping crane may use the croplands that are predominant within WDZ-E; however, whooping crane occurrence within WDZ-E is likely to be limited to migratory and stopover occurrences while LEPC occurrence within WDZ-E is likely to be limited due to lack of suitable grassland/herbaceous and shrub/scrub habitats.

3.14.1.6.1.6 WDZ-F

The dominant land cover in WDZ-F is grassland/herbaceous. Other land cover types potentially used by special status wildlife species include croplands (primarily center-pivot irrigated with some dryland areas), and shrub/scrub. LEPC may use the grassland/herbaceous vegetation that is predominant within WDZ-F. Whooping crane occurrence within WDZ-F is likely to be limited to infrequent migratory and stopover occurrences.

3.14.1.6.1.7 WDZ-G

The dominant land cover in the WDZ-G is grassland/herbaceous. Other land cover types potentially used by special status wildlife species include croplands (primarily center-pivot irrigated with some dryland areas), and shrub/scrub. LEPC may use the grassland/herbaceous that is predominant within WDZ-G. The northern end of WDZ-G is close to quality LEPC habitat in southwestern Kansas. Whooping crane occurrence within WDZ-G is likely to be limited to infrequent migratory and stopover occurrences.

3.14.1.6.1.8 WDZ-H

The dominant land cover in WDZ-H is grassland/herbaceous. Other land cover types potentially used by special status wildlife species include croplands (primarily center-pivot irrigated with some dryland areas), and shrub/scrub. LEPC may use the grassland/herbaceous that is predominant within WDZ-H that may contain large areas suitable for LEPC. Whooping crane occurrence within WDZ-H is likely to be limited to infrequent migratory and stopover occurrences.

3.14.1.6.1.9 WDZ-I

The dominant land cover in WDZ-I is croplands (primarily center-pivot irrigated with some dryland areas). Other land cover types potentially used by special status wildlife species include grassland/herbaceous, and shrub/scrub. LEPC may use the croplands that are predominant within the WDZ-I. WDZ-I is adjacent to quality LEPC to the southeast. Whooping crane occurrence within WDZ-I is likely to be limited to migratory and stopover occurrences. WDZ-I is north of Optima Lake. LEPC occurrence within WDZ-I is likely to be limited due to lack of suitable grassland/herbaceous and shrub/scrub habitats, primarily toward the eastern end.

3.14.1.6.1.10 WDZ-J

The dominant land cover in the WDZ-J is grassland/herbaceous. Other land cover types potentially used by special status wildlife species include croplands (primarily center-pivot irrigated with some dryland areas), and shrub/scrub. LEPC may use the grassland/herbaceous that is predominant within the WDZ-J. Whooping crane occurrence within WDZ-J is likely to be limited to infrequent migratory and stopover occurrences. Because WDZ-J contains a higher proportion of grassland/herbaceous cover and is located adjacent to CHAT-1 LEPC habitat and possible leks, LEPC may occur in greater abundance in this WDZ. The Shorb WMA is located outside the western boundary of WDZ-J.

3.14.1.6.1.11 WDZ-K

The dominant land cover in the WDZ-K is croplands (primarily center-pivot irrigated with some dryland areas). Other land cover types potentially used by special status wildlife species include grassland/herbaceous, and shrub/scrub. LEPC may use the croplands that are predominant within WDZ-K; however, the eastern end of the WDZ contains suitable grassland/herbaceous and possibly several lek sites and is adjacent to quality habitat (CHAT-1) to the east (Figure 3-14-1a, Appendix A). Whooping crane occurrence within WDZ-K is likely to be limited to migratory and stopover occurrences; WDZ-K is the closest of the WDZs to the primary whooping crane migration corridor (Figure 3.14-2, Appendix A).

3.14.1.6.1.12 WDZ-L

The dominant land cover in the WDZ-L is croplands (primarily center-pivot irrigated with some dryland areas). Other land cover types potentially used by special status wildlife species include grassland/herbaceous, and shrub/scrub. LEPC may use the croplands that are predominant within WDZ-L. LEPC occurrence within WDZ-L is most likely on the eastern end of the WDZ near more suitable grassland/herbaceous and shrub/scrub habitats. Whooping crane occurrence within WDZ-L is likely to be limited to infrequent migratory and stopover occurrences.

3.14.1.6.2 Optima Substation

The future Optima Substation would be constructed within a 160-acre site that is mostly grassland/herbaceous, with smaller areas of shrub/scrub and developed open space. The limited available potentially suitable habitat for piping plover, interior least tern, or bald eagle in the area suggests that none of these species are likely to occur within the future Optima Substation site. However, LEPC and whooping crane may use the grassland/herbaceous habitats that occur in the vicinity of the Optima Substation site. Whooping crane occurrence is likely to be limited to infrequent migratory and stopover occurrences. The future Optima Substation site is located west of the primary whooping crane migratory corridor in Oklahoma; however, some whooping cranes will migrate across the Oklahoma Panhandle where the Substation may be located. The substation site is located west of areas mapped as high conservation priority habitat for the LEPC; however, existing roads, power poles, and croplands adjacent to the Optima Substation site decrease the potential quality of the habitat for LEPC. Golden eagles likely occur in the region, but no suitable nesting habitat occurs in the vicinity of the future Optima Substation.

3.14.1.6.3 TVA Upgrades

The ROI for the direct assignment facilities (which are included in the Applicant Proposed Project) would occur within the Tennessee Converter Station Siting Area and more specifically within the Shelby Substation. The ROI for the network upgrades, and in particular TVA's future 500kV transmission line, cannot be fully determined at this time. The new 500kV line would be in western Tennessee. The upgrades to existing facilities would mostly be in western and central Tennessee. Upgrades to existing infrastructure would include upgrading terminal equipment at three existing 500kV substations and six existing 161kV substations; making appropriate upgrades to increase heights on 16 existing 161kV transmission lines to increase line ratings, and replacing the conductors on eight existing 161kV transmission lines. All of the network upgrades would likely occur within the range of the northern long-eared bat, Indiana bat, and bald eagle. Some upgrades to existing facilities could occur within the range of the gray bat and other special status wildlife species. Where possible, general impacts to special status terrestrial wildlife species that could occur from the required TVA upgrades are discussed in the impact sections that follow.

3.14.1.7 Impacts to Special Status Terrestrial Wildlife Species

3.14.1.7.1 Methodology

Within the ROI, Project activities were assessed that could potentially impact special status wildlife species and their habitats. Special status wildlife species and their habitats evaluated include species known to occur or to have the potential to occur within the ROI and are federally protected or proposed for federal protection under the ESA and state protected species. Potential impacts on special status wildlife resources and their habitats include the following and are discussed for each phase of the Project:

- Potential impacts from temporary or long-term displacement of special status wildlife species
- Fragmentation of special status wildlife habitat
- Potential disturbance to known populations and/or suitable habitat for species designated as candidate, threatened or endangered under the ESA
- Potential for avian collisions and/or electrocution

Species were considered at risk of experiencing these impacts if their range overlapped with the ROI and suitable habitat for the species occurred within the ROI.

The AC collection system consists of thirteen 2-mile-wide routes in Oklahoma (Beaver, Cimarron, and Texas counties) and Texas (Hansford, Ochiltree, and Sherman counties) within which an AC collection system transmission line could be sited and would connect wind energy facilities to the Project.

The Applicant has developed EPMs that would be implemented during design/engineering, construction, and operations and maintenance. The complete list of EPMs is provided in Appendix F. Implementation of these EPMs is assumed throughout the impact analysis that follows for the Project. During the initial construction phase of the Project, both general EPMs and those specific to wildlife resources would be implemented to avoid or minimize impacts to wildlife resources as described below.

General EPMs for the Project that relate to special status wildlife resources include the following:

- GE-1: Clean Line will train personnel on health, safety, and environmental matters. Training will include practices, techniques, and protocols required by federal and state regulations and applicable permits.
- GE-2: Clean Line will design, construct, maintain, and operate the Project following current Avian and Power Line Interaction Committee guidelines to minimize risk of avian mortality.
- GE-3: Clean Line will minimize clearing vegetation within the ROW, consistent with a Transmission Vegetation Management Plan (TVMP) filed with NERC, and applicable federal, state, and local regulations. The TVMP may require additional analysis under NEPA depending on whether and under what conditions DOE decides to participate in the Project.
- GE-4: Vegetation removed during clearing will be disposed of according to federal, state, and local regulations.
- GE-5: Any herbicides used during construction and operations and maintenance will be applied according to label instructions and any federal, state, and local regulations.
- GE-6: Clean Line will restrict vehicular travel to the ROW and other established areas within the construction, access, or maintenance easement(s).
- GE-7: Roads not otherwise needed for maintenance and operations will be restored to preconstruction conditions. Restoration practices may include decompacting, recontouring, and re-seeding. Roads needed for maintenance and operations will be retained.
- GE-9: Clean Line will avoid and/or minimize damage to drainage features and other improvements such as ditches, culverts, levees, tiles, and terraces; however, if these features or improvements are inadvertently damaged, they will be repaired and or restored.
- GE-13: Emergency and spill response equipment will be kept on hand during construction.
- GE-14: Clean Line will restrict the refueling and maintenance of vehicles and the storage of fuels and hazardous chemicals within at least 100 feet from wetlands, surface waterbodies, and groundwater wells, or as otherwise required by federal, state, or local regulations.
- GE-20: Clean Line will conduct construction and scheduled maintenance activities on the facilities during daylight hours, except in rare circumstances that may include, for example, emergency or unsafe situations, to avoid adverse environmental effects, to minimize traffic disruptions, or to comply with regulatory or permit requirements.
- GE-21: Clean Line will maintain construction equipment in good working order. Equipment and vehicles that show excessive emissions of exhaust gasses and particulates due to poor engine adjustments or other inefficient operating conditions will be repaired or adjusted.
- GE-22: Clean Line will impose speed limits during construction for access roads (e.g., to reduce dust emissions, for safety reasons, and for protection of wildlife).

- GE-28: Hazardous materials and chemicals will be transported, stored, and disposed of according to federal, state, or local regulations or permit requirements.
- GE-30: Clean Line will minimize the amount of time that any excavations remain open.

Agriculture-specific EPMs for the Project that relate to special status wildlife resources include the following:

- AG-3: Clean Line will consult with landowners and/or tenants to identify the location and boundaries of agriculture or conservation reserve lands and to understand the criteria for maintaining the integrity of these committed lands.

Fish, vegetation, and wildlife specific EPMs for the Project that relate to special status wildlife resources include the following:

- FVW-1: Clean Line will identify environmentally sensitive vegetation (e.g., wetlands, protected plant species, riparian areas, and large contiguous tracts of native prairie) and avoid and/or minimize impacts to these areas.
- FVW-2: Clean Line will identify and implement measures to control and minimize the spread of non-native invasive species and noxious weeds.
- FVW-3: Clean Line will clearly demarcate boundaries of environmentally sensitive areas during construction to increase visibility to construction crews.
- FVW-4: If construction- and/or decommissioning-related activities occur during the migratory bird breeding season, Clean Line will work with USFWS to identify migratory species of concern and conduct pre-construction surveys for active nests for such species. Clean Line will consult with USFWS and/or other resource agencies for guidance on seasonal and/or spatial restrictions designed to avoid and/or minimize adverse effects.
- FVW-5: If construction occurs during important time periods (e.g., breeding, migration, etc.) or at close distances to environmentally sensitive areas with vegetation, wildlife, or aquatic resources, Clean Line will consult with USFWS and/or other resource agencies for guidance on seasonal and/or spatial restrictions designed to avoid and/or minimize adverse effects.
- FVW-6: Clean Line will avoid and/or minimize construction within 300 feet of caves known to be occupied by threatened or endangered species.

Water EPMs have been developed for the Project; the following EPMs relate to special status wildlife resources:

- W-1: Clean Line will avoid and/or minimize construction of access roads in special interest waters.
- W-2: Clean Line will identify, avoid, and/or minimize adverse effects to wetlands and waterbodies. Clean Line will not place structure foundations within the Ordinary High Water Mark of Waters of the United States.

Additional site-specific EPMs may be developed as part of the ongoing consultation process between the Applicant and the federal and state agencies.

The following plans will be developed and implemented by the Applicant to avoid or minimize impacts:

- Blasting Plan: This plan will describe measures designed to minimize adverse effects due to blasting.
- Restoration Plan: This plan will describe post-construction activities to reclaim disturbed areas.
- Spill Prevention, Control and Countermeasures (SPCC) Plan: This plan will describe the measures designed to prevent, control, and clean up spills of hazardous materials.

- Storm Water Pollution Prevention Plan (SWPPP): This plan, consistent with federal and state regulations, will describe the practices, measures, and monitoring programs to control sedimentation, erosion, and runoff from disturbed areas.
- Transmission Vegetation Management Plan (TVMP): This plan would be developed and implemented pursuant to the North American Electric Reliability Corporation (NERC) Reliability Standard FAC-003 and will describe how Clean Line will conduct work on its right-of-way to prevent outages due to vegetation. The TVMP may require additional analysis under NEPA depending on whether and under what conditions DOE decides to participate in the Project.
- Avian Protection Plan (APP): This plan, consistent with Avian Power Line Interaction Committee (APLIC) guidelines, will describe a program of specific and comprehensive actions that, when implemented, reduce risk of avian mortality.

3.14.1.7.2 Impacts Associated with the Applicant Proposed Project

This section identifies the potential impacts on special status wildlife and their habitat based on three phases of the Project: (1) construction, (2) operations and maintenance, and (3) decommissioning. The Applicant would conduct each phase in compliance with applicable state and federal laws, regulations, and permits related to environmental protection. EPMs would be implemented as described in Section 3.14.1.7.1 to avoid or minimize impacts to special status wildlife. In addition, consultation with USFWS has been initiated pursuant to Section 7 of the ESA regarding the potential effects of the Project on listed species and any designated critical habitat. This consultation review is a parallel, but separate analysis conducted pursuant to the requirements of Section 7 of the ESA and the applicable implementing regulations. Through the consultation process, additional protection measures may be identified to avoid and/or minimize the impacts of the Project upon listed species and any designated critical habitat.

3.14.1.7.2.1 Construction Impacts

Mortality and Injury

Mortality, by definition, is a direct, permanent impact to an individual (i.e., the individual no-longer exists); however, the effect of an individual mortality on the larger population could vary depending on the dynamics and characteristics of the population. Smaller populations and those species with a low fecundity rate may be sensitive to individual mortalities (e.g., mortality of an individual whooping crane could have future impacts to population viability due to current low population size and a low reproductive rate). Species with larger populations or that have higher fecundity rates can more easily recover from mortalities of individuals. In general, many small mammals, small birds, and amphibians typically have higher average fecundity rates and are less sensitive to mortality. Bats are an exception because they typically bear only a single litter per year, produce one young at a time, and do not breed until their second year (Nagorsen and Brigham 1993). Large birds (e.g., raptors) typically have lower fecundity rates because of small clutch size and delayed sexual maturity. Populations of special status wildlife species may be more susceptible to mortalities because of low population size and lower average fecundity rates.

Construction of the Project could result in the direct mortality or injury of special status wildlife species. Of the construction activities, vegetation clearing and work site preparation would pose the greatest risk of mortality and injury. Most of the special status wildlife species are relatively mobile (i.e., birds and bats) and could avoid construction activities by moving to other areas. Sedentary species (e.g., American burying beetle, juvenile bats, and fledgling birds) would be most at risk for mortality because they are unable to move away from the disturbed area. Mortalities/injuries could be minimized by timing the construction activities to avoid sensitive periods (e.g., the breeding seasons) (see EPM FVW-5); however, some mortality events would occur even with the implementation of seasonal and spatial restriction. Other activities that could cause mortality or injury of special status wildlife species include exposure to hazardous materials (e.g., accidental spills and pesticides) (see Table 3.8-4). The Applicant would implement EMPs GE-1, GE-5, GE-13, GE-21, and GE-28, as well as the measures that would be outlined in the required SPCCP and SWPPP to minimize these risks.

Disturbance

A disturbance response is a behavioral response by wildlife species to a perturbation. The perturbation could be presence of human activity, noise, vibration, or other external stimulus that is sensed by wildlife species. Disturbance impacts could include physiological stress, habitat displacement, increase vulnerability to predation, and disruption of life history functions such foraging, breeding (e.g., leks), and parental care (e.g., nesting). Disturbance impacts from construction are expected to be relatively short term (e.g., limited to the construction phase), but they could last more than a year if disturbances cause reproductive failures (e.g., nest or breeding territory abandonment). Options that may be used to avoid or minimize disturbance impacts include adjusting construction schedules and the location of construction staging areas to avoid sensitive areas that are known or identified as breeding, nesting or roosting sites for special status species.

Habitat Loss and Modification

Special status wildlife species could also be impacted through either loss or modification of habitat. Habitat loss is often a major factor contributing to wildlife species being protected as either state or federal special status species. Loss of wildlife habitat could occur directly through clearing of vegetation or disturbance of non-vegetation habitats (e.g., caves, cliffs, rock outcrops) during construction. Habitat modification such as fragmentation (i.e., the breaking up of contiguous areas of vegetation/habitat into smaller patches) can reduce habitat quality and decrease species survival and reproduction. Some wildlife species require contiguous habitat of certain size and connectivity to carry out life history functions such as foraging, protective cover, breeding, parental care, and dispersal of young to adjacent suitable habitat. Habitat disturbances such as access roads could divide contiguous habitats into smaller patches that may be of lower quality or inadequate in size for some species. In addition, habitat modification includes altering the vegetation structure such as tree or shrub removal or application of herbicides. Although vegetation would remain on an area, the vegetation structure and wildlife habitat could be different and may no longer provide acceptable habitat components required by a particular species. Habitats can also be modified through the unintentional introduction or facilitation of the spread of invasive species that can alter the quality of the habitat or fire regimes (e.g., increase fire frequency). Clearing of vegetation and disturbance to soils could promote the spread and or establishment of invasive plant species. The Applicant would implement EPM FVW-2 to minimize the risk of spreading or creating new infestations of invasive plant species. Section 3.17 discusses in more detail the potential effects of invasive plants species as well as the measures that would be taken to minimize the risk of these effects.

3.14.1.7.2.2 Operations and Maintenance Impacts

Mortality and Injury

It is assumed that during the operations and maintenance phase of the Project that land disturbances and vegetation clearing would not occur as it would have during construction and these disturbances would not be a potential source of mortality and injury to special status wildlife. Some vegetation trimming would occur within the transmission line ROW to prevent regrowth of trees that could interfere with the conductors. Vegetation maintenance is not likely to be a source of mortality to special status wildlife species (e.g., bats) as large suitable roost trees for bats would not be present in the ROW during operations. American burying beetles could possibly be at risk during vegetation maintenance activities but impacts could be reduced if vehicle access was restricted to existing roads. Project structures (i.e., transmission lines and structures) present during operations and maintenance could pose a mortality and injury risk to special status avian species during migration and foraging. A variety of factors influence the rate of avian collisions with power lines or other anthropogenic structures, including: configuration and location of power lines; the tendency of specific species to collide with structures; and environmental factors such as weather, topography, and habitat (APLIC and USFWS 2005). Powerline placement with respect to other structures and topography can influence the collision rate of avian species. Because of sensory abilities unique to birds, birds may be susceptible to human structures not part of their normal environment (Martin 2014). Collisions usually occur near water or migration corridors, and occur more often during inclement weather. Less agile birds, such as large-bodied birds or birds that travel in flocks, are more likely to collide with overhead lines because they lack the ability to quickly negotiate obstacles. Among the avian special status species, the whooping crane, golden eagle, and bald eagle are the most likely species to be susceptible to collision because they are large birds with a wide wingspan (79 to 87 inches) and are less maneuverable than smaller species. The interior least tern is a small and agile flyer with a wingspan of about 20 inches that can readily avoid power lines if they are visible (Dinan et al. 2012). Data regarding collision risk for the interior least terns are inconclusive; some studies report higher risk compared to other species (McNeil et al 1985) and other studies reporting a low risk for collisions (Henderson et al. 1996; Savereno et al. 1996, Dinan et al. 2012). The potential risk of piping plover, red knot, and Sprague's pipit colliding with structures is uncertain; however, it is likely low compared to other avian species as these species are not amongst those that are typically reported to collide with structures and are smaller bodied species that are more maneuverable. The LEPC is a ground-dwelling bird that flies low in short flights and is at lower risk for collisions with power lines but higher risk for collisions with fences (Wolfe et al. 2007).

Avian species are also susceptible to electrocutions by power lines. For a bird to become electrocuted it needs to come into contact with two energized conductors at the same time. As a result, multiple factors influence the risk of avian electrocutions including: the spacing between energized conductors, the tendency of a species to perch along power lines or fly near conductors, as well as the avian species body-size and wing-length. Raptors (including eagles) have the highest probability of becoming electrocuted because these taxa will commonly perch along transmission lines and they have relatively large-bodies and wingspans compared to other taxa of birds. As described in Appendix F, the spacing for the conductors as currently proposed would minimize the risk of avian species coming into contact with two energized conductors and/or becoming electrocuted. To further minimize the risk of avian electrocutions, the Applicant would develop and implement an APP (as described in Section 3.20) consistent with APLIC guidelines.

During ROW maintenance, use of herbicides to manage vegetation and possibly control weeds and invasive species could pose a mortality risk to special status wildlife species; however, many herbicides are non-toxic to animals and use of these chemicals could be an option. Smaller, less mobile species such as the American burying beetle or juvenile individuals would be more susceptible.

Disturbance

Maintenance and repair work on the transmission system (i.e., structures and lines) would require access along the ROW. Because this activity would be periodic and short-term, disturbance impacts to special status wildlife species are not expected to be substantial unless the maintenance or repair work occurs during particular seasons when activities such as breeding (e.g., leks), nesting (e.g., eagles), roosting sites (e.g., bats, eagles, whooping cranes), and hibernation (i.e., bats) could be disrupted.

Habitat Loss and Modification

Impacts such as habitat loss and modification from construction would remain during operations and maintenance unless particular land disturbances were no longer needed and vegetation was restored. It is assumed that additional habitat loss from land clearing would not occur during the operations and maintenance phase of the Project (i.e., additional areas beyond those impacted during construction would not be directly affected during operations and maintenance). However, additional habitat loss could occur indirectly through habitat displacement (behavioral response). Some wildlife species avoid areas near human activities or structures even though the habitat has not been physically disturbed or altered. For example, transmission lines and structures may impact this species use of otherwise suitable habitats due to increased predation rates that can result from avian predators perching and roosting along the structures and line (USFWS 2014d). Recent research also suggests that avoidance of transmission lines may be linked to ultraviolet (UV) discharges on power lines and the ability of birds and mammals to detect UV light (Tyler et al. 2014).

Both physical habitat disturbances from access roads and habitat loss from behavioral avoidance could contribute to fragmentation of habitat for particular special status wildlife species. Some species such as the LEPC require large contiguous areas of undisturbed habitat. Physical disturbances and presence of vertical structure could divide habitat into smaller blocks of habitat that could be less preferred or become unsuitable.

Land disturbances during construction could provide an opportunity for weed species and invasive plant species to become established along the ROW and possibly spread into adjacent areas. Section 3.17 discusses the potential effects of invasive plant species on native habitats as well as measures that could be taken to minimize this risk. The effects of invasive plant species on native habitats could occur slowly or rapidly depending on the invasive plant species involved. In some cases, invasive species may alter the natural fire regime, making an area more susceptible to fire and thereby changing the composition of the vegetation community.

3.14.1.7.2.3 Decommissioning Impacts

Decommissioning of the Project would involve methods similar to those that would be required to construct the Project. As a result, the impacts of decommissioning would be similar to those previously described for construction. The Applicant would follow the same general and resource-specific EPMs during decommissioning that would be implemented during construction. In addition, the Applicant would develop a Decommissioning Plan prior to any decommissioning actions for review and approval by the appropriate state and federal agencies.

Although decommissioning would have short-term adverse impacts to wildlife (similar to what was discussed for construction related impacts), it is assumed that decommissioning of the Project would have long-term beneficial impacts to wildlife species and their habitats, because it would remove the Project and its related impacts from the environment.

3.14.1.7.2.4 Converter Stations and AC Interconnection Siting Areas

A detailed description of the converter stations and other terminal facilities is provided in Section 2.1.2.1.

3.14.1.7.2.4.1 Oklahoma Converter Station Siting Area and AC Interconnection Siting Area

The Oklahoma Converter Station and AC Interconnection Siting Areas are located in Region 1 of the Project in the central part of the Oklahoma Panhandle. The converter station would occupy an area of approximately 45 to 60 acres and the AC interconnection would consist of approximately 3 miles of transmission line. Region 1 is the driest area of the Project and contains vegetation adapted to semi-arid conditions (Section 3.17). Sprague's pipit, red knot, LEPC, piping plover, whooping crane, interior least tern, and golden eagle are believed to be present within Texas County in Region 1 where the Oklahoma converter station and associated AC interconnection system would be constructed (Table 3.14.1-3). Bald eagles have been documented in the area but are not common.

3.14.1.7.2.4.1.1 Construction Impacts

No mortality impacts to any of the special status species are expected from the construction of the Oklahoma converter station or the AC interconnection. Each of the special status species potential present in this area is mobile and would likely avoid construction activity. Construction would disturb approximately 60 acres of habitat, resulting in some habitat loss. Grasslands and croplands would be the dominant habitat type impacted by the Oklahoma converter station and associated AC interconnection (Sections 3.10 and 3.17). The habitat loss is unlikely to have substantial long-term direct impacts to special status wildlife populations in the area.

The only recorded occurrence of nesting piping plovers in the vicinity is at Optima Lake. No disturbance impacts or loss or modification of piping plover habitat is expected. The piping plover primarily uses riverine/lacustrine shorelines or sandbars which are not expected to be affected by construction of the Oklahoma converter station and AC interconnection. Construction would occur in Texas County, Oklahoma, west of the primary whooping crane migration corridor. It is possible that whooping cranes occasionally migrate through the Project area. No migration stopover areas occur near the siting areas for the converter station and the AC interconnection. The golden eagle occurs in the area as a resident and seasonal migrant. The golden eagle is a wide-ranging species and construction activity at the converter station and associated 3 mile AC interconnection is unlikely to cause disturbance or habitat impacts. The known existing range of the LEPC occurs east of the Oklahoma converter station and the AC interconnection (Figure 3.14-1 in Appendix A). Semi-arid grassland/herbaceous land cover is the predominant vegetation in this area. Depending on the specific quality of the habitat at the Project area, LEPC could possibly occur there. Impacts to LEPC habitats are not anticipated, but could be minimized or avoided by locating facilities in previously disturbed sites or habitat of lower quality. Suitable habitat for the interior least tern is not found within the affected area. Suitable habitat (i.e., native grasslands) for Sprague's pipit occurs in area. However, the species is an uncommon migrant and rare winter resident in Oklahoma. The low probability of occurrence would minimize impacts, and if native grasslands are avoided to the extent practicable, impacts would be low.

3.14.1.7.2.4.1.2 Operation and Maintenance Impacts

Potential impacts during operations and maintenance could include mortalities from collisions with transmission lines and building structures as well as habitat loss from potential avoidance of areas surrounding facility structures (CEC 2005). No impact to the piping plover is expected because suitable habitat does not occur in the vicinity of the Project area. The AC interconnection transmission lines and structures could pose a mortality risk to migrating whooping cranes; however, the transmission lines are only about 3 miles in length, which minimizes the potential risk. Also, the Project area is outside the whooping cranes primary migratory corridor, which is approximately 250 miles wide, and no migratory stopover areas exist in the area (Figure 3.14-2 in Appendix A). The expected risk of collision mortality is low. The golden eagle is a resident and seasonal migrant in the area. The relatively small size of the converter station (45 to 60 acres) and the AC interconnection system (3 miles) would minimize the potential collision hazard for golden eagles.

The Project area is west of the occupied range of the LEPC. If LEPC occur near the converter station and AC interconnection system, any avoidance of areas due to the potential for increased predation rates (due to consolidation of raptors and corvids along the AC lines) would constitute a loss of habitat. No impacts are expected during operations and maintenance to the Sprague's pipit, red knot, and interior least tern because of a low probability of occurring in the vicinity of the Project in Region 1. Either suitable habitat does not exist (interior least tern) or the species is an uncommon (Sprague's pipit) or rare migrant (red knot) through the Project area. Because the converter station area would be a developed site with approximately 45 acres fenced, the routine presence of operations and maintenance staff would not have any added disturbance impacts to any special status wildlife species.

3.14.1.7.2.4.1.3 Decommissioning Impacts

The type of potential impacts during Project decommissioning are expected to be similar to those during construction except areas of new land disturbance would be less than during initial construction. The Applicant would follow the same general and resource-specific EPMs during decommissioning that would be implemented during construction. In addition, the Applicant would develop a Decommissioning Plan prior to any decommissioning actions for review and approval by the appropriate state and federal agencies.

3.14.1.7.2.4.2 Tennessee Converter Station Siting Area and AC Interconnection Tie

The Tennessee Converter Station Siting Area and AC Interconnection Tie are located in Region 7 of the Project, located in Shelby County, Tennessee. The converter station would occupy an area of approximately 45 to 60 acres within the siting area. The AC Interconnection Tie would be within the footprint of the converter station and the existing TVA Shelby Substation. Region 7 receives approximately 50 inches of precipitation annually and contains vegetation adapted to relatively moist conditions (Section 3.17). Vegetation in the Tennessee Converter Station Siting Area and AC Interconnection Tie is dominated by deciduous forest (33 percent or 71 acres), pasture/hay (31 percent or 67 acres), and croplands (20 percent or 44 acres). Some woody wetlands (12 percent or 25 acres) also occur in the siting area. The northern long-eared bat, Indiana bat, interior least tern, and red knot are believed to be present within Shelby County in Region 7 where the Tennessee converter station and associated AC interconnection tie would be constructed (Table 3.14.1-3). Suitable habitat for the interior least tern and red knot do not occur in the siting area and no impacts to those species are expected. Bald eagles occur along the Mississippi River and could occur near the converter station siting area; however, the deciduous forest, croplands and pastureland habitat within the siting area is not preferred bald eagle habitat. Therefore, the following impact assessment only considers the northern long-eared bat or Indiana bat.

3.14.1.7.2.4.2.1 Construction Impacts

No mortality impacts are expected during construction to either the northern long-eared bat or Indiana bat. No winter hibernacula (i.e., caves or man-made abandoned mines) that could be disturbed by construction activities are known to occur in the Project area. Both bat species use forested or wooded habitats. Forested areas (deciduous forests or woody wetlands) compose about 45 percent of the Project area and either species could potentially occur in the area during the summer roosting season. Potential disturbance impacts could occur if construction occurred in or near forested areas. However, the siting area is composed largely of croplands and pasture land (51 percent or 111 acres), so potential impacts could be avoided. No loss of bat habitat is expected so long as construction does not require removal of any potential roost trees that may occur in forested areas.

3.14.1.7.2.4.3 Operation and Maintenance Impacts

No impacts to either the northern long-eared bat or Indiana bat are expected during operations and maintenance of the Tennessee converter station and AC interconnection tie. No disturbance to any potential bat roost trees in the adjacent areas is expected. Bats are expected to avoid any vertical structures. Because bats typically forage at dusk or during the night, the presence of maintenance personnel and equipment would not impact any bat foraging activity. EPM GE-20 as described in Section 3.14.1.7.1 would be implemented to avoid or minimize operations related direct and indirect impacts to the northern long-eared and Indiana bats.

The potential impacts (e.g., collision with Project structures and transmission lines) to the interior least tern and red knot during operations and maintenance of the converter station and AC interconnection system are not expected. Suitable habitat for the interior least tern occurs west of the Project area along the Mississippi River but not in the converter station siting area. The red knot is an occasional transient migrant across the state of Tennessee, but is not commonly found in this area; indicating that the likelihood of this species being present within the affected area and being impacted is unlikely.

Because the converter station area would be a developed site with approximately 45 acres fenced, the routine presence of operations and maintenance staff would not have any added disturbance impacts to any special status wildlife species.

3.14.1.7.2.4.4 Decommissioning Impacts

The type of potential impacts during Project decommissioning are expected to be similar to those during construction except areas of new land disturbance would be less than during initial construction. The Applicant would follow the same general and resource-specific EPMs during decommissioning that would be implemented during construction. In addition, the Applicant would develop a Decommissioning Plan prior to any decommissioning actions for review and approval by the appropriate state and federal agencies.

3.14.1.7.2.5 AC Collection System

A description of the AC collection system is provided in Section 2.1.2.3.

Semi-arid grasslands/herbaceous and croplands comprise most of the wildlife habitat in the Project area. The habitats found along the AC collection system routes are similar among the routes with variation in the proportion of grasslands and agricultural crops being the primary difference. Of the seven special status wildlife species described in Section 3.14.1.5 that potentially occur in this area, no impacts are expected to three species: piping plover, red knot and interior least tern. Two documented nesting occurrences of piping plover have been reported at Optima Lake in Texas County, Oklahoma. Given the lack of suitable habitat within the ROI for the AC collection system, no impacts to the piping plover are expected. The red knot could occur as a rare migrant through the region. Impacts to the red knot are also not expected because of the lack of suitable habitat and low probability of occurrence. Although a documented occurrence of the least tern has been made in Texas County, Oklahoma, the primary occurrence of least terns in Oklahoma occurs along the Cimarron River in Region 2 of the Project. Therefore, impacts to the interior least tern also are not expected from the development of the AC Collection system.

The special status wildlife species potentially affected by construction and operations and maintenance of the AC collection system include Sprague's pipit, LEPC, whooping crane, and golden eagle.

3.14.1.7.2.5.1 Construction Impacts

No mortality impacts are expected to Sprague's pipit, LEPC, golden eagle, and the whooping crane during construction. Sprague's pipit is an uncommon migrant and rare winter resident in Oklahoma. The AC collection system is west of the primary whooping crane migration corridor, although some individuals are likely to occasionally migrate through the area (Figure 3.14-2 in Appendix A). Therefore, construction-related mortalities to either species are not expected. The LEPC is a resident prairie grouse in western Oklahoma that prefers grasslands with a mix of shrubs (e.g., shinnery oak or sand sage) for cover and nesting. The LEPC is a ground-dwelling gamebird that typically flies in low, short flights that could avoid construction activity, and; therefore mortality impacts are not expected.

LEPCs are susceptible to disturbance. Data suggest that prairie chickens avoid buildings, roads, and other human disturbances. Of particular concern are communal breeding leks in the spring. Construction activity in the vicinity of a lek could cause abandonment and reduce reproductive success. This potential impact could be mitigated by identifying known leks and avoiding construction in the area during the breeding season (March and April). Similar disturbance impacts could occur during the nesting season and cause abandonment of nests. Most of the current estimated occupied range of the LEPC and mapped habitat occurs on the eastern half or in the northwestern corner of the AC collection system (Figure 3.14-1 in Appendix A) (Van Pelt et al. 2013). Potential AC transmission routes in those areas (AC Collection System Routes E-1, E-2, E-3, NE-1, NE-2, SE-1, and SE-3) would have a higher probability of disturbance impacts. To the extent that the AC collection transmission lines follow existing roads, transmission lines, and other ROWs, potential disturbance impacts would be minimized.

Because the whooping crane and Sprague's pipit are seasonal migrants through the area and could be present in the area for a very short time, it is unlikely that construction activities would have a disturbance impact on either species. Golden eagles occur in the area as residents and seasonal migrants. The Applicant would coordinate with the USFWS to identify any potential nest sites that could be affected and develop procedures to avoid impacts (EPM FVW-5). Known golden eagle nests occur farther west in the Oklahoma Panhandle outside of the ROI (USFWS 2014d).

Construction of the AC collection system would require land clearing for the construction of access roads and installation of transmission structures (Sections 2.1.2.3 and 2.1.2.4). Habitat loss and fragmentation of existing grassland habitat is one of the primary threats to the LEPC (79 FR 19974 and 79 FR 20074, April 10, 2014). The highest quality LEPC habitat (CHAT-1 and CHAT-2) occurs on the east side of the AC collection system area (Figure 3.14-1 in Appendix A). To the extent that the AC transmission lines and access roads cross contiguous areas of native grasslands, construction of the AC collection system may contribute to the loss of potential LEPC habitat. These impacts could be minimized with routes that follow existing ROWs, areas of cultivated fields, and grassland areas already fragmented by other activities that are areas of low quality prairie chicken habitat. The Sprague's pipit also uses native grasslands and could be similarly affected by loss of habitat and fragmentation.

3.14.1.7.2.5.2 Operations and Maintenance Impacts

Potential impacts to special status wildlife species during operations and maintenance of the AC collection system include mortalities from collisions with transmission lines and structures and possible electrocutions, disturbance impacts from routine maintenance activity, and loss of habitat by behavioral avoidance of areas surrounding vertical structures (i.e., transmission structures and lines). There is a potential risk of mortalities to whooping cranes from collisions with transmission lines and structures. The risk of collision mortality is expected to be low because the ROI is outside the primary whooping crane migration corridor reducing the probability of occurrence. However, whooping cranes could occasionally migrate through the area and some risk of collision mortality would exist. Golden eagles are also residents and winter migrants in western Oklahoma and transmission lines could be a potential collision and mortality risk. Transmission lines are unlikely to be a source of mortality for either the LEPC or Sprague's pipit. The prairie chicken is a low flier and typically avoids areas surrounding tall structures. Sprague's pipit occurs only as a winter migrant in low numbers and is a smaller, more maneuverable flier that could more likely avoid transmission lines. Routine maintenance and inspection work along the AC collection system transmission lines is unlikely to impact special status wildlife species other than a temporary displacement while work is performed. Additional loss of habitat is not expected during operations and maintenance. However, any avoidance of areas by the LEPC due to the potential for increased predation rates (due to consolidation or raptors and corvids along the AC collection lines) could constitute a potential impact to the LEPC.

3.14.1.7.2.5.3 Decommissioning Impacts

Potential impacts during Project decommissioning are expected to be similar to those during construction except areas of new land disturbance would be less than during initial construction. The Applicant would follow the same general and resource-specific EPMs during decommissioning that would be implemented during construction. In addition, the Applicant would develop a Decommissioning Plan prior to any decommissioning actions for review and approval by the appropriate state and federal agencies.

3.14.1.7.2.6 HVDC Applicant Proposed Route

The HVDC transmission line is described in Sections 2.1.2.2 and 2.4.2. The transmission line would extend approximately 700 miles from the semi-arid Oklahoma Panhandle to western Tennessee which has a humid, continental climate. Because of the significant change in vegetation and available wildlife habitats that occurs along the Applicant Proposed Route, the special status wildlife species that could be affected by the construction and operations and maintenance of the Project also varies along the route (Table 3.14.1-3 and 3.14.1-4). For the purposes of analysis and discussion, the Project has been divided into seven regions from west to east. Potential impacts to special status wildlife species from construction and operations and maintenance are discussed for each region. Impacts from decommissioning would be common to the regions and would be the same as those identified in Section 3.14.1.7.2.

See Sections 3.10 and 3.17 for a list of the types of habitats that would be impacted by the Applicant Proposed Route in each region as well as the acres that would be impacted. Table 3.14.1-5 lists the approximate length of the Applicant Proposed Route in each region, how much of the route is parallel to existing infrastructure, the predominant habitat type that would be impacted (see Sections 3.10 and 3.17 for more details regarding the acres of impact that would occur), and the special status wildlife species potentially present along the Applicant Proposed Route by region. The 23 route variations developed in response to public comments on the Draft EIS did not significantly increase or decrease (typically less than 1 mile) either the total length of the Applicant Proposed Route in each region or the length of route parallel to existing infrastructure (Table 3.14.1-5). Changes in potential impacts from the route variations are discussed for each region.

Table 3.14.1-5:
Special Status Wildlife Species Summary Information Regarding the Applicant Proposed Route

Region	Total Length of APR (miles)	Length Parallel to Existing Infrastructure (miles)	Predominant Land Cover	Special Status Species Potentially Present in the Region
1	115	Approximately 20 miles, or 18 percent of the route	Grassland/herbaceous, croplands (grasslands and croplands likely used by whooping cranes for feeding habitat)	Sprague's pipit, red knot, whooping crane, LEPC, interior least tern, and piping plover, and golden and bald eagles
2	106	Approximately 27 miles, or 25 percent of the route	Grassland/herbaceous, croplands (grasslands and croplands likely used by whooping cranes and LEPC for feeding habitats)	Whooping crane, interior least tern, and LEPC, piping plover, red knot, golden eagle
3	162	Approximately 21 miles, or 13 percent of the route	Grassland/herbaceous, deciduous forest (grasslands likely used by whooping cranes for feeding habitat; forests likely used by gray bats for foraging)	Gray bat, Sprague's pipit, interior least tern, piping plover, whooping crane, and American burying beetle, red knot, golden eagle
4	126	Approximately 11 miles, or 9 percent of the route	Grassland/herbaceous, deciduous forest, pasture/hay (forests likely used by northern long-eared bat, Ozark big-eared bat, gray bat, and Indiana bat for foraging)	northern long-eared bat, Ozark big-eared bat, gray bat, Indiana bat, Sprague's pipit, interior least tern, piping plover, American burying beetle, and bald eagle
5	113	Approximately 15 miles, or 13 percent of the route	Deciduous forest, pasture/hay (forests likely used by northern long-eared bat, Ozark big-eared bat, gray bat, and Indiana bat for foraging habitat)	northern long-eared bat, gray bat, Ozark big-eared bat, Indiana bat, interior least tern, bald eagle, and piping plover
6	54	Approximately 11 miles, or 20 percent of the route	Croplands	northern long-eared bat, Indiana bat, and piping plover
7	43	Approximately 7 miles, or 17 percent of the route	Croplands, deciduous forest (forests likely used by northern long-eared bat, and Indiana bat for foraging habitat)	northern long-eared bat, Indiana bat, interior least tern, piping plover, and bald eagle

APR = Applicant Proposed Route

The following subsections discuss region-specific factors that would affect special status wildlife species; however, refer to Sections 3.14.1.7.1 for a discussion of general impacts that would occur, and Table 3.14.1-5 for a list of the special status wildlife species potentially present.

3.14.1.7.2.6.1 Region 1

The Applicant Proposed Route in Region 1 is approximately 115 miles long. Approximately 20 miles, or 18 percent of the route, is parallel to existing infrastructure (Table 3.14.1-5). Special status wildlife species that could occur in Region 1 are Sprague's pipit, red knot, interior least tern, LEPC, whooping crane, piping plover, and golden eagle. Two documented nesting occurrences of piping plover have been reported at Optima Lake in Texas County, Oklahoma. Because of the lack of suitable habitat within the ROI for the Applicant Proposed Route, no impacts to the piping plover are expected. The red knot could occur as a rare migrant through the region. Impacts to the red knot are also not expected because of the lack of suitable habitat and low probability of occurrence. Although a documented occurrence of the least tern has been made in Texas County, Oklahoma, the primary occurrence of least terns in Oklahoma occurs along the Cimarron River in Region 2 of the Project (Lott et al. 2013). Suitable habitat for the interior least tern does not occur in the ROI. Therefore, impacts to the interior least tern also are not expected from the development of the Applicant Proposed Route in Region 1.

3.14.1.7.2.6.1.1 Construction Impacts

Species that could potentially be affected during construction include the Sprague's pipit, LEPC, whooping crane, and golden eagle. Sprague's pipit is a migrant through the ROI and could be an occasional winter resident, although the primary wintering range for the species is farther south. No mortality impacts are expected as the pipit could avoid construction activity. Construction could temporarily displace individuals during the winter, if present, but no impacts to pipit populations are expected. Sprague's pipit primarily uses native prairie and habitat loss and fragmentation of remaining native prairie is of primary concern. Disturbance and clearing of prairie habitat for access roads and placement of transmission structures could affect Sprague's pipit. However, winter ranges for the Sprague's pipit include a broader array of habitats (e.g., stubble and fallow alfalfa, soybean, and wheat fields and pastures with non-native grasses) and alternative migration habitat would be available in the vicinity of the ROI (Robbins and Dale 1999; USFWS 2011a). Because of the low probability of winter residents occurring in Region 1 and other migratory habitat would remain, measurable impacts to Sprague's pipit populations from construction of the HVDC transmission line in Region 1 is not expected.

The Applicant Proposed Route crosses the LEPC range in Region 1 (Figure 3.14-1 in Appendix A). The primary impacts that could occur during construction are disturbance and habitat loss and fragmentation. Disturbances to leks during the spring could disrupt and reduce reproduction. Similarly, construction disturbance near habitats used for nesting and brood rearing also could reduce reproduction. LEPC require large blocks of contiguous habitat (Van Pelt et al. 2013). Vegetation clearing for access roads and transmission structures would cause habitat loss but also could fragment remaining patches of habitat. Focal LEPC habitat areas and connectivity habitat areas have been mapped in Region 1 using an internet mapping tool (CHAT). Focal and connectivity habitats occur near or within the ROI in Region 1. In addition, construction disturbance could impact private lands that have been previously enrolled in the LEPC Candidate Conservation Agreements with Assurances program to preserve and restore LEPC habitat. However, the Applicant Proposed Route follows existing transmission lines through Region 1 where LEPC may occur on either side of the route, so the suitability of the habitat for LEPC is likely lower than other undisturbed areas. The route would pass adjacent (south side) to the Shorb WMA managed by the ODWC.

The whooping crane occurs as a spring and fall migrant through the region. No stopover areas have been identified in Region 1. The Applicant Proposed Route occurs on the western side of the primary whooping crane migratory corridor. No impacts to whooping cranes are expected during construction as occurrence in a construction area is unlikely and the whooping crane could avoid areas of construction.

Golden eagles occur as residents and migrants in Region 1. Golden eagles prefer the open semi-arid habitats such as grassland and shrub habitats for foraging and cliffs or ledges for nesting. Golden eagles are wide-ranging birds that could easily avoid construction and impacts are not expected. Of potential concern would be construction disturbances of nest sites in the late winter and spring that could prevent nesting or disrupt rearing of young. The preferred canyons and rocky cliff habitat occur farther west in the Oklahoma Panhandle but the Applicant would work with wildlife agencies to identify and avoid any eagle nests (EPM FVW-5) that could occur near the Applicant Proposed Route. Bald eagles have expanded their range within Oklahoma and have been observed in the Region 1 (Optima Lake).

3.14.1.7.2.6.1.2 Operations and Maintenance

Operation and maintenance of the HVDC transmission line is not expected to have an impact on Sprague's pipit. Impacts to the LEPC could include avoidance of areas by the LEPC surrounding the transmission line because of increased predation rates (resulting from consolidation of raptors and corvids along the line). Research in Kansas suggests the avoidance of suitable habitat (potently due to increased predation rates along tall structures) could extend approximately 2000 feet from a transmission line (Robel et al. 2004). The Western Association of Fish and Wildlife Agencies adopted a 1,300-foot impact zone in the *The Lesser Prairie-Chicken Range-Wide Conservation Plan* for calculating impacts from transmission lines (>69kV) (Van Pelt et al. 2013). Such a zone could increase fragmentation of LEPC habitat and create a zone of potential habitat that LEPC may avoid. However, not all habitat along the Applicant Proposed Route in Region 1 is suitable LEPC habitat, and the Applicant Proposed Route follows an existing transmission line along which LEPC may occur. Therefore, any potential habitat avoidance impacts would not be completely additive to comparable impacts that may have occurred from existing transmission lines in areas of potential suitable LEPC habitat.

Potential impacts to whooping cranes during operations and maintenance include potential mortalities from collisions with transmission lines. Although Region 1 of the Project lies west of the primary whooping crane migration corridor, some cranes migrate through the region in the spring and fall (Figure 3.14-2 in Appendix A). Although collision mortalities are possible, a lower probability of occurrence of whooping cranes and the lack of any stopover areas in the ROI would minimize the potential for mortalities in Region 1.

The transmission lines also pose a potential mortality risk to resident or migrant golden eagles. Electrocution risks to golden eagles would be lower if the transmission lines are spaced further apart than an eagle's wingspan (approximately 80 inches).

3.14.1.7.2.6.2 Region 2

The Applicant Proposed Route in Region 2 is approximately 106 miles long. Approximately 27 miles, or 25 percent of the route, is parallel to existing infrastructure. Special status wildlife species that occur in Region 2 are the red knot, interior least tern, LEPC, whooping crane, piping plover, golden eagle, and bald eagle. The piping plover is a shorebird species that is typically found along open, sandy rivers or reservoirs with sandy beaches. No documented occurrences of piping plover nests have been reported in Region 2 although the species could occur in the ROI where the Applicant Proposed Route crosses the Cimarron River. No impacts to the piping plover are expected from the construction or operations and maintenance of the Project. The red knot could occur as a rare migrant through the region. Impacts to the red knot are also not expected because of the lack of suitable habitat and low probability of occurrence.

One of the two route variations of the Applicant Proposed Route developed in Region 2 (Link 1, Variation 1) in response to public comments on the Draft EIS, would increase the amount of lower quality LEPC habitat that may be affected by less than 40 acres. Link 2, Variation 2, occurs in the whooping crane migration corridor, but it would not change any potential impacts to the whooping crane. No other species would be affected by the Region 2 route variations.

3.14.1.7.2.6.2.1 Construction Impacts

There are documented occurrences of interior least terns along the Cimarron River in Region 2 (Lott et al. 2013). Nesting locations are not well documented near the ROI crossing of the Cimarron River, but least terns are known to forage and migrate through the area. Potential short-term disturbance impacts to interior least terns could occur if construction across the Cimarron River occurs in the spring (approximately April) or fall (approximately August to early September). No construction impacts to least tern habitat or mortality impacts are expected.

The Applicant Proposed Route crosses a portion of the estimated occupied range of the LEPC in Woodward County in the western end of Region 2 (Van Pelt et al. 2013). No focal LEPC habitat areas and connectivity habitat areas have been mapped in Region 2, although some suitable habitat could occur in the area (Figure 3.14-1 in Appendix A). The primary impacts that could occur during construction are disturbance and habitat loss and fragmentation. Disturbances to leks during the spring could disrupt and reduce reproduction success. Similarly, construction disturbance near habitats used for nesting and brood rearing also could reduce reproduction success. LEPCs require large blocks of contiguous habitat (Van Pelt et al. 2013). Vegetation clearing for access roads and transmission structures would cause habitat loss but also could fragment remaining patches of habitat. To the extent that the Applicant Proposed Route avoids larger contiguous blocks of native prairie and shrub grassland, impacts to LEPCs would be minimized.

The whooping crane occurs as a spring and fall migrant through Region 2. No stopover areas have been identified in the ROI in Region 2. The Applicant Proposed Route crosses the primary whooping crane migratory corridor (approximately 75 percent of the observations) (Figure 3.14-2 in Appendix A). Minimal direct impacts to whooping cranes are expected during construction because occurrence in a construction area is unlikely and the whooping crane could avoid areas of construction. Any disturbance impacts in foraging areas would be short-term and occur only if the construction activity coincided with migration.

Golden eagles occur as residents and migrants in Region 2. Golden eagles prefer the open semi-arid habitats such as grassland and shrub habitats for foraging and cliffs or ledges for nesting. Golden eagles are wide-ranging birds that could easily avoid construction and direct impacts are not expected. Golden eagle nests are unlikely in the ROI in Region 2 because of lack of suitable habitat, but the Applicant would work with wildlife agencies to identify and avoid any potential eagle nest sites that could occur near the Applicant Proposed Route.

Bald eagles occur in Region 2 as potential nesters and winter migrants. The closest bald eagle wintering habitat is found at Canton Lake (3.5 miles south of the ROI); therefore, construction impacts to bald eagles are not expected due to the lack of suitable habitat within the ROI.

3.14.1.7.2.6.2.2 Operations and Maintenance

Operation and maintenance of the transmission line along the Applicant Proposed Route in Region 2 could impact the interior least tern, whooping crane, golden eagle, and bald eagle (e.g., result in potential collisions). Interior least terns have been documented along the Cimarron River, suggesting that interior least terns may occur within the Applicant Proposed Route ROI from about April through June. However, the least tern is a small agile flier that forages along streams, rivers, and reservoirs and would likely avoid transmission lines and the potential for collision impacts is considered to be low.

Although no known migratory or stopover locations for whooping crane have been documented in the Applicant Proposed Route ROI, the route crosses the primary whooping crane migratory corridor and cranes would typically pass through the area in March through April and September through October (Figure 3.14-2 in Appendix A). The transmission lines could cause potential whooping crane mortalities from collisions. Project locations near (e.g., approximately 1 mile) whooping crane feeding and resting sites would have the greatest potential for collisions as the birds would be flying at lower elevations.

Golden and bald eagles potentially occur in the vicinity of the ROI. Both species are wide ranging and could pass through the ROI. Each species could be at risk for potential collisions with the transmission lines, although the probability is expected to be low. The risk of electrocution for any of the large birds (eagles or cranes) would depend on the distance between wires. Wire spacing greater than the average eagle wingspan would reduce potential electrocution risk. The Applicant would develop and implement an APP, consistent with APLIC guidelines that describes a program of specific and comprehensive actions that when implemented, would reduce risk of avian mortality. Additionally, the Applicant would implement EPMs (FVW-1, FVW-2, and GE-2) to reduce risk of avian mortality.

3.14.1.7.2.6.3 Region 3

The Applicant Proposed Route in Region 3 is approximately 162 miles long. Approximately 21 miles, or 13 percent of the route, are parallel to existing infrastructure. Special status wildlife species that occur in Region 3 are the gray bat, Sprague's pipit, interior least tern, piping plover, whooping crane, American burying beetle, and red knot. The red knot could occur as a rare migrant through the region. Impacts to the red knot are not expected because of the lack of suitable habitat and low probability of occurrence. No documented occurrences of piping plover nesting have been reported in Region 3, although the species could occur in the ROI where the Applicant Proposed Route crosses the Cimarron River. Piping plovers are rarely seen at inland stopover locations as most individuals may migrate directly to wintering ranges. No impacts to the piping plover are expected from the construction or operations and maintenance of the Project. Region 3 represents a transition to more forested vegetation, which supports two special status wildlife species: the gray bat and American burying beetle.

Five route variations of the Applicant Proposed Route were developed in Region 3 in response to public comments on the Draft EIS. Sprague's pipit (Link 1 and 2, Variation 1, and Link 1, Variation 2), American burying beetle (Link 4, Variations 1 and 2, and Link 5, Variation 2), and the gray and northern long-eared bats (Link 5, Variation 2) are the only federally listed species potentially affected by the new route variations. The potential impacts to these species during construction and operations and maintenance would be similar to those of the original Applicant Proposed Route. Approximately 20 acres more forested land area and 20 acres of native prairie would potentially be affected by these changes in Region 3.

3.14.1.7.2.6.3.1 Construction Impacts

Sprague's pipit is a migrant through the ROI and could be an occasional winter resident, although the primary wintering range for the species is farther south. Sprague's pipit has been documented in Payne County. No mortality impacts are expected as the pipit could avoid construction activity. Construction could temporarily displace individuals during the winter, if present, but no impacts to pipit populations are expected. Sprague's pipit primarily uses native prairie and habitat loss and fragmentation of remaining native prairie is of primary concern. Disturbance and clearing of prairie habitat for access roads and placement of transmission structures could affect Sprague's pipit. However, winter ranges for the Sprague's pipit include a broader array of habitats (e.g., stubble and fallow alfalfa, soybean, and wheat fields and pastures with non-native grasses) and alternative migration habitat would be available in the vicinity of the ROI (Robbins and Dale 1999; USFWS 2011a). Because the probability of winter residents occurring in Region 3 is low and because other migratory habitat would remain, measurable impacts to Sprague's pipit populations from construction of the HVDC transmission line in Region 3 are not expected.

Documented occurrences of the least tern have been made along the Cimarron River in Region 3 of the Project (Lott et al. 2013). Nesting locations are not well documented near the ROI crossing of the Cimarron River in Payne County, but least terns are known to forage and migrate through the area (USFWS 2014d). Potential short-term disturbance impacts to least terns could occur if construction across the Cimarron River occurs in the spring (approximately April) or fall (approximately August to early September). No construction impacts to least tern habitat or mortality impacts are expected.

The whooping crane occurs as a spring and fall migrant through Region 3. No stopover areas have been identified in the ROI in Region 3. The Applicant Proposed Route crosses the eastern portion of whooping crane migratory corridor (≤ 25 percent of the migratory observations) (Figure 3.14-2 in Appendix A). No impacts to whooping cranes are expected during construction as occurrence in a construction area is unlikely and the whooping crane could avoid areas of construction. Any disturbance impacts in foraging areas would be short-term and occur only if the construction activity coincided with migration.

Golden eagles become less common along the Applicant Proposed Route as the route moves east into less semi-arid vegetation. Golden eagles prefer the more open semi-arid habitats in Regions 1 and 2 but both residents and migrants occur in Region 3. Golden eagles are wide-ranging birds that could easily avoid construction and impacts are not expected. Of potential concern would be construction disturbances of nest sites in the late winter and spring that could prevent nesting or disrupt rearing of young. The Applicant would work with wildlife agencies to identify and avoid any potential eagle nest sites that could occur near the proposed route. Bald eagles occur in Region 3 as potential nesters and winter migrants. Construction impacts to bald eagles are not expected because of lack of suitable habitat in the ROI.

Although the presence of the American burying beetle has not been documented in the ROI, favorable undisturbed forested and grassland habitats do occur along the corridor in Region 3. A review of presence/absence surveys conducted in Kansas, Oklahoma, and Texas from 2012 to 2014 indicated one positive survey location in Okmulgee County, Oklahoma, approximately 0.48 mile north of the 200-foot-wide representative ROW for the Applicant Proposed Route (USFWS 2015). The American burying beetle is relatively sedentary and often occurs just under soil surface, making it at risk of mortality during construction activities (especially during vegetation clearing) if it is present within the Project's ROI. Depending on the number of mortalities relative to the local population size, these impacts would be short term (mortalities low relative to population size) or long term (mortalities high relative to local population size). Herbicides used for weed control could also pose a mortality risk.

The gray bat is strictly insectivorous and inhabits caves though the year. The range of the gray bat includes Adair, Muskogee, and Sequoyah counties in Region 3 (USFWS 2014d). The gray bat has not been documented by previous studies in the ROI. Areas with known and potential caves for gray bats occur farther north in Adair County, Oklahoma and to the east in Region 4. Potential use of the ROI in Region 3 by the gray bat is likely restricted to spring through fall (USFWS 2014d). Implementation of seasonal restrictions if needed could minimize impacts to this species (see EPM FVW-5).

3.14.1.7.2.6.3.2 Operation and Maintenance

The Sprague's pipit has been observed in Payne County but the species uses grassland habitats and typically occurs near the ground and is very secretive. Empirical data that demonstrates that overhead transmission lines are a hazard to this species are lacking.

Operation and maintenance of the transmission line along the Applicant Proposed Route in Region 3 could impact the interior least tern, whooping crane, golden eagle, and bald eagle from potential collisions. Interior least terns have been documented along the Cimarron River, suggesting that interior least terns may occur within the Applicant Proposed Route from about April through June. However, the least tern is a small agile flier that forages along streams, rivers, and reservoirs and would likely avoid transmission lines and the potential for mortalities from collisions is considered to be low.

Although no known migratory or stopover locations for whooping crane have been documented in the Applicant Proposed Route and ROI, the route crosses the eastern side of whooping crane migratory corridor and cranes would typically pass through the area in March through April and September through October (Figure 3.14-2 in Appendix A). The transmission lines could cause potential mortalities from collisions. Project locations near (e.g., approximately 1 mile) whooping crane feeding and resting sites would have the greatest potential for collisions as the birds would be flying at low elevations.

Golden eagles become less common along the Applicant Proposed Route as the route moves east into less semi-arid vegetation. Golden eagles prefer the more open semi-arid habitats in Regions 1 and 2, but both residents and migrants occur in Region 3. Bald eagles are more common on the eastern end of Region 3 in Muskogee County as the Applicant Proposed Route approaches the Arkansas River. Each species could be at risk for potential collisions with the transmission lines, although the probability of collisions is difficult to predict. The ROI does not contain suitable habitat that would attract either species of eagle, so the risk could be low compared to locations near river crossings or areas where eagles concentrate. The risk of electrocution for any of the large birds (eagles or cranes) would depend on the spacing between transmission wires. Spacing transmission lines wider (approximately 80 inches) than an eagle's wingspan would reduce the risk. The Applicant would develop and implement an APP, consistent with APLIC guidelines that describes a program of specific and comprehensive actions that when implemented, would reduce risk of avian mortality. Additionally, the Applicant would implement EPMs (FVW-1, FVW-2, and GE-2) to reduce risk of avian mortality.

Potential indirect impacts to the American burying beetle during operations and maintenance could occur because of continuing effects from alteration or loss of habitat during construction. The American burying beetle depends on carrion prey. Any habitat loss or change (e.g., creation of edge habitat) that decreases potential carrion prey or increases the number of vertebrate (e.g., crows, raccoons, foxes, opossums, etc.) or invertebrate (ants) scavengers that would compete for carrion would have a long-term impact on local populations.

No impacts are expected to the gray bat during operations and maintenance as additional land disturbances are not expected.

3.14.1.7.2.6.4 Region 4

The Applicant Proposed Route in Region 4 is approximately 126 miles long. Approximately 11 miles, or 9 percent of the route, is parallel to existing infrastructure. As the Applicant Proposed Route moves east into Region 4 (Arkansas River Valley Region), the vegetation changes to more forested types (deciduous hardwoods and evergreen). In addition to the gray bat that also occurred in Region 3, the northern long-eared bat, Ozark big-eared bat, and Indiana bat could potentially occupy the Project's ROI in Region 4. Except for the Ozark big-eared bat, the occurrence and use of the ROI by these species has not been documented by previous studies. The Ozark big-eared bat was found in the ROI in two new cave hibernacula in January 2015 in Crawford County, Arkansas. The specific location of these caves is not publicly available to protect the caves and the hibernating bats. Whether the Ozark big-eared bat also uses these two caves for summer roosting is not yet known. Clean Line conducted a survey of a portion of the ROI (300-foot-wide corridor) within the range of the four species of federally listed bats (Muskogee County, Oklahoma, to Shelby County, Tennessee) to identify suitable bat habitat including potential summer roost trees (northern long-eared bat and Indiana bat) and karst features that could be used as cave roosts (Ozark big-eared bat and gray bat) or hibernacula (all four species). The report is not being made publicly available to protect the locations so the bats can use them. Potential summer bat roost trees were found throughout the ROI in Region 4. Karst features such as rock shelters and rock crevices also were found throughout Region 4 but were less numerous and few show signs of bat activity. Most of the karst features were too small or not deep enough to be used as significant hibernacula or even maternity roosts. The primary use of the ROI by bats in Region 4 is likely for roosting during the spring through fall time frame. Proper implementation of seasonal restrictions could minimize impacts to this species (see EPM FVW-5). Other special status wildlife species that could occur in the ROI for the Applicant Proposed Route include Sprague's pipit, interior least tern, piping plover, American burying beetle, and bald eagle.

The piping plover likely occurs in Region 4 as a migratory species and major rivers such as the Arkansas River could serve as migration pathways and stopover areas. However, the Project is not expected to affect the riverine or lacustrine shoreline and sandbar habitats of the piping plover as the transmission line would span the waterways. Therefore construction of the Applicant Proposed Route is not expected to impact the piping plover in Region 4.

Seven route variations of the Applicant Proposed Route were developed in Region 4 in response to public comments on the Draft EIS. The northern long-eared bat, gray bat, Ozark big-eared bat, Indiana bat, and American burying beetle are the only listed species that would potentially be affected by these variations. The potential impacts from construction or operations and maintenance activities would be similar to the original Applicant Proposed Route, even though Link 3, Variation 3, was developed specifically to avoid two recently discovered cave hibernacula used by the Ozark big-eared bat as discussed in the following sections.

3.14.1.7.2.6.4.1 Construction Impacts

Although the presence of the American burying beetle has not been documented in the areas that would be affected by the Applicant Proposed Route, it is suspected to occur within undisturbed forested and grassland habitats found in Region 4. The American burying beetle is relatively sedentary and spends part of its lifecycle within the top several inches of soil and is susceptible to traffic (vehicular and foot). Therefore, construction of Applicant Proposed Route could cause mortality of American burying beetle in suitable habitat areas that are disturbed for construction of access roads and transmission structures.

Sprague's pipit has been observed in Sequoyah County in Oklahoma and Franklin County in Arkansas. Sprague's pipit is a migrant through the ROI and could be an occasional winter resident. No mortality impacts are expected as the pipit could avoid construction activity. Construction could temporarily displace individuals during the winter, if present, but no impacts to pipit populations are expected. Sprague's pipit primarily uses native prairie and habitat loss and fragmentation of remaining native prairie is of primary concern. Disturbance and clearing of prairie habitat for access roads and placement of transmission structures could affect Sprague's pipit. However, winter ranges for the Sprague's pipit include a broader array of habitats (e.g., stubble and fallow alfalfa, soybean, and wheat fields and pastures with non-native grasses) and alternative migration habitat would be available in the vicinity of the ROI (Robbins and Dale 1999; USFWS 2011a). Because of the low probability of winter residents occurring in Region 4 and other migratory habitat would remain, measurable impacts to Sprague's pipit populations from construction of the HVDC transmission line in Region 4 are not expected.

There are documented occurrences of the least tern along the Arkansas River in Region 4 (Lott et al. 2013). Nesting locations are not well documented near the ROI crossing of the Arkansas River in Sequoyah County, but least terns could forage and migrate through the area. Sand bar habitat is limited in the vicinity of the crossing location just below Webbers Falls dam. No construction impacts to least tern habitat or mortality impacts are expected. Bald eagles are known to nest and winter along the Arkansas River and at Lake Dardanelle in Arkansas, which is located south of the Applicant Proposed Route. Construction activity could affect bald eagle nesting and winter roosting at the Arkansas River crossing depending on locations of nests or roosting sites with respect to construction. The Applicant would work with wildlife agencies to identify any nests or roosting sites and coordinate construction activity to avoid either nesting eagles or winter roosting areas (EPM FVW-5).

Of the four special status bat species, the gray bat and Ozark big-eared bat use caves for winter hibernacula and for roosting during the spring, summer, and fall, although the caves used for hibernating and roosting can be different. The northern long-eared bat and Indiana bat use caves for winter hibernation but use roost trees and snags with loose barks, cavities, or crevices and occasionally man-made structures for roosting sites. Caves occur in the Ozark Plateau region north of the Applicant Proposed Route in Region 4, but are limited in the ROI, although two new caves with hibernating Ozark big-eared bats were found within the ROI in Crawford County, Arkansas. Construction is not expected to impact cave hibernacula for any of the bat species or roosting caves for the gray and Ozark big-eared bats because the caves would be avoided by a minimum of 300 feet (EPM FVW-6) or re-routed completely to avoid a sensitive area. Trees may be removed to construct access roads and clear sites for structures on segments of the route that pass through either deciduous or evergreen forest. Trees also would be cut in the ROW to allow stringing of transmission lines and eliminate vegetation interference with overhead wires. The potential exists for the loss of bat roost trees and foraging areas during construction. Approximately 6,700 acres of forests (i.e., deciduous, evergreen, and mixed) occur within a 1,000-foot-wide corridor along the Applicant Proposed Route in Region 4 (Table 3.17-22), although the typical ROW width would range from 150 to 200 feet. Removal of roost trees could cause habitat loss and possibly mortality of bats. The Applicant would coordinate with the USFWS to minimize potential loss of bat habitat within the ROI (EPM FVW-5).

3.14.1.7.2.6.4.2 Operations and Maintenance

The Sprague's pipit has been observed in Franklin County but the species uses grassland habitats and typically occurs near the ground and is very secretive. There is a lack of empirical data that demonstrates that overhead transmission wires are a mortality hazard to this species. Impacts to Sprague's pipit are not expected from the operations and maintenance of the transmission line.

Operation and maintenance of the transmission line along the Applicant Proposed Route in Region 4 could impact the interior least tern, golden eagle, and bald eagle from potential collisions. Interior least terns have been documented along the Arkansas River, suggesting that interior least terns may occur within the Applicant Proposed Route from about April through June. However, the least tern is a small agile flier that forages along streams, rivers, and reservoirs and would likely avoid transmission lines and the potential for mortalities from collisions is considered to be low.

Bald eagles are common along the Arkansas River in Sequoyah County in Oklahoma and Crawford and Johnson counties in Arkansas. Bald eagles could be at risk for potential collisions with the transmission lines. The majority of the ROI in Region 4 does not contain suitable habitat that would attract eagles to the area, other than near the Arkansas River crossing; furthermore, the Applicant Proposed Route is north of the Arkansas River and Lake Dardanelle in Arkansas, both of which are bald eagle wintering areas. As a result, migrating bald eagles would have to cross the Applicant Proposed Route to reach their wintering areas. The risk of electrocution for eagles is expected to be low as the distance between transmission conductors is greater than the average wingspan of this species.

The Applicant would develop and implement an APP, consistent with APLIC guidelines that describes a program of specific and comprehensive actions that when implemented, would reduce risk of avian mortality. Additionally, the Applicant would implement EPMs (FVW-1, FVW-2, and GE-2) to reduce risk of avian mortality.

No additional impacts are expected to any of the four bat species during operations and maintenance as additional land disturbances are not expected. However, any bat roost trees removed during construction in the ROW underneath the transmission lines would not be allowed to regrow because of potential interference and damage to the electrical lines and would be habitat lost for the length of Project operations.

Potential indirect impacts to the American burying beetle during operations and maintenance could occur from continuing effects from alteration or loss of habitat during construction. The American burying beetle depends on carrion prey. Any habitat loss or change (e.g., creation of edge habitat) that decreases potential carrion prey or increases the number of vertebrate (e.g., crows, raccoons, foxes, opossums, etc.) or invertebrate (ants) scavengers that would compete for carrion would have a long-term impact on local populations.

3.14.1.7.2.6.5 Region 5

The Applicant Proposed Route in Region 5 is approximately 113 miles long. Approximately 15 miles, or 13 percent of the route, is parallel to existing infrastructure. Special status wildlife species that could potentially occur in the ROI along the Applicant Proposed Route include the gray bat, northern long-eared bat, Ozark big-eared bat, and Indiana bat, interior least tern, piping plover, and bald eagle.

The piping plover likely occurs in Region 5 as a migratory species and major rivers such as the Arkansas River could serve as migration pathways and stopover areas. The Arkansas River occurs south of the Applicant Proposed Route (≥ 12 + miles at the closest location). Therefore the Applicant Proposed Route is not expected to affect riverine or lacustrine shorelines and sandbars which are suitable habitat for the piping plover; and the Applicant Proposed Route is not expected to impact the piping plover in Region 5.

Documented occurrence of the least tern has been made along the Arkansas River in Region 5 of the Project. The Arkansas River occurs south of the Applicant Proposed Route (≥ 12 + miles at the closest location) and the Project is not expected to affect bare or sparsely vegetated sandy or dried mud substrates along rivers or reservoirs preferred by least terns. Therefore, the Project is not expected to impact the interior least tern in Region 5.

Five route variations of the Applicant Proposed Route were developed in Region 5 in response to public comments on the Draft EIS. The northern long-eared bat, gray bat, Ozark big-eared bat, and Indiana bat are the only special status species that would potentially be affected by these variations. The potential impacts to these species from construction or operations and maintenance activities would be similar to the original Applicant Proposed Route as discussed in the following sections.

3.14.1.7.2.6.5.1 Construction Impacts

No suitable nesting or winter roost habitat exist within the ROI and impacts to bald eagles during construction are not expected.

Of the four special status bat species, the gray bat and Ozark big-eared bat use caves for winter hibernacula and roosting during the spring, summer, and fall although the caves used for hibernating and roosting are different. The northern long-eared bat and Indiana bat use caves for winter hibernation but use roost trees or snags with loose barks, cavities, or crevices and occasionally man-made structures for roosting sites. Known caves used as winter hibernacula (all species) and summer roosts (gray bat and Ozark big-eared bat) occur in the Ozark Plateau region north of the Applicant Proposed Route in Region 5 but not in the ROI. Surveys have documented potential bat roost trees in the ROI that could be used by Indiana bat and northern long-eared bat. Several karst features also were found in the ROI in Region 5, but they showed no sign of bat use and are too small or not deep enough to serve as cave hibernacula. Construction is not expected to impact cave hibernacula for any of the bat species or roosting caves for the gray and Ozark big-eared bats. The Applicant would implement EPM FVW-6 to ensure that caves are protected from potential disturbance impacts. Trees may be removed to construct access roads and clear sites for structures on segments of the route that pass through deciduous, evergreen, or mixed forest. Trees also could be cut in the ROW to allow stringing of transmission lines and eliminate vegetation interference with overhead wires. The potential exists for the loss of roost trees for the Indiana bat and northern long-eared bat and foraging areas during construction. Removal of roost trees could cause habitat loss and possibly mortality of bats. Approximately 7,500 acres of forests occur within a 1,000-foot-wide corridor in Region 5 (Table 3.10-9), although the typical ROW width would range from 150 to 200 feet. The Applicant would coordinate with USFWS to minimize potential loss of bat habitat within the ROI. Implementation of seasonal restrictions could minimize potential impacts to these species (see EPM FVW-5).

3.14.1.7.2.6.5.2 Operations and Maintenance

Bald eagles could be at risk for potential collisions with the transmission lines. However, the risk for collision mortality is likely low because the ROI in Region 5 does not contain suitable habitat that would attract eagles and the nearest points of water bodies frequented by bald eagles are approximately 6 to 10 miles from the Applicant Proposed Route. Migrating bald eagles could cross the Applicant Proposed Route to reach wintering areas along the Arkansas River and Lake Dardanelle; therefore, some potential risk of collision related mortalities would exist.

The Applicant would develop and implement an APP, consistent with APLIC guidelines that describes a program of specific and comprehensive actions that when implemented, would reduce risk of avian mortality. Additionally, the Applicant would implement EPMs (FVW-1, FVW-2, and GE-2) to reduce risk of avian mortality.

No additional impacts are expected to any of the four bat species during operations and maintenance as additional land disturbances are not expected. However, any bat roost trees removed during construction in the ROW underneath the transmission lines would not be allowed to regrow because of potential interference and damage to the electrical conductors and would be habitat lost for the length of Project operations.

3.14.1.7.2.6.6 Region 6

The Applicant Proposed Route in Region 6 is approximately 54 miles long. Approximately 11 miles, or 20 percent of the route, is parallel to existing infrastructure. Special status wildlife species that could occur in the ROI along the Applicant Proposed Route in Region 6 include the northern long-eared bat, gray bat, Indiana bat, piping plover, interior least tern, and bald eagle.

The vegetation along the Applicant Proposed Route in Region 6 is dominated by croplands (78 percent) with about 8 percent in forests. Because of the large amount of cultivated land, there is very little habitat available in the Region 6 ROI for special status wildlife species. The piping plover prefers riverine or lacustrine shorelines and sandbars. The interior least tern prefers bare or sparsely vegetated sandy or dried mud substrates along rivers or reservoirs. While both species may occasionally occur in the area, the ROI does not contain suitable habitat for either species and no impacts are expected from construction and operations and maintenance of the Project. Bald eagles have been observed in Poinsett and Cross counties in Region 6. However, suitable nesting and winter habitat for bald eagles is absent or very limited in the ROI and impacts are not expected, although the presence of the transmission lines would remain a potential hazard to migrating bald eagles.

The relatively flat topography and lack of large forested areas within the ROI limits the available habitat for the three species of special status bats that occur in Region 6. Surveys of the ROI indicated few bat roost trees. Because the gray bat uses caves for both summer roosts and for hibernation, the distribution of the gray bat is limited to the western portion of Jackson County, Arkansas, located in Region 6. Cave hibernacula or cave roosting sites do not occur in ROI and impacts to the gray bat are not expected in Region 6.

One route variation of the Applicant Proposed Route was developed in Region 6 in response to public comments on the Draft EIS. The route variation crosses cultivated cropland and none of the special status species would be affected by this variation from the original Applicant Proposed Route. Some of the avian special status species may occur as occasional migrants through the area, but potential impacts from construction or operations and maintenance activities would be similar to those of the original Applicant Proposed Route as discussed in the following sections.

3.14.1.7.2.6.6.1 Construction Impacts

Impacts to the Indiana bat and the northern long-eared bat from construction of Applicant Proposed Route in Region 6 are not expected because of the absence of cave hibernacula and lack of forested habitat that could be used for summer roosting in this area. A forested ridge (i.e., Crowley's Ridge) that bisects Poinsett and Cross counties from north to south could provide potential roosting habitat, but this ridge is separated from other forested areas and cave hibernacula by expanses of croplands on both the west and east sides, potentially limiting its value as bat habitat.

3.14.1.7.2.6.6.2 Operations and Maintenance

Operations and maintenance of the Project is not expected to impact any of the three special status bat species that could occur in Region 6. The lack of quality habitat limits the potential for any of the three species to occur in the ROI. No additional habitat loss is expected during the operations and maintenance phase of the Project which would limit the possibility of impacts.

3.14.1.7.2.6.7 Region 7

The Applicant Proposed Route in Region 7 is approximately 43 miles long. Approximately 7 miles, or 17 percent of the route, is parallel to existing infrastructure. Special status wildlife species that could occur in the ROI along the Applicant Proposed Route in Region 7 include the northern long-eared bat, Indiana bat, piping plover, interior least tern, and bald eagle.

The vegetation along the Applicant Proposed Route in Region 7 is dominated by croplands (70 percent) with about 8 percent in deciduous forests and 7 percent in woody wetlands (Table 3.17-48). Because of the large amount of cultivated land, there is very little habitat available in the Region 7 ROI for special status wildlife species except for forested areas near the Mississippi River crossing and on the river bluffs on the east side of the river and riverine habitats (e.g., mudflats and sandbars) along the Mississippi River. Three route variations of the Applicant Proposed Route were developed in Region 7 in response to public comments on the Draft EIS. None of the special status species would likely be affected by Link 1, Variation 1, in Mississippi County, Arkansas, because the route crosses cultivated cropland. The northern long-eared bat could potentially occur in Link 1, Variation 2, but it is unlikely because the route is predominately cropland. The northern long-eared bat and Indiana bat are the only special status species that would potentially be affected by Link 5, Variation 1, in Tipton and Shelby counties in Tennessee. The potential impacts to these species from construction or operations and maintenance activities would be similar to the original Applicant Proposed Route as discussed in the following sections.

3.14.1.7.2.6.7.1 Construction Impacts

Construction of the Applicant Proposed Route could have some impact on Indiana and northern long-eared bat roosting habitat near the Mississippi River crossing from Mississippi County in Arkansas to Tipton County in Tennessee. Bats of both species could potentially use trees on either side of the river for roost sites. If trees are removed to allow stringing of lines and reduce interference with the transmission lines, potential bat habitat could be lost. No caves that could be used for hibernacula are known to occur in the ROI along the route in Region 7.

The interior least tern occurs along the Mississippi River using bare or sparsely vegetated sandy or dried mud substrates (Jones 2012; Lott et al. 2013). Potential construction impacts would be limited to where Applicant Proposed Route crosses the Mississippi River. Although construction is not expected to physically disturb potential least tern habitat, construction activity could temporarily disturb least terns in the vicinity and cause nesting terns (June and July) to abandon their nests. Nesting locations are known to occur along the Mississippi River in Shelby and Tipton County, Tennessee.

The piping plover prefers open, sparsely vegetated sand and gravel beaches or islands with similar characteristics. It is possible that piping plovers could occur where the transmission line would cross the Mississippi River. Potential impacts during construction could be temporary disturbance (i.e., displacement). Measures taken to reduce potential impacts to interior least terns would likely help minimize any potential disturbances to piping plovers.

Construction activity could potentially impact both nesting and wintering bald eagles in the vicinity of the Mississippi River crossing. Although construction activity would be a temporary disturbance, nesting eagles, if present, could abandon their nests and wintering eagles could be displaced from roosting sites. The Applicant would coordinate with USFWS to identify any potential nest sites and roosting areas that would need to be avoided (EPMs FVW-4 and FVW-5).

3.14.1.7.2.6.7.2 Operations and Maintenance

No additional habitat disturbance is expected during operations and maintenance, so impacts to either the Indiana bat or northern long-eared bat during this phase are not expected. Any roost trees in the ROW underneath the transmission lines removed during construction would not be allowed to regrow because of interference with the lines and would remain as lost habitat during the life of the Project.

Mortalities from transmission line collisions and electrocution are potential impacts to the avian special status wildlife species. Of most concern is the area surrounding the Mississippi River crossing where habitat exists for the interior least tern, piping plover, and bald eagle. Most of the remaining area of the Applicant Proposed Route in Region 7 is croplands that lack suitable conditions for these species. The least tern and piping plover, species that both forage and/or nest along the Mississippi River, are both small and agile fliers that could likely avoid transmission lines (Dinan et al. 2012). The potential for mortalities from transmission line collisions for both species is considered to be low. The bald eagle is a much larger and less maneuverable species that frequently flies for foraging and movement between feeding and roosting locations and is more susceptible to potential collisions. Marking of the transmission lines near the Mississippi River to make the lines more visible could reduce the potential risk to all avian species. Risks of electrocution hazards to eagles would depend on the electrical line spacing and would decrease if the spacing is greater than the eagle's wingspan preventing contact between two or more electrical conductors. The Applicant would implement EPM GE-2 to minimize risk of avian mortality.

The Applicant would develop and implement an APP, consistent with APLIC guidelines that describes a program of specific and comprehensive actions that when implemented, would reduce risk of avian mortality. Additionally, the Applicant would implement EPMs (FVW-1, FVW-2, and GE-2) as described in Section 3.14.1.7 to reduce risk of avian mortality.

3.14.1.7.3 Impacts Associated with the DOE Alternatives

This section identifies the potential direct and indirect impacts on special status wildlife species related to the DOE alternatives.

3.14.1.7.3.1 Arkansas Converter Station Alternative and AC Interconnection Siting Areas

A detailed description of the Arkansas converter station and other terminal facilities is provided in Section 2.4.3.1. The Arkansas Converter Station Alternative and AC Interconnection Siting Areas are located near the western end of Region 5 in Pope County. The special status wildlife species that could occur in the Project ROI include the gray bat, northern long-eared bat, Ozark big-eared bat, and Indiana bat, interior least tern, piping plover, and bald eagle. Evergreen forest (22 percent), deciduous forest (33 percent), and pasture/hay (27 percent) comprise most of the vegetation in the 360-acre converter station siting area. Hay or pasture land (72 percent) and evergreen forest (11 percent) compose most of the 662-acre Arkansas Converter Station AC Interconnection Siting Area. A substation (25- to 35-acre site) would interconnect the AC transmission line to an existing 500kV transmission line. This substation would be located near an existing transmission line in an area that is primarily grassland with some forest land. Given the absence of suitable habitat for the interior least tern and piping plover within the siting area, impacts to either species are not expected. No impacts to any of the four threatened or endangered bat species or the bald eagle are expected from the AC interconnection line or the substation owing to lack of suitable habitat for these species.

3.14.1.7.3.1.1 Construction Impacts

Sections 3.10 and 3.17 list the types of habitats that would be affected and the acres that would be impacted by the Project. As discussed in Section 3.10, the Arkansas converter station (20–35 acres) would be located within a 360-acre siting area. The AC interconnection line would be approximately 5 miles long and located within an approximate 662-acre area. The substation to connect the AC interconnection line to an existing 500 KV line would disturb 25–35 acres with an additional 5 acres disturbed during construction for materials. Cave hibernacula for the four bat species and summer roosting caves for the gray bat and Ozark big-eared bat occur farther north in the karst region of the Ozark Plateau and not within the siting areas. The converter station siting area contains about 55 percent forested habitat (197 acres) that could potentially be used by the Indiana bat and northern long-eared bat for summer roosting and foraging. The occurrence and use of forested habitat by the northern long-eared bat and Indiana bat, and possibly by the Ozark big-eared bat and gray bat as foraging, within the Project ROI is likely restricted to the spring through fall. The substation location is mostly grassland with some forested areas. To the extent that construction of the converter station, associated AC interconnection transmission line, and substation avoids forested areas, impacts to bat habitat (i.e., removal of roost trees or temporary disturbance of roost sites) would be minimized or avoided. Appropriate EPMs would be implemented (FVW-5, GE-6, GE-13, GE-20, and GE-22) to minimize potential impacts.

No bald eagle nesting or winter roost sites are known to exist within the siting area but any potential sites would be identified prior to construction and appropriate mitigation measures would be implemented to avoid potential impact to nests or winter roosts.

3.14.1.7.3.1.2 Operations and Maintenance Impacts

Once constructed, no additional land disturbance is expected to occur near the converter station or along the AC interconnection lines. No impacts to any of the special status bat species are expected from operations and maintenance of the facility. The vegetation in the ROW underneath the AC transmission lines would be maintained in a low stature to prevent interference with electrical conductors. However, most of the Arkansas Converter Station AC Interconnection Siting Area and the substation site is existing grassland and removal of trees would be minimal. Any trees removed during construction would not be allowed to regrow, including any trees that had been used as bat roost trees.

The transmission lines of the AC Interconnection could pose a risk to wintering bald eagles in the region. There is no suitable habitat within the siting area that would attract eagles to the area from surrounding wintering areas and the potential risk of collisions with the transmission lines is considered low.

3.14.1.7.3.1.3 Decommissioning Impacts

Decommissioning of the Project would involve methods similar to those that would be required to construct the Project. As a result, the impacts of decommissioning would be similar to those previously described for construction. The Applicant would follow the same general and resource-specific EPMs during decommissioning that would be implemented during construction. In addition, the Applicant would develop a Decommissioning Plan prior to any decommissioning actions for reviewed and approval by the appropriate state and federal agencies.

3.14.1.7.3.2 HVDC Alternative Routes

Descriptions of the HVDC alternative routes are provided in Section 2.4.3.2. The impacts that could occur to special status wildlife species from construction and operations and maintenance of the Applicant Proposed Route are discussed in Section 3.14.1.7.2. The expected types of impacts from construction and operations and maintenance of the HVDC alternative routes in each region would be similar to those for the Applicant Proposed Route. However, because of differences in routing (i.e., location) the potential for impacts may be slightly different (e.g., the route may be closer to or farther from an important habitat). The discussion in this section will focus on the differential impacts that could occur under each of the HVDC alternative routes compared to the Applicant Proposed Route. This discussion is broken out by construction and operational-related impacts.

3.14.1.7.3.2.1 Construction Impacts

Table 3.14.1-6 lists the approximate length of the HVDC alternative routes by region, the predominant habitat type that would be impacted (see Section 3.10 for more details regarding the acres of impact that would occur), and any significant differences in impacts by alternative compared to the Applicant Proposed Route. The difference in potential impacts to terrestrial special status wildlife species between the HVDC alternative routes and the Applicant Proposed Route each region is also discussed in Table 3.14.1-6.

HVDC Alternative Routes 1-A, 2-A, 3-C, 4-B, and 4-D could have potential for increased impacts to special status wildlife species compared to the Applicant Proposed Route (Table 3.14.1-6). HVDC Alternative Route 1-A has the potential to impact (habitat loss and fragmentation of existing habitat) more LEPC habitat mapped focal areas (CHAT-1) or connectivity zone habitat (CHAT-2) than Links 2, 3, 4, and 5 of the Applicant Proposed Route. It also has the potential to impact lands with multiple leks. HVDC Alternative Route 1-B also has the potential to impact (i.e., habitat disturbance or avoidance of habitat by LEPC) LEPC and their habitat but likely less so than HVDC Alternative Route 1-A.

HVDC Alternative Route 2-A is parallel to the Cimarron River for a portion of the route. This portion of the Cimarron River is known to be used by the interior least tern and the potential for construction impacts (disturbances) would be greater compared to Link 2 of the Applicant Proposed Route. HVDC Alternative Route 2-A also would run adjacent to ODWC's Major County WMA, which has the potential to attract migratory birds. HVDC Alternative Route 3-C has slightly more forested land and therefore could potentially impact the American burying beetle more than Links 3, 4, 5, and 6 of Applicant Proposed Route in Region 3 during construction.

HVDC Alternative Route 4-B runs north of Links 2 through 8 of the Applicant Proposed Route in Region 4. This area includes more forested lands and is closer to the Ozark Plateau region, which contains cave hibernacula for special status bat species. Because there are more undisturbed forested areas, there is a potential for greater mortality impacts to the American burying beetle during construction. The increase in forested land in closer proximity to areas of caves known to be or potentially used by bats increases the potential impacts (e.g., disturbances to or loss of roost trees) to the special status bat species along this route compared to the Applicant Proposed Route. Similarly, HVDC Alternative Route 4-D also contains more undisturbed forested land than corresponding Link 4 of the Applicant Proposed Route in Region 4. Therefore, construction impacts could also be greater to the American burying beetle and the special status bat species than along the corresponding Link 4.

3.14.1.7.3.2.2 Operations and Maintenance Impacts

It is expected that most of the HVDC alternative routes would have impacts during operations and maintenance similar to those of the Applicant Proposed Route because the habitat and species composition is similar. The presence of transmission lines in the alternative routes would have similar potential for collision mortalities for the same species as the Applicant Proposed Route. The potential impacts of HVDC Alternative Routes 1-A, 2-A, 3-C, 4-B, and 4-D could have potential for increased impacts to special status wildlife species compared to the Applicant Proposed Route for the reasons discussed in Table 3.14.1-6. HVDC Alternative Route 1-A has the potential to impact (behavioral avoidance and fragmentation of existing habitat) more LEPC habitat mapped as focal area (CHAT-1) or connectivity zone habitat (CHAT-2) than Links 2, 3, 4, and 5 of the Applicant Proposed Route. HVDC Alternative Route 1-B also has the potential to impact LEPC habitat but likely less so than HVDC Alternative Route 1-A.

HVDC Alternative Route 2-A is closer to and parallels the Cimarron River for a portion of the route compared to Link 2 of the Applicant Proposed Route. The potential for collision mortalities from the transmission lines could be potentially greater with the closer proximity to known interior least tern habitat along the river. However, terns are agile fliers and the probability of mortality is considered low.

HVDC Alternative Route 3-C has slightly more undisturbed forested land and therefore could potentially impact the American burying beetle more than Links 3, 4, 5, and 6 of the Applicant Proposed Route in Region 3; therefore, impacts to the American burying beetle from operations and maintenance likely would not be greater than those along the Applicant Proposed Route.

HVDC Alternative Route 4-B runs north of Links 2 through 8 of the Applicant Proposed Route in Region 4. This area includes more forested lands and is closer to the Ozark Plateau region that contains cave hibernacula for special status bat species; therefore, impacts to the American burying beetle from operations and maintenance likely would not be greater than those along the Applicant Proposed Route. The increase in forested land in closer proximity to areas of caves known to be or potentially used by bats increases the potential impacts (e.g., disturbances to or loss of roost trees) to the special status bat species along this route compared to the Applicant Proposed Route. Similarly, HVDC Alternative Route 4-D also contains more forested lands than the corresponding Link 4 of the Applicant Proposed Route in Region 4. Any bat roost trees or foraging habitat lost from clearing the ROW underneath the transmissions lines during construction would remain a long-term impact during operations and maintenance as the ROW would be maintained with low stature plants to avoid interference with electrical conductors.

Table 3.14.1-6:
Special Status Wildlife Species Summary Information Regarding the HVDC Alternative Routes

Region	HVDC Alternative Route	Total Length of Route (miles)	Predominant Land Cover	Impacts to Wildlife that would Differ Compared to the Applicant Proposed Route
1	1-A	123	Grassland/herbaceous (approximately 2,265.4 acres or 75.4 percent)	This alternative compares to the Applicant Proposed Route Links 2, 3, 4, and 5. HVDC Alternative Route 1-A has intersects some CHAT 1 and 2 LEPC habitat, focal areas, and connectivity zones (Van Pelt et al. 2013) that the APR does not, indicating that construction of HVDC alternative transmission lines may have more impacts from habitat loss and modification, sensory disturbance and mortality and/or injuries than the APR.
	1-B	52	Grassland/herbaceous (approximately 886.6 acres or 69.9 percent)	This alternative compares to the Applicant Proposed Route Links 2 and 3. No significant impact differences are anticipated between the Applicant Proposed Route and this alternative.
	1-C	52	Grassland/herbaceous (approximately 892.3 acres or 70.1 percent)	This alternative compares to the Applicant Proposed Route Links 2 and 3. No significant impact differences are anticipated between the Applicant Proposed Route and this alternative.
	1-D	33.5	Grassland/herbaceous (approximately 568.9 acres or 69.4 percent)	This alternative compares to the Applicant Proposed Route Links 3 and 4. No significant impact differences are anticipated between the Applicant Proposed Route and this alternative.
2	2-A	57	Grassland/herbaceous (approximately 833.5 acres or 59.7 percent)	This alternative compares to the Applicant Proposed Route Link 2. HVDC Alternative 2-A has the potential to have greater construction impacts to interior least terns compared to the Applicant Proposed Route or Alternative Route 2-B, based on proximity of this route to known nesting occurrences along the Cimarron River (as this route is located closer to the river than Alternative Route 2-B or the Applicant Proposed Route). This alternative also runs adjacent to the ODWC's Major County WMA, which has the potential to attract migratory birds.
	2-B	30	Croplands (approximately 440.3 acres or 60.5 percent) and grassland/herbaceous (approximately 240 acres or 33 percent)	This alternative compares to the Applicant Proposed Route Link 3. No significant impact differences are anticipated between the Applicant Proposed Route and this alternative.
3	3-A	38	Grassland/herbaceous (approximately 497.3 acres or 54.1 percent) and deciduous forest (187.7 acres or 20.4 percent)	This alternative compares to the Applicant Proposed Route Link 1. No significant impact differences are anticipated between the Applicant Proposed Route and this alternative.

Table 3.14.1-6:
Special Status Wildlife Species Summary Information Regarding the HVDC Alternative Routes

Region	HVDC Alternative Route	Total Length of Route (miles)	Predominant Land Cover	Impacts to Wildlife that would Differ Compared to the Applicant Proposed Route
	3-B	48	Grassland/herbaceous (approximately 645.2 acres or 55.3 percent) and deciduous forest (219 acres or 18.8 percent)	This alternative compares to the Applicant Proposed Route Links 1, 2, and 3. No significant impact differences are anticipated between the Applicant Proposed Route and this alternative.
	3-C	122	Grassland/herbaceous (approximately 1,061.2 acres or 358 percent), deciduous forest (869.2 acres or 29.3 percent), and pasture/hay (773.4 acres or 26.1 percent)	This alternative compares to the Applicant Proposed Route Links 3, 4, 5, and 6. Impacts to the American burying beetle may be higher compared to the Applicant Proposed Route due to slightly more forested areas that would be impacted, but less for the gray bat because less foraging areas near water would be impacted.
	3-D	39	Primarily pasture/hay (approximately 491.8 acres or 51.3 percent), grassland/herbaceous (188.9 acres or 19.7 percent), and deciduous forest (184.3 acres or 19.2 percent	This alternative compares to the Applicant Proposed Route Links 5 and 6. No significant impact differences are anticipated between the Applicant Proposed Route and this alternative.
	3-E	8.5	Pasture/hay (approximately 98.3 acres or 47.3 percent) and deciduous forest (74.1 acres or 35.7 percent)	This alternative compares to the Applicant Proposed Route Link 6. No significant impact differences are anticipated between the Applicant Proposed Route and this alternative.
4	4-A	58	Deciduous forest (approximately 624 acres or 43.8 percent) and pasture/hay (497.4 acres 34.9 percent)	This alternative compares to the Applicant Proposed Route Links 3, 4, 5, and 6. No significant impact differences are anticipated between the Applicant Proposed Route and this alternative.
	4-B	79	Deciduous forest (approximately 873.2 acres or 45.5 percent) and pasture/hay (459.6 acres or 23.9 percent)	This alternative compares to the Applicant Proposed Route Links 2–8. Approximately 102 acres of the federally owned land in the Ozark National Forest and an additional 157 acres of private land within the Ozark National Forest boundary (use unknown) are within the ROW for HVDC Alternative Route 4-B. HVDC Alternative Route 4-B would cross into the Ozark National Forest IBA, potentially indirectly impacting wildlife species during construction, as a result of mortality and/or injury, sensory disturbance, and habitat loss or modification. Furthermore, this route alternative would impact more forested areas compared to the Applicant Proposed Route, thereby increasing the risk of impacts to the American burying beetle. This alternative route also is closer to potential cave hibernacula in the Ozark Plateau and may have a higher potential for bat roosting and foraging in the forested areas.

Table 3.14.1-6:
Special Status Wildlife Species Summary Information Regarding the HVDC Alternative Routes

Region	HVDC Alternative Route	Total Length of Route (miles)	Predominant Land Cover	Impacts to Wildlife that would Differ Compared to the Applicant Proposed Route
	4-C	3	Deciduous forest (approximately 32.4 acres or 39.2 percent) and pasture/hay (19 acres or 23 percent)	This alternative compares to the Applicant Proposed Route Link 5. No significant impact differences are anticipated between the Applicant Proposed Route and this alternative.
	4-D	25	Pasture/hay (approximately 299.9 acres or 48.6 percent) and deciduous forest (179.6 acres or 29.1 percent)	This alternative compares to the Applicant Proposed Route Link 4. This route alternative would impact more forested areas compared to the Applicant Proposed Route, thereby increasing the risk of impacts to the American burying beetle. Because of additional forested habitat, there is potential for more impact to bat roosting and foraging habitat.
	4-E	37	Pasture/hay (approximately 395.5 acres or 44.1 percent) and evergreen forest (218.7 acres or 24.4 percent)	This alternative compares to the Applicant Proposed Route Links 8 and 9. No significant impact differences are anticipated between the Applicant Proposed Route and this alternative.
5	5-A	13	Evergreen forest (130.4 acres or 42.3 percent) and deciduous forest (78.8 acres or 25.5 percent)	This alternative compares to the Applicant Proposed Route Link 1. No significant impact differences are anticipated between the Applicant Proposed Route and this alternative.
	5-B	71	Pasture/hay (approximately 740.3 acres or 42.7 percent) and deciduous forest (479.5 acres or 27.7 percent)	This alternative compares to the Applicant Proposed Route Links 3, 4, 5, and 6. No significant impact differences are anticipated between the Applicant Proposed Route and this alternative.
	5-C	9	Deciduous forest (approximately 99.9 acres or 44.5 percent) and pasture/hay (70.9 acres or 31.6 percent)	This alternative compares to the Applicant Proposed Route Links 6 and 7. No significant impact differences are anticipated between the Applicant Proposed Route and this alternative.
	5-D	22	Deciduous forest (approximately 246.5 acres or 46.5 percent) and croplands (92 acres or 17.4 percent)	This alternative compares to the Applicant Proposed Route Link 9. No significant impact differences are anticipated between the Applicant Proposed Route and this alternative.
	5-E	36	Pasture/hay (approximately 383.5 acres or 43.3 percent) and deciduous forest (249.3 acres or 28.2 percent)	This alternative compares to the Applicant Proposed Route Links 4, 5, and 6. No significant impact differences are anticipated between the Applicant Proposed Route and this alternative.
	5-F	22	Pasture/hay (approximately 209.9 acres or 38.6 percent) and deciduous forest (153.2 acres or 28.1 percent)	This alternative compares to the Applicant Proposed Route Links 5 and 6. No significant impact differences are anticipated between the Applicant Proposed Route and this alternative.

Table 3.14.1-6:
Special Status Wildlife Species Summary Information Regarding the HVDC Alternative Routes

Region	HVDC Alternative Route	Total Length of Route (miles)	Predominant Land Cover	Impacts to Wildlife that would Differ Compared to the Applicant Proposed Route
6	6-A	16	Croplands (approximately 328.6 acres or 83 percent)	This alternative compares to the Applicant Proposed Route Links 2, 3, and 4. No significant impact differences are anticipated between the Applicant Proposed Route and this alternative.
	6-B	14	Croplands (approximately 272.1 acres or 79.2 percent) and woody wetlands (44.6 acres or 13 percent)	This alternative compares to the Applicant Proposed Route Link 3. No significant impact differences are anticipated between the Applicant Proposed Route and this alternative.
	6-C	23	Croplands (approximately 410.6 acres or 72.6 percent)	This alternative compares to the Applicant Proposed Route Links 6 and 7. No significant impact differences are anticipated between the Applicant Proposed Route and this alternative.
	6-D	9	Croplands (approximately 205.3 acres or 91.8 percent)	This alternative compares to the Applicant Proposed Route Link 7. No significant impact differences are anticipated between the Applicant Proposed Route and this alternative.
7	7-A	43	Croplands (approximately 827.8 acres or 78.7 percent) and woody wetlands (110.5 acres or 10.5 percent)	This alternative compares to the Applicant Proposed Route Link 1. No significant impact differences are anticipated between the Applicant Proposed Route and this alternative.
	7-B	9	Croplands (approximately 86.4 acres or 41.2 percent), deciduous forest (42.7 acres or 20.3 percent), pasture/hay (34 acres or 16.2 percent),and shrub/scrub (32.7 acres or 15.6 percent)	This alternative compares to the Applicant Proposed Route Links 3 and 4. No significant impact differences are anticipated between the Applicant Proposed Route and this alternative.
	7-C	24	Croplands (approximately 350.6 acres or 60.6 percent), pasture/hay (72.2 acres or 12.5 percent), and deciduous forest (58.4 acres or 10.1 percent)	This alternative compares to the Applicant Proposed Route Links 3, 4, and 5. No significant impact differences are anticipated between the Applicant Proposed Route and this alternative.
	7-D	7	Croplands (approximately 76.8 acres or 48.1 percent), pasture/hay (32.2 acres or 20.2 percent), and shrub/scrub (20.6 acres or 12.9 percent)	This alternative compares to the Applicant Proposed Route Links and 5. No significant impact differences are anticipated between the Applicant Proposed Route and this alternative.

GIS Data Source: Jin et al. 2013.

3.14.1.7.3.2.3 Decommissioning Impacts

Potential impacts during decommissioning of the HVDC alternative routes would be similar to those of the construction phase. Once the decommissioning is complete, all land could return to the pre-construction land uses according to the Restoration Plan as described in Section 3.14.1.7. The Applicant would follow the same general and resource-specific EPMs during decommissioning that would be implemented during construction. In addition, the Applicant would develop a Decommissioning Plan prior to any decommissioning actions for reviewed and approval by the appropriate state and federal agencies.

3.14.1.7.4 Best Management Practices

The Applicant has developed a comprehensive list of EPMs intended to avoid or minimize impacts to wildlife resources. A complete list of EPMs for the Project is provided in Appendix F; those EPMs that would specifically minimize the potential for impacts to special status wildlife species are summarized in Section 3.14.1.7.1. DOE and the Applicant have prepared a Biological Assessment (Appendix O of the EIS) of potential impacts on special status species protected under the ESA as part of the Section 7 consultation between DOE and the USFWS. The Section 7 consultation review is a parallel but separate process conducted pursuant to the requirements of ESA and the applicable implementing regulations. A Biological Opinion will be issued by USFWS prior to the Record of Decision. Through this process, protective measures may be identified and adopted to avoid and/or minimize impacts to special status species.

3.14.1.7.5 Unavoidable Adverse Impacts

The Applicant would implement EPMs to avoid or minimize impacts. However, some adverse impacts may remain even with the implementation of these measures. Construction and operations and maintenance of the Project could result in the mortality of some special status wildlife species if they are present in the affected areas during construction or operations and maintenance, including, but not limited to, potential mortalities associated with the clearing of vegetation as well as avian collisions with Project structures during operations and maintenance. Potential mortalities would be highest if vegetation clearing was conducted during the breeding season. Construction-related disturbances could result in temporary loss of some wildlife habitats through noise and visual disturbances. Potential loss of special status wildlife habitat during operation and maintenance could result from the effects of fragmentation, edge effects, and invasive plant species. ROW maintenance in forested habitats as well as the footprint of Project structures would result in a permanent loss of mature forest habitat.

3.14.1.7.6 Irreversible and Irretrievable Commitment of Resources

The potential permanent loss or alteration of established trees in mature forests in the eastern portion of the Project (in Regions 3, 4, 5, and 7) would last throughout the life of the Project; however, gradual recovery of habitat may occur once the Project is decommissioned. Because the exact state of this recovery is not known (e.g., substantial changes related to climate, land-use, and/or weeds or pathogens may occur during the 80 year lifespan of the Project) and mature forests are subject to long-term climatic regimes, it is reasonable to assume that some portions of the habitat for special status wildlife species in these forests would be irreversibly and irretrievably impacted.

3.14.1.7.7 Relationship between Local Short-term Uses and Long-term Productivity

Both the Applicant Proposed Route and the DOE Alternatives may result in a short-term disturbance to special status wildlife; however, these impacts should not affect the long-term productivity of populations of special status wildlife.

3.14.1.7.8 Impacts from Connected Actions

3.14.1.7.8.1 Wind Energy Generation

Potential special status wildlife species that could occur within the six-county region in Texas and Oklahoma which contain the WDZs include LEPC, whooping crane, interior least tern, piping plover, Sprague's pipit, red knot, golden eagle, and bald eagle. Specific wind farm development locations are unknown in the 6-county area; therefore, impacts to specific special status species and their habitat could vary greatly depending on where wind farms are developed. Impacts could be reduced by locating wind farms on previously disturbed lands (e.g., croplands) that have little value has habitat for special status species.

Wind energy developers are expected to develop and construct wind energy projects based on guidance outlined by the USFWS Land-Based Wind Energy Guidance (USFWS 2012c) and the APLIC guidelines (APLIC 2012). These guidelines may include the development of conservation strategies and specific actions that, when implemented, could reduce the risk of impacts to special status wildlife species and their habitats. The estimated acreage of land that could be disturbed during construction and would remained disturbed during operation (e.g., permanent access roads, footprint of wind turbines and electrical stations) of the wind farms are listed in Table 3.14.1-7. These estimates assume a 30 percent build-out of the WDZs that would supply the electrical transmission capacity of the Applicant Proposed Project with an estimated 2 percent disturbance of land area during construction and a 1 percent land disturbance remaining during operation of the wind farms.

Table 3.14.1-7:
Description of the WDZ and the Potential Special Status Wildlife Species That May Occur In Area

WDZ Name	Potentially Suitable Area for Wind Development (acres)	Estimated Acres of Impact during Construction[1]	Estimated Acres of Impact during Operation[1]	Special Status Species Potentially Present in the WDZ
WDZ-A	101,000	606 acres of primarily croplands and grasslands	303 acres	Potentially suitable habitat for piping plover is limited; however, there is a potential for piping plover to occur during migration (which generally occurs from April to June). LEPC and whooping crane may feed within the croplands and grasslands that are common in WDZ-A; however, the whooping crane occurrence within the WDZ-A is likely to be limited to occasional migratory stopover occurrences.
WDZ-B	108,000	648 acres of primarily croplands and grasslands	324 acres	Potentially suitable habitat for piping plover is limited; however, there is a potential for piping plover to occur during migration (which generally occurs from April to June). LEPC and whooping crane may feed within the croplands and grasslands that are common in WDZ-B; however, the whooping crane occurrence within the WDZ-B is likely to be limited to occasional migratory and stopover occurrences.

Table 3.14.1-7:
Description of the WDZ and the Potential Special Status Wildlife Species That May Occur In Area

WDZ Name	Potentially Suitable Area for Wind Development (acres)	Estimated Acres of Impact during Construction[1]	Estimated Acres of Impact during Operation[1]	Special Status Species Potentially Present in the WDZ
WDZ-C	123,000	738 acres of primarily croplands and grasslands	369 acres	Potentially suitable habitat for piping plover is limited; however, there is a potential for piping plover to occur during migration (which generally occurs from April to June). LEPC and whooping crane may feed within the croplands and grasslands that are common in WDZ-C; however, the whooping crane occurrence within the WDZ-C is likely to be limited to occasional migratory and stopover occurrences.
WDZ-D	43,000	258 acres of primarily grasslands	129 acres	Potentially suitable habitat for piping plover is limited; however, there is a potential for piping plover to occur during migration (which generally occurs from April to June). LEPC and whooping crane may feed within the grasslands that are common in WDZ-D; however, the whooping crane occurrence within the WDZ-D is likely to be limited to migratory and stopover occurrences. WDZ-D contains the ODWC Schultz WMAs.
WDZ-E	43,000	258 acres of primarily croplands and grasslands	129 acres	Potentially suitable habitat for piping plover is limited; however, there is a potential for piping plover to occur during migration (which generally occurs from April to June). This WDZ contains extensive cropped areas and less potential to support LEPC. Whooping crane may feed within the grasslands that are common in WDZ-E; however, the whooping crane occurrence within the WDZ-E is likely to be limited to migratory and stopover occurrences.
WDZ-F	82,000	492 acres of primarily grasslands and croplands	246 acres	Potentially suitable habitat for piping plover is limited; however, there is a potential for piping plover to occur during migration (which generally occurs from April to June). LEPC and whooping crane may feed within the croplands and grasslands that are common in WDZ-F; however, the whooping crane occurrence within the WDZ-F is likely to be limited to migratory and stopover occurrences. This WDZ is located farther from existing mapped LEPC habitat but contains grassland habitats with the potential to support LEPC.
WDZ-G	159,000	954 acres of primarily grasslands and croplands	477 acres	Potentially suitable habitat for piping plover is limited; however, there is a potential for piping plover to occur during migration (which generally occurs from April to June). WDZ-G is just south of high-quality LEPC habitat in southeastern Colorado and southwestern Kansas and could affect populations across the border in Oklahoma. Whooping crane may feed within the croplands and grasslands that are common in WDZ-G; however, the whooping crane occurrence within the WDZ-G is likely to be limited to occasional migratory and stopover occurrences.
WDZ-H	67,000	402 acres of primarily grasslands and croplands	201 acres	Potentially suitable habitat for piping plover is limited; however, there is a potential for piping plover to occur during migration (which generally occurs from April to June). Has some large grassland areas with the potential to support LEPC. Whooping crane may feed within the croplands and grasslands that are common in WDZ-H; however, the whooping crane occurrence within the WDZ-H is likely to be limited to occasional migratory and stopover occurrences.

Table 3.14.1-7:
Description of the WDZ and the Potential Special Status Wildlife Species That May Occur In Area

WDZ Name	Potentially Suitable Area for Wind Development (acres)	Estimated Acres of Impact during Construction[1]	Estimated Acres of Impact during Operation[1]	Special Status Species Potentially Present in the WDZ
WDZ-I	85,000	510 acres of primarily grasslands and croplands	255 acres	Potentially suitable habitat for piping plover and interior least tern is limited; however, there is a potential for both species to occur during migration (which generally occurs from April to June). This WDZ is just northwest of an area with LEPC, including leks. Development here could affect movement of LEPC from the Oklahoma/Kansas border to the eastern panhandle area. Whooping crane may feed within the grasslands that are common in WDZ-I; however, the whooping crane occurrence within the WDZ-I is likely to be limited to occasional migratory and stopover occurrences.
WDZ-J	44,000	264 acres of primarily grasslands	132 acres	Potentially suitable habitat for piping plover and interior least tern is limited; however, there is a potential for both species to occur during migration (which generally occurs from April to June). Whooping crane may feed within the grasslands that are common in WDZ-J; however, the whooping crane occurrence within the WDZ-J is likely to be limited to migratory and stopover occurrences. The LEPC habitat within WDZ-J is categorized as CHAT category 1 (i.e., focal area) suggesting that large areas of undeveloped, contiguous grassland/herbaceous land cover occur within the WDZ. Development here may also affect LEPC movements from the northwest to the southeast and vice versa. The ODWC Shorb WMA is located outside the western boundary of this WDZ.
WDZ-K	84,000	504 acres of primarily grasslands and croplands	252 acres	The LEPC occurs in this WDZ, particularly the eastern portion that is near existing leks and focal habitat. Potentially suitable habitat for piping plover and interior least tern is limited; however, there is a potential for both species to occur during migration (which generally occurs from April to June). Whooping crane may feed within the grasslands that are common in WDZ-K; however, occurrence within the WDZ-K is likely to be limited to occasional migratory and stopover occurrences.
WDZ-L	144,000	864 acres of primarily grasslands and croplands	432 acres	Potentially suitable habitat for piping plover is limited; however, there is a potential for piping plover to occur during migration (which generally occurs from April to June). The eastern portion of WDZ-L contains quality LEPC habitat and is near focal habitat and several leks. Whooping crane may feed within the grasslands that are common in WDZ-L; however, the whooping crane occurrence within the WDZ-L is likely to be limited to migratory and stopover occurrences.

1 The estimated acres of impact assumes a 30 percent build-out with 2 percent of the land affected during construction and 1 percent affected during operations based on the potentially suitable area for wind development in each WDZ (Table 2.5-1).

Potential impacts during wind farm development could include short-term disturbances to species (i.e., displacement in the vicinity of construction activity) during construction, loss of habitat from land disturbance, and potential mortality from vehicle collisions. Impacts to the interior least tern, piping plover, and red knot are not expected during construction. These three species use sparsely vegetated shorelines, sandbars, mudflats, and islands of rivers, lakes, and reservoirs. These habitats are relatively uncommon in the WDZs and are not likely sites that would be developed for wind energy. The LEPC could be potentially impacted during construction of wind farms by clearing of grassland habitats for access roads, wind turbines, and electrical stations.

Although the proportion of land potentially disturbed during wind farm construction is relatively small (2 percent), construction in undisturbed grasslands could fragment LEPC habitat that could reduce overall LEPC habitat quality in a larger area surrounding a wind farm. The potential for construction impacts to the LEPC and its habitat is greater in WDZs D, I, J, K, and L. These WDZs occur in eastern Texas County and western Beaver County in Oklahoma and western Ochiltree County in Texas. These WDZs are closest to areas mapped as focal and connectivity habitat areas in the LEPC Range-Wide Conservation Plan (Van Pelt et al. 2013) and include the ODWC Shultz and Shorb WMAs. Although impacts to LEPC could occur on land outside the identified focal and connectivity habitat areas, the focal areas represent high priority conservation areas to preserve larger more contiguous blocks of LEPC habitats and to encourage development in areas with less potential impact.

Sprague's pipit also is an occupant of grasslands, but it occurs as an uncommon migrant and rare winter resident in the vicinity of the WDZs and impacts to this species are expected to be minimal from construction activities (USFWS 2014d). Construction impacts to either golden eagles or bald eagles are not expected as both species are wide-ranging and nesting habitat for the golden eagle is limited in the WDZs. Once construction has been completed, temporary construction areas would revert to their previous use. Only turbines, access roads, generation tie-lines (if necessary), substations, and operations and maintenance buildings would remain. Existing land uses, primarily agriculture and grazing, would be expected to return to almost all areas of the facilities unless deemed incompatible with the operations of a wind energy development. During the operations and maintenance phase of wind energy developments, approximately 1 percent of the land could be affected (i.e., occupied by turbines, electrical stations, access roads). For the 12 WDZs, assuming 30 percent build-out, 3,249 acres could be impacted (Table 3.14.1-7).

Operation and maintenance of wind energy developments are known to have the potential to directly impact some special status wildlife species, specifically avian and bat species, due to collisions with wind turbine blades, collisions and electrocutions associated with generation tie-lines, barotrauma (physical tissue damage caused by air pressure differences) of bat species, and potential avoidance of otherwise suitable habitat surrounding vertical structures such as wind turbines and transmission structures. None of the four special status bat species (three listed as endangered, one proposed as endangered) that occurs on the Applicant Proposed Project occurs in Region 1, so none would be affected by potential wind energy development. Historically, the average number of avian species fatalities associated with operations of a wind energy facilities has varied among developments and is considered a function of a number of factors, including the proximity to known staging areas, winter ranges, nesting sites, migration stopovers or corridors, and leks or other areas of seasonal importance (USFWS 2012c).

Given the limited habitat for either the piping plover or interior least tern in the wind development zones, impacts to either species is not expected. Some whooping cranes migrate through the WDZ region, although the area is west of the primary whooping migration corridor. Because of their large size and lower maneuverability, whooping cranes could be at risk for collisions with wind turbines. Because Sprague's pipit is a relatively uncommon migrant through the region, potential collision mortalities are possible but probably unlikely. The preferred cliff and canyon nesting habitat of the golden eagle occurs west of the WDZs. However, migrant golden eagles, and some bald eagles, may occur in the WDZ region and could be at risk for mortality collisions. Occurrence of avian special status species within the WDZ and collision mortalities from wind energy facilities would likely be documented by wind energy developers under the Land-Based Wind Energy Guidelines (USFWS 2012c), in accordance with appropriate state and federal regulations.

Indirect impacts causing habitat loss and/or modification have been reported for some species of prairie-grouse; however, little is known about effects of wind farms on LEPC (Van Pelt et al. 2013). Behavioral avoidance by LEPC of otherwise suitable habitat surrounding wind turbine towers may increase the area of impact (Pruett et al. 2009, Winder et al. 2014). Empirical data on impact distances from vertical structures for LEPC is limited; however, appropriate buffer distances and restrictions near LEPC occupied habitat would be determined during any ESA consultation by the wind energy developer. The resulting habitat loss and/or modification may reduce the overall fitness of birds, reduce reproductive success, and inhibit movement and gene flow of birds (Van Pelt et al. 2013; 79 FR 20074, April 10, 2014). Although specific empirical data currently are not publically available, the suggestion that LEPC may avoid otherwise suitable habitat has led the USFWS to recommend the consideration of occupied prairie-grouse habitat (i.e., includes habitat used only periodically or temporarily during some portion of its life history) in locating wind farm facilities (USFWS 2012c).

Once the decommissioning phase has concluded, lands occupied by wind energy developments may be restored to their pre-construction conditions depending on specific contracts between the landowner and developer. Structures, including wind turbines and generation tie-lines, would be dismantled. Impacts associated with the construction, operations and maintenance of wind turbines, generation tie lines, and other permanent structures could therefore be reduced or eliminated as these areas are restored.

3.14.1.7.8.2 Optima Substation

No impacts to piping plovers, interior least terns, and bald eagles are expected from construction and operations and maintenance of the future Optima Substation because the site does not contain suitable habitat for any of these species. Because of the relatively small size (up to 160 acres) of the substation, potential collision mortalities to whooping cranes that migrate through the Oklahoma Panhandle region are unlikely to occur. The existing roads, power poles, and croplands that occur on and/or adjacent to the substation decrease the quality of the LEPC habitat. It is possible that some LEPC occur in grassland habitats in the vicinity of the future Optima Substation; however, potential impacts (loss of habitat and mortality) to LEPC and their habitat are expected to be minor. No leks are known to occur in the vicinity of the future Optima Substation and impacts to leks are not expected to occur (Figure 3.14-1a in Appendix A).

3.14.1.7.8.3 TVA Upgrades

Potential impacts are expected to be lower in areas affected by upgrades to existing TVA facilities than in areas where the new electric transmission line would be constructed. Generally, construction of the new transmission line could involve mortalities or new disturbances of habitat used (e.g., for breeding, nesting, brood-rearing, wintering, or foraging) by special status wildlife species, similar to the Project. Impacts during new construction could include loss of habitat from land clearing, temporary disturbance displacement, and possible mortality or injury by vehicles and construction equipment. These impacts would be short term except for habitat loss on sites used for the ROW, structures or access (i.e., roads) and any wildlife mortality. The new 500kV transmission line could result in mortality and injury of avian special status wildlife species from collisions and electrocutions during operations and maintenance. Existing TVA transmission lines would require fewer construction activities to complete upgrades than the new transmission line and would have proportionally fewer impacts as activities would occur primarily in previously disturbed areas. Upgrading and modifying existing substations would likely have no impact on special status wildlife.

TVA would consider potential impacts to special wildlife status species and their habitats during the siting of the new transmission line and while planning the upgrades to existing transmission facilities. TVA would avoid impacts to these species and their habitats to the extent practicable. Over the last decade, about 18 percent of TVA transmission construction projects have affected federally listed or candidate species (wildlife, fish, aquatic invertebrate, amphibian species, and plants) and about 30 percent of projects have affected state-listed special status species. Pursuant to Section 7 of the ESA, TVA is required to consult with USFWS with respect to effects of its construction of any new or upgraded transmission facilities upon threatened, endangered or candidate species.

3.14.1.7.9 Impacts Associated with the No Action Alternative

Under the No Action Alternative, the Project would not be constructed or operated, and impacts to special status wildlife species and their habitats would be consistent with current levels of disturbance related to natural conditions in the environment, such as annual changes in climates, land use changes, and wildfires. No Project-related disturbances or impacts would occur to special status wildlife or their habitats under the No Action Alternative.

3.14.2 Special Status Fish, Aquatic Invertebrate, and Amphibian Species

3.14.2.1 Regulatory Background

Regulations that influence the evaluation of special status fish, aquatic invertebrate, and amphibian species within the region of influence are primarily implemented by the USFWS and state agencies. The applicable state agencies to the Project include the ODWC, AGFC, TWRA, and TPWD. The special status fish, aquatic invertebrate, and amphibian species regulations relevant to the Project are presented in Table 3.14.2-1.

Table 3.14.2-1:
Relevant Laws and Regulations for Fish, Aquatic Invertebrate and Amphibian Species

Regulation	Regulatory Agency	Summary
Endangered Species Act (ESA) (16 USC § 1531 *et seq*.; 50 CFR Part 402)	USFWS	Establishes lists of threatened or endangered species and their designated critical habitats; requires federal agencies to ensure that actions they authorize, fund, or carry out are not likely to jeopardize the continued existence of listed species or result in adverse modification to designated critical habitat.
Oklahoma Statutes 29-5-412.1 Oklahoma Administrative Code Title 800, “Department of Wildlife Conservation”	ODWC	Establishes list of threatened or endangered species within Oklahoma. Describes the function, organization, powers, and duties of the ODWC with respect to managing fish and wildlife resources.
Texas Administrative Code 31-65.171–65.177	TPWD	Establishes list of threatened or endangered wildlife within Texas; prohibits the taking, possession, transportation, or sale of threatened or endangered species within the issuance of a permit.
Arkansas Code Annotated 15-45-301–306	AGFC[1]	Prohibits imports, transportation, sale, purchase, hunting, harassment, or possession of threatened or endangered wildlife or their parts.
Tennessee Administrative Code 70-1-101 et seq.	TWRA	Establishes a list of threatened or endangered wildlife within Tennessee; prohibits the take, attempt to take, possession, transportation, export, processing, selling, offering to sell, shipment of, or knowing receipt of shipment of threatened or endangered wildlife.

1 Arkansas does not have an endangered species law, but does maintain a list of Species of Special Concern.

3.14.2.2 Data Sources

Data sources included a desktop analysis of relevant information; research findings; and reports available to the public; a database that includes GIS data from government agencies as well as and non-governmental organizations; and information received from both regulatory agencies and stakeholders during the DOE scoping process. All data sources used for this analysis were limited to those that were open source and readily available to the public (i.e., the public may assess them without restrictions). For special status fish, aquatic invertebrate, and amphibian species, the following data sources were reviewed:

- USFWS Endangered Species Program Threatened and Endangered Species Range Maps
- USFWS Critical Habitat Portal
- Arkansas Geographic Information Office Ecologically Sensitive Streams and Waterbodies
- ADEQ Extraordinary Resource Water
- TCEQ Stream Use and Quality Information

Table 3.14.2-2 lists additional data sources analyzed for the ROI. Information and data sources have been provided for areas with exceptions to the ROI in Section 3.14.2.3.1.

Table 3.14.2-2:
Summary of Data Sources for Fish and Aquatic Invertebrate Species

3.14.2.3 Region of Influence

The general ROI considered for the Project and connected actions is described in Section 3.1. The following subsection describes where the ROI used for special status fish, aquatic invertebrate, and amphibian species was expanded beyond the area described in Section 3.1. The expansion of the ROI does not mean that impacts would necessarily occur at that distance, but instead, it identifies whether species are in the vicinity and could possibly be affected by the Project.

3.14.2.3.1 Variations of the Region of Influence for Special Status Fish, Aquatic Invertebrate, and Amphibian Species

The ROI for special status fish, aquatic invertebrate, and amphibian species consists of multiple waterbodies (e.g., perennial, intermittent) traversed by the Project, including special interest waterbodies. The ROI covers aquatic habitats and potential fish, aquatic invertebrate, and amphibian species that may be present based on literature reviews and data provided by Clean Line (2013). To thoroughly identify and assess potential occurrences of special status fish, aquatic invertebrate, and amphibian species, the ROI described in Section 3.1 was expanded to include a 3-mile buffer both upstream (1.5 miles) and downstream (1.5 miles) of the Applicant Proposed Route and HVDC alternative routes. The assessment within the 3-mile buffer included identifying waterbodies within the buffer that have documented occurrences of special status fish, aquatic invertebrate, and amphibian species designated as candidate, threatened, or endangered under the ESA and state-designated threatened and endangered species. This addition of the 3-mile buffer was identified to appropriately take into consideration the mobility of special status fish, aquatic invertebrate, and amphibian species. The assessment entailed adding the 3-mile buffer to the 1,000-foot-wide corridor and conducting database searches within the 3-mile buffer for waterbodies with documented occurrences of both state and federally protected fish, aquatic invertebrate, and amphibian species. Considering the mobility of fish and larval mussels, the 3-mile buffer is necessary both upstream and downstream of stream crossings, and extensive enough, to account for the various ranges of special status fish and aquatic invertebrate species, including the unique and varied habitat that each species potentially occupies.

To quantify potential impacts to special status fish, aquatic invertebrate, and amphibian species associated with the Applicant Proposed Route and the HVDC alternative routes, a 3-mile buffer at crossing locations (i.e., 1.5-miles upstream and 1.5-miles downstream) and a 195-foot-wide USFWS polygon of designated critical habitat were used to calculate acres of critical habitat within the 1,000-foot-wide ROI and 200-foot-wide ROW. This calculation provided the acres of USFWS designated critical habitat crossed and within the 1,000-foot-wide ROI and 200-foot-wide ROW for the Applicant Proposed Route and the HVDC alternative routes.

In general, the converter stations and Oklahoma AC interconnection are not located close to waterbodies that would affect special status species; however, any potential waterbody that may contain one or more special status fish, aquatic invertebrate, and amphibian species would be subject to the same qualifications listed above.

3.14.2.4 Affected Environment for Special Status Fish, Aquatic Invertebrate, and Amphibian Species

The following sections provide descriptions of special status fish, aquatic invertebrate, and amphibian species known to occur within or in proximity to the ROI as described above in Section 3.14.2.3.1. Section 3.14.2.4.1 provides an overview of federally proposed or listed fish, aquatic invertebrate, and amphibian species. Sections 3.14.2.4.2 and 3.14.2.4.3 provide information specific to each of the federally proposed or listed fish or aquatic invertebrate species, respectively. Section 3.14.2.4.4 provides an overview of state designations for aquatic wildlife. Descriptions of special status fish, aquatic invertebrate, and amphibian species in the ROI by Regions 1 through 7 are provided in Section 3.14.2.5.

Twenty-three route variations to the Applicant Proposed Route in Regions 2–7 were developed in response to public comments on the Draft EIS and are described in Appendix M and summarized in Sections 2.3.1 and 2.4.2.1–2.4.2.7. The route variations are discussed in relation to the special status fish, aquatic invertebrate, and amphibian species in the regional descriptions in Section 3.14.2.5. Potential impacts to these species in the route variations are discussed in Section 3.14.2.7.

3.14.2.4.1 Federally Proposed or Listed Fish, Aquatic Invertebrate, and Amphibian Species

Sixteen listed, proposed or candidate fish, aquatic invertebrate, and amphibian species designated by the USFWS under the ESA are within or in proximity to the ROI. There are a few species found north of the ROI, but within tributaries of streams where the species occur, so there is a possibility that those species could travel to areas within the ROI. These 16 fish, aquatic invertebrate, and amphibian species are within the ROI, or close enough for a review, including 12 endangered species, 3 threatened species, and 1 candidate for listing species. Table 3.14.2-3 lists the federally listed fish, aquatic invertebrate, and amphibian species potentially occurring in the ROI by state.

Table 3.14.2-3:
Federally Designated Candidate, Threatened, and Endangered Fish, Aquatic Invertebrate, and Amphibian Species Potentially Occurring in the ROI by State

Common Name[1]	Scientific Name[1]	Federal Status	County	Region
Oklahoma: Fish				
Arkansas darter	*Etheostoma cragini*	Federal Candidate	Beaver, Harper, and Woodward	1, 2
Arkansas River shiner	*Notropis girardi*	Federally Threatened	Beaver,[2] Harper,[2] Woodward,[2] Major,[2] Kingfisher,[2] Logan,[2] Garfield, and Payne	1, 2, 3
Arkansas: Fish				
Ozark Cavefish	*Amblyopsis rosea*	Federally Threatened	N/A[3]	4
Yellowcheek darter	*Etheostoma moorei*	Federally Endangered	Van Buren and Cleburne	5
Pallid sturgeon	*Scaphirhynchus albus*	Federally Endangered	Mississippi	7
Arkansas: Aquatic Invertebrates				
Spectaclecase	*Cumberlandia monodonta*	Federally Endangered	Franklin and Johnson	4
Pink mucket	*Lampsilis abrupta*	Federally Endangered	White and Jackson	5, 6
Neosho mucket	*Lampsilis rafinesqueana*	Federally Endangered	N/A[3]	4
Speckled pocketbook	*Lampsilis streckeri*	Federally Endangered	Van Buren, Pope, Cleburne, and White	4, 5
Scaleshell mussel	*Leptodea leptodon*	Federally Endangered	Crawford, Cross, Franklin, Mississippi, Poinsett, White, and Jackson	4, 5, 6
Fat pocketbook	*Potamilus capax*	Federally Endangered	White, Cross, Poinsett, Jackson, and Mississippi	5, 6, 7
Rabbitsfoot	*Quadrula cylindrica cylindrical*	Federally Threatened	Van Buren,[2] White,[2] Cleburne,[2] and Jackson[2]	5, 6
Curtis' pearlymussel	*Epioblasma florentina curtisii*	Federally Endangered	Jackson[5]	5
Fanshell	*Cyprogenia stegaria*	Federally Endangered	N/A[3]	None
Snuffbox	*Epioblasma triquetra*	Federally Endangered	Pope, Cross, Poinsett, and Mississippi	4, 5, 6, 7

Table 3.14.2-3:
Federally Designated Candidate, Threatened, and Endangered Fish, Aquatic Invertebrate, and Amphibian Species Potentially Occurring in the ROI by State

Common Name[1]	Scientific Name[1]	Federal Status	County	Region
Arkansas: Amphibians				
Ozark hellbender	*Cryptobranchus alleganiensis bishopi*	Federally Endangered	Jackson	5
Tennessee: Fish				
Pallid sturgeon	*Scaphirhynchus albus*	Federally Endangered	Tipton[6]	7
Texas: None[7]				

1 Does not include federally listed plant species or terrestrial wildlife species.
2 USFWS critical habitat occurs in this county.
3 Species not documented in counties crossed by the ROI.
4 USFWS proposed critical habitat occurs in this county.
5 Species historically known to occur in county; however, not observed since the 1990s.
6 No Tennessee counties specified by the USFWS, but species range encompass the Mississippi River in Tipton County, Tennessee, which the ROI crosses.
7 The USFWS identified the Arkansas River shiner as occurring in Hemphill, Roberts, Hutchinson, and Potter counties, Texas, all of which are outside the ROI.

Sources: USFWS (2014c, 2015a, 2015b)

3.14.2.4.2 Federally Candidate, Proposed or Listed Fish Species

3.14.2.4.2.1 Arkansas Darter

The Arkansas darter (*Etheostoma cragini*) is a candidate species for ESA listing. The species habitat exists in the Cimarron, Neosho, and Spring rivers and associated tributaries, across northern Oklahoma (USFWS 2010a). Within the ROI, populations of the Arkansas darter may exist in Beaver, Harper, and Woodward counties in western Oklahoma (USFWS 2014c). In eastern Oklahoma and into Arkansas, the species occurs north of the ROI.

The Arkansas darter is a small (approximately 2 inch) stout-bodied member of the perch family (KDWPT 2011; Natureserve 2014a). Its preferred habitat is shallow, clear cool spring-fed tributaries or headwater streams with slow currents and sand or sandy-gravel substrates (Natureserve 2014a). They prefer areas with herbaceous aquatic broad-leaved vegetation such as watercress or other aquatic plants and are often found in pools or near-shore areas with low flow and sand, fine gravel, or organic detritus as substrate (Eberle and Stark 2000; Natureserve 2014a).

The largest threat to this species is groundwater depletion, which is a result of current and likely continuing agricultural irrigation (USFWS 2010a). Habitat can be impacted by alterations in stream flow from invasive vegetation, such as saltcedar (*Tamarix* spp.), through water withdrawals and transpiration, in addition to trapping of floodwater, which decreases water quality and quantity. Water quality is also impacted by waste products from confined-animal feeding operations. An additional threat includes the creation of dams and reservoirs, which can segment drainages, block upstream and downstream movements, and cause population fragmentation (USFWS 2010a).

3.14.2.4.2.2 Arkansas River Shiner

The Arkansas River shiner (*Notropis girardi*) is a threatened species under the ESA. Within the ROI, populations of the Arkansas River shiner may exist within the Cimarron River in Beaver, Harper, Woodward, Major, Kingfisher, Logan, Garfield, and Payne counties in Oklahoma (USFWS 2014c, 2015b). The Cimarron River throughout Beaver, Harper, Woodward, Major, Kingfisher, and Logan counties in Oklahoma is designated critical habitat for the species, subject to protection under the ESA, including a lateral distance of 300 feet on each side of the stream width at bankfull discharge (USFWS 2014c). Figure 3.14-3 in Appendix A shows critical habitat for the Arkansas River Shiner.

The Arkansas River shiner is a small species of minnow that reaches a maximum length of 3 inches (CRMWA 2005; Natureserve 2014b). Its preferred habitat is wide, shallow, unshaded channels of rivers or large streams in the Arkansas River basin with silt and shifting sand bottoms (GIS Data Source: USFWS 2014a; Natureserve 2014b). Adults inhabit areas downstream of sand ridges, and are uncommonly found in quiet pools or backwaters, and are even rarer in deeper tributaries with mud or stone substrates (CRMWA 2005; Natureserve 2014b). Juveniles and larvae inhabit backwater pools, side channels, and island habitat types (GIS Data Source: USFWS 2014a; Natureserve 2014b).

Threats to this species include stream channelization, reservoir construction, streamflow alteration and depletion (from dam construction or invasive species), and possibly water quality degradation. Additional threats include off-road or all-terrain vehicle activity in and near the Cimarron River, as well as predation by introduced game fish (CRMWA 2005).

3.14.2.4.2.3 Ozark Cavefish

The Ozark cavefish (*Amblyopsis rosea*) is a threatened species under the ESA. This species' range is limited to the Springfield Plateau of the Ozark Highlands ecoregion, stretching across southwestern Missouri, northwestern Arkansas, and northeastern Oklahoma. There are 41 active caves and wells found across 10 counties in this ecoregion (USFWS 2011a). Within the ROI, occurrences of this species have not been documented. Known occurrences are north of the ROI in Oklahoma and Arkansas.

The Ozark cavefish is a small, pale, eyeless fish with a low reproductive capacity (Natureserve 2014e). The Boone and Burlington limestone formations of the Springfield Plateau Aquifer are where this species is found (USFWS 2011a). Habitat is restricted to dark caves, sinkholes, springs, or sometimes wells in clear streams with gravel or chert rubble substrates, or pools with silt or sand bottoms (USFWS 2011a; MDC 2014a; Natureserve 2014e). The Ozark cavefish is typically found in areas with the water source upwelling from the groundwater table, and rarely found in cave streams with surface water sources (USFWS 2002). Preferred habitat includes caves where gray bats (*Myotis grisescens*) reside (AGFC 2011a). Bat guano is the main energy and nutrient source for cavefish prey (AGFC 2011a).

Threats to this species include agriculture, urbanization and development, and humans entering bat caves. Additional threats include reservoirs causing cave flooding, cave entrance closures that inhibit bat use, the introduction of predatory game fish, and diminished bat populations due to white-nose syndrome of bats (USFWS 2011a).

3.14.2.4.2.4 Yellowcheek Darter

The yellowcheek darter (*Etheostoma moorei*) is an endangered species under the ESA. Within the ROI, populations of this species may exist in Van Buren and Cleburne counties in Arkansas (77 FR 63604, October 16, 2012). The only currently known population of this species is approximately 10 miles north of the ROI. Although data on movement and dispersal are generally not available (Natureserve 2014l), it is unlikely that the yellowcheek darter occupy aquatic habitat within the ROI because the ROI is approximately 10 miles from the currently known population occurrence. Aquatic habitat that is not occupied and greater than 6 miles away from a known population suggests a low probability of occurrence by the known population (Natureserve 2014l). Fish and aquatic habitat field surveys that assess seasonal changes in habitat would be required to ascertain whether the yellowcheek darter has the potential to occupy habitat within the ROI.

The yellowcheek darter is a small darter with a compressed deep body and a sharp snout (Natureserve 2014l). This species is endemic to only four streams of the Little Red River (77 FR 63604, October 16, 2012). Its preferred habitat is small to medium high-gradient clear headwater streams with high dissolved oxygen levels and gravel, rubble, or boulder bottoms (77 FR 63604; Natureserve 2014l). They are typically found in high gradient riffle areas, with adults occurring at depths of 10 to 20 in and juveniles occurring in shallower riffles (Natureserve 2014l). They are rarely found in pools or water with slower velocity (USFWS 2007a). Spawning occurs in swift, turbulent, riffles under or around large substrate particles (Natureserve 2014l).

Much of the known habitat for this species within the ROI was destroyed in 1962 as a result of the construction of the Greers Ferry Dam, which resulted in a new reservoir, Greers Ferry Lake (USFWS 2008). This limited the species' range to four headwater streams of the Little Red River above Greers Ferry Lake, creating a habitat that is vulnerable to alterations in both physical habitat characteristics and water quality degradation, as a result of gravel mining, unrestricted cattle encroachment, agricultural and recreational water withdrawals, diminishing riparian buffers, road construction and maintenance, and non-point pollution (USFWS 2008). Downstream of the Greers Ferry Lake, the yellowcheek darter was extirpated from portions of the main stem Little Red River because of cold tailwater releases from the dam (77 FR 63604, October 16, 2012). Within two tributaries of the Little Red River below Greers Ferry Dam, extensive sampling resulted in no observations of yellowcheek darter (USFWS 2008). The lack of observations suggests a low probability of occurrence of yellowcheek darter within the portion of the ROI that crosses the Little Red River based on the distance from currently known population occurrence.

3.14.2.4.2.5 Pallid Sturgeon

The pallid sturgeon (*Scaphirhynchus albus*) is an endangered species under the ESA. Within the ROI, this species occurs in the Mississippi River in Arkansas (Mississippi County) and Tennessee (Tipton County) (USFWS 2014c).

The pallid sturgeon is a large fish (up to 66 inches) with a flat, shovel-like snout that inhabits the Mississippi and Missouri river basins from Montana to Louisiana (USFWS 2014a; Natureserve 2014f). It is a large river obligate, occupying turbid free-flowing riverine habitat and occurring in strong currents over a substrate they select on a seasonal basis (EPA 2007; USFWS 2014a; Natureserve 2014f). Sand, gravel, and rocky bottoms are utilized during the winter and spring, while sand bottoms are utilized during the summer and fall (USFWS 2014a).

Threats to this species include river channelization, impoundments, and dam effluence causing altered hydrology, turbidity, and temperature (USFWS 2009a). Another threat is illegal commercial or recreational fishing, which can be a result of misidentification of the species as shovelnose sturgeon (USFWS 2009a). Additional threats include water quality degradation, dredging operations, irrigation diversions, flood control structures, and the potential for entrainment in hydroelectric dam intakes (USFWS 2013).

3.14.2.4.3 Federally Proposed or Listed Aquatic Invertebrates Species

3.14.2.4.3.1 Spectaclecase

The spectaclecase (*Cumberlandia monodonta*) is an endangered species under the ESA (USFWS 2014c). The Mulberry River, which flows generally westward through Johnson and Franklin counties, Arkansas, and is crossed by the ROI in Franklin County, is considered to harbor extant populations of the spectaclecase; however the current status of the species in the Mulberry River is unknown (77 FR 14914, March 13, 2012).

The spectaclecase is a freshwater mussel that occurs in large rivers, inhabiting riverine microhabitats that are sheltered from the current (Natureserve 2014k). In Arkansas, preferred habitat includes rocky microhabitats with ledges; large rocks with voids underneath in a moderate to fast current, on silt or fine gravel substrate; and possibly, large, sunken logs where they are adjacent to or underneath the log (Posey and Irwin 2012).

The most important threat to this species involves changes in hydrological regimes due to dam operations or other water diversion activities (Posey and Irwin 2012). Habitat destruction and modification are detrimental to this species, and may occur due to river channel alteration and maintenance, as well as pollution from municipal and industrial sources (USFWS 2012a). Other threats to this species include mining activities, oil and gas development, sedimentation, altered water temperatures, climate change, population fragmentation or isolation, and the establishment of exotic species (77 FR 14914, March 13, 2012).

3.14.2.4.3.2 Pink Mucket

The pink mucket (*Lampsilis abrupta*) is endangered under the ESA. Within the ROI, this species has been documented in tributaries of the White River in both White and Jackson counties in Arkansas (USFWS 2014c).

The pink mucket is a freshwater mussel that inhabits medium to large rivers with fast-flowing water, and can be found in both deep water and shallow riffles (MDC 2014c; USFWS 1997b; Natureserve 2014g). Preferred substrate includes sand, gravel, and rocky pockets in faster moving water, or sand and mud in slower moving water (Gordon and Layzer 1989).

The most important threat to this species is destruction and modification of habitat (USFWS 1985). Additional threats include river impoundments, gravel mining, channelization related to flood control and navigation, non-point source pollution, and erosion caused by mining, logging, farming, or road construction that adds silt to suitable habitat (MDC 2014c; USFWS 1997b). River impoundments can result in flooding of aquatic habitat, which reduces gravel substrate and limits distribution of fish hosts needed for larval development in the species (USFWS 1985; MDC 2014c). Pollution from agricultural or industrial runoff that contains chemicals and toxic metals that concentrate in body tissues of filter-feeding mussels can result in death (USFWS 1997b). Siltation builds up silt in rivers, which can prevent the mussel from feeding or bury it completely (USFWS 1997b).

3.14.2.4.3.3 Neosho Mucket

The Neosho mucket (*Lampsilis rafinesqueana*) is endangered under the ESA. This species occurs in the Illinois River in Adair County, Oklahoma; however, Adair County is not in the ROI. Within the ROI, it may exist within tributaries of the Illinois River (77 FR 63439, October 16, 2012), including the lower Illinois River below Tenkiller Dam, which is within the ROI in Sequoyah County, Oklahoma (Cumming and Cordiero 2012).

The Neosho mucket is a freshwater mussel that occurs in a wide variety of habits in both small rivers and large streams (Natureserve 2014d). Within the Illinois River in Oklahoma, it is associated with shallow riffles or runs with gravel substrate, and moderate to swift river currents (USFWS 2010b; ODWC 2011a). It can also occur in near-shore areas or other areas outside of the main current in a larger tributary, and has been found in silty, backwater areas (ODWC 2011a; Natureserve 2014d).

The estimated population of this species has a wide range of 10,000 to 100,000 individuals. The population for an 89-kilometer reach of the Illinois River, between the Arkansas-Oklahoma state line, downstream to Lake Tenkiller was estimated to be 500 to 1,000 individuals as of 1997 (Vaughn 1997; 77 FR 63440, October 16, 2012). The designated critical habitat for this species includes the Illinois River in Adair County, Oklahoma (80 FR 24692, April 30, 2015), as well as approximately 483 river miles across Oklahoma, Kansas, Arkansas, and Missouri (80 FR 24692). The species has been extirpated from approximately 62 percent of its historical range (Vaughn 1997; 77 FR 63440).

The most important threat to this species is destruction and modification of habitat. Habitat threats include waterbody impoundments, agricultural pollution, lead and zinc mining, channel instability, and sand and gravel mining (USFWS 2010b). Modifications to hydrology, sedimentation, accidental chemical releases, low-water crossings, or in-channel work could result in impacts to the habitat (USFWS 2010b). At least 11 dams have impounded large portions of the historical range of this species by fragmenting both populations and habitats (USFWS 2010b). Additional threats include the overutilization of the species for commercial, recreational, scientific, and educational reasons; disease; predation; and, the lack of regulatory mechanisms in place to protect this species, which leads to harm by construction, grazing, agriculture, silviculture, and public infrastructure works (USFWS 2010b).

3.14.2.4.3.4 Speckled Pocketbook

The speckled pocketbook (*Lampsilis streckeri*) is endangered under the ESA. It is endemic to the Little Red River system in north-central Arkansas (USFWS 2007a). Within the ROI, the species' range includes Van Buren, Pope, Cleburne, and White counties in Arkansas (USFWS 2014c).

The speckled pocketbook is a freshwater mussel that occupies sections of river with clear, constantly flowing water and a substrate ranging from coarse to muddy sand or gravel bottoms, in depths up to half a meter (USFWS 2007a; Natureserve 2014j). Another habitat type would be pools with crevices between large rocks or boulders with some accumulation of sand and gravel (USFWS 2007a).

The most important threat to this species is habitat degradation related to gravel mining, unrestricted cattle access in streams, water withdrawal for agricultural or recreational purposes, a paucity of riparian buffers, construction or maintenance of state and county roads, and non-point source pollution (USFWS 2007b). An additional threat could be drought, which can result in dried riffle habitats, thereby reducing habitat availability (USFWS 2014c). Drought can be exacerbated by both manmade changes to stream channels for flood control and stress caused by low stream flows increasing susceptibility to diseases and isolating gene pools (USFWS 2014b). This species is also preyed on by muskrats and turtles (USFWS 2007a). In addition, a more recent threat in the Little Red River system stems from the large amounts of water needed for fracturing shale during well drilling in the Fayetteville Shale, an unconventional natural gas reservoir on the Arkansas side of the Arkoma Basin (USFWS 2007b). The entire Little River watershed and nearly one-quarter of the state of Arkansas lie within the Arkoma Basin (USFWS 2007b).

3.14.2.4.3.5 Scaleshell Mussel

The scaleshell mussel (*Leptodea leptodon*) is endangered under the ESA. This species' range overlaps the ROI in Crawford, Cross, Franklin, and Jackson counties in Arkansas (USFWS 2014c, 2015b).

The scaleshell mussel is a freshwater mussel occurring in medium to large rivers with low to medium gradients and good water quality, preferably in stretches with stable channels (75 FR 17758, April 7, 2010; Natureserve 2014i). Preferred habitat includes riffles or runs with a moderate current velocity and mud or gravel substrate (75 FR 17758).

Threats to this species include water quality degradation, sedimentation, habitat destruction, and channel destabilization (75 FR 17758). Introduction of an invasive species, the zebra mussel (*Dreissena polymorpha*), along with the short life span of this species, make it vulnerable to man-made changes in the environment (75 FR 17758). These man-made changes include habitat alteration due to dam construction, resource extraction activities, confined animal operations and grazing, non-point source pollution from agriculture, and sedimentation resulting from forestry practices and road construction activities (MDC 2014d).

3.14.2.4.3.6 Fat Pocketbook

The fat pocketbook (*Potamilus capax)* is endangered under the ESA. Within the ROI, this species occurs in tributaries and drainage ditches of the St. Francis River Basin in White, Poinsett, Cross, and Mississippi counties in Arkansas (USFWS 2014c). The current distribution of the species includes that portion of the White River in White County, Arkansas, that is within the ROI (USFWS 2012b; Natureserve 2014c).

The fat pocketbook is a freshwater mussel found in fine-grained substrates such as sand, silt, and clay in large rivers with flowing water in a wide range of depths (USFWS 1989; Natureserve 2014c). It also inhabits slow-moving water in man-made ditches, bayous, sloughs, and streams, often found near the bank in mud or sand substrate in the St. Francis watershed (AGFC 2011b; Natureserve 2014c). Given the thin shell on this species, it can inhabit deep deposits of fine-grained silt, but not gravel substrate in highly erosive flow areas (Miller and Payne 2005).

The most important threat to this species is the destruction and modification of habitat (USFWS 2009b). Habitat threats include waterbody impoundments and channelization due to flood control and navigation practices (USFWS 2009b). In addition, habitat or population fragmentation as a result of human disturbance makes populations vulnerable to drought, non-point source pollution, and chemical spills (USFWS 2009b). Additional threats include construction and operation of hydropower generation facilities, siltation, turbidity, water quality degradation from both non-point and point pollution sources, competition from invasive species (e.g., zebra mussels), climate change, and the decline of host fish populations from channel dredging (USFWS 2012b).

3.14.2.4.3.7 Rabbitsfoot

The rabbitsfoot mussel (*Quadrula cylindrica cylindrica*) is threatened under the ESA. Within the ROI, this species exists in the White River and its tributaries in Van Buren, White, Jackson, and Cleburne counties in Arkansas (USFWS 2014c). The Little Red River in Cleburne and Van Buren counties and the White River through Woodruff, Jackson, White, and Independence counties are designated critical habitat for the species (80 FR 24692, April 30, 2015). In addition, the White River is proposed critical habitat for the species, specifically within the ROI (USFWS 2014c).

The rabbitsfoot mussel is a freshwater mussel that inhabits small to medium rivers with moderate to swift currents in sand or gravel substrate (Natureserve 2014h). Preferred habitat is the shallower water along banks and adjacent runs or shoals where flow rate is relatively low and substrate includes gravel or sand (77 FR 63439, October 16, 2012). It can also be found in smaller streams, inhabiting bars or gravel and cobble close to the current (Natureserve 2014h). It has been found in deeper water runs with depths of 3 meters (77 FR 63439; Natureserve 2014h).Threats to this species include activities related to habitat alteration (impoundments, dredging, channelization) and habitat degradation (chemical contamination, mining, sedimentation, oil and gas development) (77 FR 63439). The most important threat of these is the creation of impoundments or dams, which can alter river flow, increase or trap silt loads, alter the water quality or temperature, and cause isolation of populations (77 FR 63439). All of these potential alterations can affect the feeding and reproduction of this species as well.

3.14.2.4.3.8 Curtis' Pearlymussel

The Curtis' pearlymussel (*Epioblasma florentina curtisii)* is listed as endangered under the ESA (41 FR 24062, June 14, 1976). No critical habitat has been designated. This species is not currently known to occur in the ROI but historically occurred in the White River drainages (e.g., White River, south Fork Spring River, Black River, Little Black River) (USFWS 2010c), which the Project crosses in Jackson County, Arkansas. In the last 30 years it was known to be present in Fulton County, Arkansas, north of the ROI (USFWS 1986, 1997a). But extensive surveys in Arkansas from 1996 to 2006 did not find any specimens in 11 streams sampled (Harris et al. 2007) and it is possible the species has been extirpated from Arkansas (NatureServe 2014p).

Suitable habitat within the basin locations of Curtis' pearlymussel is in silt-free streams between headwaters and lowlands. Habitat is generally stream riffles or runs within this basin area, with preferred habitat of sand- to gravel-dominated substrate where individuals position themselves between cobbles and boulders in water 2 to 30 inches deep (USFWS 1986, 1997a). They remain buried in the substrate except during spring, when ripe females move to the substrate surface.

Because of their need for shallow fast-flowing water, the greatest threat to this species has been river impoundments, channelization and dredging (USFWS 1986, 2010c, 2007a; MDC 2000). These actions have caused direct mussel removal, habitat inundation and destabilization, and modified flow regime. Typical development-induced water quality degradation, such as point and non-point pollution, are also hazards. Invasive non-native species (e.g., zebra mussels) may also cause limitations if they occur in their habitat.

3.14.2.4.3.9 Fanshell

The Fanshell (*Cyprogenia stegaria)* is listed as endangered under the ESA (USFWS 2015b) and is known or assumed to occur in multiple states in the Midwest (i.e., Alabama, Illinois, Indiana, Kentucky, Ohio, Tennessee, Virginia, and West Virginia). In addition, the species is listed on the USFWS (2015b) list for the state of Arkansas. The University of Michigan's Museum of Zoology (2015) lists two specimen collections from the 1930s as having come from the St. Francis River in Cross County and the White River in Jackson County.

3.14.2.4.3.10 Snuffbox

The snuffbox (*Epioblasma triquetra)* is listed as endangered under the ESA (77 FR 8631, February 14, 2012). No critical habitat has been designated. Within the ROI, this species has the potential to occur in perennial streams in Pope, Poinsett, Cross, and Mississippi counties, Arkansas. The USFWS (2015b) lists the species as occurring in 13

Arkansas counties (Baxter, Boone, Clay, Fulton, Greene, Lawrence, Madison, Marion, Newton, Pope, Randolph, Sharp, Stone), only one of which, Pope, is crossed by the ROI. In addition, information provided by the USFWS (2014b) indicates that the species may occur within the ROI in Pope County. Furthermore, the Natureserve watershed based assessment indicates that watersheds within Poinsett, Cross, and Mississippi counties are within the current distribution of the species (NatureServe 2014). Some major rivers north of the Project in Arkansas (e.g. Buffalo River, Strawberry River, and Spring River) have been documented to contain this species (77 FR 8631).

Typical habitat includes fast water riffles in small to medium size streams in water two inches to two feet deep in clear water systems. Substrate ranges from sandy to rocky bottoms. Other than during spawning adults burrow deep into the substrate (77 FR 8631).

The major important threat to this species is the destruction and modification of habitat (Bruenderman et al. 2002; 77 FR 8631, February 14, 2012.). Specific habitat threats include poor water quality, channelization, sand and gravel mining, dredging, sedimentation and impoundments (Bruenderman et al. 2002; 77 FR 8631). Impoundments have effects on both substrate and temperature, which can adversely affect habitat suitability. Construction in or near streams may increase sedimentation, which may affect the suitability of habitat, affect feeding, and can including burial of individuals (Bruenderman et al. 2002; 77 FR 8631). Adverse modification of in-stream flow conditions (e.g., dewatering) may also occur from in-stream construction on a local basis (USFWS 2014d).

3.14.2.4.4 Federally Proposed or Listed Amphibian Species

3.14.2.4.4.1 Ozark Hellbender

The Ozark hellbender (*Cryptobranchus alleganiensis bishopi)* is listed as endangered under the ESA (76 FR 61956, October 6, 2011). No critical habitat has been designated. This species is a large salamander native to the White River drainage in southern Missouri and northern Arkansas (USFWS 2012d, MDC 2014b). They are known to be present in the White River, with the only documented occurrences located in Baxter and Independence counties; both of which occur upstream of the ROI crossing of the White River (which is located in Jackson County) (USFWS 2015b). Viability of populations in the White River system is unknown because much of their habitat was modified by the construction of dams on the Upper White River and records of individuals in this system may be relics separated from North Fork White River populations by the Norfork Reservoir (76 FR 61956).

This salamander requires well oxygenated flowing water of cool temperatures to survive (76 FR 61956). Because they acclimate slowly to temperature changes, they require consistent temperatures often in spring feed streams. Typical adult habitat includes deep (3 to 10 feet deep) fast flowing water where they reside under large flat limestone or dolomite rocks (Johnson 2000; USFWS 2011b; MDC 2014b; 76 FR 61956). Large and small rocks may be used for cover by larvae and juveniles in gravel substrate streams (USFWS 2011b). The territory they occupy in streams is small, and ranges from 92 to 266 square feet in size (Peterson and Wilkinson 1996; 76 FR 61956).

Because they are habitat specialists, the greatest threat to their survival is modification of flowing stream habitat primarily from dam construction and reservoir formation (76 FR 61956). Dam construction changes the water temperature regime and flowing water conditions required for their survival and the stream barrier fragments and isolates populations (76 FR 61956). Because they are habitat specialists, even small modifications to water conditions may affect survival. Other impacts to this species include mine development, turbidity, bank erosion, siltation, and food source (e.g., crayfish) contamination from metals or other toxics. Typical water quality changes resulting from agricultural fertilizer use, and logging can also have adverse effects (76 FR 61956). Recreational vehicle use in streams and active collection of this species (both permitted an unpermitted) also play a role in impacts to their survival (USFWS 2011b; 76 FR 61956). Additional threats include disease (e.g., chytrid fungus), and predation by non-native fish species, such as rainbow trout (USFWS 2011b; 76 FR 61956).

3.14.2.4.5 State Designations for Aquatic Species

In addition to federally listed, proposed, or candidate special status fish, aquatic invertebrate, and amphibian species, three species of aquatic wildlife with state-level designations have the potential to occur within the ROI. Oklahoma has two listed fish and Tennessee has one listed fish. Arkansas recognizes the federally listed species, but has no additional species with state level designations that have the potential to occur within the ROI. Texas has no state-designated aquatic wildlife. The state-designated aquatic wildlife of Oklahoma and Tennessee that could potentially occur in the ROI are summarized in Table 3.14.2-4.

Table 3.14.2-4:
State Designated Threatened and Endangered Aquatic Wildlife Species by State, County, and Region

Common Name	Scientific Name	State Status	County	Region
Oklahoma: Fish				
Black-sided darter	*Percina maculata*	State Threatened	Sequoyah	4
Long-nosed darter	*Percina nasuta*	State Endangered	Sequoyah	4
Arkansas: None[1]				
Tennessee: Fish				
Blue sucker	*Cycleptus elongatus*	State Threatened	Tipton and Shelby	7
Texas: None				

1 Arkansas recognizes the federally listed species, but no additional species are considered state listed within the ROI. Federally designated species are provided in Table 3.14.2-3.

Sources: ODWC (2014), ANHC (2014), TDEC (2014), TPWD (2014)

3.14.2.5 Regional Description

As discussed above, there are 16 federally listed, proposed, or candidate fish, aquatic invertebrate, and amphibian species and three state designated aquatic wildlife species known to occur or have the potential to occur within the ROI. A summary of the federally listed, proposed, or candidate fish, aquatic invertebrates, and amphibian species and USFWS-designated critical habitat occurrence by Project region is provided in the sections below. Information from ANHC Natural Areas and Focal Areas and state natural heritage program species occurrence records, including related waterbodies found by Project region, are included in Table 3.14.2-5.

Table 3.14.2-5:
State Natural Heritage Occurrences within the ROI or Waterbodies Crossed by the ROI

Common Name	Scientific Name	State Rank[1] or Status[2]	Waterbody	Project Region
Oklahoma				
Fish				
Arkansas River shiner	*Notropis girardi*	S1 / ST	Beaver River, Palo Duro Creek, Kiowa Creek, Coldwater Creek, and Cimarron River	1, 2, 3
Long-nosed darter	*Percina nasuta*	S1 / SE	Lee Creek	4

Table 3.14.2-5:
State Natural Heritage Occurrences within the ROI or Waterbodies Crossed by the ROI

Common Name	Scientific Name	State Rank[1] or Status[2]	Waterbody	Project Region
Arkansas				
Fish				
Long-nosed darter	*Percina nasuta*	S2 / INV	Mulberry River[4], Lee Creek[5], Frog Bayou[5], Illinois Bayou Drainage[5], and White River[5]	4, 5
Aquatic Invertebrates				
Speckled pocketbook[3]	*Lampsilis streckeri*	S1 /SE	Big Creek	5
Fat pocketbook[3]	*Potamilus capax*	S1 / SE	St. Francis floodway ditch[4,5], St. Francis River[5], Tyronza River[5], and White River	6, 7
Pink mucket[3]	*Lampsilis abrupta*	S2 /SE	White River[4,5]	5
Rabbitsfoot[3]	*Quadrula cylindrica*	S2 / ST	White River[4]	5
Scaleshell[3]	*Leptodea leptodon*	S1 / SE	Frog Bayou[5], Mulberry River, and White River	4
Snuffbox	*Epioblasma triquetra*	S1 / SC	Perennial streams in designated counties	4, 5, 6, 7
Curtis' pearlymussel	*Epioblasma florentina curtisii*	S1 / SE	White River[6]	5
Amphibians				
Ozark hellbender	*Cryptobranchus alleganiensis bishopi*	S2 / SC	White River	5
Tennessee				
Fish				
Blue sucker	*Cycleptus elongatus*	S2 / ST	Mississippi River	7
Texas				
None				

1 State rank is a conservation rank used by State Heritage Programs and The Nature Conservancy that indicates the relative rarity of and element throughout the state. S1 = Critically imperiled; S2 = Imperiled; S3 = Vulnerable; S4 = Apparently secure; S5 = Secure in the state
2 State status: INV = Inventory Element; SC= Species of Concern, SE = State Endangered; ST = State Threatened.
3 Species has a federal designation, see *Federal Designations* within this section.
4 Occurrence element located within the ROI.
5 Occurrence element located outside the ROI, but within a waterbody that is crossed by the Project.
6 Historical occurrence in this river system but not documented since the 1990s.
Sources: ODWC (2014), ANHC (2014), TDEC (2014), TPWD (2014), AGFC (2013), USFWS (2015b)

3.14.2.5.1 Region 1

The ROI in Region 1 is referred to as the Oklahoma Panhandle Region and includes the Applicant Proposed Route, HVDC Alternative Routes I-A through I-D, Oklahoma converter station and AC interconnection, and the AC collection system. In the ROI in Region 1, there is one federally threatened fish (Arkansas River shiner) and one fish that is a candidate for listing (Arkansas darter). There are documented occurrences of both the Arkansas darter and the Arkansas River shiner within the Oklahoma portion of the ROI. There are no special status species found within the Texas portion of the ROI.

Populations of the Arkansas River shiner may exist within the ROI in the Cimarron River in Beaver, Harper, and Woodward counties in Region 1. Designated critical habitat for the Arkansas River shiner includes portions of the

Cimarron River in Oklahoma (USFWS 2014c). Critical habitat units for this species are located in Beaver, Harper, and Woodward counties in Oklahoma, but these critical habitat units do not occur within the ROI (USFWS 2014c).

Populations of the Arkansas darter may exist within the ROI in the Cimarron River in Beaver, Harper, and Woodward counties in Region 1.

No route variations were proposed in Region 1.

3.14.2.5.1.1 AC Collection System

The AC collection system consists of thirteen 2-mile-wide routes in Oklahoma (Beaver, Cimarron, and Texas counties) and Texas (Hansford, Ochiltree, and Sherman counties) within which an AC collection system transmission line could be sited. Within this area, the AC collection system routes cross the Beaver River, Palo Duro Creek, Dry Sand Draw, Coldwater (Frisco) Creek, North Frisco Creek, Dry Creek, Peacher Creek, and Hackberry Creek. Floodplains in the ROI are discussed in Section 3.19. Of these waterbodies that are crossed, the Beaver River and Palo Duro Creek may have populations of the Arkansas River shiner that may exist within the ROI for the AC collection system.

3.14.2.5.2 Region 2

Region 2 is referred to as the Oklahoma Central Great Plains Region and includes the Applicant Proposed Route and HVDC Alternative Routes 2-A and 2-B. In the ROI in Region 2, there is one federally threatened fish (Arkansas River shiner) and one fish that is a candidate for listing (Arkansas darter). There are documented occurrences of both the Arkansas darter and the Arkansas River shiner within the Oklahoma portion of the ROI.

Populations of the Arkansas River shiner may exist within the ROI in the Cimarron River in Woodward and Major counties in Region 2. Designated critical habitat for the Arkansas River shiner includes portions of the Canadian River and portions of the Cimarron River, both in Oklahoma within the ROI (USFWS 2014c). Critical habitat units for this species are located in Woodward and Major counties within the ROI in Oklahoma (USFWS 2014c).

Populations of the Arkansas darter may exist within the ROI in the Cimarron River in Woodward County of Region 2.

Two route variations to the Applicant Proposed Route were developed in Region 2 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.2. The variations are illustrated in Exhibit 1 of Appendix M. These variations represent minor adjustments to the Applicant Proposed Route. Link 1, Variation 1, as well as Link 2, Variation 2, would cross through the same types of wetlands and habitat as the original Applicant Proposed Route Links 1 and 2.

3.14.2.5.3 Region 3

Region 3 is referred to as the Oklahoma Cross Timbers Region and includes the Applicant Proposed Route and HVDC Alternative Routes 3-A through 3-E. In the ROI in Region 3, there is one federally threatened fish (Arkansas River shiner) and one fish found north of the ROI (Arkansas darter). There are documented occurrences of the Arkansas River shiner within the Oklahoma portion of the ROI.

Populations of the Arkansas River shiner may exist within the ROI in the Cimarron River in Kingfisher and Logan counties in Region 3. Designated critical habitat for the Arkansas River shiner includes portions of the Canadian

River in Oklahoma and portions of the Cimarron River in Oklahoma (USFWS 2014c). Critical habitat units for this species are located in Kingfisher and Logan counties within the Oklahoma portion of the ROI (USFWS 2014c).

Habitat exists for the Arkansas Darter in the Neosho River, as well as associated tributaries, just north of the ROI in Region 3.

Five route variations to the Applicant Proposed Route were developed in Region 3 in response to public comments on the Draft EIS. The route variations are described in Exhibit 1 of Appendix M and summarized in Section 2.4.2.3. These variations represent minor adjustments to the Applicant Proposed Route. Links 1 and 2, Variation 1; Link 1, Variation 2; Link 4, Variation 1; and Link 5, Variation 2, would cross through the same types of wetlands and habitats as the original Applicant Proposed Route Links 1, 2, 4, and 5. The number of waterbodies crossed decreases from three to none in Links 1 and 2, Variation 1, while the number of waterbodies crossed increases from one to two in the Link 1, Variation 2, compared to the original links of the Applicant Proposed Route.

3.14.2.5.4 Region 4

Region 4 is referred to as the Arkansas River Valley Region and includes the Applicant Proposed Route, including the Lee Creek Variation, and HVDC Alternative Routes 4-A through 4-E. In the ROI for Region 4, there are five federally endangered species of aquatic invertebrates (Neosho mucket, spectaclecase, speckled pocketbook, scaleshell mussel, and snuffbox), one candidate fish (Arkansas darter), and one federally endangered fish (Ozark cavefish) found north of the ROI.

In Adair County, Oklahoma, the Neosho mucket is found north of the ROI where there is also proposed critical habitat for this species (USFWS 2014c). Although the ROI crosses just south of Adair County, tributaries of the Illinois River may flow within the ROI.

There are documented occurrences of the scaleshell mussel, the speckled pocketbook, spectaclecase, and the snuffbox within the Arkansas portion of Region 4. The scaleshell mussel has been documented in the ROI in Crawford and Franklin counties. The speckled pocketbook has a range that includes Van Buren, Pope, Cleburne, and White counties in the Little Red River basin in Arkansas. The spectaclecase has been documented in Johnson County, within the ROI. The snuffbox has been documented in streams of Pope County of region 4, and may occur in the ROI.

Habitat exists for the Arkansas Darter in the Neosho and Spring rivers, as well as associated tributaries, just north of the ROI in Region 4.

Known or potential occurrences of the Ozark cavefish occur north of Region 4 in Benton and Madison counties in Arkansas and Ottawa, Delaware, and Mayes counties in Oklahoma.

Seven route variations to the Applicant Proposed Route were developed in Region 4 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.4. The variations are illustrated in Exhibit 1 of Appendix M. These variations represent minor adjustments to the Applicant Proposed Route. Link 3, Variation 1; Link 3, Variation 3, Link 6, Variation 1; Link 6, Variation 2; Link 6, Variation 3; and Link 9, Variation 1, would cross through the same types of wetlands and habitats as the original Applicant Proposed Route Links 3, 6, and 9. The Link 3, Variation 2, would parallel almost four times the length of existing infrastructure as the original Applicant Proposed Route Link 3, and it would cross through areas that contain fewer wetland and waterbody features than the original Applicant Proposed Route.

3.14.2.5.5 Region 5

Region 5 is referred to as the Central Arkansas Region and includes the Applicant Proposed Route and HVDC Alternative Routes 5-A through 5-F. In the ROI in Region 5, there are eight federally endangered species, the yellowcheek darter, the scaleshell mussel, the speckled pocketbook, the pink mucket, the fat pocketbook, the snuffbox, Curtis' pearlymussel, and the Ozark hellbender. Within the Arkansas portion of Region 5, all eight species occur or have the potential to occur. In addition, documented occurrences of the rabbitsfoot, a federally threatened species, occur within the ROI.

The yellowcheek darter's only currently known populations are located 10 miles to the north of ROI in Region 5, but populations may potentially occur in Van Buren and Cleburne counties in tributaries of the Little Red River. Much of their habitat was previously destroyed in these counties, but there is a potential that populations persist.

The scaleshell mussel range overlaps with the ROI in White and Jackson counties. The speckled pocketbook is only found in the Little Red River basin, which covers Pope, Van Buren, Cleburne, and White counties. The pink mucket is found within the ROI in Region 5, with documented occurrences in the tributaries of the White River in both White and Jackson counties in Arkansas. The fat pocketbook occurs within the ROI of the White River in White County in Arkansas. The snuffbox has been documented in streams of Pope County of Region 5, and may occur in the ROI. The Curtis' pearlymussel historically was in the White River system that is crossed by the Project in Jackson County. The salamander (Ozark hellbender) has been documented in the White River in Jackson County, and may occur in the ROI of the White River crossing.

The rabbitsfoot is also found within the ROI in Region 5, with known and potential occurrences in the tributaries of the White River in Van Buren, White, and Jackson counties in Arkansas. Proposed critical habitat for this species occurs in the White River in Van Buren, White, and Jackson counties (USFWS 2014c).

Five route variations to the Applicant Proposed Route were developed in Region 5 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.5. The variations are illustrated in Exhibit 1 of Appendix M. These variations represent minor adjustments to the Applicant Proposed Route. Link 1, Variation 2; Link 2, Variation 2; Links 2 and 3, Variation 1; Links 3 and 4, Variation 2; and Link 7, Variation 1, would cross the same types of wetlands and habitats as the original links of the Applicant Proposed Route.

3.14.2.5.6 Region 6

Region 6 is referred to as the Cache River and Crowley's Ridge Region and includes the Applicant Proposed Route and HVDC Alternative Routes 6-A through 6-D. In the ROI in Region 6, there are four federally endangered species (pink mucket, scaleshell mussel, fat pocketbook, and the snuffbox) and one federally threatened species (rabbitsfoot).

The pink mucket is found within the ROI in Region 6, with documented occurrences in the tributaries of the White River in Jackson County in Arkansas. The scaleshell mussel has been documented within the ROI in Jackson

County. The fat pocketbook occurs within the ROI in tributaries and drainage ditches of the St. Francis River in Poinsett County in Arkansas.

The rabbitsfoot is also found within the ROI in the Arkansas portion of Region 6, with documented occurrences in the White River in Jackson County. The snuffbox has been documented in streams of Poinsett and Cross counties of Region 6, and may occur in the ROI.

One route variation to the Applicant Proposed Route in Region 6 (i.e., Applicant Proposed Route Link 2, Variation 1) was developed in response to public comments on the Draft EIS. This route variation is described in Appendix M and summarized in Section 2.4.2.6. The variation is illustrated in Exhibit 1 of Appendix M. This variation represents a minor adjustment to the Applicant Proposed Route. Link 2, Variation 1, would cross through the same types of wetlands and habitats as the original Applicant Proposed Route Link 2 and includes increased acreage of forested wetland habitat.

3.14.2.5.7 Region 7

Region 7 is referred to as the Arkansas Mississippi River Delta and Tennessee Region and includes the Applicant Proposed Route and HVDC Alternative Routes 7-A through 7-D. In the ROI in Region 7, there are three federally endangered species (the pallid sturgeon, pocketbook, and the snuffbox).

The pallid sturgeon occurs within the ROI along the Mississippi River in Mississippi County in Arkansas and three counties in Tennessee (Lauderdale, Shelby, and Tipton).

The fat pocketbook occurs within the ROI in tributaries and drainage ditches of the St. Francis River in Poinsett and Mississippi counties in Arkansas. The snuffbox has been documented in streams of Poinsett and Mississippi counties of Region 7, and may occur in the ROI.

Three route variations to the Applicant Proposed Route were developed in Region 7 in response to public comments on the Draft EIS. The route variations are described in Exhibit 1 of Appendix M and summarized in Section 2.4.2.7. Link 1, Variation 1; Link 1, Variation 2; and Link 5, Variation 1, would cross through the same types of wetlands and habitats as the original Applicant Proposed Route Links 1 and 5. The number of waterbodies crossed potentially decreased by two in the Applicant Proposed Route Link 1, Variation 2.

3.14.2.6 Connected Actions

3.14.2.6.1 Wind Energy Generation

Wind energy generation would likely occur within WDZs. Two federally designated special status aquatic species potentially occur within the WDZs, the Arkansas darter (a candidate species) and the Arkansas River shiner (a threatened species). Both species occur in Beaver County, Oklahoma. USFWS-designated critical habitat for these species is not located within any WDZs. No aquatic wildlife species with state designations are known to occur within any WDZs.

The Arkansas darter may occur within WDZ-G. Habitat exists for this species in the Cimarron River and its tributaries. Section 3.14.2.4.2 includes a more detailed description of this species and its habitat.

The Arkansas River shiner may occur within WDZ-G. Habitat exists for this species in the Cimarron River and its tributaries. Section 3.14.2.4.2 includes a more detailed description of this species and its habitat.

No Oklahoma or Texas state-listed aquatic wildlife species are known to occur within the WDZs.

3.14.2.6.2 Optima Substation

The future Optima Substation would be constructed within a 160-acre site that is mostly grassland/herbaceous land cover with smaller areas of shrub/scrub and developed open space. Because there are no waterbodies within the future Optima Substation site, there are no likely occurrences of special status fish, aquatic invertebrate, and amphibian species.

3.14.2.6.3 TVA Upgrades

The ROI for the direct assignment facilities (which are included in the Applicant Proposed Project) would occur within the Tennessee Converter Station Siting Area and more specifically within the Shelby Substation. The ROI for the network upgrades, and in particular TVA's future 500kV transmission line, cannot be fully determined at this time. The new 500kV line would be in western Tennessee. The upgrades to existing facilities would mostly be in western and central Tennessee. Upgrades to existing infrastructure would include upgrading terminal equipment at three existing 500kV substations and six existing 161kV substations, making appropriate upgrades to increase heights on 16 existing 161kV transmission lines to increase line ratings, and replacing the conductors on eight existing 161kV transmission lines. Where possible, general impacts associated with the required TVA upgrades are discussed in the impact sections that follow.

3.14.2.7 Impacts to Special Status Fish, Aquatic Invertebrate, and Amphibian Species

3.14.2.7.1 Methodology

The methodology for evaluating impacts on fish, aquatic invertebrate, and amphibian species included comparisons of impacts of the Applicant Proposed Route to impacts of the HVDC alternative routes. Within the ROI, Project activities were assessed that could potentially impact special status fish, aquatic invertebrate, and amphibian species and their habitats. Fish, aquatic invertebrate, and amphibian resources to be evaluated include river, stream, or creek crossings, as well as any perennial waterbodies that fall within the ROI. Potential impacts on fish, aquatic invertebrate, and amphibian resources include the following, and are further discussed for each phase of the Project:

- Potential impacts from permanent removal of terrestrial vegetation, or temporary mechanical damage to terrestrial vegetation
- Possible spread and/or introduction of invasive plants or listed noxious weed species
- Potential impacts associated with ROW vegetation maintenance, including the use of herbicides on terrestrial vegetation during operations and maintenance of the Project
- Potential disturbance to known populations and/or suitable habitat for species designated as candidate, threatened, or endangered under the ESA
- Potential disturbance to known populations of state-listed species of concern
- Potential impacts from construction and maintenance of roads and road crossings
- Potential for sediment loading and introduction of chemicals from spills in aquatic habitat

Sixteen federally listed fish, aquatic invertebrate, and amphibian species may occur in waterbodies located within the ROI or close enough that the warrant inclusion in the discussion on impacts. Two fish are listed as endangered under the ESA, two fish listed as threatened, and one fish that is a candidate for listing. Eight mussels are listed as endangered under the ESA and one mussel is listed as threatened. One salamander is listed as endangered under the ESA.

The Applicant has developed a comprehensive list of EPMs that would cover the protection measures intended to avoid or minimize impacts to special status fish, aquatic invertebrate, and amphibian species. Implementation of these EPMs is assumed throughout the impact analysis that follows for the Project. A complete list of EPMs for the Project is provided in Appendix F; those EPMs that would specifically minimize the potential for impacts on special status fish, aquatic invertebrate, and amphibian species are described below:

General EPMs for the Project that relate to special status fish and aquatic resources:

- GE-1: Clean Line will train personnel on health, safety, and environmental matters. Training will include practices, techniques, and protocols required by federal and state regulations and applicable permits.
- GE-3: Clean Line will minimize clearing vegetation within the ROW, consistent with a TVMP filed with NERC, and applicable federal, state, and local regulations. The TVMP may require additional analysis under NEPA depending on whether and under what conditions DOE decides to participate in the Project.
- GE-5: Any herbicides used during construction and operations and maintenance will be applied according to label instructions and any federal, state, and local regulations.
- GE-7: Roads not otherwise needed for maintenance and operations will be restored to preconstruction conditions. Restoration practices may include decompacting, recontouring, and re-seeding. Roads needed for maintenance and operations will be retained.
- GE-9: Clean Line will avoid and/or minimize damage to drainage features and other improvements such as ditches, culverts, levees, tiles, and terraces; however, if these features or improvements are inadvertently damaged, they will be repaired and or restored.
- GE-10: Clean Line will work with landowners to repair damage caused by construction, operation, or maintenance activities of the Project. Repairs will take place in a timely manner, weather and landowner permitting.
- GE-11: Clean Line will conduct construction, operation, and maintenance activities to minimize the creation of dust. This may include measures such as limitations on equipment, speed, and/or travel routes utilized. Water, dust palliative, gravel, combinations of these, or similar control measures may be used. Clean Line will implement measures to minimize the transfer of mud onto public roads.
- GE-13: Emergency and spill response equipment will be kept on hand during construction.
- GE-14: Clean Line will restrict the refueling and maintenance of vehicles and the storage of fuels and hazardous chemicals within at least 100 feet from wetlands, surface waterbodies, and groundwater wells, or as otherwise required by federal, state, or local regulations.
- GE-15: Waste generated during construction or maintenance, including solid waste, petroleum waste, and any potentially hazardous materials will be removed and taken to an authorized disposal facility.
- GE-21: Clean Line will maintain construction equipment in good working order. Equipment and vehicles that show excessive emissions of exhaust gases and particulates due to poor engine adjustments or other inefficient operating conditions will be repaired or adjusted.

- GE-27: Clean Line will minimize compaction of soils and rutting through appropriate use of construction equipment (e.g., low ground pressure equipment and temporary equipment mats).
- GE-28: Hazardous materials and chemicals will be transported, stored, and disposed of according to federal, state, or local regulations or permit requirements.
- GE-30: Clean Line will minimize the amount of time that any excavations remain open.

Fish, vegetation, and wildlife EPMs have been developed for the Project; the following EPMs relate specifically to special status fish and aquatic resources:

- FVW-1: Clean Line will identify environmentally sensitive vegetation (e.g., wetlands, protected plant species, riparian areas, large contiguous tracts of native prairie) and avoid and/or minimize impacts to these areas.
- FVW-2: Clean Line will identify and implement measures to control and minimize the spread of non-native invasive species and noxious weeds.
- FVW-3: Clean Line will clearly demarcate boundaries of environmentally sensitive areas during construction to increase visibility to construction crews.
- FVW-4: If construction- and/or decommissioning-related activities occur during the migratory bird breeding season, Clean Line will work with USFWS to identify migratory species of concern and conduct pre-construction surveys for active nests for such species. Clean Line will consult with USFWS and/or other resource agencies for guidance on seasonal and/or spatial restrictions designed to avoid and/or minimize adverse effects.
- FVW-5: If construction occurs during important time periods (e.g., breeding, migration, etc.) or at close distances to environmentally sensitive areas with vegetation, wildlife, or aquatic resources, Clean Line will consult with USFWS and/or other resource agencies for guidance on seasonal and/or spatial restrictions designed to avoid and/or minimize adverse effects.

Water EPMs have been developed for the Project; the following EPMs relate specifically to special status fish and aquatic resources:

- W-1: Clean Line will avoid and/or minimize construction of access roads in special interest waters.
- W-2: Clean Line will identify, avoid, and/or minimize adverse effects to wetlands and waterbodies. Clean Line will not place structure foundations within the Ordinary High Water Mark of Waters of the United States.
- W-3: Clean Line will establish streamside management zones within 50 feet of both sides of intermittent and perennial streams and along margins of bodies of open water where removal of low-lying vegetation is minimized.
- W-4: If used, Clean Line will selectively apply herbicides within streamside management zones.
- W-5: Clean Line will construct access roads to minimize disruption of natural drainage patterns including perennial, intermittent, and ephemeral streams.
- W-6: Clean Line will not construct counterpoise or fiber optic cable trenches across waterbodies.
- W-7: Dewatering will be conducted in a manner designed to prevent soil erosion (e.g., through discharge of water to vegetated areas and/or the use of flow control devices).

One EPM that is specifically applicable to the Ozark cavefish:

- FVW-6: Clean Line will avoid and/or minimize construction within 300 feet of caves known to be occupied by threatened or endangered species.

In addition, the following plans will be developed and implemented by the Applicant to avoid or minimize impacts:

- Blasting Plan: This plan will describe measures designed to minimize adverse effects due to blasting.
- Restoration Plan: This plan will describe post-construction activities to reclaim disturbed areas.
- Spill Prevention, Control and Countermeasures (SPCC) Plan: This plan describes the measures designed to prevent, control, and clean up spills of hazardous materials.
- Storm Water Pollution Prevention Plan (SWPPP): This plan, consistent with federal and state regulations, will describe the practices, measures, and monitoring programs to control sedimentation, erosion, and runoff from disturbed areas.
- Transmission Vegetation Management Plan (TVMP): This plan would be developed and implemented pursuant to the North American Electric Reliability Corporation (NERC) Reliability Standard FAC-003 and will describe how Clean Line will conduct work on its right-of-way to prevent outages due to vegetation. The TVMP may require additional analysis under NEPA depending on whether and under what conditions DOE decides to participate in the Project.

3.14.2.7.2 Impacts Associated with the Applicant Proposed Project

The impacts discussed in the sections below are common to all aspects of the Applicant Proposed Project, which includes the Oklahoma Converter Station Siting Area and AC Interconnection Siting Area, the Tennessee Converter Station and AC Interconnection Tie, the Applicant Proposed Route, the AC collection system routes, access roads, multi-use construction yards and other temporary construction areas, and communications sites. The Applicant Proposed Project is described in Sections 2.1.2 through 2.1.7.

The sections below identify the potential impacts to special status fish, aquatic invertebrate, and amphibian species and their aquatic habitat based on the three phases of the Project: (1) construction, (2) operations and maintenance, and (3) decommissioning. The Applicant would conduct each phase of the Project in compliance with applicable state and federal laws, regulations, and permits related to environmental protection. EPMs would be implemented as described in Section 3.14.2.7.1 to avoid or minimize impacts to special status fish, aquatic invertebrate, and amphibian species and aquatic habitat. In addition, consultation with USFWS has been initiated pursuant to Section 7 of the ESA regarding the potential effects of the Project on listed species and any designated critical habitat. This consultation review is a parallel, but separate analysis conducted pursuant to the requirements of ESA, Section 7 and the applicable implementing regulations. Through the consultation process additional protection measures may be the identified to avoid and/or minimize the impacts of the Project upon listed species and any designated critical habitat.

3.14.2.7.2.1 Construction Impacts

During the construction phase of the Project, potential impacts to fish, aquatic invertebrate, and amphibian resources as a result of the Project can be divided into two categories: (1) temporary (short term or long term) and (2) permanent. In addition, impacts may have direct or indirect effects. Direct or indirect effects may be temporary or permanent depending on the type and short- or long-term need of the construction activity. Direct construction impacts that could potentially affect special status fish, aquatic invertebrate, and amphibian species and their habitats include vegetation clearing, grading, access roads, herbicide use, and handling of fuel and lubricants at stream and river crossings. Indirect construction impacts that could potentially affect special status fish, aquatic invertebrate, and amphibian species and their habitats include vegetation clearing, grading, access roads, herbicide use, and handling of fuel and lubricants at locations where construction activities would result in sedimentation or contaminant runoff. Vegetation clearing has the potential to increase sedimentation and decrease cover. Increased sedimentation can directly or indirectly suffocate, bury, or limit feeding of fish, aquatic invertebrate, and amphibian species. Grading and access roads have the potential to increase sedimentation, decrease cover, and increase runoff. Increased runoff can alter stream and river hydrology and provide a mechanism for delivery of sediment, herbicides, and fuel and lubricants to streams and rivers. Herbicide use and handling of fuel and lubricants have the potential to concentrate in body tissues of fish, amphibians, and filter-feeding mussels, which can result in death.

To avoid or minimize impacts during the construction phase of the Project, both general EPMs and those specific to special status fish and aquatic resources, as listed in Section 3.14.2.7.1, would be implemented. Specific to sedimentation and vegetation clearing, detailed EPMs for both construction and ROW maintenance would be in place prior to construction, specifically designed to ensure slope stability, prevent excessive soil erosion, prevent other hazardous runoff to waters, retain low-growing near-stream vegetation, and reduce sedimentation in streams (see Sections 3.14.2.7.1 and 3.20.2.7.1; see Appendix F for a complete list of EPMs). In addition, state permits would need to be obtained prior to construction that will require that Project actions do not violate state water quality standards and further aid in the protection of aquatic resources, including food resources and spawning and rearing habitat. Furthermore, Clean Line would develop a SWPPP that would control sedimentation, erosion, and runoff and would be consistent with the state and federal regulations. Specifically regarding increased sediment load from vegetation clearing, Clean Line has committed to maintaining a streamside management zone (EPM W-3, see Sections 2.1.7 and 3.20.2.7.1 and Appendix F of the EIS) of 50 feet on both sides of streams and waterbodies where removal of low-growing vegetation would be minimized, which would aid in protection of the stream environment and reduce the likelihood of excessive sediment loads reaching the streambed. Pursuant to the NERC Reliability Standard FAC-003, the Applicant is required to create and implement a documented vegetation management program for the Project’s permanent ROW to prevent vegetation-caused outages on the transmission system. The vegetation management program will provide the framework for the Project’s Transmission Vegetation Management Plan (TVMP). The TVMP may require additional analysis under NEPA depending on whether and under what conditions DOE decides to participate in the Project. The EPMs for both construction and ROW maintenance, for which the Applicant will need approval for through the state and federal permitting process, would be in place prior to construction and would ensure actions with the potential to impact water and aquatic resources would be avoided or minimized.

Specific to spills and chemical exposures associated with herbicide use and handling of fuel and lubricants, the Applicant would implement EMPs GE-1, GE-5, GE-13, GE-21, and GE-28, as well as the measures that would be outlined in the required SPCCP and SWPPP to minimize these risks. These EPMs include measures that would reduce the risks of accidental spills (e.g., GE-13, GE-21, GE-28) as well as measures that would ensure that the use of herbicides is conducted in accordance with labeled instructions and any federal, state, and local regulations (i.e., GE-5). In addition, a TVMP would be prepared and would address situations where herbicide use is necessary (e.g., the Applicant would evaluate herbicidal treatment options in consideration of site-specific ecological conditions, surrounding and underlying land uses, and any environmental sensitivities before selecting and applying a control). The Vegetation Program and TVMP would be developed to comply with federal, state, and local regulations and standards for reliability and ROW vegetation clearing and maintenance, including NERC Reliability Standard FAC-003. The Vegetation Program and TVMP would also comply with relevant regulations applicable to all lands, including, but not limited to, the Clean Water Act (CWA) Sections 303(d) and 404 and the Endangered Species Act (ESA) of 1973, as amended in Section 7(a)(2). Section 3.17 provides a detailed discussion of the Vegetation

Program and use of herbicides. The TVMP may require additional analysis under NEPA depending on whether and under what conditions DOE decides to participate in the Project. Furthermore, the USFWS and other resource agencies would be consulted if construction efforts occur during time periods that are important to a species (e.g., spawning) or near environmentally sensitive areas with important aquatic resources, to avoid or minimize impacts to species (EPM FVW-5). The Applicant would identify, avoid, and/or minimize adverse effects to wetlands and waterbodies (EPM W-2).

The following information provides an overview of construction related impacts associated for each of the special status fish, aquatic invertebrate, and amphibian species.

Special Status Fish Species

Arkansas Darter. The Arkansas darter, a candidate species for listing under the ESA, has populations that may exist in Beaver, Harper, and Woodward counties within the Cimarron River in Regions 1 and 2 (USFWS 2014c). Habitat for the species occurs within the Neosho and Spring rivers, and associated tributaries, north of the ROI in Regions 3 and 4 (USFWS 2010a). Construction impacts (i.e., vegetation clearing, grading, access roads, herbicide use, and handling of fuel and lubricants) to this species would be limited to very specific stream and river crossings or locations where construction could result in sedimentation or contaminant runoff to Arkansas Darter habitat within the ROI in Regions 1 and 2. Under EPM FVW-5, for construction in the vicinity of sensitive areas as well as during sensitive time periods (e.g., spawning), the Applicant would consult with the USFWS and/or ODWC for guidance on seasonal and/or spatial restrictions to avoid or minimize adverse effects.

Arkansas River Shiner. The Arkansas River shiner, a federally listed threatened species, has a population that may exist in the Cimarron River across Beaver, Harper, Woodward, Major, Kingfisher, and Logan counties in Oklahoma in Regions 1, 2, and 3 (USFWS 2014c. Construction impacts (i.e., vegetation clearing, grading, access roads, herbicide use, and handling of fuel and lubricants) to this species would be limited to very specific stream and river crossings or locations where construction would result in sedimentation or contaminant runoff to Arkansas River shiner habitat within the ROI in Regions 1, 2, and 3. In Region 2, the HVDC transmission line crosses critical habitat in the Cimarron River for the species within Logan and Major counties, including a lateral distance of 300 feet on each side of the stream width at bankfull discharge (Clean Line 2013). The Applicant has not proposed in-stream activities or installation of transmission structures within the critical habitat boundaries; however, clearing of riparian vegetation would likely be necessary to ensure operational safety and system reliability (Clean Line 2013). The Applicant would establish streamside management zones within 50 feet of both sides of intermittent and perennial streams and along margins of bodies of open water where removal of low-lying vegetation is minimized (EPM W-3). The Applicant would consult with the USFWS and/or ODWC for guidance on seasonal and/or spatial restrictions designed to avoid and/or minimize adverse effects (EPM FVW-5).

Ozark Cavefish. The Ozark cavefish, a federally listed threatened species, has a limited range, only occurring in the Springfield Plateau of the Ozark Highlands ecoregion, which covers southwestern Missouri, northwestern Arkansas, and northeastern Oklahoma (Natureserve 2014e). This species does not have any known occurrences that are in counties crossed by the ROI, so no impacts to this species or its habitat are expected to occur. The closest known occurrences are in caves located north of the ROI in Region 4.

Yellowcheek Darter. The yellowcheek darter, a federally listed endangered species, has populations that may exist in Van Buren and Cleburne counties in Arkansas, but the only currently known populations are located approximately

10 miles north of the ROI (USFWS 2014c). This species is endemic to four streams of the Little Red River, all located north of the ROI (77 FR 63604, October 16, 2012). Construction impacts (i.e., vegetation clearing, grading, access roads, herbicide use, and handling of fuel and lubricants) to this species are not expected, but would be limited to very specific stream and river crossings or locations where construction would result in sedimentation or contaminant runoff to yellow darter habitat within the ROI in Region 5.

Pallid Sturgeon. The pallid sturgeon, a federally listed endangered species, occurs in the Mississippi River across Mississippi County in Arkansas, and Lauderdale, Shelby, and Lake counties in Tennessee (USFWS 2014c). Construction impacts (i.e., vegetation clearing, grading, access roads, herbicide use, and handling of fuel and lubricants) may occur along the representative ROW near the Mississippi River crossing of the ROI within Region 7 (Clean Line 2013). These impacts are expected to be minimal because construction equipment would not enter the Mississippi River. The discharge of sediments or any contaminants into the river would be an unlikely occurrence due to the Applicants implementation of the SWPPP.

Special Status Aquatic Invertebrate Species

For aquatic invertebrates occurring or potentially occurring in the ROI, only mussel species have been given special status. Since freshwater mussels require a fish host to complete their reproductive cycle, all fish-related impacts are also pertinent to mussels, and could affect them as well (Jennings 1998). The Applicant would not place structure foundations within the Ordinary High Water Mark of Waters of the United States, and would minimize construction of access roads in special interest waters as much as possible (EPM W-2). In addition, the USFWS and other resource agencies would be consulted with for guidance on seasonal and/or spatial restrictions to avoid or minimize adverse effects (EPM FVW-5). The Applicant would identify, avoid, and/or minimize adverse effects to wetlands and waterbodies (EPM W-2). The Applicant does not anticipate impacts to mussels because impacts to waters containing these species can generally be avoided through implementation of the EPMs described in Section 3.14.2.7.1.

Spectaclecase. The spectaclecase, a federally listed endangered species, is found within the ROI in Johnson County, Arkansas (USFWS 2014c). There is limited spectaclecase habitat available within the ROI. Construction impacts (i.e., vegetation clearing, grading, access roads, herbicide use, and handling of fuel and lubricants) to this species would be limited to very specific stream and river crossings or locations where construction impacts would result in sedimentation or contaminant runoff to spectaclecase habitat within the ROI in Region 4.

Pink Mucket. The pink mucket, a federally listed endangered species, is found in tributaries associated with the White River in White and Jackson counties in Arkansas (USFWS 2014c). Construction impacts (i.e., vegetation clearing, grading, access roads, herbicide use, and handling of fuel and lubricants) to this species would be limited to crossings of the White River and associated tributaries, or locations where construction impacts would result in sedimentation or contaminant runoff to pink mucket habitat within the ROI in Regions 5 and 6.

Neosho Mucket. The Neosho mucket is a federally listed endangered species. This species occurs in the Illinois River in Adair County, Oklahoma; however, Adair County is not in the ROI. Within the ROI, the species may exist within tributaries of the Illinois River (77 FR 63439, October 16, 2012). Given the current known locations for this species, impacts are not likely to occur to this species or its habitat within the ROI in Region 4.

Speckled Pocketbook. The speckled pocketbook, a federally listed endangered species, is endemic to the Little Red River and its tributaries in Van Buren, Pope, Cleburne, and White counties in Arkansas (USFWS 2007a, 2014b).

Construction impacts (i.e., vegetation clearing, grading, access roads, herbicide use, and handling of fuel and lubricants) to this species would be limited to crossings of and activities adjacent to, the Little Red River and associated tributaries, or locations where construction impacts would result in sedimentation or contaminant runoff to speckled pocketbook habitat within the ROI in Regions 4 and 5.

Scaleshell Mussel. The scaleshell mussel, a federally listed endangered species, has a range that overlaps with the ROI in Crawford, Franklin, White, and Jackson counties in Arkansas (USFWS 2014c). Construction impacts (i.e., vegetation clearing, grading, access roads, herbicide use, and handling of fuel and lubricants) to this species would be limited to very specific stream and river crossings or locations where construction impacts would result in sedimentation or contaminant runoff to scaleshell mussel habitat within the ROI in Regions 4, 5, and 6.

Fat Pocketbook. The fat pocketbook, a federally listed endangered species, occurs in tributaries and drainage ditches within the St. Francis River Basin in White, Poinsett, and Mississippi counties in Arkansas, as well as in the White River (USFWS 2014c; Natureserve 2014c). Construction impacts (i.e., vegetation clearing, grading, access roads, herbicide use, and handling of fuel and lubricants) to this species would be limited to very specific stream and river crossings or locations where construction impacts would result in sedimentation or contaminant runoff to fat pocketbook habitat within the ROI in Regions 5, 6, and 7.

Rabbitsfoot. The rabbitsfoot, a federally listed threatened species, occurs in tributaries of the White River in Van Buren, White, and Jackson counties in Arkansas, while the White River is proposed critical habitat for the species (USFWS 2014c; Natureserve 2014h). Construction impacts (i.e., vegetation clearing, grading, access roads, herbicide use, and handling of fuel and lubricants) to this species would be limited to crossings of the White River and associated tributaries, or locations where construction impacts would result in sedimentation or contaminant runoff to rabbitsfoot habitat within the ROI in Regions 5 and 6. The Applicant would consult with the USFWS and/or other resource agencies for guidance on seasonal and/or spatial restrictions designed to avoid and/or minimize adverse effects (EPM FVW-5) related to the proposed critical habitat associated with potential crossings of the White River.

Snuffbox. The snuffbox, a federally listed endangered species, has a range that overlaps with the ROI in Polk, Cross, Poinsett, and Mississippi. Construction impacts (i.e., vegetation clearing, grading, access roads, herbicide use, and handling of fuel and lubricants) to this species would be limited to very specific stream and river crossings or locations where construction impacts would result in sedimentation or contaminant runoff to snuffbox habitat within the ROI in Regions 4, 5, 6 and 7.

Curtis' Pearlymussel. The Curtis' pearlymussel, a federally listed endangered species, has an historical range that may overlap with the ROI in the White River drainage. Construction impacts (i.e., vegetation clearing, grading, access roads, herbicide use, and handling of fuel and lubricants) to this species would be limited to very specific stream and river crossings or locations where construction impacts would result in sedimentation or contaminant runoff to Curtis' pearlymussel habitat within the ROI in Region 5 if this species were present.

Special Status Amphibian Species

Ozark Hellbender. The Ozark hellbender salamander, a federally listed endangered species, and has a range that overlaps with the ROI in Republic County at the White River Crossing. Construction impacts (i.e., vegetation clearing, grading, access roads, herbicide use, and handling of fuel and lubricants) to this species would be limited to the

White River crossing where construction could result in sedimentation or contaminant runoff to Ozark hellbender habitat within the ROI in Region 5.

3.14.2.7.2.2 Operations and Maintenance Impacts

The operations and maintenance phase of the Project could potentially impact special status fish, aquatic invertebrate, and amphibian resources. Potential impacts in the operations and maintenance phase of the Project would be similar to the potential impacts in the construction phase of the Project; however impacts would occur at a lesser extent than in the construction phase, but occur throughout the life of the Project. During the operations and maintenance phase, the use of both access roads and the ROW for repair and maintenance activities could result in both direct and indirect impacts. In addition, the maintenance of ROW clearing in forested riparian areas could result in both direct and indirect impacts to habitat for special status species. The potential application of herbicides during operations and maintenance of the Project could result in indirect impacts, and to a lesser extent, direct impacts.

Both general EPMs and those specific to fish and aquatic resources as listed in Section 3.14.2.7.1, would be implemented to avoid or minimize impacts to fish and aquatic resources during the operations and maintenance phase of the Project.

Special Status Fish Species

Operations and maintenance impacts of the Project on special status fish species would be similar to the potential impacts in the construction phase of the Project. Routine maintenance or unplanned repairs may require crews and/or machinery to visit an area for ROW maintenance in which a special status fish occurs. This disturbance would not be expected to result in greater impacts than those of construction activities, but it would occur throughout the life of the Project.

Special Status Aquatic Invertebrate Species

Similar to fish, special status aquatic invertebrate species (i.e., special status mussels) may experience direct or indirect impacts during operations and maintenance, though they would likely be less in extent than construction impacts. Crews and equipment may require access to habitat of special status mussels while performing routine maintenance or unplanned repairs within the ROW. This work, however, is not likely to impact special status aquatic invertebrates to a greater extent than construction activities.

Special Status Amphibian Species

Similar to fish, special status amphibian species (i.e., special status salamander) may experience direct or indirect impacts during operations and maintenance, though they would likely be less in extent than construction impacts. Crews and equipment may require access to habitat of special status salamanders while performing routine maintenance or unplanned repairs within the ROW. This work, however, is not likely to impact special status amphibians to a greater extent than construction activities.

3.14.2.7.2.3 Decommissioning Impacts

During the third phase of the Project, decommissioning of the Project could cause potential impacts to special status fish, aquatic invertebrate, and amphibian resources. Decommissioning impacts would be similar in nature to those described for construction phase of the Project. The Applicant would develop a Decommissioning Plan prior to the start of decommissioning that would be submitted for review and approval by the appropriate federal and state resources agencies.

During the decommissioning phase of the Project, all general EPMs and those specific to special status fish and aquatic resources that were implemented during the construction phase of the Project would continue to be implemented to avoid or minimize impacts to fish and aquatic resources (see Section 3.14.2.7.1 for relevant EPMs).

Long-term effects of decommissioning are likely to benefit special status species, as Project impacts would be removed and riparian vegetation and adjacent land use returns to a less disturbed state.

3.14.2.7.2.4 Converter Stations and AC Interconnection Siting Areas

A detailed description of the converter stations and other terminal facilities is provided in Section 2.1.2.1.

This section covers the data reviewed within the footprint of the converter station siting areas and associated AC interconnection siting area and tie. No impacts are expected to affect fish and aquatic resources due to construction or operations and maintenance activities related to these facilities.

3.14.2.7.2.4.1 Construction Impacts

3.14.2.7.2.4.1.1 Oklahoma Converter Station Siting Area and AC Interconnection Siting Area

The western portion of the Project would interconnect to the existing transmission system in Texas County, Oklahoma. The construction of the Oklahoma converter station and AC interconnection would not likely result in any direct or indirect impacts to special status fish, aquatic invertebrate and amphibian species or their habitat because no waterbodies are located within the footprint of the converter station. However upslope erosion associated site or access road construction or use may increase sediment runoff to streams if the station is constructed near a waterbody that contains special status fish, aquatic invertebrate, or amphibian species.

3.14.2.7.2.4.1.2 Tennessee Converter Station Siting Area and AC Interconnection Tie

The Tennessee Converter Station Siting Area is located within Region 7, with the AC Interconnection Tie contained entirely within the Tennessee converter station and the Shelby Substation footprints. The only special status fish, aquatic invertebrate, or amphibian species identified near this portion of the Project include the pallid sturgeon (federally endangered) and blue sucker (state threatened), which occur within the Mississippi River. Although the Mississippi River is more than 10 miles from the siting area, construction activities could impact tributaries draining into the Mississippi River. Big Creek runs adjacent to the western edge of the siting area. Construction activities occurring along the western edge of the siting area could introduce sediment, herbicides, and/or fuel and lubricants into the aquatic system that could travel to the Mississippi River due to construction activities such as road crossings.

3.14.2.7.2.4.2 Operations and Maintenance Impacts

3.14.2.7.2.4.2.1 Oklahoma Converter Station Siting Area and AC Interconnection Siting Area

The operations and maintenance of the Oklahoma converter station and AC interconnection likely not result in any direct or indirect impacts to special status fish, aquatic invertebrate and amphibian species or their habitat because no waterbodies are located within the footprint of the converter station. However upslope erosion associated site or access road construction or use may increase sediment runoff to streams if the station is constructed near a waterbody that contains special status fish, aquatic invertebrate, or amphibian species.

3.14.2.7.2.4.2.2 Tennessee Converter Station Siting Area and AC Interconnection Tie

The Tennessee converter station would interconnect to the existing transmission system in Shelby County, Tennessee. The operations and maintenance of the Tennessee converter station and AC interconnection tie should be less than during construction. The only special status fish, aquatic invertebrate, or amphibian species identified near this portion of the Project include the pallid sturgeon (federally endangered) and blue sucker (state threatened), which occur within the Mississippi River. Although the Mississippi River is more than 10 miles from the siting area, operations and maintenance activities could impact tributaries draining into the Mississippi River. If the converter station is built adjacent to Big Creek, riparian clearing maintenance, road maintenance activities, and facilities operations could result in increased risk of chemical spills and contamination and increased sedimentation that could travel to the Mississippi River.

3.14.2.7.2.4.3 Decommissioning Impacts

The decommissioning of both converter stations and AC interconnection tie would result in short-term impacts, especially in the form of increased sedimentation during structure and road removal, and surface re-contouring activities. Long-term impacts would benefit special status fish, aquatic invertebrate, or amphibian species and their habitat, by removing effects from operations and maintenance activities, as well as removal of road and cleared areas that impact hydrology and sedimentation.

3.14.2.7.2.5 AC Collection System

This section covers the data reviewed within the 2-mile-wide ROI of the AC collection system routes. A description of the AC collection system is provided in Section 2.1.2.3. There is one special status fish, aquatic invertebrate, or amphibian species potentially occurring within the ROI for the AC collection system routes that might be affected: the Arkansas River shiner (federally threatened and state threatened in Oklahoma). The Beaver River and Palo Duro Creek, which are crossed by the ROI for the AC Collection System Routes E-1, E-2, E-3, SE-1, SE-3, NE-1, NE-2, and NW-1, may provide aquatic habitat where populations of the Arkansas River shiner could occur. No USFWS-designated critical habitat is present in the ROI for the AC collection system routes (USFWS 2014c).

3.14.2.7.2.5.1 Construction Impacts

Potential direct impacts to Arkansas River shiner include grading, access roads, herbicide use, and handling of fuel and lubricants where the Beaver River and Palo Duro Creek would be crossed by the AC collection system routes. Because semi-arid grasslands/herbaceous and croplands comprise most of the terrestrial habitats along the AC collection system routes, vegetation clearing is not likely to cause a direct impact. Potential indirect impacts include vegetation clearing, grading, access roads, herbicide use, and handling of fuel and lubricants at locations where construction activities would result in sedimentation or contaminant runoff into the Beaver River and Palo Duro Creek.

During the initial construction phase of the Project, both general EPMs and those specific to fish and aquatic resources as listed in Section 3.14.2.7.1, would be implemented to avoid or minimize impacts.

3.14.2.7.2.5.2 Operations and Maintenance Impacts

Potential impacts in the operations and maintenance phase of the Project would be similar to the potential impacts in the construction phase of the Project; however impacts would be at a lesser extent than in the construction phase, but occur throughout the life of the project. During the operations and maintenance phase, the use of both access roads and the ROW for repair and maintenance activities could result in both direct and indirect impacts to the Arkansas River shiner or its potential habitat in the Beaver River and Palo Duro Creek. In addition, the potential application of herbicides during operations and maintenance of the Project could result in indirect impacts, and to a lesser extent, direct impacts.

During the operations and maintenance phase of the Project, both general EPMs and those specific to fish and aquatic resources as listed in Section 3.14.2.7.1, would be implemented to avoid or minimize impacts to fish and aquatic resources.

3.14.2.7.2.5.3 Decommissioning Impacts

During the third phase of the Project, decommissioning of the AC transmission lines could cause potential direct and indirect impacts to the Arkansas River shiner or its potential habitat in the Beaver River and Palo Duro Creek. Decommissioning impacts would be similar in nature to those described for construction impacts. The Applicant would develop a Decommissioning Plan prior to the start of decommissioning that would be submitted for review and approval by the appropriate federal and state resources agencies.

During the decommissioning phase of the Project, all general EPMs and those specific to special status fish and aquatic resources that were implemented during the construction phase of the Project would continue to be enforced to avoid or minimize impacts to fish and aquatic resources (see Section 3.14.2.7.1 for relevant EPMs).

Long-term effects of decommissioning are likely to benefit the Arkansas River shiner or its potential habitat, as Project impacts would be removed and riparian vegetation and adjacent land use returns to a less disturbed state.

3.14.2.7.2.6 HVDC Applicant Proposed Route

The Applicant Proposed Route is described in Sections 2.1.2.2 and 2.4.2. This section identifies the potential impacts on special status fish, special status aquatic invertebrates, and special status amphibians, and these species aquatic habitat based on the three phases of the Project: construction, operations and maintenance, and decommissioning. Each phase of the Project would be conducted in such a way as to protect the quality of the environment. The Applicant would conduct each phase in compliance with applicable state and federal laws, regulations, and permits related to environmental protection. Specific EPMs developed to avoid or minimize impacts are described in Section 3.14.2.7.1.

3.14.2.7.2.6.1 Construction Impacts

This section covers the data reviewed for impacts to special status fish, aquatic invertebrate, and amphibian species during the construction phase of the Project. Specifically, impacts are assessed within the 1,000-foot-wide ROI of the Applicant Proposed Route and the expanded 3-mile buffer both upstream and downstream of the Applicant Proposed Route along waterbodies that have documented occurrences of special status fish, aquatic invertebrate, and amphibian species designated as candidate, threatened, or endangered under the ESA and state-designated threatened and endangered species. The expansion of the ROI that is specific to special status fish, aquatic invertebrate and amphibian species are described in Section 3.14.2.3.1. Species-specific descriptions are described in Section 3.14.2.4 and by region in Section 3.14.2.5.

Potential impacts to special status aquatic species during construction would be similar to those described in Section 3.14.2.7.2. Impacts to special status fish species would be reduced through implementation of EPMs described in Section 3.14.2.7.1.

3.14.2.7.2.6.1.1 Region 1

In the ROI in Region 1, one federally threatened fish (Arkansas River shiner) and one fish that is a candidate for listing (Arkansas darter) have the potential to be present. Populations of the Arkansas River shiner are known to occur within the ROI in the Cimarron River in Beaver, Harper, and Woodward counties in Region 1.

No route variations were proposed in Region 1.

3.14.2.7.2.6.1.2 Region 2

In the ROI in Region 2, one federally threatened fish (Arkansas River shiner) and one fish that is a candidate for listing (Arkansas darter) have the potential to be present. Populations of the Arkansas River shiner are known to occur within the ROI in the Cimarron River in Woodward and Major counties of Oklahoma in Region 2.

As described in Section 3.14.2.5, two route variations to the Applicant Proposed Route in Region 2 were developed in response to public comments on the Draft EIS7. Because these route variations are located adjacent to the original Applicant Proposed Route, and mostly cross through the same types of habitats as the original Applicant Proposed Route, impacts from most of these route variations on special status aquatic species would be similar to those that would occur as a result of the original Applicant Proposed Route. These variations represent minor adjustments to the Applicant Proposed Route. Link 1, Variation 1, as well as Link 2, Variation 2, would cross through the same types of wetlands and habitat as the original Applicant Proposed Route Links 1 and 2.

3.14.2.7.2.6.1.3 Region 3

In the ROI in Region 3, one federally threatened fish (Arkansas River shiner) has the potential to be present. Populations of the Arkansas River shiner are known to occur within the ROI in the Cimarron River in Kingfisher and Logan counties of Oklahoma in Region 3. One special status fish has the potential to occur north of Region 3, the candidate Arkansas darter; however, this fish potentially occurs just beyond the ROI.

As described in Section 3.14.2.5, five route variations to the Applicant Proposed Route in Region 3 were developed in response to public comments on the Draft EIS. Because these route variations are located adjacent to the original Applicant Proposed Route, and mostly cross through the same types of habitats as the original Applicant Proposed Route, impacts from most of these route variations on special status aquatic species would be similar to those that would occur as a result of the original Applicant Proposed Route. However, the Applicant Proposed Route Link 1, Variation 2, would result in a larger area of impact to wetland habitats (see Section 3.17), thereby potentially resulting in a larger extent of long-term impacts to special status aquatic species and their habitats. In addition, Link 1, Variation 2, would potentially cross more waterbodies, thereby resulting in greater impacts to special status aquatic species and their habitats. In contrast, the Links 1 and 2, Variation 1, would potentially cross fewer waterbodies, thereby resulting in fewer impacts to special status aquatic species and their habitats.

3.14.2.7.2.6.1.4 Region 4

In the ROI in Region 4, there are five federally endangered species of aquatic invertebrates (Neosho mucket, spectaclecase, speckled pocketbook, scaleshell mussel and snuffbox) with the potential to occur. Two special status fish species potentially occur north of Region 4, the candidate Arkansas darter and the federally endangered Ozark cavefish. Note that these fish potentially occur just beyond the ROI.

As described in Section 3.14.2.5, seven route variations to the Applicant Proposed Route in Region 4 were developed in response to public comments on the Draft EIS. Because these route variations are located adjacent to the original Applicant Proposed Route, and mostly cross through the same types of habitats as the original Applicant Proposed Route, impacts from most of these route variations on special status aquatic species would be similar to those that would occur as a result of the original Applicant Proposed Route. Two route variations would result in a significant decrease in acreage of impact to wetland habitats compared to the original Applicant Proposed Route (see Section 3.17), thereby potentially resulting in fewer long-term impacts to fish and aquatic resources and their habitats: Link 3, Variation 1, and Link 3, Variation 2. In addition, Link 9, Variation 1, in Region 4 would potentially cross fewer waterbodies, thereby resulting in fewer impacts to special status aquatic species and their habitats. Link 3, Variation 2, would parallel almost four times the length of existing infrastructure compared to the original Applicant Proposed Route (thereby reducing the impacts to areas that have not already been impacted by existing infrastructure), and would cross through areas that contain fewer wetland and waterbody features compared to the original links of the Applicant Proposed Route.

3.14.2.7.2.6.1.5 Region 5

In the ROI in Region 5, there are seven federally endangered species, one fish (yellowcheek darter) and six mussels (scaleshell mussel, speckled pocketbook, pink mucket, fat pocketbook, snuffbox, and Curtis' pearlymussel), as well as one federally threatened species (rabbitsfoot) with the potential to occur. The yellowcheek darter potentially occurs north of the ROI, but has the potential to inhabit areas within the ROI as well. Also the Ozark hellbender salamander could occur at the White River Crossing in Republic County.

As described in Section 3.14.2.5, five route variations to the Applicant Proposed Route in Region 5 were developed in response to public comments on the Draft EIS. Because these route variations are located adjacent to the original Applicant Proposed Route, and mostly cross through the same types of habitats as the original Applicant Proposed Route, impacts from most of these route variations on special status aquatic species would be similar to those that would occur as a result of the original Applicant Proposed Route. However, Link 1, Variation 2, would result in a significant decrease in acreage of impact to wetland habitats compared to the original Applicant Proposed Route (see Section 3.17), thereby potentially resulting in fewer long-term impacts to special status aquatic species and their habitats. In contrast, Link 7, Variation 1, would potentially cross more waterbodies, thereby resulting in greater impacts to special status aquatic species and their habitats. Link 1, Variation 2, would potentially cross fewer waterbodies, thereby resulting in fewer impacts to special status aquatic species and their habitats.

3.14.2.7.2.6.1.6 Region 6

In the ROI in Region 6, there are four federally endangered mussels (pink mucket, scaleshell, fat pocketbook and snuffbox) and one federally threatened mussel (rabbitsfoot) with the potential to occur.

As described in Section 3.14.2.5, one route variation to the Applicant Proposed Route in Region 6 was developed in response to public comments on the Draft EIS. Because this route variation is located adjacent to the original Applicant Proposed Route, and mostly crosses through the same types of habitats as the original Applicant Proposed Route Link 2, impacts on special status aquatic species would be similar to those that would occur as a result of the original Applicant Proposed Route. This variation represents minor adjustments to the Applicant Proposed Route. However, Link 2, Variation 1, would result in a larger area of impact to wetland habitats (see Section 3.17), thereby potentially resulting in a larger extent of long-term impacts to special status aquatic species and their habitats.

3.14.2.7.2.6.1.7 Region 7

In the ROI in Region 7, three federally endangered species (one fish and two mussels) have the potential to be present (the pallid sturgeon the fat pocketbook, and snuffbox).

As described in Section 3.14.2.5, three route variations to the Applicant Proposed Route in Region 7 were developed in response to public comments on the Draft EIS. Because these route variations are located adjacent to the original Applicant Proposed Route, and mostly cross through the same types of habitats as the original Applicant Proposed Route, impacts from most of these route variations on special status aquatic species would be similar to those that would occur as a result of the original Applicant Proposed Route. However, Link 1, Variation 2, would result in a larger area of impact to wetland habitats (see Section 3.17), thereby potentially resulting in a larger extent of long-term impacts to special status aquatic species and their habitats. In contrast, Link 1, Variation 2, would result in a significant decrease in acreage of impact to wetland habitats compared to the original Applicant Proposed Route (see Section 3.17), thereby potentially resulting in fewer long-term impacts to special status aquatic species and their habitats. Finally, Link 1, Variation 2, would potentially cross fewer waterbodies, thereby resulting in fewer impacts to special status aquatic species and their habitats.

3.14.2.7.2.6.2 Operations and Maintenance Impacts

Impacts to special status fish species (as identified in Section 3.14.2.7.6.1 for each region) during operations and maintenance would be similar to those described in Section 3.14.2.7.2.2. During the operations and maintenance phase of the Project, both general EPMs and those specific to fish and aquatic resources as described in Section 3.14.2.7.1, would be implemented to avoid or minimize impacts to special status fish and aquatic resources.

3.14.2.7.2.6.3 Decommissioning Impacts

The short-term impacts during decommissioning of Applicant Proposed Route would be similar to the impacts that would occur during the construction phase. Structure removal, road decommissioning, and removal of road crossings is likely to have potential impacts to special status fish and aquatic resources due to increased sedimentation from runoff of disturbed areas and direct impact of removal of instream crossing structures. Following EPMs as described in Section 3.14.2.7.1 would help reduce the level of short-term impacts from decommissioning activities.

Long-term impacts of Project decommissioning would benefit special status fish, aquatic invertebrate, and amphibian species due to removal of impacts from Project components, such as roads and road maintenance activities, as well as allowing the vegetation in any cleared ROW areas to regrow.

3.14.2.7.3 Impacts Associated with the DOE Alternatives

This section identifies the potential direct and indirect impacts on special status fish species, special status aquatic invertebrate species, and special status amphibian species and their aquatic habitat related to the DOE alternatives.

3.14.2.7.3.1 Arkansas Converter Station Alternative Siting Area and AC Interconnection Siting Area

A detailed description of the Arkansas converter station and other terminal facilities is provided in Section 2.4.3.1. The Arkansas Converter Station Alternative Siting Area and AC Interconnection Siting Area are located near the western end of Region 5 in Pope County. In addition to the Arkansas Converter Station Alternative and AC Interconnection Siting Area, a new substation would be constructed that would interconnect the AC transmission line to an existing 500kV transmission line. This substation would be located near an existing transmission line in an area that is primarily grassland with some forest land.

3.14.2.7.3.1.1 Construction Impacts

The construction of the Arkansas converter station and AC transmission line, as well as the new substation, would not likely result in any direct impacts to special status fish, aquatic invertebrate and amphibian species or their habitat because no major waterbodies are located within the footprint of the construction area or along the interconnection area. However upslope erosion associated site or access road construction or use may increase sediment runoff to streams if the station is constructed near a waterbody that contains special status fish, aquatic invertebrate, or amphibian species.

3.14.2.7.3.1.2 Operations and Maintenance Impacts

The operations and maintenance of the Arkansas converter station and AC transmission line, as well as the new substation, would not likely result in any direct impacts to special status fish, aquatic invertebrate and amphibian species or their habitat because no major waterbodies are located within the footprint of the construction area or along the interconnection area. However upslope erosion associated road use may increase sediment runoff to streams if the station was constructed near a waterbody that contains special status fish, aquatic invertebrate, or amphibian species.

3.14.2.7.3.1.3 Decommissioning Impacts

The impacts during decommissioning of the Arkansas converter station and AC transmission line, as well as the new substation, would be similar to the impacts occurring during the construction phase. Decommissioning would not likely result in any direct impacts to special status fish, aquatic invertebrate and amphibian species or their habitat because no major waterbodies are located within the footprint of the construction area or along the interconnection area. However upslope erosion associated road use may increase sediment runoff to streams if the station was constructed near a waterbody that contains special status fish, aquatic invertebrate, or amphibian species.

3.14.2.7.3.2 HVDC Alternative Routes

Descriptions of the HVDC alternative routes are provided in Section 2.4.3.2. The impacts that could occur to special status fish, aquatic invertebrate, and amphibian species from construction and operations and maintenance of the Applicant Proposed Route are discussed in Section 3.14.2.7.2.6. The expected types of impacts from construction and operations and maintenance of the HVDC alternative routes in each region would be similar to those for the Applicant Proposed Route. However, because of differences in routing (i.e., location) the potential for impacts may be different (e.g., the route may be closer to or farther from an important stream or river crossing). The discussion in this section focuses on the differential impacts that could occur under each of the HVDC alternative routes compared to the Applicant Proposed Route.

3.14.2.7.3.2.1 Construction Impacts

This section describes construction impacts associated with the 1,000-foot-wide ROI of the HVDC alternative routes and the expanded 3-mile buffer both upstream and downstream. Available data used in the impacts comparison include USWFS-designated critical habitat. Analyses are presented for the ROI in Regions 1 through 7. During the construction phase of the Project, all general EPMs and those specific to special status fish and aquatic resources would be implemented to avoid or minimize impacts to fish and aquatic resources (see Section 3.14.2.7.1 for relevant EPMs).

For all regions except Region 2, there would be no difference in impacts between the Applicant Proposed Route and the HVDC alternative routes. For Region 2, the following differences would exist between alternative routes:

- HVDC Alternative Route 2-A is approximately 57 miles long and corresponds to Applicant Proposed Route Link 2. HVDC Alternative Route 2-A has more acres of waters designated by the USFWS as critical habitat for the Arkansas River shiner within the ROI. Both the HVDC Alternative Route 2-A and the corresponding Link 2 of the Applicant Proposed Route cross the Cimarron River at separate locations where it is USFWS designated critical habitat, but HVDC Alternative Route 2-A is within the critical habitat for more acres.
- The Applicant Proposed Route Link 2 has 101 acres of critical habitat for the Arkansas River shiner within Region 2 of the HVDC transmission line 1,000-foot-wide ROI and 3-mile buffer, while HVDC Alternative Route 2-A has 635 acres of critical habitat for the Arkansas River shiner within the ROI and 3-mile buffer.
- The Applicant Proposed Route Link 2 has 95 acres of critical habitat for the Arkansas River shiner within Region 2 of the HVDC transmission line 200-foot-wide ROW and 3-mile buffer, while HVDC Alternative Route 2-A has 586 acres of critical habitat for the Arkansas River shiner within the ROW and 3-mile buffer.
- HVDC Alternative Route 2-B is approximately 30 miles long and corresponds to Applicant Proposed Route Link 3. HVDC Alternative Route 2-B has fewer acres of waters designated by the USFWS as critical habitat for the Arkansas River shiner within the ROI. Neither the HVDC Alternative Route 2-B or the corresponding Link 3 of the Applicant Proposed Route cross the Cimarron River where it is USFWS-designated critical habitat, but HVDC Alternative Route 2-B is within the critical habitat for fewer acres.
- The Applicant Proposed Route Link 3 has 71 acres of critical habitat for the Arkansas River shiner within Region 2 of the HVDC transmission line 1,000-foot-wide ROI and 3-mile buffer, while HVDC Alternative Route 2-B has 6 acres of critical habitat for the Arkansas River shiner within the ROI and 3-mile buffer.
- The Applicant Proposed Route Link 3 has 52 acres of critical habitat for the Arkansas River shiner within Region 2 of the HVDC transmission line 200-foot-wide ROW and 3-mile buffer, while HVDC Alternative Route 2-B has 2 acres of critical habitat for the Arkansas River shiner within the ROW and 3-mile buffer.

As described in Appendix M, a route adjustment was developed for HVDC Alternative Routes 3-A, 5-B, 5-E, and 6-Ato maintain an end-to-end route with the Applicant Proposed Route and the new route variations. These route adjustments would cross through the same types of wetlands and habitats as the original Applicant Proposed Route. HVDC Alternative Routes 5-E and 6-A potentially have a reduction in number of floodplains from two to one for each route, which would potentially result in fewer impacts to special status fish, aquatic invertebrates, and amphibian species and their habitat.

3.14.2.7.3.2.2 Operations and Maintenance Impacts

Impacts to special status fish species (as identified in Section 3.14.2.7.6.1 for each region) during operations and maintenance of the HVDC alternative routes would be similar to those described in Section 3.14.2.7.2.2. The amount of critical habitat for the Arkansas River shiner along HVDC Alternative Routes 2-A and 2-B (as mentioned above for construction) would be the only difference between the alternative routes and the Applicant Propose Route. During the operations and maintenance phase of the Project, both general EPMs and those specific to fish and aquatic resources as described in Section 3.14.2.7.1, would be implemented to avoid or minimize impacts to special status fish and aquatic resources.

3.14.2.7.3.2.3 Decommissioning Impacts

Decommissioning of the HVDC alternative routes could cause potential impacts to special status fish, aquatic invertebrate, and amphibian resources. Decommissioning impacts would be similar in nature to those described during construction. During the decommissioning phase of the Project, all general EPMs and those specific to special status fish and aquatic resources that were implemented during the construction phase of the Project would continue to be implemented to avoid or minimize impacts to fish and aquatic resources (see Section 3.14.2.7.1). The Applicant would develop a Decommissioning Plan prior to the start of decommissioning that would be submitted for review and approval by the appropriate federal and state resources agencies.

3.14.2.7.4 Best Management Practices

The Applicant has developed a list of EPMs intended to avoid or minimize impacts to special status fish, aquatic invertebrate, and amphibian species. A complete list of EPMs for the Project is provided in Appendix F; those EPMs that would specifically minimize the potential for impacting special status fish, aquatic invertebrate, and amphibian species are summarized in Section 3.14.2.7.1. In addition, DOE and the Applicant have prepared a Biological Assessment (Appendix O of the EIS) of potential impacts on special status species protected under the ESA as part of the Section 7 consultation between DOE and the USFWS. The Section 7 consultation review is a parallel but separate process conducted pursuant to the requirements of ESA and the applicable implementing regulations. A Biological Opinion will be issued by USFWS prior to the Record of Decision. Through this process, additional protective measures may be identified and adopted to avoid or minimize impacts to special status fish, aquatic invertebrate and amphibian species and their habitat.

3.14.2.7.5 Unavoidable Adverse Impacts

The Applicant would implement EPMs to avoid or minimize impacts; however, some adverse impacts may occur to special status fish, aquatic invertebrate, and amphibian species or their habitat even with the implementation of these measures. Construction and operations and maintenance of the Project could result in the mortality and injury of some special status fish, aquatic invertebrate, and amphibian species if they are present in the affected areas during construction or operations and maintenance. Construction mortalities and injuries could result from crushing during waterbody crossings with equipment, sedimentation, potential exposure to hazardous materials, and blasting. Operation mortalities and injuries could result from sedimentation and potential exposure to hazardous materials. Unavoidable impacts to special status fish, aquatic invertebrate, and amphibian species and their habitat include the potential loss or alteration of aquatic habitat in streams that may require culverts or vehicle crossings, potential loss or disturbance to riparian vegetation along streams on private or public lands where the ROW is parallel and adjacent to the stream, and potential short-term sedimentation effects on aquatic resources as a result of vehicular traffic causing disturbances within or adjacent to streams. Although these impacts have the potential to occur, the likelihood of occurrence would be limited through implementation of the EPMs.

3.14.2.7.6 Irreversible and Irretrievable Commitment of Resources

The potential permanent loss or alteration of aquatic habitat in smaller streams that may require road crossings would last throughout the life of the Project; however, gradual recovery of habitat may occur once the road crossing was removed. As the exact state of this recovery is not known (e.g., substantial changes related to climate, land-use, and/or watershed hydrology may occur during the 80 year lifespan of the Project), and aquatic habitat is subject to long-term climatic regimes and changes in land-use and watershed hydrology, it is reasonable to assume that some portions of the aquatic habitat for special status fish, aquatic invertebrate, and amphibian species in these smaller streams would be irreversibly and irretrievably impacted.

3.14.2.7.7 Relationship between Local Short-term Uses and Long-term Productivity

The Project may result in a short-term disturbance to special status fish, aquatic invertebrate, and amphibian resources; however, these impacts would not likely affect the long-term productivity of populations of special status fish and aquatic invertebrate species.

3.14.2.7.8 Impacts from Connected Actions

3.14.2.7.8.1 Wind Energy Generation

Two aquatic species listed under the ESA potentially occur within the WDZs, the Arkansas darter (a candidate species) and the Arkansas River shiner (a threatened species). Both species occur in Beaver County, Oklahoma. USFWS-designated critical habitat for these species is not located within the WDZs. Both species are located in close enough proximity to the WDZ to warrant inclusion here. Wind energy developers follow guidance outlined in the Land-based Wind Energy Guidance (USFWS 2012c) to develop, construct, and operate and maintain projects in a manner that would avoid and/or minimize adverse effects on both species.

The Arkansas darter and Arkansas River shiner may occur within the WDZs. Habitat exists for both species in the Cimarron River and its tributaries. WDZ-J and -K are both located in Beaver County, and would be the most likely to have appropriate habitat for both species of all the WDZs.

Potential construction impacts to these species would be similar to those defined in Section 3.14.2.7; however, the severity of impacts would be higher given these species' vulnerability due to reduced population numbers, restricted ranges, and any other limitations. Wind farm developers would need to consider developing site-specific EPMs that would be implemented as necessary after consultation with federal and state agencies regarding seasonal or spatial restrictions. Potential impacts due to operations and maintenance, as well as decommissioning, would be similar to those defined in Section 3.14.2.7.

3.14.2.7.8.2 Optima Substation

Because there are no waterbodies within the future Optima Substation site, occurrences of special status fish, aquatic invertebrate, and amphibian species are not likely. Accordingly, impacts associated with future Optima Substation site to fish, aquatic invertebrate, and amphibian species would not be likely.

3.14.2.7.8.3 TVA Upgrades

The ROI for the direct assignment facilities cannot be determined at this time as described in Section 3.14.2.6.3. A precise ROI has not been identified for the TVA upgrades. Where possible, general impacts associated with the required TVA upgrades are discussed below.

Potential impacts of concern to special status fish, aquatic invertebrate, and amphibian species from the required TVA upgrades, like the Project, could include mortality of individuals, sensory disturbance, and aquatic habitat disturbance or modification by construction or operations and maintenance activities associated with the new transmission line. Generally, construction and operations and maintenance of the new 500kV transmission line would have impacts similar to the Project, although on a smaller scale. These impacts may include mechanical damage and/or removal of vegetation by heavy machinery, potential introduction of invasive species from construction equipment or spread of existing invasive species, alteration of hydrology during road construction, which could affect special status fish, aquatic invertebrate, and amphibian species habitat, sedimentation from grading, access roads, and stream crossings, and contamination from herbicide drift or runoff or from accidental spills of fuels or lubricants that could cause mortality or injury of special status fish, aquatic invertebrate, and amphibian species. These potential impacts would be short term except for habitat loss at sites used for access (i.e., roads and stream crossings) and any special status fish, aquatic invertebrate, and amphibian species mortality.

The required TVA upgrades to existing facilities (including existing transmission lines and existing substations) would require fewer construction activities to complete than the new 500kV transmission line. Existing TVA facilities already experience operations and maintenance activities. As a result, potential impacts would be expected to be less substantial in areas affected by upgrades to existing TVA facilities than in areas where the new 500kV transmission line would be constructed.

TVA would consider potential impacts to special status fish, aquatic invertebrate, and amphibian species and their habitats during the siting of the new 500kV transmission line and while planning the upgrades to existing transmission facilities. TVA would avoid impacts to these species and their habitats to the extent practicable. Pursuant to Section 7 of the ESA, TVA is required to consult with the USFWS with respect to effects of its construction of any new or upgraded transmission facilities upon threatened, endangered, or candidate species.

3.14.2.7.9 Impacts Associated with the No Action Alternative

Under the No Action Alternative, DOE assumes for analytical purposes that the Project would not be constructed. No disturbances would occur due to the Project, including disturbances in waterbodies that could affect special status aquatic species and their habitats. No disturbances related to construction vehicles, equipment, or access roads would affect aquatic resources. No impacts related to the Project would occur due to vegetation removal or the use of herbicides.

Impacts to aquatic species and their habitats would be consistent with present levels of disturbance due to natural conditions in the environment, such as annual changes in stream flow, erosion, and wildfire.

3.15 Surface Water

3.15.1 Regulatory Background

Laws and regulations are associated with the management and protection of surface waters that could affect the Project or the manner in which it would be implemented. Key elements of select federal and state laws and regulations associated with surface water management are summarized in Table 3.15-1.

Table 3.15-1:
Federal and State Laws and Regulations Associated with Surface Water Management

Statute/Regulation	Key Elements
Clean Water Act (33 USC § 1251 *et seq.*)	CWA Section 404 establishes USACE as responsible for regulating the discharge or dredge of fill material to Waters of the U.S.
	CWA Section 401 stipulates that a federal agency (such as the USACE) issuing a permit or license for a discharge to waters of the U.S. must first have the applicable state or tribe grant or waive a Section 401 water quality certification indicating the discharge will comply with the state's water quality standards
	CWA Section 402 establishes the NPDES permit program to regulate discharges of pollutants into surface waters
	CWA Section 303(d) requires states to develop and submit to EPA, lists of impaired waters
	CWA Section 305(b) requires states to develop and periodically update an inventory of the water quality of all water bodies in the state
Rivers and Harbors Appropriation Act of 1899, Section 10 (33 USC § 403)	Section 10 of the Act prohibits obstruction or alteration of any navigable water of the U.S. without a permit from the USACE
Wild and Scenic Rivers Act (16 USC §§ 1271–1287)	Requires federal agencies proposing an action that could affect a Wild and Scenic River to consult with management agency on action and recommended measures to avoid adverse effects
	Per a 1980 CEQ memorandum, federal agencies must consult with the National Park Service on actions that could affect a river segment on the Nationwide Rivers Inventory
Oklahoma Administrative Codes 785:20 and 785:45	Requires a permit be applied for and obtained prior to diversion of surface water Establishes surface water protection measures through water classification, beneficial use designations, and numerical and narrative criteria to maintain and protect such classifications Establishes state policy to protect all waters of the state from degradation of water quality and three levels of protection: Tier 1—attainment and maintenance of an existing or designated beneficial use Tier 2—maintenance or protection of High Quality Waters and Sensitive Public and Private Water Supply Tier 3—no degradation of water quality allowed in Outstanding Resource Waters
Arkansas Natural Resources Commission, Title 3, Rules for the Utilization of Surface Water (ANRC 2009)	Requires anyone proposing to divert surface water for non-riparian use to submit an application to ANRC for determination that the water to be used is excess surface water, is intended for reasonable and beneficial use, and will cause no significant adverse environmental impact
Arkansas Act 81 of 1957	Requires diverters of surface water in excess of 1 acre-foot per year to register their diversion on an annual basis with the ANRC
Arkansas Pollution Control and Ecology Commission, Regulation No. 2, Regulation Establishing Water Quality Standards for Surface Waters of the State of Arkansas (APCEC 2011)	Establishes water quality standards for all surface waters of the State of Arkansas and assigns designated uses per ecoregion (Appendix A of Regulation Number 2).
	As its anti-degradation policy, requires existing in-stream water uses and water quality necessary to protect existing uses be maintained and protected, with High Quality Waters and Outstanding Resource Waters receiving additional protection (sections 2.201 to 2.203)
	Requires (in section 2.305) any work in waters of the state with potential to cause a violation of Water Quality Standards to have a STAA

Table 3.15-1:
Federal and State Laws and Regulations Associated with Surface Water Management

Statute/Regulation	Key Elements
Arkansas Code Annotated 23-3-5	Identifies the Arkansas Public Service Commission as having jurisdiction over crossing of navigable waterways by public service facilities, including electric power lines and specifies filing a petition with the Commission to request approval
Rules of Tennessee Department of Environment and Conservation Chapter 0400-40-03, General Water Quality Criteria (TDEC 2013a) Chapter 0400-45-08, Water Registration Requirements (TDEC 2012)	Establishes surface water classifications and numeric or narrative quality criteria
	Establishes an anti-degradation policy to fully protect existing uses of all surface waters and provides a process for authorizing degradation in waters under specific conditions including if it is in the public interest and there are no other reasonable options
	Requires users withdrawing water from either a surface or groundwater source at an average rate of 10,000 gallons or more per day to be pre-registered with the TDEC (agricultural, emergency and certain non-recurring withdrawals are exempt)
	Purchase of water from a utility is not considered withdrawal
Tennessee Administrative Code 69-3-108	Requires an Aquatic Resource Alteration Permit from the TDEC for alterations or withdrawals from streams, lakes, or wetlands of the state of Tennessee
Texas Water Code, Title 2, Chapter 11	Establishes requirements for temporary water use permits, which the Texas Commission on Environmental Quality may issue provided the temporary use does not interfere with or adversely affect prior appropriations or vested rights on the surface water.
Texas Administrative Code (TAC) 30-1-307	Establishes general water quality criteria applicable to all surface waters of the state unless exempt under TAC 30-307.8–9.
	Establishes Texas's anti-degradation policy and implementation procedures that apply to regulated actions that could increase pollution of water in the state. The policy sets three tiers of protection: (1) protect existing water uses and quality; (2) degradation of waters in excess of fishable/swimmable quality is not allowed unless TCEQ determines it is necessary for important economic or social development; and (3) the quality of Outstanding National Resource waters are to be maintained and protected.

3.15.2 Data Sources

Data were obtained from multiple publicly available sources. GIS datasets were used heavily to develop a picture of resources within the ROI. GIS datasets were obtained primarily from federal and state programs. For example, the USGS National Hydrography Dataset (GIS Data Resource: USGS 2014a) was used as part of the effort to characterize the affected environment. Surface waters of special interest were identified through federal and state listings of special designations as part of water quality or water resource protection efforts. For state designation waters, the listing information was found in state regulations, reports, or plans. Representatives of state agencies were contacted in some cases and information was obtained via conversations or electronic correspondence. Some information presented in this section was obtained from state webpages. References for specific sources of information are provided.

3.15.3 Region of Influence

For surface water, the ROI for the Project and connected actions is the same as described in Section 3.1.1.

3.15.4 Affected Environment

The affected environment for surface water, as described separately for each region below, addresses the following elements:

- Watersheds—This section describes the watersheds where the Project components would be located as a means of identifying the area's surface water drainage features. Watersheds presented here are as defined in the USGS methodology for defining and cataloging the nation's surface water drainage systems (Seaber et al. 1987; GIS Data Source: USGS 2014a). The watersheds or hydrologic units are identified to the eight-digit Hydrologic Unit Code (HUC).
- Surface Water Features—This section characterizes the surface water features within the ROI for the Applicant Proposed Route, HVDC alternative routes, AC collection system routes, and three converter station siting areas. This includes identification of specific water features of special interest, which include the federal and state designations listed in Table 3.15-2. Not all surface water designations identified in the table were applicable to the ROI, but the analysis included a review to make that determination.
- Water Quality—Water quality information is presented primarily in terms of those surface water features that do not meet applicable water quality standards based on the surface water's designated uses and, as a result, have been identified as impaired waters in the states' most recent CWA Section 303(d) reports.
- Water Use—Water use is presented by county based on 2010 data published by the USGS. The USGS compiles water use data every 5 years and since the Draft EIS, the USGS data for 2010 were published and are presented in this Final EIS. The USGS data are presented by use category and include whether a water's source is groundwater or surface water. A detailed summary of water use by county is provided in Section 3.7.

Surface Water Features

Perennial Stream—A stream that normally has water in its channel at all times.

Intermittent Stream—A stream that flows only when it receives water from rainfall runoff or springs, or from some surface source such as snowmelt.

Major Waterbody—For purposes of this evaluation, any surface water feature (perennial stream, lake, pond, etc.) for which a route crossing distance is 100 feet or more.

Feature of Special Interest—A surface water designated by a federal or state agency as having unique natural characteristics and/or requiring added protection.

Table 3.15-2:
Federal and State Surface Water Designations of Special Interest

Government Level	Surface Water Designations of Special Interest
Federal	Rivers listed in the National Park Service's Nationwide Rivers Inventory, a listing of free-flowing U.S. river segments believed to have "outstandingly remarkable" natural or cultural values of more than local or regional significance (GIS Data Source: USGS 1996)
	Rivers listed in the National Wild and Scenic Rivers System, created to preserve rivers with outstanding natural, cultural, and recreational values (National Wild and Scenic Rivers System 2014)
	Waters designated by the USFWS as critical habitat for federally listed threatened or endangered species
	Waters designated by the USACE as navigable waters of the U.S. per Section 10 of the Rivers and Harbors Act of 1899
State—Common to all	State-designated Source Water Protection Areas
	Surface water intakes for public water systems within 3 miles downstream of ROI
Oklahoma	Sensitive Public and Private Water Supplies, Outstanding Resource Waters, and High Quality Waters and their special provision watersheds as identified in Appendix A of OAC 785:45, Oklahoma's Water Quality Standards
	Scenic River Areas, Culturally Significant Waters, or Nutrient Limited Watersheds per Appendix A of OAC 785:45
	Waters of Recreational and/or Ecological Significance per Appendix B of OAC 785:45

Table 3.15-2:
Federal and State Surface Water Designations of Special Interest

Government Level	Surface Water Designations of Special Interest
Arkansas	Extraordinary Resource Waters or Natural and Scenic Waterways per Appendix A of APCEC Regulation No. 2 (APCEC 2014)
	Ecologically Sensitive Waterbodies or Trout Waters per Appendix A of APCEC Regulation No. 2 (APCEC 2014)
Tennessee	Exceptional Tennessee Waters or Outstanding National Resource Waters per Chapter 0400-40-03 of the TDEC Rules (TDEC 2013a)
	State Scenic Rivers pursuant to the Tennessee Scenic Rivers Act
Texas	Sole-source Surface Drinking Water Supplies and their protection zones per Appendix B of TAC 30-307
	Ecologically Unique River and Stream Segments per Texas Administrative Code Title 31, Chapter 357.43

Ephemeral streams, which are streams or segments of streams that flow briefly in direct response to precipitation in the immediate vicinity, are not addressed as unique surface water features in this section, but are considered to be a subset of the intermittent stream category. The USGS National Hydrography Dataset, which was used heavily in characterizing surface water features in the Project vicinity, does not distinguish between ephemeral and other intermittent streams. Where impacts to intermittent streams are discussed they would also apply to ephemeral streams.

Several route variations for the Applicant Proposed Route in Regions 2 to 7 were developed in response to public comments on the Draft EIS and are described in Appendix M and summarized in Section 2.4.2.1 to 2.4.2.7. Brief descriptions of the surface water elements that could be affected by the route variations by Project region, including accompanying HVDC alternative route adjustments, are provided below. The variations are presented graphically in Exhibit 1 of Appendix M.

3.15.5 Regional Description

The following sections provide detailed descriptions of watersheds, surface water features, water quality, and water use in the ROI for Regions 1 through 7. The regional descriptions in this section also identify surface water features and elements found within a representative ROW consisting of a 200-foot-wide corridor within the 1,000-foot-wide ROI of the HVDC transmission line routes. Information for the AC collection system (included in the Region 1 description) is similarly presented in terms of a 2-mile-wide ROI and a 200-foot-wide representative ROW. This information is used in evaluating potential impacts of the Project in Section 3.15.6. The ROW features and elements are included here in the affected environment to provide the reader an easy comparison between features in the ROI and what would be expected in a smaller ROW.

3.15.5.1 Region 1

Region 1 is referred to as the Oklahoma Panhandle Region and includes the Applicant Proposed Route, HVDC Alternative Routes 1-A through 1-D, and the Oklahoma converter station with its associated AC interconnection line. Although the AC collection system routes overlap with portions of the Applicant Proposed Route and HVDC alternative routes, they are addressed separately below because the AC collection system routes would also extend into areas well outside the HVDC transmission corridor.

No route variations were proposed in Region 1.

3.15.5.1.1 Region 1 Watersheds

The ROI, including the AC collection system routes, is within the Arkansas-White-Red drainage system, which combines the drainage areas for the Arkansas, White, and Red rivers, representing a large portion of south-central United States and draining into the Mississippi River. Within that large drainage system, the ROI is primarily within the North Canadian subregion; a small portion of the eastern edge of the ROI is in the Lower Cimarron subregion. The Mississippi River is the end point for the overall drainage system, and the general direction of the primary flow within the Region 1 watersheds is from west to east. Local streams may flow in different directions, even north to south or south to north, but as they join larger streams, the overall progression is from west to east.

At USGS's eight-digit coding level, the ROI lies within eight different watersheds as shown in Figure 3.15-1a (located at Appendix A). A ninth watershed, the Lower Wolf (11100203), is just outside the ROI, but is shown in the figure because it lies between two of the eight. Table 3.15-3 lists the applicable watersheds in a general west-to-east order and provides additional detail, including the primary surface water or waters that drain the watershed. Surface waters for the ROI are shown on Figure 3.15-2 in Appendix A.

Table 3.15-3:
Watersheds Crossed by the Applicant Proposed Routes and HVDC Alternative Routes and the AC Collection System Routes—Region 1

USGS HUC Number and Watershed Name	Area Drained (square miles)	Description of Primary Surface Water Features
11100101, Upper Beaver	2,732	Beaver River drains the watershed that extends from the river's headwaters to its convergence with Goff Creek.
11100102, Middle Beaver	1,356	Beaver River drains the watershed that extends from its convergence with Goff Creek through Lake Optima and to the community of Beaver.
11100103, Coldwater[1]	1,962	Coldwater and Frisco creeks drain the watershed into Lake Optima.
11100104, Palo Duro	1,937	Palo Duro Creek drains the watershed into Beaver River.
11100201, Lower Beaver	1,781	Beaver River, which becomes the North Canadian River, drains the watershed. Several smaller streams converge with the Beaver River within the watershed.
11100202, Upper Wolf	833	Wolf Creek drains the watershed and after running through another watershed joins the Beaver River to form the North Canadian River.
11100301, Middle North Canadian	1,858	North Canadian River drains the watershed, which includes Canton Lake and Ramsey Lake, both on the North Canadian River
11050001, Lower Cimarron-Eagle Chief	2,422	Cimarron River and Eagle Chief Creek drain the watershed. The Cimarron is to the northeast and parallels the North Canadian.

1 The proposed Oklahoma converter station would be within the Coldwater watershed.

GIS Data Source: USGS (2014a)

As outlined in Table 3.15-3, the ROI follows along the Beaver River/North Canadian River drainage from west to east except at the eastern edge of the ROI, where the Applicant Proposed Route and HVDC alternative routes pass into a watershed of the Cimarron River. At this point, the Cimarron River basically flows parallel to the North Canadian River, but at a distance to the northeast.

3.15.5.1.2 Region 1 Surface Water Features

Surface water features are described below in terms of the compiled length of streams or acreage of lakes or reservoirs within the 1,000-foot-wide corridors and 200-foot-wide representative ROWs of the HVDC transmission line routes. Surface water features along the transmission line corridor that are of special interest or of impaired quality are identified individually in subsequent discussions.

Table 3.15-4 lists the total length of perennial streams, intermittent streams, and major waterbodies within the ROI and, in parentheses, the 200-foot-wide representative ROW. The table includes the total acreage of reservoirs, lakes, and ponds that occur within the ROI.

Table 3.15-4:
Miles and Acreage of Surface Water Features within the 1,000-Foot-Wide Corridors (and 200-Foot-Wide Representative ROWs) of the Applicant Proposed Route and HVDC Alternative Routes—Region-1

Route—Proposed and Alternatives[1, 2]	Link 1	Link 2	Link 3	Link 4	Link 5	Region 1 Total
Perennial Streams						
APR (miles)	0.07 (0)	2.01 (0.32)	0	1.22 (0.13)	2.15 (0.41)	5.45 (0.86)

With AR 1-C (acres)	0.6 (0)	3.4 (1.2)		8.5 (1.0)	8.7 (1.7)	21.2 (3.9)
With AR 1-D (acres)	0.6 (0)	31.2 (7.2)	6.6 (0.2)		8.7 (1.7)	47.1 (9.1)

1 Each region of the Applicant Proposed Route (APR) is divided into links that lie between points, or nodes, where the APR is intersected by alternative routes (ARs). ARs bypass specific links of the APR as shown in the table.
2 For the ARs, the unshaded portion of the rows provides the data for the length of the AR. The shaded portion of the rows provides the data for the balance of the APR, thereby providing perspective across the region.
GIS Data Source: USGS (2014a)

The analysis included an assumption when compiling the perennial and intermittent stream data shown in Table 3.15-4 and corresponding tables for the other regions. Stream data came from the USGS National Hydrography Dataset, which includes an "artificial path" category in addition to perennial and intermittent streams.

The artificial paths are manually inserted flow lines in place of wide features (expanded river beds, ponds, reservoirs, etc.) in the flow paths of either perennial or intermittent streams. For ease of data compilation, the analysis summed artificial paths as if part of perennial streams. This assumption could make some perennial stream values slightly high and some intermittent stream values slightly low. If the feature is a wide river bed, however, the artificial paths are more often associated with perennial streams; and if the features are ponds or reservoirs that hold water all year even though fed by intermittent streams, it may be more appropriate to characterize them as perennial segments.

DOE also considered the surface water features that would be within the 2-mile-wide corridors and 200-foot-wide representative ROWs of the AC collection system routes. Using similar breakouts to those shown in Table 3.15-4, the lengths and areas of surface water features within the total AC collection system routes are shown in Table 3.15-5.

Table 3.15-5:
Surface Water Features within the 2-Mile-Wide Corridors (and 200-Foot-Wide ROWs) of the AC Collection System Routes

AC Route Designation	Perennial Streams (miles)	Intermittent Streams (miles)	Major Waterbodies (miles)	Reservoirs, Lakes, and Ponds (acres)
E-1	9.17 (0.23)	100.18 (1.61)	0	33.83 (0.45)
E-2	13.47 (0.37)	100.05 (2.18)	0.07 (0.07)	148.99 (0.99)
E-3	10.06 (0.12)	137.62 (2.39)	0.01 (0.01)	36.71 (0.31)
NE-1	24.11 (0.41)	32.97 (0.25)	0.12 (0.12)	141.04 (0)
NE-2	7.75 (0.20)	78.31 (1.33)	0.10 (0.10)	70.77 (1.95)
NW-1	13.05 (0.16)	110.93 (2.03)	0.09 (0.09)	167.26 (0)
NW-2	31.13 (0.51)	77.72 (0.95)	0.18 (0.18)	119.20 (0.04)
SE-1	21.52 (0.42)	75.70 (2.09)	0.04 (0.04)	677.83 (2.61)
SE-2	0.80 (0)	26.67 (0.30)	0	97.95 (0.38)
SE-3	14.47 (0.37)	98.54 (2.07)	0.07 (0.07)	768.03 (1.00)
SW-1	0.97 (0)	58.06 (0.86)	0	14.24 (0)
SW-2	7.98 (0.14)	125.14 (2.91)	0.08 (0.08)	57.42 (0.21)
W-1	6.16 (0.17)	45.09 (1.05)	0.08 (0.08)	9.27 (0.49)

GIS Data Source: USGS (2014a)

The above ROI numbers are large in comparison to the values shown in Table 3.15-4 for the Applicant Proposed Route and HVDC alternative routes primarily because the corridors evaluated for the AC collection system are 2 miles wide and the HVDC corridors are 1,000 feet wide.

The Oklahoma Converter Station and AC Interconnection Siting Areas include 1.6 miles of intermittent streams, no perennial streams, and no major waterbodies. A 200-foot-wide representative ROW for the AC Interconnection Siting Area encompasses 0.2 mile of intermittent streams.

3.15.5.1.2.1 Surface Water Features of Special Interest

Considering the entire HVDC transmission line route, Region 1 has fewer surface water features as compared to Regions 2 through 7. The most prominent water features within Region 1 are the Beaver River and several of its tributaries that are crossed by the Applicant Proposed Route and HVDC alternative routes or are within the area of the AC collection system routes. With the exception of Wolf Creek, DOE identified no surface waters in the ROI in

Region 1 that have federal or state classifications of special interest other than the water quality designations addressed in the next section. Wolf Creek is a Texas stream in the Upper Wolf (11100202) watershed (Table 3.15-3) that is crossed by the AC Collection System Route SE-3. Per guidelines in Texas regulations (TAC 31-357.43), Wolf Creek is designated as an "ecologically unique river or stream segment." It is identified as a reference stream for development of a regionalized index of biotic integrity for Texas and exhibiting high water quality and diverse benthic macroinvertebrate and fish communities (TPWD 2014).

3.15.5.1.3 Region 1 Water Quality

The CWA (33 USC § 1251 et seq.) establishes a framework for regulating quality standards for surface waters and discharges into those waters. Under that framework, the states evaluate their surface waters, determine applicable beneficial uses, set water quality criteria to support those uses, and implement rules and regulations to achieve or maintain water quality criteria. Section 305(b) of the CWA requires states to develop and periodically update an inventory of the water quality of all water bodies in the state. These inventories, provided to EPA and released to the public, indicate if the water quality supports the designated uses. Section 303(d) requires states to develop and periodically update an inventory of water bodies that do not meet water quality standards, which the states also provide to EPA and release to the public.

Table 3.15-6 identifies surface water features within the ROI that do not meet applicable water quality standards based on the surface water's designated uses and, as a result, have been identified as an impaired water in Oklahoma's most recent Section 303(d) list. All of the surface waters in the table cross the 200-foot-wide representative ROWs of the identified Project components as well as the wider ROI. The table identifies the specific water, the designated use that is impaired and what is causing the impairment. A primary element in the process of improving the water quality in impaired waters is the development of "total maximum daily loads" or TMDLs, which are the maximum amount of a pollutant that a waterbody can receive and still meet water quality standards. Once TMDLs have been determined, discharge requirements can be developed that will bring a waterbody back into compliance. The table identifies the status of the TMDL development process, generally in the form of a date when the TMDL is expected to be developed and approved. In some instances, a TMDL has already been developed and approved by EPA and is noted as such in the table.

Table 3.15-6:
Waters with Impaired Quality within the 1,000-Foot-Wide Corridors of the Applicant Proposed Route and HVDC Alternative Routes and the 2-Mile-Wide Corridors of the AC Collection System Routes—Region 1

Water Segment and Watershed	Impaired Uses—Impairment	TMDL Status[1]	Project Components Crossing Impaired Segment
Beaver River (North Canadian), OK (OK720510000190_00) Upper Beaver watershed (HUC 11100101)	Fish and Wildlife Propagation/Warm Water Aquatic Community—dissolved oxygen impairment	Priority Date: 2020 Approved TMDLs for fecal coliform, E. Coli, *and Enterococcu*s	AC Collection System Route: NW-1

Table 3.15-6:
Waters with Impaired Quality within the 1,000-Foot-Wide Corridors of the Applicant Proposed Route and HVDC Alternative Routes and the 2-Mile-Wide Corridors of the AC Collection System Routes—Region 1

Water Segment and Watershed	Impaired Uses—Impairment	TMDL Status[1]	Project Components Crossing Impaired Segment
Palo Duro Creek, OK (OK720500020500_00) Palo Duro watershed (HUC 11100104)	Primary Body Contact Recreation—*Enterococcus*, and *E. coli* impairments Fish and Wildlife Propagation/Warm Water Aquatic Community—dissolved oxygen and selenium impairments Agricultural—sulfates and total dissolved solids impairments	Priority Date: 2023 Approved TMDLs for fecal coliform and total suspended solids	HVDC: APR Link 2, ARs 1-A, 1-B, and 1-C AC Collection System Routes: E-1, E-2, E-3, SE-1, and SE-3
Kiowa Creek, OK (OK720500020130_00) Lower Beaver watershed (HUC 11100201)	Primary Body Contact Recreation—*E. coli* impairments	Priority Date: 2023 Approved TMDLs for fecal coliform *and Enterococcus*	HVDC: APR Link 4, ARs 1-A and 1-D
Beaver River (North Canadian), OK (OK720500020010_00) Lower Beaver watershed (HUC 11100201)	Fish Consumption—lead impairment Primary Body Contact Recreation—*E. coli* impairment	Priority Date: 2020 Approved TMDLs for fecal coliform, *and Enterococcus*	HVDC: APR Link 5, AR 1-A
Clear Creek, OK (OK720500020070_00) Lower Beaver watershed (HUC 11100201)	Fish and Wildlife Propagation/Warm Water Aquatic Community—benthic-macroinvertebrate bioassessments	Priority Date: 2020 Approved TMDLs for fecal coliform, *E. coli and Enterococcus*	HVDC: APR Link 4, AR 1-D
Otter Creek. OK (OK720500020050_00) Lower Beaver watershed (HUC 11100201)	Fish and Wildlife Propagation/Warm Water Aquatic Community—benthic-macroinvertebrate bioassessments	Priority Date: 2020 Approved TMDLs for *E. coli and Enterococcus*	HVDC: APR Link 5
Sand Creek, OK (OK620920050050_00) Lower Cimarron-Eagle Chief watershed (HUC 11050001)	Fish and Wildlife Propagation/Warm Water Aquatic Community—dissolved oxygen impairment Agriculture—sulfates impairment	Priority Date: 2023 Approved TMDLs for *E. coli and Enterococcus*	HVDC: AR 1-A

1 TMDL = Total Maximum Daily Load—TMDLs are the maximum amount of a pollutant that a waterbody can receive and still meet water quality standards. Once TMDLs have been determined, discharge requirements can be developed that will bring a waterbody back into compliance.

Sources: ODEQ (2014, 2013), EPA (2013b)

Because of the great area and number of surface waters crossed by the ROI, the analysis focuses only on those surface waters identified by the states as being out of compliance, or impaired. The list of surface waters in the table provides an indication of some of the water features that could be encountered along or within the ROIs of the various project components and the types of water pollutants of concern. Table 3.15-6 does not identify surface waters along or within the ROIs that have water quality good enough to meet all of their designated uses.

3.15.5.1.4 Region 1 Water Use

Water use—surface water and groundwater—was previously summarized in Table 3.7-5. The average use of surface water in the four-county area of Beaver, Harper, Texas, and Woodward counties in Oklahoma was about 5.1 million gallons per day in 2010, which was all attributed to irrigation, compared to 372 million gallons per day of groundwater used in the same counties. Surface water, therefore, accounts for only about 1.3 percent of total water usage in the four-county area and none of the area's public water supplies include water from surface sources. The scarcity of surface water also is evidenced in the greater abundance of intermittent streams in this area compared to perennial streams.

Table 3.7-6 summarizes water use in the five-county area of Beaver and Texas counties in Oklahoma and Hansford, Ochiltree, and Sherman counties in Texas that encompass the AC collection system routes. The predominant use of groundwater in the five-county area is even more apparent than for the Region 1 counties. In the five-county area, surface water use at about 2.0 million gallons per day is less than 0.3 percent of the area's total water use of 736 million gallons per day. All of the surface water use in the five-county area is attributed to the categories of irrigation, livestock, and mining.

3.15.5.2 Region 2

Region 2 is referred to as the Oklahoma Central Great Plains Region and includes the Applicant Proposed Route and HVDC Alternative Routes 2-A and 2-B.

Two route variations to the Applicant Proposed Route were developed in Region 2 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.2. The variations (Applicant Proposed Route Link 1, Variation 1, and Applicant Proposed Route Link 2, Variation 2) are illustrated in Exhibit 1 of Appendix M. The discussion of Region 2 surface water elements that follows includes identification of differences, if any, that would be expected with the route variations as compared to the original Applicant Proposed Route.

3.15.5.2.1 Region 2 Watersheds

Still within the large Arkansas-White-Red drainage system, the ROI in Region 2 is primarily within the Lower Cimarron subregion, but portions of the western end of the ROI are within the North Canadian subregion. Primary surface water flow in both of these subregions is from west to east, toward the Mississippi River. Local streams may flow in different directions, even north-south, but as they join larger streams the overall progression is from west to east.

At USGS's eight-digit coding level, the ROI lies within three different watersheds as shown in Figure 3.15-1 in Appendix A. Table 3.15-7 lists the applicable watersheds and provides additional detail, including the primary surface water or waters that drain the watershed. Surface waters for the ROI are shown on Figure 3.15-2 in Appendix A.

Table 3.15-7:
Watersheds Crossed by the Applicant Proposed Route and HVDC Alternative Routes—Region 2

USGS HUC Number and Watershed Name	Area Drained (square miles)	Description of Primary Surface Water Feature(s)
11100301, Middle North Canadian	1,858	North Canadian River drains the watershed, which includes Canton Lake and Ramsey Lake, both on the North Canadian River
11050001, Lower Cimarron-Eagle Chief	2,422	Cimarron River and Eagle Chief Creek drain the watershed. The Cimarron is to the northeast and parallels the North Canadian.
11050002, Lower Cimarron-Skeleton	3,236	Cimarron River is the primary drain for the watershed. Skeleton, Turkey, Kingfisher, and Cottonwood creeks also drain the watershed and are tributaries to the Cimarron River.

GIS Data Source: USGS (2014a)

The watersheds in the ROI in Region 2 are in two different river systems (the Cimarron and the North Canadian), but further downstream, both converge with the Arkansas River (although the North Canadian first joins the Canadian River). Neither of the two route variations to the Applicant Proposed Route developed in Region 2 would change the watersheds that would be crossed.

3.15.5.2.2 Region 2 Surface Water Features

As presented and described for Region 1, Table 3.15-8 lists the total length of perennial streams, intermittent streams, and major waterbodies within the Applicant Proposed Route and HVDC alternative routes in Region 2. The table includes the total acreage of reservoirs, lakes, and ponds located within Applicant Proposed Route and HVDC alternative routes.

Table 3.15-8:
Miles and Acreage of Surface Water Features within the 1,000-Foot-Wide Corridors (and 200-Foot-Wide Representative ROWs) of the Applicant Proposed Route and HVDC Alternative Routes—Region 2

Route—Proposed and Alternatives[1, 2, 3]	Link 1	Link 2	Link 3	Region 2 Total
Perennial Streams				
APR (miles)	0	6.47 (1.32)	0.85 (0.11)	7.32 (1.43)
With AR 2-A (miles)	0	16.90 (3.35)	0.85 (0.11)	17.75 (3.46)
With AR 2-B (miles)	0	6.47 (1.32)	2.47 (0.49)	8.94 (1.81)
Intermittent Streams				
APR (miles)	0	9.34 (1.81)	9.80 (1.94)	19.14 (3.75)
With AR 2-A (miles)	0	4.73 (0.59)	9.80 (1.94)	14.53 (2.53)
With AR 2-B (miles)	0	9.34 (1.81)	8.32 (1.34)	17.66 (3.15)
Major Waterbodies				
APR (miles)	0	0.01 (0.01)	0	0.01 (0.01)
With AR 2-A (miles)	0	0.05 (0.05)	0	0.05 (0.05)
With AR 2-B (miles)	0	0.01 (0.01)	0	0.01 (0.01)
Reservoirs, Lakes, and Ponds				
APR (acres)	1.1 (<0.1)	3.7 (0.8)	8.8 (1.1)	13.6 (1.9)
With AR 2-A (acres)	1.1 (<0.1)	25.2 (6.5)	8.8 (1.1)	35.0 (7.6)
With AR 2-B (acres)	1.1 (<0.1)	3.7 (0.8)	19.4 (1.6)	24.2 (2.4)

1 The values in the table do not reflect the minor changes that would result from application of the minor route variations and adjustments.
2 Each region of the Applicant Proposed Route (APR) is divided into links that lie between points, or nodes, where the APR is intersected by alternative routes (ARs). ARs bypass specific links of the APR as shown in the table.
3 For the ARs, the unshaded portion of the rows provides the data for the length of the AR. The shaded portion of the rows provides the data for the balance of the APR, thereby providing perspective across the region.
GIS Data Source: USGS (2014a)

The two Region 2 route variations would involve no changes to the surface water features crossed by the 200-foot-wide representative ROW of the original Applicant Proposed Route. Neither of the route variations has any of the surface water features identified in Table 3.15-8, similar to the original Applicant Proposed Route.

3.15.5.2.2.1 Surface Water Features of Special Interest

As described for the watersheds in the ROI for Region 2, the North Canadian and Cimarron rivers are important surface water features in the area from a drainage system standpoint and the Cimarron River would be crossed by the Applicant Proposed Route as well as Alternative Route 2-A. Table 3.15-9 identifies surface waters within the ROI that have specific federal or state designations of special interest beyond significance as drainage features. The surface water identified in the table is crossed by the 200-foot-wide representative ROW as well as the 1,000-foot-wide corridor of the ROI.

Table 3.15-9:
Surface Waters of Special Interest within the 1,000-Foot-Wide Corridor of the Applicant Proposed Route and HVDC Alternative Routes—Region 2

Surface Water and Watershed	Designation(s)	Basis for Designation	Route/Alternative Affected		
			APR	2-A	2-B
Cimarron River, OK Lower Cimarron-Skeleton watershed (HUC 11050002)	USFWS critical habitat	Critical habitat for federally listed threatened Arkansas River shiner (*Notropis girardi*)	X	X	
	Oklahoma Water of Recreational and/or Ecological Significance	State protected water due to federally listed species (above)	X	X	

Sources: USFWS (2014), Appendix B of OAC 785:45

Neither of the Region 2 route variations would involve changes to the surface waters of special interest within the 1,000-foot-wide corridor of the Applicant Proposed Route.

3.15.5.2.3 Region 2 Water Quality

Table 3.15-10 identifies surface water features within the ROI in Region 2 that do not meet applicable water quality standards based on the surface water's designated uses and, as a result, have been identified as an impaired water in the state's most recent Section 303(d) list. All of the water segments identified in the table would cross the 200-foot-wide representative ROWs of the identified Project components as well as the wider ROI.

Table 3.15-10:
Waters with Impaired Quality within the 1,000-Foot-Wide Corridors of the Applicant Proposed Route and HVDC Alternative Routes—Region 2

Water Segment and Watershed	Impaired Uses—Impairment	TMDL Status[1]	Project Components Crossing Impaired Segment
Main Creek, OK (OK620920010180_00) Lower Cimarron-Eagle Chief watershed (HUC 11050001)	Fish and Wildlife Propagation/Warm Water Aquatic Community—fishes bioassessments impairment Agriculture—sulfates impairment	Priority Date: 2023 Approved TMDLs for *Enterococcus*, *E. coli*, and total suspended solids	AR 2-A
Griever Creek, OK (OK620920010130_00) Lower Cimarron-Eagle Chief watershed (HUC 11050001)	Fish and Wildlife Propagation/Warm Water Aquatic Community—benthic-macroinvertebrate bioassessments impairment Primary Body Contact Recreation—*E. coli* impairment	Priority Date: 2020 Approved TMDL for *Enterococcus*	AR 2-A

Table 3.15-10:
Waters with Impaired Quality within the 1,000-Foot-Wide Corridors of the Applicant Proposed Route and HVDC Alternative Routes—Region 2

Water Segment and Watershed	Impaired Uses—Impairment	TMDL Status[1]	Project Components Crossing Impaired Segment
East Griever Creek, OK (OK620920010140_00) Lower Cimarron-Eagle Chief watershed (HUC 11050001)	Primary Body Contact Recreation—*Enterococcus* impairment Agriculture—sulfates impairment	Priority Date: 2020	APR Link 2, AR 2-A
Cottonwood Creek, OK (OK620920010080_00) Lower Cimarron-Eagle Chief watershed (HUC 11050001)	Primary Body Contact Recreation—*E. coli* and *Enterococcus* impairments Fish and Wildlife Propagation/Warm Water Aquatic Community—pH impairment	Priority Date: 2023 Approved TMDLs for fecal coliform, and total suspended solids	AR 2-A
Cimarron River, OK (OK620910020010_10) Lower Cimarron-Skeleton watershed (HUC 11050002)	Fish and Wildlife Propagation/Warm Water Aquatic Community—selenium impairment Agriculture—sulfates, total dissolved solids, and chloride impairments	Priority Date: 2020 Approved TMDLs for *Enterococcus* and *E. coli*	APR Link 2, AR 2-A
Turkey Creek, OK (OK620910060010_00) Lower Cimarron-Skeleton watershed (HUC 11050002)	Primary Body Contact Recreation—*E. coli* impairment	Priority Date: 2023 Approved TMDLs for fecal coliform and turbidity	APR Link 3, AR 2-B
Buffalo Creek, OK (OK620910060030_00) Lower Cimarron-Skeleton watershed (HUC 11050002)	Fish and Wildlife Propagation/Warm Water Aquatic Community—dissolved oxygen impairment	Priority Date: 2023 Approved TMDLs for fecal coliform and turbidity	APR Link 3, AR 2-B

1 TMDL = Total Maximum Daily Load—TMDLs are the maximum amount of a pollutant that a waterbody can receive and still meet water quality standards. Once TMDLs have been determined, discharge requirements can be developed that will bring a waterbody back into compliance.

Sources: ODEQ (2014, 2013), EPA (2013b)

Neither of the two Region 2 route variations would involve changes to the impaired waters within the 1,000-foot-wide corridor of the Applicant Proposed Route or the areas at which such waters would be crossed by the route.

3.15.5.2.4 Region 2 Water Use

As described for Region 1 (Section 3.15.5.1.4), groundwater accounts for the majority of the total water use in the three counties (Garfield, Major, and Woodward counties, Oklahoma) that encompass Region 2. Table 3.7-9 shows that the average use of surface water was about 2.6 million gallons per day in 2010 compared to 49 million gallons per day of groundwater used in the same area. Surface water, therefore, accounts for only about 5 percent of area's total water usage; none of the three counties' public water supplies include water from surface sources. Total water use (groundwater and surface water) is described in more detail in Section 3.7.5.2.4.

3.15.5.3 Region 3

Region 3 is referred to as the Oklahoma Cross Timbers Region and includes the Applicant Proposed Route and HVDC Alternative Routes 3-A through 3-E.

Five route variations to the Applicant Proposed Route were developed in Region 3 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.3. The Applicant

Proposed Route variations (Link 1, Variation 2; Links 1 and 2, Variation 1; Link 4, Variation 1; Link 4, Variation 2; and Link 5, Variation 2) are illustrated in Exhibit 1 of Appendix M. It should be noted that a route adjustment was made for HVDC Alternative Route 3-A to maintain an end-to-end route with Links 1 and 2, Variation 1. The discussion of Region 3 surface water elements that follows includes identification of differences, if any, that would be expected with the route variations as compared to the original Applicant Proposed Route. The element discussions also address any changes attributed to the adjustment to HVDC Alternative Route 3-A.

3.15.5.3.1 Region 3 Watersheds

The ROI in Region 3 remains within the large Arkansas-White-Red drainage system, but passes through five watersheds in three subregions: the Lower Cimarron (1105), the North Canadian (1110), and the Lower Arkansas (1111). The Lower Arkansas subregion begins where the Cimarron and Arkansas rivers converge, so the downstream watershed in the Lower Cimarron subregion transitions directly into the watershed of the Lower Arkansas subregion. The western portion of the ROI in Region 3 is primarily within the Lower Cimarron subregion, the central portion is within the North Canadian subregion, and the eastern end is within the Lower Arkansas subregion. Primary surface water flow in these subregions is still from west to east, possibly southeast, toward the Mississippi River. Local streams may flow in different directions, but as they join larger streams the overall progression is from west to east/southeast.

At USGS's eight-digit coding level, the ROI lies within five different watersheds as shown in Figure 3.15-1 in Appendix A. Table 3.15-11 lists the applicable watersheds and provides additional detail, including the primary surface water or waters that drain the watershed. Surface waters for the ROI are shown on Figure 3.15-2 in Appendix A. None of the five route variations developed for the Applicant Proposed Route in Region 3 would change the watersheds that would be crossed.

Table 3.15-11:
Watersheds Crossed by the Applicant Proposed Route and HVDC Alternative Routes—Region 3

USGS HUC Number and Watershed Name	Area Drained (square miles)	Description of Primary Surface Water Feature(s)
11050002, Lower Cimarron-Skeleton	3,236	Cimarron River is the primary drain for the watershed. Skeleton, Turkey, Kingfisher, and Cottonwood creeks also drain the watershed and are tributaries to the Cimarron River.
11050003, Lower Cimarron	1,385	Cimarron River is the primary drain for the watershed, which extends from the Cimarron's confluence with Skeleton Creek to Keystone Lake. Beaver, Drought, Stillwater, Euchee, and Lagoon creeks also drain the watershed and are tributaries to the Cimarron River. Lake Carl Blackwell is also in this watershed.
11100303, Deep Fork	2,536	Deep Fork River is the primary drain for the watershed, which passes through Deep Fork National Wildlife Refuge and drains into Eufaula Lake in the southeast portion of the watershed.
11110101, Polecat-Snake	1,322	Arkansas River is the primary drain for the watershed. Polecat Creek and Snake Creek also drain portions of the watershed and are tributaries to the Arkansas River.
11110102, Dirty-Greenleaf	797	Arkansas River is the primary drain for the watershed. Dirty Creek and Greenleaf Creek also drain portions of the watershed and are tributaries to the Arkansas River. Greenleaf Lake is on Greenleaf Creek.

GIS Data Source: USGS (2014a)

3.15.5.3.2 Region 3 Surface Water Features

Table 3.15-12 lists the total length of perennial streams, intermittent streams, major waterbodies present within the ROI and the 200-foot-wide representative ROW in Region 3. The table includes the total acreage for reservoirs, lakes, and ponds that occur within the ROI.

Table 3.15-12:
Miles and Acreage of Surface Water Features within the 1,000-Foot-Wide Corridors (and 200-Foot-Wide Representative ROWs) of the Applicant Proposed Route and HVDC Alternative Routes—Region 3

</table>

1 The values in the table do not reflect the minor changes that would result from application of the minor route variations and adjustments.
2 Each region of the Applicant Proposed Route (APR) is divided into links that lie between points, or nodes, where the APR is intersected by alternative routes (ARs). ARs bypass specific links of the APR as shown in the table.
3 For the ARs, the unshaded portion of the rows provides the data for the length of the AR. The shaded portion of the rows provides the data for the balance of the APR, thereby providing perspective across the region.
GIS Data Source: USGS (2014a)

Region 3, particularly the areas of the Applicant Proposed Route Link 4 and the corresponding portion of Alternative Route 3-C, passes through an area of Oklahoma where there are many small dams and reservoirs constructed by NRCS for flood prevention, management of soil erosion, and irrigation. The Applicant Proposed Route Link 4 contains all or portions of the following:

- Little Deep Fork 12—The dam and part of the small reservoir is inside the 1,000-foot-wide corridor, but outside the 200-foot-wide ROW.
- Little Deep Fork 44—The dam and most of the reservoir is inside the corridor; the southeast end of the dam and a small corner of the reservoir would be inside the 200-foot-wide ROW.
- Little Deep Fork 45—The dam and most of the reservoir is inside the corridor and would be crossed by the 200-foot-wide ROW.
- Little Deep Fork 51r—The dam is to the south and the reservoir extends into the corridor, but not as far as the 200-foot-wide ROW.

The five Region 3 route variations would involve only minor changes to the surface water features crossed by the 200-foot-wide representative ROW of the original Applicant Proposed Route. The ROWs of the variations would have about 0.2 mile less of stream beds (perennial and intermittent), but would incorporate one more minor water body. None of the variations contains major waterbodies. The area of the adjustment to HVDC Alternative Route 3-A includes no surface water features.

3.15.5.3.2.1 Surface Water Features of Special Interest

As described for the watersheds in the ROI for Region 3, the Cimarron, Deep Fork, and Arkansas rivers are important surface water features in the area from a drainage system standpoint. Lake Carl Blackwell, Eufaula Lake, and Greenleaf Lake are notable surface water impoundments within the watersheds. This portion of the ROI has many streams and impoundments throughout its course. Table 3.15-13 identifies surface waters within the ROI in Region 3 that have specific federal or state designations of special interest beyond significance as drainage features. Each of the water features and designations identified in the table is applicable to the 200-foot-wide representative ROWs as well as the wider ROI.

Table 3.15-13:
Surface Waters of Special Interest within the 1,000-Foot-Wide Corridor of the Applicant Proposed Route and HVDC Alternative Routes—Region 3

Surface Water and Watershed	Designation(s)	Basis for Designation	Route/Alternative Affected					
			APR	3-A	3-B	3-C	3-D	3-E
Lake Carl Blackwell, OK Lower Cimarron watershed (HUC 11050003)	Oklahoma Source Water Protection Area	The lake and drainage areas in close proximity are designated for protection because the lake is a drinking water source. ARs 3-A and 3-B cross protected drainage area, but not the lake.		X	X			
	Oklahoma Special Provision Watershed for Sensitive Public and Private Water Supply	The lake is a protected water supply source. ARs 3-A and 3-B cross five protected streams flowing into the lake.		X	X			

Table 3.15-13:
Surface Waters of Special Interest within the 1,000-Foot-Wide Corridor of the Applicant Proposed Route and HVDC Alternative Routes—Region 3

Surface Water and	Designation(s)	Basis for Designation	Route/Alternative Affected					
Cushing Lake, OK Lower Cimarron watershed (HUC 11050003)	Oklahoma Special Provision Watershed for Sensitive Public and Private Water Supply	The lake is a protected water supply source. The APR and AR 3-C cross two and four protected streams, respectively, that flow into the lake.	X L4			X		

Source: OWRB (2011d)

The five Region 3 route variations would involve no changes to the list (Table 3.15-13) of surface waters of special interest within the 1,000-foot-wide corridor of the Applicant Proposed Route. Similarly, the adjustment to HVDC Alternative Route 3-A is not in an area where there are surface waters of special interest.

3.15.5.3.3 Region 3 Water Quality

Table 3.15-14 identifies surface water features within the ROI in Region 3 that do not meet applicable water quality standards based on the surface water's designated uses and, as a result, have been identified as an impaired water in the state's most recent Section 303(d) list. As noted by a table footnote, Dirty Creek would be within the 1,000-foot-wide corridor of the ROI, but not the 200-foot-wide representative ROW. Link 3 of the Applicant Proposed Route would cross Stillwater Creek and the creek would be encompassed by the 1,000-foot-wide corridor of Link 4, but it would be avoided by the 200-foot-wide ROW of Link 4. All of the other segments would cross both the ROI and the ROW.

Table 3.15-14:
Waters with Impaired Quality within the 1,000-Foot-Wide Corridors of the Applicant Proposed Route and HVDC Alternative Routes—Region 3

Water Segment and Watershed	Impaired Uses—Impairment	TMDL Status[1]	Project Components Crossing Impaired Segment
Skeleton Creek, OK (OK620910030010_00) Lower Cimarron-Skeleton watershed (HUC 11050002)	Fish and Wildlife Propagation/Warm Water Aquatic Community—selenium impairment	Priority Date: 2023 Approved TMDLs for *Enterococcus*, *E. coli*, fecal coliform, and total suspended solids	APR Link 1
West Beaver Creek, OK (OK620900030260_00) Lower Cimarron watershed (HUC 11050003)	Primary Body Contact Recreation—*E. coli* and *Enterococcus* impairments	Priority Date: 2023 Approved TMDL for turbidity	ARs 3-A and 3-B
Stillwater Creek, OK (OK620900040040_00) Lower Cimarron watershed (HUC 11050003)	Fish and Wildlife Propagation/Warm Water Aquatic Community—dissolved oxygen impairment	Priority Date: 2017 Approved TMDLs for *Enterococcus*, *E. coli*, and turbidity	APR Link 3 and Link 4[2], AR 3-B
Little Stillwater Creek, OK (OK620900040050_00) Lower Cimarron watershed (HUC 11050003)	Public and Private Water Supply—nitrates impairment	Priority Date: 2017	AR 3-B
Cimarron River, OK (OK620900030010_00) Lower Cimarron watershed (HUC	Fish Consumption—lead impairment	Priority Date: 2017 Approved TMDLs for *Enterococcus* and turbidity	APR Link 4, AR 3-C

Table 3.15-14:
Waters with Impaired Quality within the 1,000-Foot-Wide Corridors of the Applicant Proposed Route and HVDC Alternative Routes—Region 3

Water Segment and Watershed	Impaired Uses—Impairment	TMDL Status[1]	Project Components Crossing Impaired Segment
11050003)			
Little Deep Fork Creek, OK (OK520700060130_10) Deep Fork watershed (HUC 11100303)	Primary Body Contact Recreation—*E. coli* and *Enterococcus* impairments	Priority Date: 2018	AR 3-C
West Spring Creek, OK (OK520700060210_00 Deep Fork watershed (HUC 11100303)	Agriculture—chloride and total dissolved solids impairments	Priority Date: 2020	APR Link 4
Browns Creek, OK (OK520700060050_00) Deep Fork watershed (HUC 11100303)	Fish and Wildlife Propagation/Warm Water Aquatic Community—dissolved oxygen impairment	Priority Date: 2020	APR Link 4, AR 3-C
Begger Creek, OK (OK520700020155_00) Deep Fork watershed (HUC 11100303)	Agriculture—chloride and total dissolved solids impairments	Priority Date: 2023	APR Link 4
Salt Creek, OK (OK520700020150_00) Deep Fork watershed (HUC 11100303)	Agriculture—chloride impairment Fish and Wildlife Propagation/Warm Water Aquatic Community—dissolved oxygen impairment	Priority Date: 2023	APR Link 4, AR 3-C
Adams Creek, OK (OK520700020080_00) Deep Fork watershed (HUC 11100303)	Fish and Wildlife Propagation/Warm Water Aquatic Community—dissolved oxygen impairment	Priority Date: 2023	APR Link 4, AR 3-C
Butler Creek, OK (OK120400020160_00) Dirty-Greenleaf watershed (HUC 11110102)	Fish and Wildlife Propagation/Warm Water Aquatic Community—dissolved oxygen impairment	Priority Date: 2023 Approved TMDLs for *Enterococcus*, *E. coli*, and turbidity	ARs 3-C and 3-D
Dirty Creek, OK (OK120400020010_00) Dirty-Greenleaf watershed (HUC 11110102)	Fish and Wildlife Propagation/Warm Water Aquatic Community—dissolved oxygen impairment	Priority Date: 2020 Approved TMDLs for *Enterococcus* and turbidity	ARs 3-C[2], 3-D[2], and 3-E[2]

1 TMDL = Total Maximum Daily Load—TMDLs are the maximum amount of a pollutant that a waterbody can receive and still meet water quality standards. Once TMDLs have been determined, discharge requirements can be developed that will bring a waterbody back into compliance.
2 The 1,000-foot-wide ROI corridor of this route component would encompass the water segment, but the corresponding 200-foot-wide ROW would not.
Sources: ODEQ (2014, 2013), EPA (2013b)

The five Region 3 route variations would involve no changes to the list (Table 3.15-14) of impaired waters within the 1,000-foot-wide corridor of the Applicant Proposed Route or the areas at which such waters would be crossed by the route. Similarly, there are no impaired waters in the area of the adjustment to HVDC Alternative Route 3-A.

3.15.5.3.4 Region 3 Water Use

The contribution of surface water becomes more important in the eight counties (Creek, Garfield, Kingfisher, Lincoln, Logan, Muskogee, Okmulgee, and Payne counties, Oklahoma) that encompass Region 3 as compared to Regions 1 and 2. Table 3.7-12 shows that the average use of surface water was about 81 million gallons per day in 2010 compared to about 267 million gallons per day of groundwater. Surface water, therefore, accounts for about 23 percent of area's total water usage. Total water use (groundwater and surface water) is described in more detail in Section 3.7.5.3.4.

3.15.5.4 Region 4

Region 4 is referred to as the Arkansas River Valley Region and includes the Applicant Proposed Route and HVDC Alternative Routes 4-A through 4-E as well as the Lee Creek Variation.

Seven route variations to the Applicant Proposed Route were developed in Region 4 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.4. The Applicant Proposed Route variations (Link 3, Variation 1; Link 3, Variation 2; Link 3, Variation 3; Link 6, Variation 1; Link 6, Variation 2; Link 6, Variation 3; and Link 9, Variation 1) are illustrated in Exhibit 1 of Appendix M. The discussion of Region 4 surface water elements that follows includes identification of differences, if any, that would be expected with the route variations as compared to the original Applicant Proposed Route.

3.15.5.4.1 Region 4 Watersheds

The ROI in Region 4 is entirely within the Lower Arkansas subregion (1111) of the larger Arkansas-White-Red drainage system. Primary drainage of this subregion is provided by the Arkansas River and, consistent with the Arkansas River flow in this area, the predominant flow direction is to the southeast toward the Mississippi River. Local streams may flow in different directions, but as they join larger streams and eventually the Arkansas River, the overall progression is to the southeast.

At USGS's eight-digit coding level, the ROI lies within five different watersheds as shown in Figure 3.15-1 in Appendix A. Table 3.15-15 lists the applicable watersheds and provides additional detail, including the primary surface water or waters that drain the watershed. Surface waters for the ROI are shown on Figure 3.15-2 in Appendix A. None of the seven route variations to the Applicant Proposed Route developed in Region 4 would change the watersheds that would be crossed.

Table 3.15-15:
Watersheds Crossed by the Applicant Proposed Route and HVDC Alternative Routes—Region 4

USGS HUC Number and Watershed Name	Area Drained (square miles)	Description of Primary Surface Water Feature(s)
11110102, Dirty-Greenleaf	797	Arkansas River is the primary drain for the watershed. Dirty Creek and Greenleaf Creek also drain portions of the watershed and are tributaries to the Arkansas River. Greenleaf Lake is on Greenleaf Creek.
11110103, Illinois	1,654	Illinois River is the primary drain for the watershed. The Illinois River converges with the Arkansas River just downstream of the watershed's south border. Tenkiller Ferry Lake is a major water body in the watershed.
11110104, Robert S. Kerr Reservoir	1,762	Arkansas River is the primary drain for the watershed and the Robert S. Kerr Reservoir, formed by a dam on the Arkansas River is a primary waterbody in the watershed. Sans Bois, Sallisaw, Negro, and Little Vian creeks are some of the streams draining portions of

Table 3.15-15:
Watersheds Crossed by the Applicant Proposed Route and HVDC Alternative Routes—Region 4

USGS HUC Number and Watershed Name	Area Drained (square miles)	Description of Primary Surface Water Feature(s)
		the watershed and flowing into the reservoir. The Canadian River also joins the Arkansas River system at the reservoir. Lee Creek, flowing south from the Ozark National Forest, converges with the Arkansas River near the eastern edge of the watershed.
11110201, Frog-Mulberry	1,286	Arkansas River is the primary drain for the watershed. Frog Bayou and the Mulberry River flow through the Ozark National Forest in the northern portion of the watershed and then flow south into the Arkansas River.
11110202, Dardanelle Reservoir	1,865	Arkansas River is the primary drain for the watershed and the Dardanelle Reservoir, formed by a dam on the Arkansas River is a primary waterbody in the watershed. Big Piney Creek and the Illinois Bayou flow through the Ozark National Forest in the northern portion of the watershed and then flow south into the Arkansas River.

GIS Data Source: USGS (2014a)

3.15.5.4.2 Region 4 Surface Water Features

Table 3.15-16 lists the total length of perennial streams, intermittent streams, and major waterbodies within the ROI and the 200-foot-wide representative ROW in Region 4. The table includes the total acreage for reservoirs, lakes, and ponds that occur within the ROI.

Table 3.15-16:
Miles and Acreage of Surface Water Features within the 1,000-Foot-Wide Corridors (and the 200-Foot-Wide Representative ROW) of the Applicant Proposed Route and HVDC Alternative Routes—Region 4

1 The values in the table do not reflect the minor changes that would result from application of the minor route variations and adjustments.
2 Each region of the Applicant Proposed Route (APR) is divided into links that lie between points, or nodes, where the APR is intersected by alternative routes (ARs). ARs bypass specific links of the APR as shown in the table.
3 For the ARs, the unshaded portion of the rows provides the data for the length of the AR. The shaded portion of the rows provides the data for the balance of the APR, thereby providing perspective across the region.
GIS Data Source: USGS (2014a)

The Applicant has proposed a route variation in Region 4, the Lee Creek Variation, that is not included in Table 3.15-16. The Lee Creek Variation would move the Applicant Proposed Route slightly to the north in the area of the Lee Creek Reservoir, which is roughly on the Oklahoma-Arkansas border. Within this small variation in Link 3 of the route, surface water features are summarized as follows (GIS Data Source: USGS 2014a):

- Perennial streams—0.25 mile in the 1,000-foot-wide corridor of the ROI and 0.04 mile in the 200-foot-wide ROW

- Intermittent streams—0.79 mile in the 1,000-foot-wide corridor of the ROI and 0.29 mile in the 200-foot-wide ROW
- Major waterbodies—0.01 mile in both the 1,000-foot-wide corridor of the ROI and the 200-foot-wide ROW
- Reservoirs, lakes, and ponds—Neither the ROI nor the ROW include reservoirs, lakes, or ponds

The western end of the ROI in Region 4 passes through the same area of Oklahoma described for the ROI in Region 3 where the NRCS has constructed many small dams and reservoirs for flood prevention, management of soil erosion, and irrigation. The ROI for HVDC Alternative Routes 4-A and 4-B (in a segment where the routes overlap) contains the dam and a small strip of the reservoir named Sallisaw Creek 6, presumably because it is located in a small drainage that drains to the east to Sallisaw Creek (Table 3.15-17 below). The 200-foot-wide ROW for HVDC Alternative Routes 4-A and 4-B would pass roughly 200 feet to the south of the dam and the reservoir.

The seven Region 4 route variations would involve only minor changes to the surface water features crossed by the 200-foot-wide representative ROW of the Applicant Proposed Route. The ROWs of the variations would have about 0.5 mile less of stream beds (perennial and intermittent) and would incorporate two fewer minor water bodies. There would be no change in major waterbodies from the original Applicant Proposed Route.

3.15.5.4.2.1 Surface Water Features of Special Interest

As described in the discussion of watersheds in the ROI in Region 4, the Arkansas and Illinois rivers are important surface water features in the area from a drainage system standpoint, but Mulberry River and Big Piney Creek are identified as being of particular value based on several designations. This portion of the proposed transmission line route passes through or by several Oklahoma and Arkansas communities as well as numerous surface water features. Consistent with the presence of communities in the area, the HVDC transmission line routes also pass through several areas that are protected as waters and drainage areas associated with drinking water supplies. Table 3.15-17 identifies surface waters within the ROI in Region 4 that have specific federal or state designations of special interest beyond significance as drainage features. The surface waters are presented in a rough west-to-east order. Each of the water features and designations identified in the table is applicable to the 200-foot-wide representative ROWs as well as the wider ROI.

Table 3.15-17:
Surface Waters of Special Interest within the 1,000-Foot-Wide Corridors of the Applicant Proposed Route and HVDC Alternative Routes—Region 4

Surface Water and Watershed	Designation(s)	Basis/Description	Route/Alternative Affected					
			APR	4-A	4-B	4-C	4-D	4-E
Arkansas River, OK Dirty-Greenleaf watershed (HUC 11110202)	Section 10 Navigable Waters of the U.S	Any action that would obstruct or alter a navigable water is prohibited without a USACE permit. APR Link 1 crosses the river.	X L1					
Lower Illinois River, OK Illinois watershed (HUC 11110103)	Section 10 Navigable Waters of the U.S	Any action that would obstruct or alter a navigable water is prohibited without a USACE permit. APR Link 1 crosses the river.	X L1					
	Oklahoma High Quality Water	APR Link 1 crosses the river and its special provision watershed.	X L1

Brushy Creek, OK Robert S. Kerr Reservoir watershed (HUC 11110104)	Oklahoma Sensitive Public and Private Water Supply	AR 4-A and AR 4-B cross the special provision watershed of Brushy Creek Reservoir, including two streams with the water supply designation.		X	X			
Little Lee Creek, OK Robert S. Kerr Reservoir watershed (HUC 11110104)	Oklahoma Outstanding Resource Water	AR 4-A and AR 4-B cross the creek and its special provision watershed.		X	X			
	Oklahoma Scenic River Area	AR 4-A and AR 4-B cross the creek		X	X			
Lee Creek, OK Robert S. Kerr Reservoir watershed (HUC 11110104)	National Park Service Nationwide Rivers Inventory	APR Link 3, AR 4-A, and AR 4-B cross the creek	X L3	X	X			
	Oklahoma Outstanding Resource Water	APR Link 3, AR 4-A, and AR 4-B cross the creek and its special provision watershed	X L3	X	X			
	Oklahoma Scenic River Area	AR 4-A and AR 4-B cross the creek where it is designated a Scenic River. (The APR crosses outside of the designated area.)		X	X			
	Arkansas Extraordinary Resource Water	AR 4-B crosses the creek in Crawford County, AR			X			
Briar Creek (Bear Creek), OK Robert S. Kerr Reservoir watershed (HUC 11110104)	Oklahoma Outstanding Resource Water	The creek lies between the APR and AR 4-B, but APR Link 3 crosses the creek's special provision watershed	X L3					
Webbers Creek, OK Robert S. Kerr Reservoir watershed (HUC 11110104)	Oklahoma Outstanding Resource Water	The creek lies south of AR 4-A, but AR 4-A crosses the creek's special provision watershed		X				
Lee Creek Reservoir, OK and AR Robert S. Kerr Reservoir watershed (HUC 11110104)	Lee Creek Reservoir Buffer Zone	The city of Fort Smith manages a 300-foot, restrictive buffer zone around the reservoir. APR Link 3 crosses the buffer zone in both states.	X L3			X	X	X
Not publicly available location (APR Link 3), AR Robert S. Kerr Reservoir watershed (HUC 11110104)	Arkansas Source Water Protection Area (and public water intakes)[1]	APR Link 3, AR 4-A, and AR 4-D cross the area and APR Link 3 is less than 3 miles upstream of the associated source water intake.	X L3	X			X	

Table 3.15-17:
Surface Waters of Special Interest within the 1,000-Foot-Wide Corridors of the Applicant Proposed Route and HVDC Alternative Routes—Region 4

Surface Water and Watershed	Designation(s)	Basis/Description	Route/Alternative Affected					
			APR	4-A	4-B	4-C	4-D	4-E
Mulberry River, AR Frog-Mulberry watershed (HUC 11110201)	Section 10 Navigable Waters of the U.S	Any action that would obstruct or alter a navigable water is prohibited without a USACE permit. APR Link 6, AR 4-A, AR 4-B, and AR 4-D cross the river	X L6	X	X		X	
	Arkansas Extraordinary Resource Water	APR Link 6, AR 4-A, AR 4-B, and AR 4-D cross the river	X L6	X	X		X	
	Arkansas Natural and Scenic Waterway	Same as above	X L6	X	X		X	
Not publicly available location, AR Frog-Mulberry watershed (HUC 11110201)	Arkansas Source Water Protection Area (and public water intakes)[1]	AR 4-A, AR 4-B, and AR 4-D cross the area, but each is greater than 3 miles upstream of the associated source water intake.		X	X		X	
Not publicly available location, AR Frog-Mulberry watershed (HUC 11110201)	Arkansas Source Water Protection Area (and public water intakes)[1]	AR 4-A, AR 4-B, and AR 4-D cross the area. AR 4-B is about 3 miles upstream of the associated source water intake; AR 4-A and AR 4-D are downstream of the intake.		X	X		X	
Not publicly available location (APR Link 7), AR Frog-Mulberry watershed (HUC 11110201)	Arkansas Source Water Protection Area (and public water intakes)[1]	APR Link 7 and AR 4-B cross the area. AR 4-B is just over 3 miles upstream of the associated source water intake; APR Link 7 is downstream of the intake.	X L7		X			
Big Piney Creek, AR Dardanelle reservoir watershed (HUC 11110202)	National Park Service Nationwide Rivers Inventory	APR Link 9 and AR 4-E cross the creek.	X L9					X
	Arkansas Extraordinary Resource Water	Same as above	X L9					X
	Arkansas Natural and Scenic Waterway	Same as above	X L9					
Not publicly available location (APR Link 9, AR 4-E) Dardanelle reservoir watershed (HUC 11110202)	Arkansas Source Water Protection Area (and public water intakes)[1]	APR Link 9 and AR 4-E cross the area. APR Link 9 is over 3 miles upstream of the associated source water intake; AR 4-E is less than 3 miles upstream of the intake.	X L9					

L3 (for example) = Link 3 of the Applicant Proposed Route in Region 4
1 Confidential data are excluded to avoid privacy/security concerns.
Sources: USACE (2014b), USACE (2004), NPS (2010, 2004), NWSRS (2012), OWRB (2011a, 2011b, 2011c, 2011d), APCEC (2011), Clean Line (2013)

It is worth noting that the Mulberry River and Big Piney Creek, both listed in Table 3.15-17, are designated as National Wild and Scenic Rivers. However, in both cases, the designations end when the streams exit the National Forest, which is to the north of the Project components and, as a result, those designations are not shown in the table.

The Lee Creek Variation mentioned above is not included in Table 3.15-17, but this variation would avoid the 300-foot buffer zone established around the reservoir by the city of Fort Smith. The applicable portion of the Applicant Proposed Route (with or without the variation) would be within the area designated as the Lee Creek Outstanding Water Resource special provision watershed (OWRB 2011b) as well as the area established as a Source Water Protection Area.

The seven Region 4 route variations would involve no changes to the list (Table 3.15-17) of surface waters of special interest within the 1,000-foot-wide corridor of the Applicant Proposed Route. Compared to the original Applicant Proposed Route, Link 3, Variation 2 would cross Salisaw Creek at a slightly different location, and Link 9, Variation 1, would cross Big Piney Creek at a slightly different location.

3.15.5.4.3 Region 4 Water Quality

Table 3.15-18 identifies surface water features within the ROI in Region 4 that do not meet applicable water quality standards based on the surface water's designated uses and, as a result, have been identified as an impaired water in the states' most recent Section 303(d) lists. Each of the water segments identified in the table is applicable to the 200-foot-wide representative ROWs as well as the wider ROI.

Table 3.15-18:
Waters with Impaired Quality within the 1,000-Foot-Wide Corridors of the Applicant Proposed Route and HVDC Alternative Routes—Region 4

Water Segment and Watershed	Impaired Uses—Impairment	TMDL Status[1]	Project Components Crossing Impaired Segment
Sallisaw Creek, OK (OK220200030010_10) Robert S. Kerr Reservoir watershed (HUC 11110104)	Primary Body Contact Recreation—*Enterococcu*s impairment	Priority Date: 2017	APR Link 3
Sallisaw Creek, OK (OK220200030010_20) Robert S. Kerr Reservoir watershed (HUC 11110104)	Primary Body Contact Recreation—*Enterococcu*s impairment	Priority Date: 2017	ARs 4-A and 4-B
Little Sallisaw Creek, OK (OK220200020040_00) Robert S. Kerr Reservoir watershed (HUC 11110104)	Fish and Wildlife Propagation/Warm Water Aquatic Community—copper impairment	Priority Date: 2017	APR Link 3, ARs 4-A, and 4-B

Lee Creek, OK (OK220200050010_00) Robert S. Kerr Reservoir watershed (HUC 11110104)	Primary Body Contact Recreation—*Enterococcu*s impairment Fish and Wildlife Propagation/Cool Water Aquatic Community—lead impairment	Priority Date: 2017	APR Link 3
Lee Creek, OK (OK220200050010_10 Robert S. Kerr Reservoir watershed (HUC 11110104)	Fish and Wildlife Propagation/Cool Water Aquatic Community—copper and lead impairments	Priority Date: 2017	ARs 4-A and 4-B

1 TMDL = Total Maximum Daily Load—TMDLs are the maximum amount of a pollutant that a waterbody can receive and still meet water quality standards. Once TMDLs have been determined, discharge requirements can be developed that will bring a waterbody back into compliance.
Sources: ODEQ (2014, 2013), EPA (2013b), ADEQ (2014a, 2014b, 2014c)

The seven Region 4 route variations would involve no changes to the list (Table 3.15-18) of impaired waters within the 1,000-foot-wide corridor of the Applicant Proposed Route. Compared to the original Applicant Proposed Route, Link 3, Variation 2, would cross Salisaw Creek at a slightly different location and Link 3, Variation 1 would cross Little Salisaw Creek at a slightly different location.

3.15.5.4.4 Region 4 Water Use

Water use in the six counties (Muskogee and Sequoyah counties, Oklahoma, and Crawford, Franklin, Johnson, and Pope counties, Arkansas) that encompass Region 4 has clearly shifted in favor of surface water compared to that described for Region 3. Table 3.7-15 shows that average use of surface water was almost 1,090 million gallons per day in 2010 and average use of groundwater was 9.4 million gallons per day. Surface water, therefore, accounts for 99 percent of area's total water usage. Total water use (groundwater and surface water) is described in greater detail in Section 3.7.5.4.4.

3.15.5.5 Region 5

Region 5 is referred to as the Central Arkansas Region and includes the Applicant Proposed Route and HVDC Alternative Routes 5-A through 5-F.

Five route variations to the Applicant Proposed Route were developed in Region 5 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.5. The Applicant Proposed Route variations (Link 1, Variation 2; Link 2, Variation 2; Links 2 and 3, Variation 1; Links 3 and 4, Variation 2; and Link 7, Variation 1) are illustrated in Exhibit 1 of Appendix M. It should be noted that route adjustments were made for HVDC Alternative Route 5-B to maintain an end-to-end route with Links 2 and 3, Variation 1, and for HVDC Alternative Route 5-E to maintain an end-to-end route with Links 3 and 4, Variation 2. The discussion of Region 5 surface water elements that follows includes identification of differences, if any, that would be expected with the route variations as compared to the original Applicant Proposed Route. The element discussions also address any changes attributed to the adjustments to HVDC Alternative Route 5-B and HVDC Alternative Route 5-E.

3.15.5.5.1 Region 5 Watersheds

The ROI in Region 5 is primarily within the Lower Arkansas (1111) and Upper White (1101) subregions of the larger Arkansas-White-Red drainage system. The only exception is in the eastern portion of Region 5 where several of the alternative routes drop southward and cross through the Lower Mississippi-St. Francis subregion (0802) of the larger Lower Mississippi drainage system. The Lower Mississippi drainage system incorporates drainage areas along the Mississippi River downstream of the confluence of the Mississippi and Ohio rivers. Both drainage systems still flow toward the Mississippi River, but the flow routes can be different. By the USGS methodology, as the larger river systems, such as the Arkansas, White, and Red rivers, approach the Mississippi River, they move out of their own subregion and into subregions of the Lower Mississippi drainage system.

At USGS's eight-digit coding level, the ROI lies within six different watersheds as shown in Figure 3.15-1 in Appendix A. Table 3.15-19 lists the applicable watersheds and provides additional detail, including the primary surface water or waters that drain the watershed. Surface waters for the ROI are shown on Figure 3.15-2 in Appendix A. None of the five route variations to the Applicant Proposed Route developed in Region 5 would change the watersheds that would be crossed.

Table 3.15-19:
Watersheds Crossed by the Applicant Proposed Route and HVDC Alternative Routes—Region 5

USGS HUC Number and Watershed Name	Area Drained (square miles)	Description of Primary Surface Water Feature(s)
11110202, Dardanelle Reservoir	1,865	Arkansas River is the primary drain for the watershed and the Dardanelle Reservoir, formed by a dam on the Arkansas River is a primary waterbody. Big Piney Creek and the Illinois Bayou flow through the Ozark National Forest in the northern portion of the watershed and then flow south into the Arkansas River.
11110203, Lake Conway-Point Remove[1]	1,139	Arkansas River is the primary drain for the watershed. Lake Conway (Greens Lake) connects to the Arkansas River through Palarm Creek. Point Remove Creek is also a tributary to the Arkansas River and its upstream branches, West and East Point Remove creeks, are dammed at multiple points to create reservoirs.
11110205, Cadron	757	Cadron Creek is the primary drain for the watershed and flows into the Arkansas River at the southern boundary of the watershed. Other waterbodies of note in this watershed are East Fork Cadron Creek and Beaver Fork Lake.
11010014, Little Red	1,801	Little Red River is the primary drain for this watershed and drains into the White River at the southeastern end of the watershed. Archey Creek, South Fork Little Red River, Beech Fork, and Big Creek are tributaries to the Little Red River. Greers Ferry Lake is located on the Little Red River.
08020301, Lower White-Bayou Des Arc	1,136	White River is the primary drain for this watershed. Cypress Bayou, fed by creeks such as Bayou Des Arc, Bull Creek, and Fourmile Creek, flows into the White River. Wattensaw Bayou also flows into the White River.
11010013, Upper White-Village	740	White River and its tributary Village Creek are primary drains for this watershed. The Black River also drains a portion of the watershed before it converges with the White River. Departee and Glaise creeks are also tributaries of note to the White River.

1 The proposed Arkansas converter station alternative would be within the Lake Conway–Point Remove watershed.

GIS Data Source: USGS (2014a)

As summarized in Table 3.15-19, the Arkansas River is the primary drain for western portion of the ROI in Region 5, but the primary drain changes to the White River in the eastern portion of the region. The White River flows into the Mississippi River just north of where the Arkansas River meets the Mississippi, but in the ROI the White River's flow is primarily to the south.

3.15.5.5.2 Region 5 Surface Water Features

Table 3.15-20 lists the total length of perennial streams, intermittent streams, and major waterbodies within the ROI and the 200-foot-wide representative ROW in Region 5. The table includes the total acreage for reservoirs, lakes, and ponds that occur within the ROI.

Table 3.15-20:
Miles and Acreage of Surface Water Features within the 1,000-Foot-Wide Corridors (and 200-Foot-Wide Representative ROW) of the Applicant Proposed Route and HVDC Alternative Routes—Region 5

With AR 5-E (acres)	5.68 (0.9)	0.8 (0)	21.8 (6.8)	21.8 (3.2)			0.2 (0.1)	0.5 (0.5)	6.4 (2.0)	57.2 (13.5)
With AR 5-F (acres)	5.68 (0.9)	0.8 (0)	21.8 (6.8)	18.5 (3.6)	10.4 (0.7)		0.2 (0.1)	0.5 (0.5)	6.4 (2.0)	64.3 (14.6)

1 The values in the table do not reflect the minor changes that would result from application of the minor route variations and adjustments.
2 Each region of the Applicant Proposed Route (APR) is divided into links that lie between points, or nodes, where the APR is intersected by alternative routes (ARs). ARs bypass specific links of the APR as shown in the table.
3 For the ARs, the unshaded portion of the rows provides the data for the length of the AR. The shaded portion of the rows provides the data for the balance of the APR, thereby providing perspective across the region.
GIS Data Source: USGS (2014a)

The siting area for the Arkansas converter station alternative would include no perennial streams, 0.63 mile of intermittent streams, no major waterbodies, and 2.6 acres of reservoirs, lakes, and ponds. The 200-foot-wide ROW for the AC interconnection siting area and the site for the substation at the southwestern end of the interconnection line would encompass 0.16 mile of perennial streams, 1.49 miles of intermittent streams, and 1.66 acres of reservoirs, lakes, and ponds (GIS Data Source: USGS 2014a).

The five Region 5 route variations would involve only minor changes to the surface water features crossed by the 200-foot-wide representative ROW of the Applicant Proposed Route. The ROWs of the variations would have about 0.2 mile less of stream beds (perennial and intermittent). There would be no change in major waterbodies from the original Applicant Proposed Route and the number of other minor waterbodies would even out with one less in Link 1, Variation 2, and one more in Link 7, Variation 1. The adjustments to HVDC Alternative Routes 5-B and 5-E would involve no differences in surface water features.

3.15.5.5.2.1 Surface Water Features of Special Interest

As described in the discussion of watershed in the ROI in Region 5, the Arkansas, Little Red, and White rivers along with Cadron Creek are important surface water features in the area from a drainage system standpoint. Table 3.15-21 identifies surface waters within the ROI that have specific federal or state designations of special interest beyond significance as drainage features. The surface waters are presented in a roughly west-to-east order. The ROI for the Arkansas converter station alternative contains no significant surface waters. Each of the water features and designations identified in the table is applicable to the 200-foot-wide representative ROWs as well as the wider ROI.

Table 3.15-21:
Surface Waters of Special Interest within the 1,000-Foot-Wide Corridors of the Applicant Proposed Route and HVDC Alternative Routes—Region 5

Surface Water and Watershed	Designation(s)	Basis/Description	Route/Alternative Affected						
			APR	5-A	5-B	5-C	5-D	5-E	5-F
Illinois Bayou, AR Dardanelle Reservoir watershed (HUC 11110202)	Arkansas Extraordinary Resource Water	APR Link 1 and AR 5-A cross the bayou.	X L1	X					
Not publicly available location (APR Link 3), AR Cadron watershed (HUC 11110205)	Arkansas Source Water Protection Area (and public water intakes)[1]	APR Link 3 and AR 5-B cross the area and both are greater than 3 miles upstream of the associated source water intake.	X L3		X				
Cadron Creek, AR Cadron watershed (HUC 11110205)	National Park Service Nationwide Rivers Inventory	APR Links 3 and 4, AR 5-B, and AR 5-E cross or abut the creek.	X L3 L4		X			X	
	Arkansas Extraordinary Resource Water	Same as above.	X L3 L4		X			X	
East Fork Cadron Creek, AR Cadron watershed (HUC 11110205)	National Park Service Nationwide Rivers Inventory	AR 5-B, AR 5-E, and AR 5-F cross the creek.			X			X	X
Not publicly available location (APR Links 5 to 9), AR Little Red watershed (HUC 11010014)	Arkansas Source Water Protection Area (and public water intakes)[1]	APR Links 5 to 9 and ARs 5-B to 5-F cross; all are greater than 3 miles upstream of the associated source water intake.	X L5 to L9		X	X	X	X	X
Little Red River, AR Little Red watershed (HUC 11010014)	Arkansas Trout Water	APR Link 7 and AR 5-C cross the reach of the river (from below Greers Ferry Dam to Searcy) with this designation.	X L7			X			
Departee Creek, AR Upper White-Village watershed (HUC 11010013)	Arkansas Ecologically Sensitive Waterbody	AR 5-D crosses the reach of the creek with this designation, which is due to the presence of the flat floater mussel (*Anodonta suborbiculata*).					X		
White River, AR Upper White-Village watershed (HUC 11010013)	Section 10 Navigable Waters of the U.S	Any action that would obstruct or alter a navigable water is prohibited without a USACE permit. APR Link 9 and AR 5-D cross the river.	X L9				X		

L1 (for example) = Link 1 of the Applicant Proposed Route in Region 5
1 Confidential data are excluded to avoid privacy/security concerns.
Sources: APCEC (2011), NPS (2004), USACE (2004), Clean Line (2013)

The five Region 5 route variations would involve a minor change to the list (Table 3.15-21) of surface waters of special interest within the 1,000-foot-wide corridor of the Applicant Proposed Route. Using Links 3 and 4, Variation 2, Cadron Creek would no longer be within the 1,000-foot-wide corridor of Link 3, but the creek would still be crossed by Link 4. Comparatively, Link 1, Variation 2, would cross Illinois Bayou at a slightly different location. The minor adjustments to HVDC Alternative Routes 5-B and 5-E would cause no changes to the list of surface waters of special interest.

3.15.5.5.3 Region 5 Water Quality

Table 3.15-22 identifies surface water features within the ROI in Region 5 that do not meet applicable water quality standards based on the surface water's designated uses and, as a result, have been identified as an impaired water in Arkansas' most recent Section 303(d) list. The table identifies the specific water, the designated use that is impaired and what is causing the impairment. The table identifies the status of the TMDL development process. This status is in the form of the priority the state has placed on the TMDL process or that a TMDL has already been developed and approved by EPA. Finally, the table identifies the project elements that would cross the identified surface water. Each of the water segments identified in the table is applicable to the 200-foot-wide representative ROWs as well as the wider ROI.

Table 3.15-22:
Waters with Impaired Quality within the 1,000-Foot-Wide Corridors of the Applicant Proposed Route and HVDC Alternative Routes—Region 5

Water Segment and Watershed	Impaired Uses—Impairment	TMDL Status[1]	Project Components Crossing Impaired Segment
West Fork Point Remove Creek, AR (Reach 016) Lake Conway-Point Remove watershed (HUC 11110203)	Turbidity impairment	Priority: Not Assigned	AR 5-B
West Fork Point Remove Creek, AR (Reach 017) Lake Conway-Point Remove watershed (HUC 11110203)	Turbidity impairment	Priority: Not Assigned	APR Link 3
East Fork Point Remove Creek, AR (Reach 014) Lake Conway-Point Remove watershed (HUC 11110203)	Turbidity impairment	Priority: Not Assigned	APR Link 3, AR 5-B
Cypress Creek, AR (Reach 917) Cadron watershed (HUC 11110205)	Fisheries—copper and zinc impairments	Priority: Low	AR 5-B
Little Red River, AR (Reach 008) Little Red water shed (HUC 11010014)	Pathogens impairment	Completed	APR Link 7
Little Red River, AR (Reach 010) Little Red watershed (HUC 11010014)	Pathogens impairment	Completed	AR 5-C
Ten Mile Creek, AR (Reach 009) Little Red watershed (HUC 11010014)	Turbidity and pathogens impairments	Completed	APR Links 7 and 8, AR 5-C
Glaise Creek, AR (Reach 021) Upper White-Village watershed (HUC 11010013)	Aquatic Life—dissolved oxygen and zinc impairments	Priority: Low	APR Link 9, AR 5-D
Departee Creek, AR Upper White-Village watershed (HUC 11010013)	Fisheries—dissolved oxygen and turbidity impairments	Priority: Low	APR Link 9, AR 5-D

1 TMDL (Total Maximum Daily Load): TMDLs are the maximum amount of a pollutant that a waterbody can receive and still meet water quality standards. Once TMDLs have been determined, discharge requirements can be developed that will bring a waterbody back into compliance.

Sources: ADEQ (2014a, 2014b, 2014c), EPA (2013b)

The five Region 5 route variations would involve no changes to the list (Table 3.15-22) of impaired waters within the 1,000-foot-wide corridor of the Applicant Proposed Route. Similarly, the adjustments to HVDC Alternative Routes 5-B and 5-E would involve no changes.

3.15.5.5.4 Region 5 Water Use

Water use in the seven counties (Cleburne, Conway, Faulkner, Jackson, Pope, Van Buren, and White counties, Arkansas) that encompass this region is more even in terms surface water versus groundwater than was described for the ROI in Region 4, but surface water is still the predominant source. As shown in Table 3.7-17, the average use of surface water was about 1,120 million gallons per day in 2010 compared to about 460 million gallons per day of groundwater. Surface water, therefore, accounts for about 71 percent of area's total water usage. Total water use (groundwater and surface water) is described in more detail in Section 3.7.5.5.4.

3.15.5.6 Region 6

Region 6 is referred to as the Cache River and Crowley's Ridge Region and includes the Applicant Proposed Route and HVDC Alternative Routes 6-A through 6-D.

One route variation to the Applicant Proposed Route was developed in Region 6 after publication of the Draft EIS to parallel more parcel boundaries to minimize impacts to agricultural operations and is illustrated in Exhibit 1 of Appendix M. It should be noted that a route adjustment was made for HVDC Alternative Route 6-A to maintain an end-to-end route with the Link 2, Variation 1. The discussion of Region 6 surface water elements that follows includes identification of differences, if any, that would be expected with the route variation as compared to the original Applicant Proposed Route. The element discussions also address any changes attributed to the adjustment to HVDC Alternative Route 6-A.

3.15.5.6.1 Region 6 Watersheds

The ROI in Region 6 begins at the western end of the Upper White subregion (1101) of the larger Arkansas-White-Red drainage system, but to the east it quickly moves into the Lower Mississippi-St. Francis subregion (0802) of the larger Lower Mississippi drainage system. As noted previously, under USGS's methodology, as the larger river systems, such as the Arkansas, White, and Red rivers approach the Mississippi River, they move out of their own subregion and into subregions of the Lower Mississippi drainage system.

At USGS's eight-digit coding level, the ROI lies within four different watersheds as shown in Figure 3.15-1 in Appendix A. Table 3.15-23 lists the applicable watersheds and provides additional detail, including the primary surface water or waters that drain the watershed. Surface waters for the ROI are shown on Figure 3.15-2 in Appendix A. The route variation to the Applicant Proposed Route developed in Region 6 would not change the watersheds that would be crossed.

Table 3.15-23:
Watersheds Crossed by the Applicant Proposed Route and HVDC Alternative Routes—Region 6

USGS HUC Number and Watershed Name	Area Drained (square miles)	Description of Primary Surface Water Feature(s)
11010013, Upper White-Village	740	White River and its tributary Village Creek are primary drains for this watershed. The Black River also drains a portion of the watershed before it converges with the White River. Departee and Glaise creeks are also tributaries of note to the White River.
08020302, Cache	2,007	Cache River is the primary drain for this watershed and it flows into the White River at the watershed's downstream boundary. The watershed also includes Bayou DeView as a tributary to the Cache River.

Table 3.15-23:
Watersheds Crossed by the Applicant Proposed Route and HVDC Alternative Routes—Region 6

USGS HUC Number and Watershed Name	Area Drained (square miles)	Description of Primary Surface Water Feature(s)
08020205, L'Anguille	955	L'Anguille River is the primary drain for this watershed and it converges with the Madison-Marianna Diversion in the southern portion of the watershed. Brushy, First, and Second creeks are noted tributaries to the L'Anguille River.
08020203, Lower St. Francis	3,579	St. Francis River is the primary drain for this watershed, which stretches from Lake Wappepello (in Missouri) south to where the St. Francis River flows into the Mississippi River.

GIS Data Source: USGS (2014a)

In the ROI in Region 6, the rivers that are the primary drains for the watersheds are generally oriented north-south with flow to the south toward the Mississippi River.

3.15.5.6.2 Region 6 Surface Water Features

As described for the watersheds in the ROI for Region 6, the White, Cache, L'Anguille, and St. Francis rivers are important surface water features in the area from a drainage system standpoint. Table 3.15-24 lists the total length of perennial streams, intermittent streams, and major waterbodies within the ROI and the 200-foot-wide representative ROW in Region 6. The table includes the total acreage for reservoirs, lakes, and ponds that occur within the ROI and the ROW.

Table 3.15-24:
Miles and Acreage of Surface Water Features within the 1,000-Foot-Wide Corridors (and 200-Foot-Wide Representative ROW) of the Applicant Proposed Route and HVDC Alternative Routes—Region 6

Route—Proposed and Alternatives[1, 2, 3]	Link 1	Link 2	Link 3	Link 4	Link 5	Link 6	Link 7	Link 8	Region 6 Total
Perennial Streams									
APR (miles)	1.10 (0.18)	0.23 (0.05)	0.71 (0.14)	0.75 (0.12)	0	1.27 (0.16)	8.20 (0.12)	0.26 (0.06)	12.52 (0.83)

With AR 6-D (acres)	14.3 (3.0)	0	2.7 (0.9)	6.4 (1.0)	0	4.7 (0.1)	0	0.5 (0.2)	28.6 (5.2)

1 The values in the table do not reflect the minor changes that would result from application of the minor route variations and adjustments.
2 Each region of the Applicant Proposed Route (APR) is divided into links that lie between points, or nodes, where the APR is intersected by alternative routes (ARs). ARs bypass specific links of the APR as shown in the table.
3 For the ARs, the unshaded portion of the rows provides the data for the length of the AR. The shaded portion of the rows provides the data for the balance of the APR, thereby providing perspective across the region.
GIS Data Source: USGS (2014a)

Neither the variation to the Applicant Proposed Route nor the adjustment to HVDC Alternative Route 6-A would involve no changes to the surface water features crossed by the 200-foot-wide representative ROW.

3.15.5.6.2.1 Surface Water Features of Special Interest

As described for the watersheds in the ROI for Region 6, the White, Cache, L'Anguille, and St. Francis rivers are important surface water features in the area from a drainage system standpoint. Table 3.15-25 identifies surface waters within the ROI that have specific federal or state designations of special interest beyond significance as drainage features. The water feature and designation identified in the table are applicable to the 200-foot-wide representative ROW as well as the wider ROI.

Table 3.15-25:
Surface Waters of Special Interest within the 1,000-Foot-Wide Corridors of the Applicant Proposed Route and HVDC Alternative Routes—Region 6

Surface Water and Watershed	Designation(s)	Basis/Description	Route/Alternative Affected				
			APR	6-A	6-B	6-C	6-D
L'Anguille River, AR L'Anguille watershed (HUC 08020205)	National Park Service Nationwide Rivers Inventory	APR Link 6 crosses the reach of the river that the Park Service lists on the inventory. (AR 6-C does not cross that reach.)	X L6				

L6 = Link 6 of the Applicant Proposed Route in Region 6
Sources: NPS (2004), APCEC (2011)

The Region 6 route variation would involve no changes to the list (Table 3.15-25) of surface waters of special interest within the 1,000-foot-wide corridor of the Applicant Proposed Route. Similarly, the adjustment to HVDC Alternative Route 6-A is not in an area where there are surface waters of special interest.

3.15.5.6.3 Region 6 Water Quality

Table 3.15-26 identifies surface water features within the ROI that do not meet applicable water quality standards based on the surface water's designated uses and, as a result, have been identified as an impaired water in the state's most recent Section 303(d) list. Each of the water segments identified in the table is applicable to the 200-foot-wide representative ROWs as well as the wider ROI.

Table 3.15-26:
Waters with Impaired Quality within the 1,000-Foot-Wide Corridors of the Applicant Proposed Route and HVDC Alternative Routes—Region 6

Water Segment and Watershed	Impaired Uses—Impairment	TMDL Status[1]	Project Components Crossing Impaired Segment
Cache River, AR (Reach 019) Cache watershed (HUC 08020302)	Fisheries—lead impairment	Priority: Low	APR Link 3, ARs 6-A and 6-B
Bayou DeView, AR (Reaches 006 and 007) Cache watershed (HUC 08020302)	Fisheries—sulfate and lead impairments	Priority: Low	APR Link 4, AR 6-A
L'Anguille River, AR (Reach 005) L'Anguille watershed (HUC 08020205)	Fisheries—turbidity, dissolved oxygen, chloride, sulfate, and total dissolved solids impairment Primary Contact—pathogens impairment	Priority: Low Approved TMDL for siltation/turbidity	APR Link 6, AR 6-C

1 TMDL = Total Maximum Daily Load—TMDLs are the maximum amount of a pollutant that a waterbody can receive and still meet water quality standards. Once TMDLs have been determined, discharge requirements can be developed that will bring a waterbody back into compliance.
Sources: ADEQ (2014a, 2014b, 2014c), EPA (2013b)

The Region 6 route variation would involve no changes to the list (Table 3.15-25) of impaired waters within the 1,000-foot-wide corridor of the Applicant Proposed Route. Similarly, the adjustment to HVDC Alternative Route 6-A is not in an area where there are impaired waters.

3.15.5.6.4 Region 6 Water Use

In the three counties (Cross, Jackson, and Poinsett counties, Arkansas) that encompass Region 6, groundwater again accounts for the majority of the total water use. Table 3.7-20 shows that the average use of surface water was about 152 million gallons per day in 2010 compared to about 1,790 million gallons per day of groundwater. Surface water, therefore, accounts for about 8 percent of area's total water usage. Total water use (groundwater and surface water) is described in more detail in Section 3.7.5.6.4.

3.15.5.7 Region 7

Region 7 is referred to as the Arkansas Mississippi River Delta and Tennessee Region and includes the Applicant Proposed Route and HVDC Alternative Routes 7-A through 7-D.

Three route variations to the Applicant Proposed Route were developed in Region 7 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.7. The Applicant Proposed Route variations (Link 1, Variation 1; Link 1, Variation 2; and Link 5, Variation 1) are illustrated in Exhibit 1 of Appendix M. The discussion of Region 7 surface water elements that follows includes identification of differences, if any, that would be expected with the route variations as compared to the original Applicant Proposed Route.

3.15.5.7.1 Region 7 Watersheds

The ROI in Region 7 lies within two subregions of the larger Lower Mississippi drainage system: the Lower Mississippi-St. Francis subregion (0802) and the Lower Mississippi-Hatchie subregion (0801). The ROI crosses the Mississippi River and includes a crossing location for the Applicant Proposed Route and a separate crossing location for HVDC Alternative Route 7-A.

At USGS's eight-digit coding level, the ROI lies within three different watersheds as shown in Figure 3.15-1 in Appendix A. Table 3.15-27 lists the applicable watersheds and provides additional detail, including the primary surface water or waters that drain the watershed. Surface waters for the ROI are shown on Figure 3.15-2 in Appendix A.

Table 3.15-27:
Watersheds Crossed by the Applicant Proposed Route and HVDC Alternative Routes—Region 7

USGS HUC Number and Watershed Name	Area Drained (square miles)	Description of Primary Surface Water Feature(s)
08020203, Lower St. Francis	3,579	St. Francis River is the primary drain for this watershed, which stretches from Lake Wappepello (in Missouri) south to where the St. Francis River flows into the Mississippi River.
08010100, Lower Mississippi-Memphis	1,097	Mississippi River is the primary drain for this watershed, which is a narrow watershed running on either side of the river from the Mississippi River's confluence with the Ohio River downstream to the river's convergence with Horn Lake Pass south of Memphis, TN.
08010209, Loosahatchie[1]	742	Loosahatchie River is the primary drain for this water shed. Other creeks drain portions of the watershed and ultimately flow into the Loosahatchie River, which flows into the Mississippi River at the southwestern end of the watershed.

1 The proposed Tennessee converter station would be within the Loosahatchie watershed.
GIS Data Source: USGS (2014a)

As shown in Figure 3.15-1 in Appendix A and described in Table 3.15-27, the ROI crosses three watersheds in Region 7, one is on the western side of the Mississippi River, one is on the eastern side of the river, and the center one straddles the river. The predominant rivers in the first two watersheds (i.e., Lower Mississippi-St. Francis and Lower Mississippi-Memphis) flow toward the south. The Loosahatchie River in the third watershed of the same name flows primarily to the southwest. The three route variations developed for the Applicant Proposed Route in Region 6 would not change the watersheds that would be crossed.

3.15.5.7.2 Region 7 Surface Water Features

Table 3.15-28 lists the total length of perennial streams, intermittent streams, and major waterbodies within the ROI and the 200-foot-wide ROW in Region 7. The table includes the total acreage for reservoirs, lakes, and ponds that occur within the ROI and ROW.

Table 3.15-28:
Miles and Acreage of Surface Water Features within the 1,000-Foot-Wide Corridors (and 200-Foot-Wide Representative ROWs) of the Applicant Proposed Route and HVDC Alternative Routes—Region 7

Route—Proposed and Alternatives[1, 2, 3]	Link 1	Link 2	Link 3	Link 4	Link 5	Region 7 Total
Perennial Streams

With AR 7-A (miles)	14.11 (4.69)	0.05 (0)	2.35 (0.63)	0.80 (0.15)	3.58 (0.83)	20.89 (6.30)
With AR 7-B (miles)	11.52 (2.69)	0.05 (0)	2.51 (0.57)		3.58 (0.83)	17.66 (4.09)
With AR 7-C (miles)	11.52 (2.69)	0.05 (0)	9.07 (1.93)			20.64 (4.62)
With AR 7-D (miles)	11.52 (2.69)	0.05 (0)	2.35 (0.63)	4.10 (0.90)		18.02 (4.22)
Major Waterbodies						
APR	0.62 (0.64)	0	0	0	0	0.62 (0.64)
With AR 7-A (miles)	0.68 (0.90)	0	0	0	0	0.68 (0.90)
With AR 7-B (miles)	0.62 (0.64)	0	0		0	0.62 (0.64)
With AR 7-C (miles)	0.62 (0.64)	0	0 (0.01)			0.62 (0.65)
With AR 7-D (miles)	0.62 (0.64)	0	0	0		0.62 (0.64)
Reservoirs, Lakes, and Ponds						
APR (acres)	14.4 (1.5)	0	1.6 (0.1)	0	5.5 (0.8)	21.5 (2.4)
With AR 7-A (acres	27.8 (2.4)	0	1.6 (0.1)	0	5.5 (0.8)	34.9 (3.3)
With AR 7-B (acres	14.4 (1.5))	0	0.7 (0)		5.5 (0.8)	20.6 (2.3)
With AR 7-C (acres	14.4 (1.5)	0	2.2 (0.9)			16.6 (2.4)
With AR 7-D (acres	14.4 (1.5)	0	1.6 (0.1)	2.7 (0)		18.7 (1.6)

1 The values in the table do not reflect the minor changes that would result from application of the minor route variations and adjustments.
2 Each region of the Applicant Proposed Route (APR) is divided into links that lie between points, or nodes, where the APR is intersected by alternative routes (ARs). ARs bypass specific links of the APR as shown in the table.
3 For the ARs, the unshaded portion of the rows provides the data for the length of the AR. The shaded portion of the rows provides the data for the balance of the APR, thereby providing perspective across the region.
GIS Data Source: USGS (2014a)

The three Region 7 route variations would involve only minor changes to the surface water features crossed by the 200-foot-wide representative ROW of the Applicant Proposed Route. The ROWs of the variations would have about 0.7 mile more of stream beds (perennial and intermittent). The increase is due to Link 1, Variation 1, which parallels channels running between farm fields. There would be no change in major waterbodies from the original Applicant Proposed Route; Link 1, Variation 2, would cross the same major waterbodies as the original Applicant Proposed Route, but at a slightly different location. The number of other minor waterbodies would decrease by two.

The Tennessee Converter Station Siting Area and AC Interconnection Tie, reduced in size from 743 acres to 218 acres since the Draft EIS, would include 0.21 mile of perennial streams, 1.5 miles of intermittent streams, and no major or other waterbodies (GIS Data Source: USGS 2014a).

3.15.5.7.2.1 Surface Water Features of Special Interest

As described for the watersheds in the ROI for Region 7, the St. Francis, Mississippi, and Loosahatchie rivers are important surface water features in the area from a drainage system standpoint. Table 3.15-29 identifies surface waters within the ROI that have specific federal or state designations of special interest beyond significance as drainage features. The surface waters are presented in a roughly west-to-east order. The water features and designations identified in the table are applicable to the 200-foot-wide ROW as well as the wider ROI.

Table 3.15-29:
Surface Waters of Special Interest within the 1,000-Foot-Wide Corridors of the Applicant Proposed Route and HVDC Alternative Routes—Region 7

Surface Water and Watershed	Designation(s)	Basis/Description	Route/Alternative Affected				
			APR	7-A	7-B	7-C	7-D
St. Francis River, AR Lower St. Francis watershed (HUC 08020203)	Section 10 Navigable Waters of the U.S	Any action that would obstruct or alter a navigable water is prohibited without a USACE permit. APR Link 1 and AR 7-A cross the river.	X L1	X			
Mississippi River, TN Lower Mississippi-Memphis watershed (HUC 08010100)	Section 10 Navigable Waters of the U.S	Any action that would obstruct or alter a navigable water is prohibited without a USACE permit. APR Link 1 and AR 7-A cross the river.	X L1	X			
	Exceptional Tennessee Water	APR Link 1 and AR 7-A cross the river. The river has this designation due to the presence of the federally and state-listed endangered pallid sturgeon (*Scaphirhynchus albus*) and the state-listed threatened blue sucker (*Cycleptus elongatus*).	X L1	X			

L1 = Link 1 of the Applicant Proposed Route in Region 7
Sources: USACE (2014a), TDEC (2013c)

The three Region 7 route variations would involve no changes to the list (Table 3.15-29) of surface waters of special interest within the 1,000-foot-wide corridor of the Applicant Proposed Route.

3.15.5.7.3 Region 7 Water Quality

Table 3.15-30 identifies surface water features within the ROI in Region 7 that do not meet applicable water quality standards based on the surface water's designated uses and, as a result, have been identified as an impaired water in the states' most recent Section 303(d) lists. Each of the water segments identified in the table is applicable to the 200-foot-wide representative ROWs as well as the wider ROI.

Table 3.15-30:
Waters with Impaired Quality within the 1,000-Foot-Wide Corridors of the Applicant Proposed Route and HVDC Alternative Routes—Region 7

Water Segment and Watershed	Impairment Cause—TMDL[1] Priority	Approved TMDLs	Project Components Crossing Impaired Segment
Tyronza River, AR (Reach 909) Lower St. Francis watershed (HUC 08020203)	Turbidity impairment—NA	None	APR Link 1, AR 7-A
Mississippi River, TN (TN08010100001-2000) Lower Mississippi-Memphis watershed (HUC 08010100)	Physical substrate habitat alternations—Low PCBs, dioxin, and chlordane—Not applicable	Approved TMDLs for chlordane, chlordane in fish tissue, dioxin in fish tissue, and PCBs	APR Link 1, AR 7-A
Royster Creek, TN (TN08010209021-0200) Loosahatchie watershed (HUC 08010209)	Total phosphorus—Medium Low dissolved oxygen, physical substrate habitat alternations, loss of biological integrity due to siltation—Low *E. coli*—Not applicable	Approved TMDL for *E. coli*	APR Link 3, ARs 7-B and 7-C
North Fork Creek, TN (TN08010209021-0300 Loosahatchie watershed (HUC 08010209)	Total phosphorus—Medium Low dissolved oxygen, physical substrate habitat alternations, loss of biological integrity due to siltation—Low *E. coli*—Not applicable	Approved TMDL for *E. coli*	APR Links 3 and 4, ARs 7-B and 7-D
Big Creek, TN (TN08010209021-1000) Loosahatchie watershed (HUC 08010209)	Low dissolved oxygen, physical substrate habitat alternations, and loss of biological integrity due to siltation—Low Nitrate + nitrite and total phosphorus—Medium *E. coli*—Not applicable	Approved TMDL for *E. coli*	AR 7-C
Big Creek, TN (TN08010209021-2000) Loosahatchie watershed (HUC 08010209)	Low dissolved oxygen, physical substrate habitat alternations, and loss of biological integrity due to siltation—Low Total phosphorus—Medium *E. coli*—Not applicable	Approved TMDL for *E. coli*	AR 7-C
Big Creek, TN (TN08010209021-3000) Loosahatchie watershed (HUC 08010209)	Low dissolved oxygen, physical substrate habitat alternations, and loss of biological integrity due to siltation—Low Total phosphorus—Medium *E. coli*—Not applicable	Approved TMDL for *E. coli*	APR Link 5, ARs 7-C and 7-D Tennessee Converter Station Siting Area
Big Creek, TN (TN08010209021-4000) Loosahatchie watershed (HUC 08010209)	*E. coli*—High	Approved TMDL for *E. coli*	AR 7-D

1 TMDL = Total Maximum Daily Load—TMDLs are the maximum amount of a pollutant that a waterbody can receive and still meet water quality standards. Once TMDLs have been determined, discharge requirements can be developed that will bring a waterbody back into compliance.

APR = Applicant Proposed Route; AR = HVDC Alternative Routes

Sources: ADEQ (2014a, 2014b, 2014c), EPA (2013b), TDEC (2014, 2013b)

The three Region 7 route variations would involve no changes to the list (Table 3.15-30) of impaired waters within the 1,000-foot-wide corridor of the Applicant Proposed Route.

3.15.5.7.4 Region 7 Water Use

The distribution of water use in the four counties (Mississippi and Poinsett counties in Arkansas and Shelby and Tipton counties in Tennessee) that encompass Region 7 again shows groundwater as the predominant source. Table 3.7-22 shows that the average use of surface water was 536 million gallons per day in 2010 compared to 1,440 million gallons per day of groundwater. Surface water, therefore, accounts for about 27 percent of area's total water usage. Total water use (groundwater and surface water) is described in more detail in Section 3.7.5.7.4.

3.15.5.8 Connected Actions

3.15.5.8.1 Wind Energy Generation

Wind energy generation would likely occur within WDZs. The WDZs are shown in Figure 3.15-1 in Appendix A with the designations of Zones A through L. Also shown in the figure are the watersheds in which the WDZs are located and the notable surface waters of the vicinity. Surface waters for the ROI are shown on Figure 3.15-2 in Appendix A.

3.15.5.8.1.1 Watersheds

Because the WDZs are basically located at the western end of the proposed HVDC transmission line, the zones are within many of the same watersheds described for Region 1 in Section 3.15.5.1. All of the zones are within the Lower Cimarron (1104) and North Canadian (1110) subsystems of the larger Arkansas-White-Red drainage system (11). Only the northernmost edge of WDZ-G is within the Lower Cimarron subsystem; the remainder of WDZ-G and the other WDZs are within the North Canadian subsystem. At USGS's eight-digit coding level, the 12 WDZs lie within eight different watersheds as shown in Figure 3.15-1 in Appendix A. Table 3.15-31 lists the applicable watersheds in the order of their HUC numbers, which is roughly in a northwest-to-southeast order. The table provides the land area drained, the primary surface water or waters that drain the watershed, and the WDZs that lie within, or partially within, each of the watersheds (even if only a small portion of the zone is within the watershed). Surface waters for the ROI are shown on Figure 3.15-2 in Appendix A.

Table 3.15-31:
Watersheds Containing Wind Development Zones

USGS HUC Number and Watershed Name	Area Drained (square miles)	Description of Primary Surface Water Features	WDZs within Watershed
11040002, Upper Cimarron	1,750	Cimarron River drains the watershed that extends from the northwest corner of Oklahoma to the northeast into Kansas and its convergence with the North Fork Cimarron River.	G
11040006, Upper Cimarron–Liberal	1,720	Cimarron River drains the watershed that extends from its convergence with the North Fork Cimarron River to the southeast to its convergence with Crooked Creek just inside the north border of Oklahoma.	G
11100101, Upper Beaver	2,732	Beaver (or North Canadian) River drains the watershed that extends from the river's headwaters to its convergence with Goff Creek.	F, G, H
11100102, Middle Beaver	1,356	Beaver River drains the watershed that extends from its convergence with Goff Creek, through Lake Optima, and to the community of Beaver.	A, D, E, F, I, J, K
11100103, Coldwater	1,962	Coldwater and Frisco creeks drain the watershed into Lake Optima.	B, C, D, E, F
11100104, Palo Duro	1,937	Palo Duro Creek drains the watershed into Beaver River.	A, B, D, J, L

Table 3.15-31:
Watersheds Containing Wind Development Zones

USGS HUC Number and Watershed Name	Area Drained (square miles)	Description of Primary Surface Water Features	WDZs within Watershed
11100201, Lower Beaver	1,781	Beaver River, which becomes the North Canadian River, drains the watershed. Several smaller streams converge with the Beaver River within the watershed.	A, J, K
11100202, Upper Wolf	833	Wolf Creek drains the watershed and after running through another watershed joins the Beaver River to form the North Canadian River.	A, L

GIS Data Source: USGS (2014a)

3.15.5.8.1.2 Surface Water Features

Table 3.15-32 lists the total length of perennial streams and intermittent streams and acreage of reservoirs, lakes, and ponds within each of the WDZs. The USGS National Hydrography Dataset used to determine the values in the table also designates an "intermittent" category for reservoirs, lakes, and ponds and, in this instance, the intermittent category was routinely larger than the perennial group. Accordingly, the table provides a breakout for both perennial and intermittent reservoirs, lakes, and ponds. The total area of each WDZ is provided in the table to allow a comparison with the area represented by the water features. A category of "major waterbodies," as included in the preceding descriptions of Regions 1 through 7, is not included in Table 3.15-32. The definition used in this document for a major waterbody (i.e., a surface water with a crossing distance of 100 feet or more—see Section 3.15.4) is not applicable to an area with no specific route or direction.

Table 3.15-32:
Surface Water Features within the Wind Development Zones

Wind Development Zone Designation	Total Acreage of Zone	Streams (miles)		Reservoirs, Lakes, and Ponds (acres)	
		Perennial	Intermittent	Perennial	Intermittent
Zone A	109,747	4.9	103.4	38	1,330
Zone B	125,479	8.0	124.1	164	812
Zone C	161,048	6.4	204.4	125	198
Zone D	69,189	12.7	134.9	57	109
Zone E	47,092	2.6	43.6	25	8
Zone F	112,461	13.0	207.1	24	28
Zone G	187,315	6.8	191.7	12	269
Zone H	116,226	19.9	205.4	8	203
Zone I	105,203	1.7	17.5	17	688
Zone J	92,567	26.2	285.0	123	41
Zone K	92,894	6.3	220.2	60	427
Zone L	165,848	31.6	190.6	650	3,218
Totals		140.1	1,927.8	1,303	8,634

GIS Data Source: USGS (2014a)

It can be seen in Table 3.15-32 that the lengths of intermittent streams far outdistance those of perennial streams in every WDZ. The same can be said with regard to the acres of reservoirs, lakes, and ponds with the exception of WDZs E, F, and J. In each of those three zones, the area of perennial reservoirs, lakes, and ponds is greater than the area of the intermittent features.

3.15.5.8.1.3 Surface Water Features of Special Interest

Surface water features of special interest considered for the WDZs are the same as considered for the region evaluations; that is, the federal, Oklahoma, and Texas surface water designations described in Table 3.15-2. As was described for the watersheds in Table 3.15-31, the Cimarron and Beaver rivers, along with Coldwater, Frisco, Palo Duro, and Wolf creeks are the important surface water features in the area from a drainage system standpoint. Table 3.15-33 identifies surface waters within the WDZs that have specific federal or state designations of special interest beyond significance as drainage features.

Table 3.15-33:
Surface Waters of Special Interest within the Wind Development Zones

Surface Water and Watershed	Designation(s)	Basis for Designation	Affected Wind Development Zone
Beaver River[1], OK Middle Beaver watershed (HUC 11100102) Coldwater Creek[1], OK Coldwater watershed (HUC 11100103)	Area with water of recreational or ecological significance	Optima Wildlife Management Area	Zone D
Wolf Creek, TX Upper Wolf watershed (HUC 11100202)	Ecologically significant river and stream segment	High water quality, exceptional aquatic life, high aesthetic value stream; diverse benthic macroinvertebrate and fish communities	Zone L

1 The portions of Beaver River and Coldwater Creek with this designation are limited to those segments of the streams within the Optima Wildlife Management Area.

Sources: TPWD (2014), Appendix B, Table 1 of OAC 785:45

The designations of surface water of special interest in Table 3.15-33 are both state designations; there are no applicable federal designations. With respect to the Oklahoma designation, only the northern edge of WDZ D extends into the Optima Wildlife Management Area and in Texas, Wolf Creek passes through a relatively small portion of WDZ L, near the zone's northeast limit. In Cimarron County, Oklahoma, the Cimarron and Beaver rivers are both designated Oklahoma High Quality Streams with associated areas of special provision watershed (OWRB 2011a). WDZ G, the only zone in Cimarron County, is located to the east, just outside of the watershed areas for these two high quality streams.

3.15.5.8.1.4 Water Quality

Table 3.15-34 identifies the surface water features within the WDZs that do not meet applicable water quality standards based on the surface water's designated uses and, as a result, have been identified as impaired waters in the states' most recent Section 303(d) lists. As noted in the table, the WDZs in Texas are not located over any impaired surface waters. In Texas, the closest impaired surface water is the Canadian River (TCEQ 2013a, 2013b), which is in a separate watershed to the south of the WDZs, so stormwater runoff from the WDZs would not be expected to flow in the direction of the Texas section of the Canadian River.

Table 3.15-34:
Waters with Impaired Quality within the Wind Development Zones

Water Segment and Watershed	Impaired Uses—Impairment	TMDL Status[1]	Affected WDZ
Beaver River (North Canadian), OK (OK720510000190_00) Upper Beaver watershed (HUC 11100101)	Fish and Wildlife Propagation/Warm Water Aquatic Community—dissolved oxygen impairment	Priority Date: 2020 Approved TMDLs for fecal coliform, E. Coli, and *Enterococcu*s	WDZ-F
Beaver River (North Canadian), OK (OK720500020450_00) Middle Beaver watershed (HUC 11100102)	Agricultural—sulfates, total dissolved solids, and chloride impairments Fish and Wildlife Propagation/Warm Water Aquatic Community—sedimentation/siltation and fishes bioassessments impairments	Priority Date: 2023 Approved TMDLs for fecal coliform, E. Coli, and *Enterococcu*s	WDZ-J
Palo Duro Creek, OK (OK720500020500_00) Palo Duro watershed (HUC 11100104)	Primary Body Contact Recreation—*Enterococcu*s, and *E. coli* impairments Fish and Wildlife Propagation/Warm Water Aquatic Community—dissolved oxygen and selenium impairments Agricultural—sulfates and total dissolved solids impairments	Priority Date: 2023 Approved TMDLs for fecal coliform and total suspended solids	WDZ-J
No Texas impaired waters are within the Wind Development Zones.			

1 TMDL = Total Maximum Daily Load—TMDLs are the maximum amount of a pollutant that a waterbody can receive and still meet water quality standards. Once TMDLs have been determined, discharge requirements can be developed that will bring a waterbody back into compliance.

Sources: ODEQ (2014, 2013), EPA (2013b), TCEQ (2013a, 2013b)

3.15.5.8.1.5 Water Use

Table 3.7-26 summarizes the 2010 water use in the six-county area of Beaver, Cimarron, and Texas counties in Oklahoma and Hansford, Ochiltree, and Sherman counties in Texas that encompass the WDZs. As described in the Region 1 discussion (Section 3.15.5.1.4), by far the predominant source of water in the six-county area is groundwater. The average surface water use of about 2.4 million gallons per day is 0.3 percent of the area's total water use of 791 million gallons per day. All of the surface water use in the six-county area is attributed to the categories of irrigation, livestock, and mining. Correspondingly, surface water is not used as a source of drinking water in the area, either for public systems or private domestic systems.

3.15.5.8.2 Optima Substation

The future Optima substation would be on a 160-acres site located just east of the Oklahoma Converter Station and partially within the AC Interconnection Siting Areas. Surface water features in the ROI for the future Optima substation would be as described in the Region 1 discussion above (Section 3.15.5.1) for the Oklahoma Converter Station and AC Interconnection. There is an intermittent stream channel, or channels, in the area of the AC interconnection, but no perennial streams or other waterbodies, including no special interest surface waters or impaired waters.

3.15.5.8.3 TVA Upgrades

The ROI for the direct assignment facilities (which are included in the Applicant Proposed Project) would occur within the Tennessee Converter Station Siting Area and more specifically within the Shelby Substation. The ROI for the network upgrades, and in particular TVA's future 500kV transmission line, cannot be fully determined at this time.

The new 500kV line would be constructed in western Tennessee. The upgrades to existing facilities would mostly be in western and central Tennessee. Upgrades to existing infrastructure would include upgrading terminal equipment at three existing 500kV substations and six existing 161kV substations, making appropriate upgrades to increase heights on 16 existing 161kV transmission lines to increase line ratings, and replacing the conductors on eight existing 161kV transmission lines. Surface waters of special interest in western Tennessee include the Hatchie State Scenic River (flows into the Mississippi River east of HVDC Alternative Route 7-A, more than 10 miles northwest of the Shelby Substation) and in central Tennessee, the Duck and Harpeth State Scenic Rivers. Where possible, general impacts associated with the required TVA upgrades are discussed in the impact sections that follow.

3.15.6 Impacts to Surface Water

3.15.6.1 Methodology

This section addresses potential impacts to surface waters that would be expected from typical construction actions, whether those actions were for construction of converter stations or transmission lines for the Project. The primary areas of concern with regard to surface waters are:

- Potential for runoff or other discharges from construction or support areas to carry sediments or other contaminants to receiving waters
- Changes to runoff rates
- Direct impacts or disturbances to surface water or drainage channels
- Effects on water availability

3.15.6.1.1 Potential for Surface Water Contamination

Soil disturbances typical of construction actions are often associated with increased potential for soil erosion. Eroded materials can be carried by wind or runoff, but primarily runoff, to receiving waters, which can cause these waters to exceed instream water quality standards for turbidity that in turn can cause damage to the waters' natural flora and fauna or make the water unfit for its designated uses. If not contained properly, accidental releases of construction-related hazardous materials may also be carried from the site of a release to receiving waters. In the case of the Project, these hazardous materials would typically consist of fuels and lubricants present in equipment or storage containers at locations where construction activities would occur and at construction staging or storage yards. Additional potential contaminants would be associated with concrete operations, including at temporary concrete batch plants that would be needed for areas too far from commercial batch plants. In any of these locations there would be the potential for contaminants to leak, spill, or otherwise accidently release to the environment. If the released quantity was large enough and it was not cleaned up quickly, it could flow (if liquid) or be carried by runoff to an existing drainage channel and eventually reach surface water. If this were to occur, instream water quality standards could be threatened and downstream uses of the water could be put at risk.

Stormwater control and pollution prevention measures, as well as the construction actions in which they would be integrated, would be managed in accordance with plans and procedures that the Applicant would be required to develop and implement. The construction would require a stormwater discharge permit under the EPA's NPDES program. Each of the states in which construction actions would occur has been given the authority by EPA to implement a state program. Arkansas and Tennessee implement their own state programs pursuant to this authority; Oklahoma and Texas implement their own programs except in Indian Country and for specific discharges (not applicable to the Project) where EPA implements the permitting program for stormwater discharges during construction (EPA 2013a). Each of these states implements its NPDES stormwater discharge permit program through a general permit; referred to here simply as the construction general permit. Common to all of the construction general permits is the requirement for the permit applicant to prepare a SWPPP. Information that must be presented in a SWPPP includes the following (EPA 2014):

- Descriptions and locations of the stormwater control measures to be installed and maintained during construction to minimize erosion and discharge of sediments
- Procedures for inspection, maintenance, and, if necessary, corrective actions for stormwater control measures
- A list of construction site pollutants and locations of all potential pollutant-generating activities
- Descriptions of the procedures to be followed to prevent and respond to spills and leaks of site pollutants
- Identification of all sources of allowable non-stormwater discharges
- Description of staff training applicable to implementation of the SWPPP
- A map or maps showing drainage areas of the work site, before and after major grading, and stormwater discharge locations
- A map or maps showing locations of all potential pollutant-generating activities and stormwater control measures

Measures to prevent spills and leaks of site pollutants may include items such as using secondary containment for onsite fueling tanks or containers; providing cover, containment, and protection for chemicals, liquid products, petroleum products, and other potentially hazardous materials; using spill prevention and control measures when conducting maintenance, fueling, and repair of equipment and vehicles; and providing immediate response to any spill incident. Similarly, the Applicant would develop and follow its own plans to implement these measures as described in Section 2.1.7 to minimize the potential for accidental discharge of hazardous or controlled substances. The elements of the planning, either part of the SWPPP or the SPCCP if developed to include construction, would also minimize the potential for contaminants to leave the site should a discharge occur.

Concrete operations are mentioned separately because they are common to construction actions and involve equipment carrying materials of concern in addition to fuels and lubricants that could become sources of contamination to surface waters if managed improperly or accidentally released. The Applicant would perform washout of concrete trucks and equipment, either at the construction site or at a temporary batch plant, at storage tanks, plastic-lined berms, or some similar containment structure. Captured liquids would not be discharged; rather they would be allowed to evaporate or removed for disposal at an approved off-site location. Dried concrete would similarly be hauled off for proper disposal or recycling, or be broken up and used as clean fill. The Applicant may also bury hardened concrete in on-site embankments in accordance with applicable permit requirements.

It is also anticipated that in some areas equipment and vehicle washing would be required to prevent spread of weeds (removing them from the equipment at or near their source rather than allowing equipment to carry them out of the area). Such actions would generate only a minimal amount of wastewater, but would be done in designated, approved wash stations.

The deepest foundations would be those for the transmission line structures. In most areas of the Project, foundation depths for lattice structures would be about 15 feet and for pole structures the depths would be about 30 feet. Within the Mississippi floodplain, foundation depths generally would be greater: from 17 to 158 feet deep for lattice structures (with most foundation depths not exceeding 40 feet) and from 26 to 115 feet deep for pole structures (with most not exceeding 56 feet) as described in Appendix F. Structure foundations would have to be deeper in the floodplain areas given the expected soil conditions. In the floodplain, pole structures are identified as having a more shallow range of foundations than lattice structures because, due to engineering constraints, the Applicant would need to limit the height of poles in floodplains to 130 feet to minimize the foundation depth (Thomas 2014). Lattice structures would be used exclusively in floodplain locations requiring greater heights than 130 feet. Other than possibly in the Texas and Oklahoma Panhandle regions, these foundation depths could reach the water table in some areas of each region of the Project. As a result, it is expected that at some construction sites, groundwater would have to be pumped from excavations or boreholes to complete foundation construction and the discharge, if mismanaged, could be of concern to area surface waters. In such cases, water would be discharged to vegetated areas through the use of flow control devices (EPM W-8 in Section 3.15.6.1.5).

The Applicant has also identified two types of Project-related materials that would be used as needed in excavations and boreholes: Super Mud™ and high yield bentonite gel, both products of PDSCo. Inc. (Polymer Drilling Systems) of El Dorado, Arkansas. Super Mud™ is described as a synthetic polymer used to create high viscosity slurries for stabilizing excavations. High yield bentonite gel is described as a polymer extended sodium bentonite as described in Appendix F, which is a naturally occurring clay material. The bentonite, in a slurry, is designed for use in drilling applications and acts to stabilize the borehole walls and while it circulates back to the surface, cooling the drill bit and transporting drill cuttings in the process. Because of the potential for these materials to come into contact with groundwater, they are described in more detail in Section 3.7.6.2. After use of either material, disposition of a relatively large volume of slurry would be necessary and discharge to any surface water would be inappropriate. These slurry fluids would be recycled to the extent practicable, but if disposal was necessary, it would be sent offsite. The Applicant may add cement to solidify residual slurry so that the slurry can be disposed in a public landfill. All disposal would be in accordance with applicable federal, state, and local regulations.

Considering the requirements of the construction general permits for stormwater discharges, the measures that the Applicant would implement per its internal plans and procedures, and the limited amount of potentially hazardous materials involved (i.e., the Project would not include large bulk storage operations), it is unlikely that construction activities would result in contaminants, either sediment or chemicals, reaching surface water. This conclusion is applicable to the surface waters of special interest and impaired waters identified in Section 3.15.5 as well as other surface waters. With regard to surface waters of special interest and impaired waters, additional regulatory requirements identified in the subsequent discussions of site-specific impacts would further reduce the potential for adverse impacts.

3.15.6.1.2 Changes to Runoff Rates

Changes to stormwater runoff rates over large areas have the potential to affect water levels in receiving streams, reservoirs, or ponds. If the change is an increase in runoff, it could be associated with flooding around the receiving waters or in upgradient drainage channels. During construction, soils at the sites of the transmission line structures and converter stations would be broken up and loosened for some period of time, either in areas of disturbed soils or in soil stockpiles, and would be expected to have lower runoff rates, than before the disturbance. Higher infiltration rates would mean less water reaching drainage channels and receiving waters. At the same time, the soil in unpaved areas where heavy equipment traveled to, from, or around construction sites and in the temporary staging or storage areas could become more compacted than natural conditions and result in increased runoff. Conditions of loosened soil, however, would be relatively short-term and, for the most part, the disturbed areas would be restored to a pre-disturbance condition once the foundations and structures were in place. With regard to soils that may become compacted as a byproduct of equipment traffic, the Applicant would take measures to prevent serious impacts, to include the use of low ground pressure equipment and, as appropriate, the use of temporary equipment mats (see EPM GE-27 in Section 3.15.6.1.5). If necessary, the Applicant would also undertake soil remediation actions including decompaction, particularly in agricultural areas, to return soils to pre-disturbance conditions (see EPM AG-2 in Section 3.15.6.1.5). As each converter station was constructed, it would represent an area of impervious surfaces and increased runoff, but proper management of the runoff would be part of the facility design. Whether it involved retention or detention ponds, or simply to tie in with an existing municipal stormwater drainage system, the facility design would be required to include a stormwater management approach that did not adversely impact facilities or surface waters in the area. Also, the facilities are not so large that they would involve large increases in the amount of runoff to manage. The relatively small and short-term changes in runoff rates associated with the proposed construction actions would not be expected to cause noticeable changes in the area's existing (natural or man-made) drainage systems or surface waters.

3.15.6.1.3 Direct Impacts or Disturbances to Surface Water or Drainage Channels

Construction actions would occur over a great distance and variety of land types that, as described in Section 3.15.5, contain many streams and drainage channels, some with intermittent flow and others with perennial flow, and other waterbodies. The Applicant would avoid surface waters and their floodplains, to the extent practicable, in siting converter stations and transmission line foundations (EPM GE-9 in Section 3.15.6.1.5); would not construct counterpoise or fiber optic cable trenches across waterbodies (EPM W-6 in Section 3.15.6.1.5); and, in general, would avoid damage to drainage features as practicable. There is sufficient flexibility in the micrositing of facilities away from surface water features and, in the case of transmission lines, in placing structures such that surface waters and drainage features can be spanned by the lines. Therefore, the impact evaluations in this section are based on the assumption that Project facilities, including transmission line structures, would not be constructed in streams (perennial or intermittent) or their channels, or in any lakes, reservoirs, or ponds. The siting of access roads, however, generally does not include the same means of avoidance and, as a result, access roads are components of the Project most likely to require disturbance of drainage features. Since the Project has not yet progressed to the stage of detailed, location-specific design, the manner in which surface waters and drainage features would be crossed or the full extent of existing crossing routes are not yet available. The Applicant has, however, identified four typical crossing methods for access roads if they are necessary. Selection of one of the crossing methods would depend on stream characteristics as well as requirements associated with permits for crossing waters or floodplains (Appendix C). The four types of crossing methods are briefly summarized as follows (see Appendix F):

- Type 1, Drive-Through Crossings—This type of crossing applies to seasonally dry, non-fish-bearing drainages that would require no more than minimal grading or fill to support vehicle travel. Fill material, if needed, would generally consist of commercially available aggregate and the Applicant would limit the quantity used to that needed for safe vehicle travel. The average disturbance for a Type 1 crossing would be about 25 feet along the waterbody.
- Type 2, Ford Crossings—This type of crossing applies to streams (seasonally dry or perennial) with shallow, but defined channels that require grading and stabilization of stream banks and, in some cases, the channel bed to allow vehicle travel. Approaches and, if needed, the streambed would be rock armored with commercially available aggregate or large angular rock (pit run), placed to maintain the dimensions of the natural streambed

and not impede natural flow. The average disturbance for a Type 2 crossing would be about 75 feet along the waterbody.

- Type 3, Culvert—This type of crossing applies to more incised stream channels and with consistent flow regimes sufficient to maintain fishery populations. Typically, the culvert would be designed to be partially buried so that streambed material can be maintained in its bottom. Scour-resistant materials would be installed around the edges of the culvert and a stable travel surface installed across the culvert. The average disturbance for a Type 3 crossing would be about 30 to 60 feet, depending on the channel profile along the waterbody.
- Type 4, Spanning Structure—These bank-to-bank crossing structures apply to higher quality defined perennial stream channels up to a width of about 30 feet. The type of structure designed would depend on the width of the channel. The average disturbance for a Type 4 crossing would be about 30 to 60 feet along the waterbody.

Crossing a drainage feature, no matter the type, would result in impacts to the drainage feature. The extent of those impacts would depend on the nature of the drainage feature and the type of crossing method used. As indicated in the description of crossing types, the higher the quality of the stream, the more elaborate the crossing method that would be expected. In any of the crossing types, however, the intent would be to minimize the length of the drainage feature that would be affected and to maintain flow characteristics through the disturbed section so that effects upstream or downstream would also be minimized. In flowing streams, there could be local impacts to bottom-dwelling aquatic communities, and during construction there would likely be increased turbidity to downstream areas. Increased turbidity would be expected to be short-lived, but depending on the type of crossing, it would likely take longer for bottom communities to recover.

3.15.6.1.4 Effects on Water Availability

Adverse effects on water availability could result if the Project hindered the use of a local surface water source or if the Project's need for water reduced the amount of water available for other existing users. The former situation could result from the Project accidentally causing contamination or physical damage to a stream or even an intake structure so that the water could not be withdrawn. The potential to damage surface water sources would be expected to be limited to access road crossings as was discussed in Section 3.15.6.1.3; the potential for surface water contamination was discussed in Section 3.15.6.1.1.

Water would be needed to support the Project's construction activities, but the activities would not involve major demands for water. The types of water needs expected during construction were described in the groundwater discussion of Section 3.7.6.1.3 and, as noted in that section, the Applicant estimates the Project would require approximately 110 million gallons of water. Construction duration is anticipated to be 36 to 42 months Assuming a 36 month duration, this water demand equates to about 0.1 million gallons per day, which the Applicant plans to obtain from municipal water providers along the transmission line route. The Applicant does not anticipate the need to drill wells to obtain water or to withdraw water directly from surface water sources to support construction actions. The water demand also would be spread out over a large geographic area, so the average demand of 0.1 million gallons per day would be experienced in different areas along the 700-mile route as construction progressed. Construction of the proposed converter stations, however, would be expected to cause their portions of the overall HVDC transmission line route to be associated with a higher percentage of the water demand than those sections with only transmission lines being constructed. As summarized in the average 2010 water use tables in Section 3.7.5, the use of surface water varied from 3 to 1,125 million gallons per day within the seven regions along the HVDC transmission line route. Because water for the Project is expected to come from municipal providers, its source could be groundwater or surface water depending on which part of the route is being worked. The only regions where surface water use is less than 80 million gallons per day are Regions 1 and 2, where public water supplies come entirely from groundwater. Similarly, water to support the Project in these two regions would not be expected to come from surface water sources. In Regions 3 through 7, a water demand of 0.1 million gallons per day over a 36-month construction period is minor compared to quantities of surface water already being used. Water demand associated with the Project is therefore not expected to have noticeable effects on surface water resources beyond those resulting from existing water usage.

3.15.6.1.5 Environmental Protection Measures

The Applicant has developed and would implement a comprehensive list of EPMs to avoid and minimize impacts to surface water. Implementation of these EPMs is assumed throughout the impact analysis that follows for the Project. A complete list of EPMs for the Project is provided in Appendix F. The EPMs associated with surface water are presented below in three general potential impact categories: (1) contamination, (2) runoff rates, and (3) physical impacts. Each EPM is identified by its Applicant-designated reference number.

Practices will be implemented to specifically minimize the potential for release or mismanagement of hazardous materials that could eventually result in surface water contamination. These EPMs include the following:

- GE-1: Clean Line will train personnel on health, safety, and environmental matters. Training will include practices, techniques, and protocols required by federal and state regulations and applicable permits.
- GE-5: Any herbicides used during construction and operations and maintenance will be applied according to label instructions and any federal, state, and local regulations.
- GE-13: Emergency and spill response equipment will be kept on hand during construction.
- GE-14: Clean Line will restrict the refueling and maintenance of vehicles and the storage of fuels and hazardous chemicals within at least 100 feet from wetlands, surface waterbodies, and groundwater wells, or as otherwise required by federal, state, or local regulations.
- GE-21: Clean Line will maintain construction equipment in good working order. Equipment and vehicles that show excessive emissions of exhaust gases and particulates due to poor engine adjustments or other inefficient operating conditions will be repaired or adjusted.
- GE-28 Hazardous materials and chemicals will be transported, stored, and disposed of according to federal, state, or local regulations or permit requirements.
- GE-31: Clean Line will provide sanitary toilets convenient to construction; these will be located greater than 100 feet from any stream or tributary or to any wetland. These facilities will be regularly serviced and maintained; waste disposal will be properly manifested. Employees will be notified of sanitation regulations and will be required to use sanitary facilities.
- W-12: If blasting is required within 150 feet of a spring or groundwater well, Clean Line will conduct preconstruction monitoring of yield and water quality in cooperation with the landowner. In the event of damage, Clean Line will arrange for a temporary water supply through a local supplier until a permanent solution is identified.
- W-14: Clean Line will ensure that there is no off-site discharge of wastewater from temporary batch plant sites.

Practices will be implemented to minimize changes to stormwater runoff rates that could potentially change drainage patterns and runoff quantity or quality. These EPMs include the following:

- GE-3: Clean Line will minimize clearing vegetation within the ROW, consistent with a Transmission Vegetation Management Plan (TVMP) filed with NERC, and applicable federal, state, and local regulations. The TVMP may require additional analysis under NEPA depending on whether and under what conditions DOE decides to participate in the Project.
- GE-6: Clean Line will restrict vehicular travel to the ROW and other established areas within the construction, access, or maintenance easement(s).
- GE-7: Roads not otherwise needed for maintenance and operations will be restored to preconstruction conditions. Restoration practices may include decompacting, recontouring, and re-seeding. Roads needed for maintenance and operations will be retained.
- GE-27: Clean Line will minimize compaction of soils and rutting through appropriate use of construction equipment (e.g., low ground pressure equipment and temporary equipment mats).
- GE-30: Clean Line will minimize the amount of time that any excavations remain open.
- GEO-1: Clean Line will stabilize slopes exposed by its activities to minimize erosion.
- W-3: Clean Line will establish streamside management zones within 50 feet of both sides of intermittent and perennial streams and along margins of bodies of open water where removal of low-lying vegetation is minimized.
- W-7: Clean Line will locate spoil piles from foundation excavations and fiber optic cable trenches outside of streamside management zones.
- W-8: Dewatering will be conducted in a manner designed to prevent soil erosion (e.g., through discharge of water to vegetated areas and/or the use of flow control devices).

Practices will be implemented to minimize direct, physical impacts to surface water features and the potential to restrict the use of a surface water. These EPMs include the following:

- GE-9: Clean Line will avoid and/or minimize damage to drainage features and other improvements such as ditches, culverts, levees, tiles, and terraces; however, if these features or improvements are inadvertently damaged, they will be repaired and/or restored.
- W-1: Clean Line will avoid and/or minimize construction of access roads in special interest waters.
- W-2: Clean Line will identify, avoid, and/or minimize adverse effects to wetlands and waterbodies. Clean Line will not place structure foundations within the Ordinary High Water Mark of Waters of the United States.
- W-5: Clean Line will construct access roads to minimize disruption of natural drainage patterns including perennial, intermittent, and ephemeral streams.
- W-6: Clean Line will not construct counterpoise or fiber optic cable trenches across waterbodies.
- W-15: Clean Line will seek to procure water from municipal water systems where such water supplies are within a reasonable haul distance; any other water required will be obtained through permitted sources or through supply agreements with landowners. (As noted in Section 3.7.6.1.3, the Applicant does not anticipate the need to drill wells to obtain water to support construction actions, but if new wells became necessary to support operational facilities, the Applicant would obtain the necessary approvals and limit withdrawal volumes so as to not adversely affect supplies for other uses.)

3.15.6.2 Impacts Associated with the Applicant Proposed Project

3.15.6.2.1 Converter Stations and AC Interconnection Siting Areas

3.15.6.2.1.1 Construction Impacts

3.15.6.2.1.1.1 Oklahoma Converter Station Siting Area and AC Interconnection Siting Area

Limited surface water features consisting of 1.6 miles of intermittent stream beds, no perennial streams, and no major waterbodies are present within the Oklahoma Converter Station and AC Interconnection Siting Areas. Considering a representative 200-foot-wide ROW for the AC interconnection, the length of intermittent streams enclosed is 0.2 mile. Potential impacts associated with construction of the station and AC interconnection would be the same as those common impacts described in Section 3.15.6.1. Water needed to support construction of the converter station and AC interconnection—although expected to be obtained from a municipal provider—would likely not come from surface water because groundwater is the predominant source of water in Texas County.

3.15.6.2.1.1.2 Tennessee Converter Station Siting Area and AC Interconnection Tie

Limited surface water features consisting of only a few drainage features, including only 0.21 mile of perennial streams, 1.5 miles of intermittent streams, and no major waterbodies are present within the Tennessee Converter Station and AC Interconnection Tie. Potential impacts associated with construction of the station and AC interconnection would be the same as those common impacts described in Section 3.15.6.1. The Applicant would avoid surface waters to the extent practicable in selecting the ultimate construction site for the station. Potential impacts associated with construction of the station and AC interconnection tie would be the same as those common impacts described in Section 3.15.6.1. Water needed to support the construction of the converter station would likely not come from surface water because public water supplies in Shelby County come entirely from groundwater.

3.15.6.2.1.2 Operations and Maintenance Impacts

Operations and maintenance of the Oklahoma and Tennessee converter stations and AC interconnections would not be expected to have any impacts on surface water. There would be no water demand other than the minor amount of drinking water required to support fewer than 15 full-time workers at each station and the station would be connected to the municipal water system and the public water systems in the region use groundwater sources (Tables 3.7-5 and 3.7-22). USACE notes that any water lines that support converter station operation may require permit verification.

3.15.6.2.1.3 Decommissioning Impacts

Decommissioning of converter stations and the associated AC interconnection transmission line or tie would be expected to have impacts similar to those described in Section 3.15.6.1 for common construction activities, i.e., the same types of measures would be required to manage the fuels and lubricants that would be present in equipment and actions to protect stormwater runoff at the site would ensure that contaminants did not reach surface water. Decommissioning actions may require larger equipment than required during typical operation and maintenance activities. As a result, access to some areas may need to be improved or even reestablished and, as during construction, could involve direct disturbances to surface water or drainage channels. Water demand during decommissioning would be limited to that needed for actions such as dust suppression, soil compaction, and possibly re-seeding or landscaping to put the ground back into suitable condition. Water demand would be expected to be less than for construction and would not adversely impact surface water resources.

3.15.6.2.2 AC Collection System

3.15.6.2.2.1 Construction Impacts

As indicated in the discussion of common construction impacts (Section 3.15.6.1), the Applicant would avoid surface waters to the extent practicable in selecting the sites for transmission line structures for any of the AC collection system routes. However, as noted in Section 3.15.6.1.3, access roads may have to cross drainage features. If an access road required a new crossing over any of the impaired streams in any of the regions, or if construction sites were close enough to contribute stormwater runoff to these streams, there would be additional requirements to ensure no adverse impacts to water quality. For example, Oklahoma's NPDES construction general permit includes additional requirements for construction actions that could involve stormwater runoff to impaired waters. These added requirements include an increased frequency for inspections as well as protective measure planning that is specific to the surface water and contaminants of concern (ODEQ 2012). Also common to all of the AC collection system routes, groundwater is the predominant source of water in the area (Table 3.7-6), so water to support construction of any collector line, although expected to be obtained from a municipal provider, would likely not come from surface water.

3.15.6.2.2.1.1 AC Collection System Route E-1

As shown in Table 3.15-5, the 200-foot-wide representative ROW of AC Collection System Route E-1 encompasses 0.23 mile of perennial streams, 1.61 miles of intermittent streams, no major waterbodies, and 0.45 acre of reservoirs, lakes, and ponds. AC Collection System Route E-1 is only one of three AC collection system routes (along with SE-2 and SW-1) to encompass no major waterbodies. AC Collection System Route E-1 also encompasses a section of Palo Duro Creek, which is identified as an Oklahoma impaired water (Table 3.15-6) and additional requirements could be applicable as identified in Section 3.15.6.2.2.1 above. Potential impacts associated with construction of AC Collection System Route E-1 would be the same as those common impacts described in Section 3.15.6.1.

3.15.6.2.2.1.2 AC Collection System Route E-2

The 200-foot-wide ROW of AC Collection System Route E-2 encompasses 0.37 mile of perennial streams, 2.18 miles of intermittent streams, 0.07 mile of major waterbodies, and 0.99 acre of reservoirs, lakes, and ponds (Table 3.15-5). AC Collection System Route E-2 also encompasses a section of Palo Duro Creek, an Oklahoma impaired water (Table 3.15-6) and additional requirements could be applicable as identified in Section 3.15.6.2.2.1 above. Potential impacts associated with construction of the AC Collection System Route E-2 would be the same as those common impacts described in Section 3.15.6.1.

3.15.6.2.2.1.3 AC Collection System Route E-3

The 200-foot-wide ROW of AC Collection System Route E-3 encompasses 0.12 mile of perennial streams, 2.39 miles of intermittent streams, 0.01 mile of major waterbodies, and 0.31 acre of reservoirs, lakes, and ponds (Table 3.15-5). AC Collection System Route E-3 also encompasses a section of Palo Duro Creek, an Oklahoma impaired water (Table 3.15-6) and additional requirements could be applicable as identified in Section 3.15.6.2.2.1 above. Potential impacts associated with construction of AC Collection System Route E-3 would be the same as those common impacts described in Section 3.15.6.1.

3.15.6.2.2.1.4 AC Collection System Route NE-1

The 200-foot-wide ROW of AC Collection System Route NE-1 encompasses 0.41 mile of perennial streams, 0.25 mile of intermittent streams, 0.12 mile of major waterbodies, and no area of reservoirs, lakes, and ponds

(Table 3.15-5). Potential impacts associated with construction of AC Collection System Route NE-1 would be the same as those common impacts described in Section 3.15.6.1.

3.15.6.2.2.1.5 AC Collection System Route NE-2

The 200-foot-wide ROW of AC Collection System Route NE-2 encompasses 0.2 mile of perennial streams, 1.33 miles of intermittent streams, 0.10 mile of major waterbodies, and 1.95 acres of reservoirs, lakes, and ponds (Table 3.15-5). Potential impacts associated with construction of AC Collection System Route NE-2 would be the same as those common impacts described in Section 3.15.6.1.

3.15.6.2.2.1.6 AC Collection System Route NW-1

The 200-foot-wide ROW of AC Collection System Route NW-1 encompasses 0.16 mile of perennial streams, 2.03 miles of intermittent streams, 0.09 mile of major waterbodies, and no area of reservoirs, lakes, and ponds (Table 3.15-5). The AC Collection System Route NW-1 also encompasses a section of the Beaver River, an Oklahoma impaired water (Table 3.15-6) and additional requirements could be applicable as identified in Section 3.15.6.2.2.1 above. Potential impacts associated with construction of AC Collection System Route NW-1 would be the same as those common impacts described in Section 3.15.6.1.

3.15.6.2.2.1.7 AC Collection System Route NW-2

The 200-foot-wide ROW of AC Collection System Route NW-2 encompasses 0.51 mile of perennial streams, 0.95 mile of intermittent streams, 0.18 mile of major waterbodies, and 0.04 acre of reservoirs, lakes, and ponds (Table 3.15-5). The distance of major waterbodies is the highest of any of the AC collection system routes. Potential impacts associated with construction of AC Collection System Route NW-2 would be the same as those common impacts described in Section 3.15.6.1.

3.15.6.2.2.1.8 AC Collection System Route SE-1

The 200-foot-wide ROW of AC Collection System Route SE-1 encompasses 0.42 mile of perennial streams, 2.09 miles of intermittent streams, 0.04 mile of major waterbodies, and 2.61 acres of reservoirs, lakes, and ponds. The area of reservoirs, lakes, and ponds is the highest of any of the AC collection system routes. AC Collection System Route SE-1 also encompasses a section of Palo Duro Creek, an Oklahoma impaired water (Table 5.15-6) and additional requirements could be applicable as identified in Section 3.15.6.2.2.1 above. Potential impacts associated with construction of AC Collection System Route SE-1 would be the same as those common impacts described in Section 3.15.6.1.

3.15.6.2.2.1.9 AC Collection System Route SE-2

The 200-foot-wide corridor of AC Collection System Route SE-2 encompasses no perennial streams, 0.3 miles of intermittent streams, no major waterbodies, and 0.38 acre of reservoirs, lakes, and ponds (Table 3.15-5). The ROW of AC Collection System Route SE-2 is only one of two AC collection system routes encompassing no perennial streams—the length of intermittent streams is the second lowest of any of the routes—and it is only one of three alternatives with no major waterbodies. Potential impacts associated with construction of AC Collection System Route SE-2 would be the same as those common impacts described in Section 3.15.6.1.

3.15.6.2.2.1.10 AC Collection System Route SE-3

The 200-foot-wide ROW of AC Collection System Route SE-3 encompasses 0.37 mile of perennial streams, 2.07 miles of intermittent streams, 0.07 mile of major waterbodies, and 1 acre of reservoirs, lakes, and ponds (Table 3.15-5). AC Collection System Route SE-3 also encompasses a section of Palo Duro Creek, an Oklahoma impaired water (Table 3.15-6), and additional requirements could be applicable as identified in Section 3.15.6.2.2.1 above. SE-3 also encompasses a section of Wolf Creek, which is designated by Texas as a water of high water quality/exceptional aquatic life/high aesthetic value. Texas Surface Water Quality Standards (TAC 30-307) prohibit discharges to Wolf Creek that could lower its water quality such that its designations could not be maintained. Potential impacts associated with construction of AC Collection System Route SE-3 would be the same as those common impacts described in Section 3.15.6.1.

3.15.6.2.2.1.11 AC Collection System Route SW-1

The 200-foot-wide ROW of AC Collection System Route SW-1 encompasses no perennial streams, 0.86 miles of intermittent streams, no major waterbodies, and no area of reservoirs, lakes, and ponds (Table 3.15-5). The ROW of SW-1 is only one of two AC collection system routes encompassing no perennial streams and only one of three routes with no major waterbodies or no area of reservoirs, lakes, and ponds. Potential impacts associated with construction of the AC Collection System Route SW-1 would be the same as those common impacts described in Section 3.15.6.1.

3.15.6.2.2.1.12 AC Collection System Route SW-2

The 200-foot-wide ROW of AC Collection System Route SW-2 encompasses 0.14 mile of perennial streams, 2.91 miles of intermittent streams, 0.08 mile of major waterbodies, and 0.21 acre of reservoirs, lakes, and ponds (Table 3.15-5). The length of intermittent streams is the highest of any of the AC collection system routes. Potential impacts associated with construction of AC Collection System Route SW-2 would be the same as those common impacts described in Section 3.15.6.1.

3.15.6.2.2.1.13 AC Collection System Route W-1

The 200-foot-wide corridor of AC Collection System Route W-1 encompasses 0.17 mile of perennial streams, 1.05 miles of intermittent streams, 0.08 mile of major waterbodies, and 0.49 acre of reservoirs, lakes, and ponds (Table 3.15-5). Potential impacts associated with construction of AC Collection System Route W-1 would be the same as those common impacts described in Section 3.15.6.1.

3.15.6.2.2.2 Operations and Maintenance Impacts

Operations and maintenance of AC collection system routes would not impact surface water. During operations and maintenance, no notable sources of contaminants would be in use other than the typical fuels and lubricants found in vehicles and equipment, herbicides used to maintain ROWs and access roads would be applied in accordance with label instructions and any federal, state, and local regulations to minimize the potential for spreading, and no soil disturbance would occur. Access roads developed during construction would be maintained as needed to support long-term operations and maintenance actions.

3.15.6.2.2.3 Decommissioning Impacts

Decommissioning of AC collection system lines would be expected to have impacts similar to those described in Section 3.15.6.1 for common construction activities, i.e., the same types of measures would be required to manage the fuels and lubricants that would be present in equipment and actions to protect stormwater runoff at the site would ensure that contaminants did not reach surface water. Decommissioning actions may require larger equipment than required during typical operation and maintenance activities. As a result, access to some areas may need to be improved or even reestablished and, as during construction, could involve direct disturbances to surface water or drainage channels. Water demand during decommissioning would be limited to that needed for actions such as dust suppression, soil compaction, and possibly re-seeding or landscaping to put the ground back into suitable condition and would be expected to be less than for construction and would not adversely impact surface water resources.

3.15.6.2.3 HVDC Applicant Proposed Route

3.15.6.2.3.1 Construction Impacts

This section addresses potential impacts from construction of the HVDC transmission line within each of the seven regions of the Applicant Proposed Route. The surface water features described in each region are those located within a 200-foot-wide representative ROW of the Applicant Proposed Route. Surface water features and elements within the ROWs were presented in the regional discussions of Section 3.15.5 along with the information for the 1,000-foot-wide ROI. Changes to impacts due to route variations developed in response to public comments on the Draft EIS are described at the end of the applicable sections.

Common to construction in all of the regions and as described in Section 3.15.6.1.3, the Applicant would avoid surface waters to the extent practicable in selecting the sites for transmission line structures, but access roads may have to cross surface drainage features. If an access road required a new crossing over any of the impaired streams in any of the regions, or if construction sites were close enough to contribute stormwater runoff to these streams, there would be additional requirements to ensure no adverse impacts to water quality. For example, the Oklahoma, Arkansas, and Tennessee general NPDES stormwater construction permits each include additional requirements for construction actions that could involve stormwater runoff to impaired waters as follows:

- Oklahoma's added requirements include an increased frequency for inspections as well as protective measure planning that is specific to the surface water and contaminants of concern (ODEQ 2012).
- Arkansas' added requirements include consideration of additional BMPs to address specific contaminants of concern and additional monitoring to ensure the BMPs are effective (ADEQ 2011).
- Tennessee's added requirements include an increased width of the required buffer zone, design of structures against a greater intensity storm, and specific training requirements for the preparer of the operator's SWPPP (TDWPC 2011).

3.15.6.2.3.1.1 Region 1

As shown in Table 3.15-4, the 200-foot-wide ROW of the Applicant Proposed Route in Region 1 encompasses 0.86 mile of perennial streams, 5.92 miles of intermittent streams, 0.03 mile of major waterbodies, and 9.9 acres of reservoirs, lakes, and ponds. The only federal or state surface water designations of special interest in Region 1 are those identified by the state of Oklahoma as impaired waters. The five impaired waters within the ROW of the Applicant Proposed Route are Palo Duro Creek, Kiowa Creek, Beaver River, Clear Creek, and Otter Creek (Table 3.15-6). With the added requirements if impaired waters were to be affected, potential impacts associated with construction of the Applicant Proposed Route in Region 1 would be the same as those common impacts described in Section 3.15.6.1. Groundwater is the predominant source of water in the four-county area of Region 1, so water to support construction of the transmission line, although expected to be obtained from a municipal provider, would likely not come from surface water.

No route variations were proposed in Region 1.

3.15.6.2.3.1.2 Region 2

The 200-foot-wide ROW of the Applicant Proposed Route in Region 2 encompasses 1.43 miles of perennial streams, 3.75 miles of intermittent streams, 0.01 mile of major waterbodies, and 1.9 acres of reservoirs, lakes, and ponds (Table 3.15-8). Federal or state surface water designations of special interest in Region 2 consist of the Cimarron River, designated as critical habitat by both the USFWS and the state of Oklahoma (Table 3.15-9), and several streams identified by the state of Oklahoma as impaired waters. Four impaired waters occur within the ROW of the Applicant Proposed Route in Region 2: East Griever Creek, Cimarron River, Turkey Creek, and Buffalo Creek (Table 3.15-10). With the added requirements if impaired waters were to be affected, potential impacts associated with construction of the Applicant Proposed Route in Region 2 would be the same as those common impacts described in Section 3.15.6.1. Groundwater is the predominant source of water in the three-county area of Region 2, so water to support construction of the transmission line, although expected to be obtained from a municipal provider, would likely not come from surface water.

Two route variations to the Applicant Proposed Route were developed in Region 2 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.2. The variations are illustrated in Exhibit 1 of Appendix M. The variations would involve no changes to the surface water features within the 200-foot-wide representative ROW of the Applicant Proposed Route and no different waters of special interest or impaired waters are present within the 1,000-foot-wide corridor. The minor route variations in Region 2 of the Applicant Proposed Route would not affect the potential impacts to surface waters associated with construction.

3.15.6.2.3.1.3 Region 3

The 200-foot-wide ROW of the Applicant Proposed Route in Region 3 encompasses 10.45 miles of perennial streams, 7.75 miles of intermittent streams, 0.15 mile of major waterbodies, and 39.5 acres of reservoirs, lakes, and ponds (Table 3.15-12). As indicated in Section 3.15.5.3.2, there are many small dams and reservoirs in areas of Region 3, which have been captured, as applicable, in the acreage of reservoirs, lakes, and ponds and possibly miles of major waterbodies. Because of their relatively small size, it is expected these features would be easily avoided by transmission line structures and access roads. Federal or state surface water designations of special interest in the Region 3 ROW include the source or watershed protection area for Cushing Lake (Table 3.15-13), which is used as a source for drinking water. The ROW only passes through the special provision watershed of Cushing Lake. The Region 3 ROW of the Applicant Proposed Route also encompasses eight streams identified by the state of Oklahoma as impaired waters: Skeleton Creek, Cimarron River, Stillwater Creek, West Spring Creek, Browns Creek, Begger Creek, Salt Creek, and Adams Creek (Table 3.15-14). With the added requirements if impaired waters were to be affected, potential impacts associated with construction of the Applicant Proposed Route in Region 3 would be the same as those common impacts described in Section 3.15.6.1. Groundwater is the predominant source of water in the eight-county area of Region 3, but surface water use is also notable, so water to support construction of the transmission line, although expected to be obtained from a municipal provider, could come from both surface water and groundwater.

Five route variations to the Applicant Proposed Route were developed in Region 3 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.3. The variations are illustrated in Exhibit 1 of Appendix M. The variations would involve minor changes to the surface water features within the 200-foot-wide representative ROW of the Applicant Proposed Route; no different waters of special interest or impaired waters are present within the 1,000-foot-wide corridor. The minor route variations in Region 3 of the Applicant Proposed Route would not affect the potential impacts to surface waters associated with construction.

3.15.6.2.3.1.4 Region 4

As shown in Table 3.15-16, the 200-foot-wide ROW of the Applicant Proposed Route in Region 4 encompasses 3.5 miles of perennial streams, 8.96 miles of intermittent streams, 0.24 mile of major waterbodies, and 16.1 acres of reservoirs, lakes, and ponds. As noted for Region 3, the small dams and reservoirs in the western portion of Region 4 (Section 3.15.5.4.2), are captured, as applicable, in the acreage of reservoirs, lakes, and ponds and possibly miles of major waterbodies and would be easily avoided by transmission line structures and access roads. Region 4 of the transmission line route includes a large number of surface waters with designations of special interest as shown in Table 3.15-17. Rather than attempting to identify each of the surface water features of interest that could be affected by construction, this discussion simply identifies the number of features along the route being discussed and the number of designations involved; Table 3.15-17 can be consulted for additional detail. Federal or state surface water designations of special interest within the ROW of the Applicant Proposed Route in Region 4 includes eight surface waters with a total of 14 designations plus three non-specific source water protection areas. Three of the surface waters (the Arkansas, Lower Illinois, and Mulberry rivers) are designated Section 10 Navigable Waters and, as indicated in Table 3.15-1, any action involving dredging or filling or any other obstruction or alteration of these rivers would require a permit from the USACE; requirements under Section 404 of the CWA would also be applicable. Section 10 Navigable Waters are also addressed in Section 3.19.

As noted in Section 3.15.5.4.2, the Lee Creek Variation within the Applicant Proposed Route avoids the 300-foot buffer zone established around Lee Creek Reservoir by the city of Fort Smith, which is one of the special designations considered in the preceding paragraph.

The ROW of the Applicant Proposed Route also encompasses three streams identified by the state as impaired waters: Sallisaw, Little Sallisaw, and Lee creeks, all in Oklahoma. With the added requirements if impaired waters were to be affected, potential impacts associated with construction of the Applicant Proposed Route in Region 4 would be the same as those common impacts described in Section 3.15.6.1. Surface water is the predominant source of water in the six-county area of Region 4, so water to support construction of the transmission line, although expected to be obtained from a municipal provider, would likely come from surface water.

Seven route variations to the Applicant Proposed Route were developed in Region 4 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.4. The variations are illustrated in Exhibit 1 of Appendix M. The variations would involve minor changes to the surface water features within the 200-foot-wide representative ROW of the Applicant Proposed Route; no different waters of special interest or impaired waters are present within the 1,000-foot-wide corridor. Three streams, however, would be crossed in slightly different locations. The minor route variations in Region 4 of the Applicant Proposed Route would not affect the potential impacts to surface waters associated with construction.

3.15.6.2.3.1.5 Region 5

The 200-foot-wide ROW of the Applicant Proposed Route in Region 5 encompasses 2.16 miles of perennial streams, 9.32 miles of intermittent streams, 0.24 mile of major waterbodies, and 17.3 acres of reservoirs, lakes, and ponds (Table 3.15-20). Federal or state surface water designations of special interest within the ROW of the Region 5 Applicant Proposed Route includes four specific surface waters (Illinois Bayou, Cadron Creek, Little Red River, and White River) with five designations as shown in Table 3.15-21 and two non-specific source water protection areas. Since the White River is designated a Section 10 Navigable Water, any action involving dredging or filling or any other obstruction or alteration of this river would require a permit from the USACE; requirements under Section 404 of the CWA would also be applicable (Table 3.15-1). The ROW of the Applicant Proposed Route in Region 5 also encompasses six streams identified by the state as impaired waters: West Fork Point Remove Creek, East Fork Point Remove Creek, Little Red River, Ten Mile Creek, Glaise Creek, and Departee Creek (Table 3.15-22). With the added requirements if impaired waters were to be affected, potential impacts associated with construction of the Applicant Proposed Route in Region 5 would be the same as those common impacts described in Section 3.15.6.1. Surface water is the predominant source of water in the seven-county area of Region 5, but groundwater use is also notable, so water to support construction of the transmission line, although expected to be obtained from a municipal provider, could come from surface water or groundwater.

Five route variations to the Applicant Proposed Route were developed in Region 5 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.5. The variations are illustrated in Exhibit 1 of Appendix M. The variations would involve minor changes to the surface water features within the 200-foot-wide representative ROW of the Applicant Proposed Route; no different waters of special interest or impaired waters are present within the 1,000-foot-wide corridor. One stream, however, would be crossed in a slightly different location. The minor route variations in Region 5 of the Applicant Proposed Route would not affect the potential impacts to surface waters associated with construction.

3.15.6.2.3.1.6 Region 6

The 200-foot-wide corridor of the Applicant Proposed Route in Region 6 encompasses 0.83 mile of perennial streams, 3.48 miles of intermittent streams, 0.2 mile of major waterbodies, and 5.2 acres of reservoirs, lakes, and ponds (Table 3.15-24). Federal or state surface water designations of special interest within the ROW of the Applicant Proposed Route in Region 6 include only the L'Anguille River, which is on the Nationwide Rivers Inventory (Table 3.15-25). The ROW of the Applicant Proposed Route also encompasses three streams identified by the state as impaired waters: Cache River, Bayou DeView, and L'Anguille River (Table 3.15-26). With the added requirements if impaired waters were to be affected, potential impacts associated with construction of the Applicant Proposed Route in Region 6 would be the same as those common impacts described in Section 3.15.6.1. Groundwater is the predominant source of water used in the three-county area of Region 6, so water to support construction of the transmission line, although expected to be obtained from a municipal provider, would likely not come from surface water.

One route variation to the Applicant Proposed Route was developed in Region 6 in response to public comments on the Draft EIS. The route variation is described in Appendix M and summarized in Section 2.4.2.6. The variation is illustrated in Exhibit 1 of Appendix M. The variation would involve no changes to the surface water features within the 200-foot-wide representative ROW of the Applicant Proposed Route; no different waters of special interest or impaired waters are present within the 1,000-foot-wide corridor. The minor route variation in Region 6 of the Applicant Proposed Route would not affect the potential impacts to surface waters associated with construction.

3.15.6.2.3.1.7 Region 7

The 200-foot-wide ROW of the Applicant Proposed Route in Region 7 encompasses 0.54 mile of perennial streams, 4.3 miles of intermittent streams, 0.64 mile of major waterbodies, and 2.4 acres of reservoirs, lakes, and ponds (Table 3.15-28). Federal or state surface water designations of special interest within the corridor of the Applicant Proposed Route include two surface waters, St. Francis River and Mississippi River, and three designations (Table 3.15-29). Because of the Section 10 Navigable Waters designation on both these rivers, any action involving dredging or filling or any other obstruction or alteration would require a permit from the USACE; requirements under Section 404 of the CWA would also be applicable (Table 3.15-1). The ROW of the Applicant Proposed Route in Region 7 also encompasses one stream in Arkansas and four streams in Tennessee identified as impaired waters: Tyronza River, Mississippi River, Royster Creek, North Fork Creek, and Big Creek (Table 3.15-30). With the added requirements if impaired waters were to be affected, potential impacts associated with construction of the Applicant Proposed Route in Region 7 would be the same as those common impacts described in Section 3.15.6.1. Groundwater is the predominant source of water used in the four-county area of Region 7, but surface water use is notable, so water to support construction of the transmission line, although expected to be obtained from a municipal provider, could come from groundwater and surface water.

Three route variations to the Applicant Proposed Route were developed in Region 7 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.7. The variations are illustrated in Exhibit 1 of Appendix M. The variations would involve minor changes to the surface water features within the 200-foot-wide representative ROW of the Applicant Proposed Route; no different waters of special interest or impaired waters are present within the 1,000-foot-wide corridor. One stream, however, would be crossed in a slightly different location. The minor route variations in Region 7 of the Applicant Proposed Route would not affect the potential impacts to surface waters associated with construction.

3.15.6.2.3.2 Operations and Maintenance Impacts

Operations and maintenance of the HVDC transmission line in Regions 1 through 7, using the Applicant Proposed Route, would not impact surface water. During operations and maintenance, no notable sources of contaminants would be in use other than the typical fuels and lubricants found in vehicles and equipment; herbicides used to maintain ROWs and access roads would be applied in accordance with label instructions and any federal, state, and local regulations to minimize the potential for spreading; no soil disturbance would occur; and water needs would be limited to personal needs of the few workers that would be associated with maintenance of facilities and equipment. Access roads developed during construction would be maintained as needed to support long-term operations and maintenance actions.

3.15.6.2.3.3 Decommissioning Impacts

Decommissioning of HVDC transmission lines would be expected to have impacts similar to those described in Section 3.15.6.1 for common construction activities. The same types of measures would be required to manage the fuels and lubricants that would be present in equipment and actions to protect stormwater runoff at the site would ensure that contaminants did not reach surface water. Decommissioning actions may require larger equipment than required during typical operation and maintenance activities. As a result, access to some areas may need to be improved or even reestablished and, as during construction, could involve direct disturbances to surface water or drainage channels. Water demand during decommissioning would be limited to that needed for actions such as dust suppression, soil compaction, and possibly re-seeding or landscaping to put the ground back into suitable condition. Water demand would be less than for construction and would not adversely impact surface water resources.

3.15.6.3 Impacts Associated with the DOE Alternatives

3.15.6.3.1 Arkansas Converter Station Alternative Siting Area and AC Interconnection Siting Area

3.15.6.3.1.1 Construction Impacts

The siting area for the Arkansas alternative converter station has been reduced since the Draft EIS, but still contains drainage features, including no perennial streams, 0.63 mile of intermittent streams, no major waterbodies, and 2.6 acres of reservoirs, lakes, and ponds. The 200-foot-wide representative ROW for the AC interconnection line in addition to the area for the new substation at the southern end of the AC Interconnection Siting Area would encompass 0.16 mile of perennial streams, 1.49 miles of intermittent streams, and 1.66 acres of reservoirs, lakes, and ponds. As indicated previously, the Applicant would avoid surface waters to the extent practicable in selecting the ultimate construction site for the station. Potential impacts associated with construction of the station, the AC interconnection line, and substation would be the same as those common impacts described in Section 3.15.6.1. Surface water is the predominant source of water in Pope County, where the siting area is located, so water to support construction of the converter station, interconnection transmission line, and substation would likely come from surface water even though it is expected to be obtained from a municipal provider.

3.15.6.3.1.2 Operations and Maintenance Impacts

Operations and maintenance of the Arkansas converter station basically would be the same as described in Section 3.15.6.2.1.2 for the Oklahoma and Tennessee converter stations. The public water systems in the region predominantly use surface water (Table 3.7-15).

3.15.6.3.1.3 Decommissioning Impacts

Decommissioning of the Arkansas converter station and the associated AC interconnection line and substation would be as described in Section 3.15.6.2.1 for the Oklahoma and Tennessee stations.

3.15.6.3.2 HVDC Alternative Routes

3.15.6.3.2.1 Construction Impacts

This section addresses potential impacts from construction of transmission line along HVDC alternative routes within each of the seven regions of the Project. The surface water features described in each region are those located within a 200-wide representative ROW of the HVDC alternative routes. Surface water features and elements within the ROWs were presented in the regional discussions of Section 3.15.5 along with the information for the corresponding 1,000-foot-wide ROI. Changes to impacts due to route adjustments developed in response to maintain an end-to-end route with variations to the Applicant Proposed Route are described at the end of the applicable sections.

The same considerations described for the Applicant Proposed Route in Section 3.15.6.2.3.1 would be applicable to the HVDC alternative routes. That is, the same considerations of avoiding surface waters to the extent practicable, the potential need for access roads to cross surface drainage features, and the additional stormwater runoff control measures needed if impaired waters could be affected would be applicable to the HVDC alternative routes.

3.15.6.3.2.1.1 Region 1

Table 3.15-4, provides the miles of perennial streams, intermittent streams, and major waterbodies that would be crossed by the 200-foot-wide ROWs of HVDC Alternative Routes 1-A, 1-B, 1-C, and 1-D. Table 3.15-4 also provides the acreage of reservoirs, lakes, and ponds within each of the ROWs. As shown in the table, the ROWs of the HVDC alternative routes would contain the following in comparison to the corresponding links of the Applicant Proposed Route.

- Perennial streams—1-A, 1-B, and 1-C would encompass smaller amounts (by 0.11, 0.2, and 0.1 mile, respectively) and 1-D would encompass the same amount
- Intermittent streams—1-A, 1-B, and 1-C would encompass greater amounts (by 2.69, 0.59, and 0.22 miles, respectively) and 1-D would encompass a smaller amount (by 0.33 mile)
- Major Waterbodies—1-A and 1-C would encompass greater amounts (both by 0.01 mile), 1-B would encompass a smaller amount (by 0.02 mile), and 1-D would encompass the same amount
- Reservoirs, Lakes, and Ponds—1-A, 1-B, 1-C, and 1-D would encompass smaller amounts (by 3.1, 6.1, 6.0, and 0.8 acres, respectively)

No surface waters within the Region 1 ROI have federal or state classifications of special interest other than those identified as having impaired water quality. As shown in Table 3.15-6, Region 1 of the Applicant Proposed Route would contain six surface water segments identified by the state of Oklahoma as having impaired water quality: Palo Duro Creek, Kiowa Creek, Beaver River, Clear Creek, Otter Creek, and Sand Creek. These six impaired waters would also be crossed the corresponding HVDC alternative routes, except that HVDC Alternative Route 1-A would avoid Clear Creek and Otter Creek. However, 1-A would cross an additional impaired water, Sand Creek, which would not be crossed by any of the other Region 1 HVDC transmission line routes.

Groundwater is the predominant source of water in the four-county area of Region 1, so water to support construction of the transmission line, although expected to be obtained from a municipal provider, would likely not come from surface water. Potential impacts associated with construction of an HVDC alternative route in Region 1 would be the same as those common impacts described in Section 3.15.6.1.

3.15.6.3.2.1.2 Region 2

Table 3.15-8, provides the miles of perennial streams, intermittent streams, and major waterbodies that would be crossed by the 200-foot-wide ROWs of HVDC Alternative Routes 2-A and 2-B. Table 3.15-8 also provides the acreage of reservoirs, lakes, and ponds within each of the ROWs. As shown in the table, the ROWs of the HVDC alternative routes would contain the following in comparison to the corresponding links of the Applicant Proposed Route:

- Perennial streams—2-A and 2-B would encompass greater amounts (by 2.03 and 0.38 mile, respectively)
- Intermittent streams—2-A and 2-B would encompass smaller amounts (by 1.22 and 0.6 mile, respectively)
- Major Waterbodies—2-A would encompass a greater amount (by 0.04 mile) and 2-B would encompass the same amount

- Reservoirs, Lakes, and Ponds—2-A and 2-B would encompass greater amounts (by 5.7 and 0.5 acres, respectively)

As shown in Table 3.15-9, the Cimarron River is the only surface water within the Region 2 ROI that has federal or state classifications of special interest other than those identified as having impaired water quality. The Cimarron River, which is within the 200-foot-wide ROW of both the Applicant Proposed Route and HVDC Alternative Route 2-A, has a USFWS designation of critical habitat and an Oklahoma designation as a water of recreational and/or ecological significance. As shown in Table 3.15-10, the Applicant Proposed Route in Region 2 would cross four surface water segments identified by the state of Oklahoma as having impaired water quality: East Griever Creek, Cimarron River, Turkey Creek, and Buffalo Creek. These four also would be crossed by the corresponding HVDC alternative routes. However, 2-A would cross three additional impaired waters; Main Creek, Griever Creek, and Cottonwood Creek, which would not be crossed any of the other Region 2 HVDC transmission line routes.

Groundwater is the predominant source of water in the three-county area of Region 2, so water to support construction of the transmission line, although expected to be obtained from a municipal provider, would likely not come from surface water. Potential impacts associated with construction of an HVDC alternative route in Region 2 would be the same as those common impacts described in Section 3.15.6.1.

3.15.6.3.2.1.3 Region 3

Table 3.15-12 provides the miles of perennial streams, intermittent streams, and major waterbodies that would be crossed by the 200-foot-wide ROW of HVDC Alternative Routes 3-A through 3-E. Table 3.15-12 also provides the acreage of reservoirs, lakes, and ponds within each of the ROWs. As shown in the table, the ROWs of the HVDC alternative routes would contain the following in comparison to the corresponding links of the Applicant Proposed Route:

- Perennial streams—3-A, 3-B, and 3-E would encompass greater amounts (by 0.87, 0.62 and 0.06 mile, respectively) and 3-C and 3-D would encompass smaller amounts (by 1.66 and 1.13 miles, respectively)
- Intermittent streams—3-A and 3-B encompass smaller amounts (both by 0.76 mile) and 3-C, 3-D, and 3-E would encompass greater amounts (by 3.18, 2.27, and 0.74 miles, respectively)
- Major Waterbodies—3-A, 3-B, 3-C, and 3-D would encompass smaller amounts (by 0.02, 0.03, 0.02, and 0.01 mile, respectively) and 3-E would encompass the same amount
- Reservoirs, Lakes, and Ponds—3-A, 3-B, and 3-D would encompass greater amounts (by 5.6, 6.0, and 2.0 acres, respectively) and 3-C and 3-E would encompass smaller amounts (11.9 and 0.2 acres, respectively)

As shown in Table 3.15-13, Lake Carl Blackwell and Cushing Lake are the surface waters within the Region 3 ROI that have federal or state classifications of special interest other than those identified as having impaired water quality. Oklahoma classifies both lakes as special provision watersheds for sensitive public and private water supplies; the state also designates Lake Carl Blackwell as a source water protection area. The special provision watershed of Cushing Lake is within the 200-foot-wide ROW of both the Applicant Proposed Route and the corresponding HVDC Alternative Route (i.e., 3-C) and the watershed of Carl Blackwell is only within the ROWs of HVDC Alternative Routes 3-A and 3-B.

As shown in Table 3.15-14, the Applicant Proposed Route in Region 3 would cross eight streams identified by the state of Oklahoma as impaired waters: Skeleton Creek, Cimarron River, Stillwater Creek, West Spring Creek, Browns

Creek, Begger Creek, Salt Creek, and Adams Creek. Of those eight, HVDC Alternative Routes 3-A and 3-B would avoid Skeleton Creek and 3-C would avoid West Spring Creek and Begger Creek; the other five would be crossed by corresponding alternative routes. However, several of the HVDC alternative routes would cross additional impaired waters that would not be crossed by the Applicant Proposed Route: 3-A/3-B would cross West Beaver Creek, 3-B would cross Stillwater Creek, 3-C would cross Little Deep Fork Creek, and 3-C/3-D would cross Butler Creek.

Groundwater is the predominant source of water in the eight-county area of Region 3, but surface water use is also notable, so water to support construction of the transmission line, although expected to be obtained from a municipal provider, could come from both surface water and groundwater. Potential impacts associated with construction of an HVDC alternative route in Region 3 would be the same as those common impacts described in Section 3.15.6.1.

As described in Appendix M and summarized in Section 2.4.2.3, a route adjustment was developed for HVDC Alternative Route 3-A to maintain an end-to-end route with the Applicant Proposed Route Region 3 Links 1 and 2, Variation 1. The adjustment to HVDC Alternative Route 3-A would involve no change in the surface water features within the 200-foot-wide representative ROW and no different waters of special interest or impaired waters are present within the 1,000-foot-wide corridor. The minor adjustment to HVDC Alternative Route 3-A would not affect the potential impacts associated with construction. The route adjustment is illustrated in Exhibit 1 of Appendix M.

3.15.6.3.2.1.4 Region 4

Table 3.15-16 provides the miles of perennial streams, intermittent streams, and major waterbodies that would be crossed by the 200-foot-wide ROWs of HVDC Alternative Routes 4-A through 4-E. Table 3.15-16 also provides the acreage of reservoirs, lakes, and ponds within each of the ROWs. As shown in the table, the ROWs of the HVDC alternative routes would contain the following in comparison to the corresponding I of the HVDC Applicant Proposed Route:

- Perennial streams—4-A, 4-B, 4-D, and 4-E would encompass smaller amounts (by 0.36, 0.92, 0.62, and 0.37 mile, respectively) and 4-C would encompass a greater amount (by 0.16 mile)
- Intermittent streams—4-A, 4-B, 4-D, and 4-E would encompass greater amounts (by 0.4, 1.17, 0.84 and 0.92 mile, respectively) and 4-C would encompass a smaller amount (by 0.16 mile)
- Major Waterbodies—4-A, 4-B, and 4-D would encompass smaller amounts (by 0.05, 0.06, and 0.08 mile, respectively), and 4-C would encompass the same amount, and 4-E would encompass a greater amount (by 0.08 mile)
- Reservoirs, Lakes, and Ponds—4-A, 4-C, 4-D, and 4-E would encompass greater amounts (by 1.1, 0.5, 0.2, and 4.3 acres, respectively) and 4-B would encompass a smaller amount (by 2.6 acres)

Region 4 of the HVDC transmission line route includes a large number of surface waters with designations of special interest as shown in Table 3.15-17. The table lists 11 named surface water features, many with multiple designations, and 6 non-specific (not publicly available) source water protection areas. Of those table listings, the ROW of the Applicant Proposed Route would encompass eight named surface water features and three non-specific source water protection areas. Compared to features along the Applicant Proposed Route:

- HVDC Alternative Routes 4-A/4-B would avoid two (Briar Creek and Lee Creek Reservoir) but would encompass three (Brushy Creek, Little Lee Creek, and the portion of Lee Creek that is an Oklahoma Scenic River) additional features.

- HVDC Alternative Route 4-A would encompass Webbers Creek.
- HVDC Alternative Route 4-B would encompass Lee Creek where it is an Arkansas extraordinary resource water.
- HVDC Alternative Routes 4-A, 4-B, 4-D would encompass two non-specific source water protection areas.
- HVDC Alternative Route 4-E would encompass a non-specific source water protection area.

HVDC Alternative Route 4-B and the corresponding Link 7 of the Applicant Proposed Route would cross the Mulberry River, which is designated a Section 10 Navigable Water and, as indicated in Table 3.15-1, any action involving dredging or filling or any other obstruction or alteration of these rivers would require a permit from the USACE; requirements under Section 404 of the CWA would also be applicable.

As shown in Table 3.15-18, the Applicant Proposed Route in Region 4 would cross three streams identified by the state of Oklahoma as having impaired water quality: Sallisaw Creek, Little Sallisaw Creek, and Lee Creek. Of those three, each would be crossed by corresponding alternative routes (specifically 4-A and 4-B). HVDC Alternative Routes 4-A and 4-B would also cross an additional impaired stream, Little Lee Creek, that would not be crossed by the Applicant Proposed Route.

Surface water is the predominant source of water in the six-county area of Region 4, so water to support construction of the transmission line, although expected to be obtained from a municipal provider, would likely come from surface water. Potential impacts associated with construction of an HVDC alternative route in Region 4 would be the same as those common impacts described in Section 3.15.6.1.

3.15.6.3.2.1.5 Region 5

Table 3.15-20 provides the miles of perennial streams, intermittent streams, and major waterbodies that would be crossed by the 200-foot-wide ROWs of HVDC Alternative Routes 5-A through 5-F. Table 3.15-20 also provides the acreage of reservoirs, lakes, and ponds within each of the ROWs. As shown in the table, the ROWs of the HVDC alternative routes would contain the following in comparison to the corresponding links of the Applicant Proposed Route:

- Perennial streams—5-A, 5-C, and 5-F would encompass smaller amounts (by 0.18, 0.08, and 0.01 mile, respectively) and 5-B, 5-D, and 5-E would encompass greater amounts (by 0.18, 0.02, and 0.09 mile, respectively)
- Intermittent streams—5-A, 5-B, 5-D, 5-E and 5-F would encompass greater amounts (by 0.33, 2.0, 0.3, 0.99, and 0.46 miles, respectively) and 5-C would encompass a smaller amount (by 0.14 mile)
- Major Waterbodies—5-A, 5-E, and 5-F would encompass the same amount, 5-B and 5-C would encompass greater amounts (by 0.02 and 0.01, respectively), and 5-D would encompass a smaller amount (by 0.01)
- Reservoirs, Lakes, and Ponds—5-A, 5-B, 5-C, 5-D, 5-E, and 5-F would all encompass greater amounts (by 0.4, 3.4, 1.0, 0.4, 3.8, and 2.7 acres, respectively)

As shown in Table 3.15-21, there are six specific surface waters within the Region 5 ROI that have federal or state classifications of special interest and two non-specific (not publicly available) source water protection areas. The ROW of the Applicant Proposed Route would encompass four of specific surface waters (Illinois Bayou, Cadron Creek, Little Red River, and White River) as well as both of the non-specific source water protection areas, and these same items would be encompassed by corresponding HVDC alternative routes. The remaining two specific surface waters in Table 3.15-21 are East Fork Cadron Creek, which would be encompassed by 5-B/5-E/5-F, and Departee

Creek, which would be encompassed by 5-D. HVDC Alternative Route 5-D would cross the White River, which is designated as Section 10 Navigable Waters and, as indicated in Table 3.15-1, any action involving dredging or filling or any other obstruction or alteration of this river would require a permit from the USACE; requirements under Section 404 of the CWA would also be applicable.

Table 3.15-22 identifies the seven Region 5 surface waters identified by the state of Arkansas as having impaired water quality: West Fork Point Remove Creek, East Fork Point Remove Creek, Cypress Creek, Little Red River, Ten Mile Creek, Glaise Creek, and Departee Creek. Of these seven streams, the first six listed would be encompassed by both the Applicant Proposed Route and a corresponding HVDC alternative route. Cypress Creek would be encompassed only by HVDC Alternative Route 5-B.

Surface water is the predominant source of water in the seven-county area of Region 5, but groundwater use is also notable, so water to support construction of the transmission line, although expected to be obtained from a municipal provider, could come from surface water or groundwater. Potential impacts associated with construction of an HVDC alternative route in Region 5 would be the same as those common impacts described in Section 3.15.6.1.

As described in Appendix M and summarized in Section 2.4.2.5, a route adjustment was developed for HVDC Alternative Route 5-B to maintain an end-to-end route with the Applicant Proposed Route Region 5 Links 2 and 3, Variation 1. Another route adjustment was developed for HVDC Alternative Route 5-E to maintain an end-to-end route with the Applicant Proposed Route Region 5 Links 3 and 4, Variation 2. The adjustments to HVDC Alternative Routes 5-B and 5-E would involve no change in the surface water features within the 200-foot-wide representative ROW; no different waters of special interest or impaired waters are present within the 1,000-foot-wide corridor. The minor adjustments in HVDC Alternative Routes 5-B and 5-E would not affect the potential impacts associated with construction. The route adjustments are illustrated in Exhibit 1 of Appendix M.

3.15.6.3.2.1.6 Region 6

Table 3.15-24 provides the miles of perennial streams, intermittent streams, and major waterbodies that would be crossed by the 200-foot-wide ROWs of HVDC Alternative Routes 6-A through 6-D. Table 3.15-24 also provides the acreage of reservoirs, lakes, and ponds within each of the ROWs. As shown in the table, the ROWs of the HVDC alternative routes would contain the following in comparison to the corresponding links of the Applicant Proposed Route:

- Perennial streams—6-A would encompass a smaller amount (by 0.06 mile) and 6-B, 6-C, and 6-D would encompass greater amounts (by 0.02, 0.1, and 0.13 mile, respectively)
- Intermittent streams—6-A would encompass the same amount, 6-B would encompass a smaller amount (by 0.45 mile) and 6-C and 6-D would encompass greater amounts (by 0.02 and 0.14 mile, respectively)
- Major Waterbodies—6-A would encompass the same amount and 6-B, 6-C, and 6-D would encompass smaller amounts (by 0.02, 0.05, and0.04 mile, respectively)
- Reservoirs, Lakes, and Ponds—6-A would encompass a smaller amount (by 1.5 acres), 6-B and 6-C would encompass greater amounts (both by 1.5 acres), and 6-D would encompass the same amount

As shown in Table 3.15-25, the L’Anguille River is the only surface water within the Region 6 ROI that has federal or state classifications of special interest other than those identified as having impaired water quality. The portion of the L’Anguille River that is in the National Rivers Inventory runs south from the Poinsett-Cross county line, so the ROW of HVDC Alternative Route 6-C avoids the designated section of the river. Table 3.15-26 lists the three surface water segments in Region 6 that are identified by the state of Arkansas as having impaired water quality: Cache River, Bayou DeView, and the L'Anguille River. All three of the impaired waters are encompassed by the Applicant Proposed Route and the corresponding HVDC alternative routes.

Groundwater is the predominant source of water used in the three-county area of Region 6, so water to support construction of the transmission line, although expected to be obtained from a municipal provider, would likely not come from surface water. Potential impacts associated with construction of an HVDC alternative route in Region 6 would be the same as those common impacts described in Section 3.15.6.1.

As described in Appendix M and summarized in Section 2.4.2.6, a route adjustment was developed for HVDC Alternative Route 6-A to maintain an end-to-end route with the Applicant Proposed Route Region 6 Link 2, Variation 1. The adjustment to HVDC Alternative Route 6-A would involve no change in the surface water features within the 200-foot-wide representative ROW and no different waters of special interest or impaired waters are present within the 1,000-foot-wide corridor. The minor adjustment to HVDC Alternative Route 6-A would not affect the potential impacts associated with construction. The route adjustment is illustrated in Exhibit 1 of Appendix M.

3.15.6.3.2.1.7 Region 7

Table 3.15-28 provides the miles of perennial streams, intermittent streams, and major waterbodies that would be crossed by the 200-foot-wide ROWs of HVDC Alternative Routes 7-A through 7-D. Table 3.15-28 also provides the acreage of reservoirs, lakes, and ponds within each of the ROWs. As shown in the table, the ROWs of the HVDC alternative routes would contain the following in comparison to the corresponding links of the Applicant Proposed Route:

- Perennial streams—7-A, 7-C, and 7-D would encompass greater amounts (by 1.47, 0.15, and 0.22 miles, respectively) and 7-B would encompass a smaller amount (by 0.01 mile)
- Intermittent streams—7-A and 7-C would encompass greater amounts (by 2.0 and 0.32 miles, respectively), and 7-B and 7-D would encompass smaller amounts (by 0.21 and 0.08 mile, respectively)
- Major Waterbodies—7-A and 7-C would encompass greater amounts (by 0.26 and 0.01 mile, respectively) and 7-B and 7-D would encompass the same amount
- Reservoirs, Lakes, and Ponds—7-A would encompass a greater amount (by 0.9 acre), 7-B and 7-D would encompass smaller amounts (by 0.1 and 0.8 acre, respectively), and 7-C would encompass the same amount

As shown in Table 3.15-29, the St. Francis River and the Mississippi River are the only surface waters within the Region 7 ROI that have federal or state classifications of special interest other than those identified as having impaired water quality. Both rivers would be crossed by HVDC Alternative Route 7-A and Link 1 of the Applicant Proposed Route. Also as shown in Table 3.15-29, both rivers are designated Navigable Waters of the U.S and the Mississippi River is also designated an exceptional Tennessee Water. Because the Region 7 alternatives would cross two surface waters designated as Section 10 Navigable Waters, any action involving dredging or filling or any other obstruction or alteration of these rivers would require a permit from the USACE as indicated in Table 3.15-1; requirements under Section 404 of the CWA would also be applicable.

Table 3.15-30 identifies the five Region 7 surface waters identified by the state of Arkansas or the state of Tennessee as having impaired water quality: Tyronza River in Arkansas; and Mississippi River, Royster Creek, Big Creek, and

North Fork Creek in Tennessee. Also as shown in Table 3.15-30, the state identifies eight different stream segments for these five streams that are within the 200-foot-wide ROWs of the HVDC transmission line routes. Although crossings may be over different segments of the same stream, both the Applicant Proposed Route and corresponding HVDC alternative routes would encompass each stream.

Groundwater is the predominant source of water used in the four-county area of Region 7, but surface water use is notable, so water to support construction of the transmission line, although expected to be obtained from a municipal provider, could come from surface water and groundwater. Potential impacts associated with construction of an HVDC alternative route in Region 7 would be the same as those common impacts described in Section 3.15.6.1.

3.15.6.3.2.2 Operations and Maintenance Impacts

Operations and maintenance of an HVDC transmission line in Regions 1 through 7, using any of the HVDC alternative routes, would not impact surface water. During operations and maintenance, no notable sources of contaminants would be in use other than the typical fuels and lubricants found in vehicles and equipment, herbicides used to maintain ROWs and access roads would be applied in accordance with label instructions and any federal, state, and local regulations to minimize the potential for spreading, no soil disturbance would occur, and water needs would be limited to personal needs of the few workers that would be associated with maintenance of facilities and equipment. Access roads developed during construction would be maintained as needed to support long-term operations and maintenance actions.

3.15.6.3.2.3 Decommissioning Impacts

Decommissioning of HVDC transmission lines with the Applicant Proposed Route or any of the HVDC alternative routes, would be expected to have impacts similar to those described in Section 3.15.6.1 for common construction activities, i.e., the same types of measures would be required to manage the fuel and lubricants that would be present in equipment and actions to protect stormwater runoff at the site would ensure that contaminants did not reach surface water. Decommissioning actions may require larger equipment than required during typical operation and maintenance activities. As a result, access to some areas may need to be improved or even reestablished and, as during construction, could involve direct disturbances to surface water or drainage channels. Water demand during decommissioning would be limited to that needed for actions such as dust suppression, soil compaction, and possibly re-seeding or landscaping to put the ground back into suitable condition. Water demand would be less than for construction and would not adversely impact surface water resources.

3.15.6.4 Best Management Practices

The Applicant has developed a comprehensive list of EPMs that would avoid and minimize impacts to surface water. A complete list of EPMs for the Project is provided in Appendix F; those EPMs that would minimize: (1) the potential for contamination to reach surface water, (2) changes to stormwater runoff or drainage patterns, and (3) direct, physical impacts to surface water features or restrictions on the use of a surface water are summarized in Section 3.15.6.1.5. The EPMs are comprehensive enough to avoid or minimize potential adverse impacts to surface water. DOE has therefore not identified any additional surface-water-related BMPs.

3.15.6.5 Unavoidable Adverse Impacts

Proper construction practices and measures, including those necessary to meet regulatory requirements and those protective measures proposed by the Applicant, should minimize adverse impacts to surface waters. In spite of these measures, adverse impacts to surface water resources, although minor, would still be likely. Construction and operations and maintenance of the Project would require a moderate level of water use, and some access roads would likely traverse through or over stream channels.

Sediment-laden runoff from a construction site could occur and could have adverse effects on a receiving water. The construction general permit for stormwater discharges would minimize the potential for such incidents and would keep potential adverse impacts to these surface waters to a minimum.

3.15.6.6 Irreversible and Irretrievable Commitment of Resources

The Project would involve a commitment of surface water resources, but at least to some extent, those resources would be replenished by cyclic precipitation and snow melt. The commitment of surface water resources would be irreversible in that it would limit, in the short term, future options for use of that resource. Over time, however, the amounts of water used to support construction would be expected to have a negligible effect on surface water resources. In other words, the surface water resource would be renewable or recoverable, so the commitment would not be considered irretrievable.

3.15.6.7 Relationship between Local Short-term Uses and Long-term Productivity

Surface water required to support the Project would represent a new, short-term use of the resource, but would have negligible effect on its long-term productivity. Any alterations to streambeds required by access road construction would have short term impacts on the altered segment of stream, but over time the impacts would be expected to fade as natural flora and fauna reestablished and the impacted stream segments would be small.

3.15.6.8 Impacts from Connected Actions

3.15.6.8.1 Wind Energy Generation

3.15.6.8.1.1 Construction Impacts

Construction of wind farms in the Oklahoma and Texas Panhandle regions would be expected to involve potential impacts to surface waters similar to those described in Section 3.15.6.1 for common construction activities. Sources of contamination, primarily in the form of fuels and lubricants, would be present at construction sites and at associated construction staging and storage yards. Soils in construction areas, access routes, and support areas would be disturbed and, for at least some period of time, would be expected to experience changes in stormwater runoff rates as compared to undisturbed conditions. Construction actions, particularly for access roads, could result in direct disturbances of surface waters or drainage channels. Water needs to support construction activities could affect the availability of surface water resources for other users in the region.

The surface water features that could be affected by construction or that could alter construction approaches due to added requirements are presented in Section 3.15.5.8.1 by WDZ. All of the WDZs contain various lengths of perennial and intermittent streams as well as various areas of reservoirs, lakes, and ponds (Table 3.15-32). Beaver River in WDZ D and Wolf Creek in WDZ L are the only surface water segments of special interest in any of the WDZs (Table 3.15-33). Segments of Beaver River in WDZ-F and -J and a segment of Palo Duro Creek in WDZ J are the only impaired waters in any of the WDZs (Table 3.5-34). Although there are differences in surface water features between the WDZs, DOE has no way of predicting precisely where wind farms might be constructed within the WDZs and, therefore, cannot address whether those features would be of concern to a specific wind farm action. Further, it is estimated that only 20 to 30 percent of any WDZ would actually be included within wind farms and the nature of wind farms is that large areas are required, but only relatively small areas are physically impacted. As a result, wind farm design would be expected to have flexibility on where roads and facilities were placed and what locations, specifically those with environmental concerns, could be avoided. Because of these factors, DOE has not identified potential surface water impacts for individual WDZs; rather the discussion that follows provides more detail on the typical impacts that would be expected from the construction of wind farms within any of the WDZs.

3.15.6.8.1.1.1 Potential for Surface Water Contamination

Construction of even one large wind turbine would involve land disturbance of more than 1 acre (BLM 2005), which is the trigger in both Oklahoma and Texas for requiring a construction general permit for stormwater discharges under the EPA NPDES program as implemented by each state. Accordingly, construction of a wind farm in either state would be subject to the requirements of a construction general permit and the standard permit provisions described in Section 3.15.6.1.2. The future wind farm developer would be required to prepare and implement a SWPPP, which would in turn act to prevent surface water contamination by requiring actions to prevent contaminant releases, including sediment-laden runoff. If a wind farm construction action were to require setup of a temporary concrete batch plant, its operation would also be subject to permit requirements.

Wind farm construction activities could involve foundation depths up to 40 feet if pier foundations are used, but the often-used mat foundations, while requiring more land area, generally do not require excavations of more than 10 feet in depth (DOE 2013). As shown by the water table depths in Table 3.7-23, construction of pier foundations in WDZs in Beaver County, Oklahoma, or in Ochiltree County, Texas, could encounter groundwater, but construction would be unlikely to reach groundwater in the other counties. Construction of mat foundations would be unlikely to encounter groundwater in any of the WDZs. As described in Section 3.15.6.1.2 for the Project, were it necessary to pump groundwater from excavations or boreholes to complete foundation construction, water would likely be discharged to vegetated areas through flow control devices or in some other manner approved by the regulatory agency. Also, excavation of deep foundations could involve additives such as drilling muds or bentonite to help stabilize excavation or borehole walls. These materials would also have to be disposed in accordance with applicable federal, state, and local regulations.

With the wind farm development elements described above, it is expected that construction of the connected action would involve the same minor potential for surface water contamination impacts as described in Section 3.15.6.1.1 for general construction under the Project.

3.15.6.8.1.1.2 Changes to Runoff Rates

As described in Section 3.15.6.1.2 for the Project, soils at connected action construction sites would be broken up, loosened, and stockpiled for some period of time during which such soils would have lower stormwater runoff rates than undisturbed soils. Similarly, soil in some areas could be compacted to improve its stability or simply from equipment traffic and have higher runoff rates as a result. However, such conditions would be expected to be relatively short term, with most soils being restored to a pre-disturbance condition once foundations and structures were in place. Also, disturbed areas would be relatively small in comparison to surrounding areas not disturbed by the connected action; it is estimated that the footprint of all wind farm facilities and structures, including access roads, would be no more than 5 to 10 percent of the total wind farm area (BLM 2005) and could be as low as 1 to 3 percent of the total area (DOE 2013). The total area disturbed during construction would be higher, but the relatively small and short-term changes in runoff rates would not be expected to result in any noticeable changes in the area's existing drainage systems or surface waters.

3.15.6.8.1.1.3 Direct Impacts or Disturbances to Surface Water or Drainage Channels

Since wind farm developments require relatively small amounts of dedicated land (or restated, there are large areas of unused land between individual wind turbines), developers would have the ability to avoid small drainage channels in positioning wind turbines. As a matter of reducing costs and protecting valuable equipment, it is assumed developers would want to avoid locating wind turbines or support facilities in large channels or surface waters, unless for some reason channel relocation was a viable option.

Similar to what was described in Section 3.15.6.1.3 for the construction impacts under the Project, the components of a wind farm most likely to result in disturbance of drainage features would be the access roads. It is reasonable to assume that wind farm developers would want to avoid crossing drainage channels to the extent practicable simply to avoid the associated issues (e.g., risks to equipment, difficulty in maintaining long-term access, potential for added regulatory requirements, and other issues that could add to project costs in the long-term), but in some cases options may be limited. It is also reasonable to assume that wind farm developers would establish some criteria for the manner in which drainage channels would be crossed such as those identified by the Applicant and described in Section 3.15.6.1.3. Also as described in that section, the impacts from putting access roads across drainage channels would depend on the nature of the drainage feature and the type of crossing used. Streams or other surface waters already identified as impaired or designated to be of special value would require more elaborate and protective crossing methods if they could not be avoided.

3.15.6.8.1.1.4 Effects on Water Availability

Water would be needed to support construction of the connected action wind farms. Primary water needs would include use for soil compaction during road, substation, and wind turbine foundation construction; as a component of concrete; and for dust suppression. As shown in Table 3.7-26, the vast majority of water used in the six-county area of the WDZs comes from groundwater. Accordingly, it is assumed that a great majority, if not all, of the water needed to support construction of the connected action wind farms would be from groundwater sources, so the availability of surface waters would not be directly impacted.

Section 3.7.6.8.1 describes the basis for estimating a peak average water demand of about 0.54 million gallons per day for wind farm construction. As described in that section, this water demand would be spread over the 12 WDZs. At any given time, the water demand could be focused in a small number of the zones, but over time the average in any single zone would be expected to be only a fraction of the 0.54 million gallons per day. Although this water demand is only a small portion (0.07 percent) of the total water used in the six-county area in which the WDZs are located, it represents more than one-fifth of the same area's surface water usage. These values highlight the disparity of groundwater usage over surface water usage in the six-county region and the high effects on surface water availability that would be expected if a large portion of the water demand for wind farm construction were to come from surface water. In some situations, heavy groundwater usage can have indirect impacts on surface water by such effects as decreasing spring flows or increasing the portion of surface flow that is lost to infiltration. However, the amount of water that would be needed to support wind farm construction actions would represent such a small portion of the amount of groundwater already used in the area that it would not be expected to result in noticeable changes to existing interrelationships between surface waters and groundwater of the region.

3.15.6.8.1.2 Operations and Maintenance Impacts

Compared to pre-wind farm conditions, long-term operations and maintenance of wind farms in any one of the WDZs would only result in minor changes to stormwater runoff and drainage. As noted in Section 3.15.6.8.1, the footprint of all long-term wind farm facilities and structures would likely be approximately 1 percent of the total wind farm area. Much of this footprint would be expected to be relatively impervious to water and, therefore, involve increased runoff. However, the nature of a wind farm is that the footprint of built-up facilities would be reasonably well dispersed over its entire area. For example, an access road, substation, and control building, if collocated, would likely represent the largest single footprint of built-up area and the wind turbine locations would always be widely dispersed. Added runoff from these dispersed impervious areas would be small and easily managed in the semiarid climate of the Oklahoma and Texas Panhandle regions and would not be expected to cause adverse impacts to existing surface waters.

Operations and maintenance of wind farm facilities would not impact surface water. During operations and maintenance, no notable sources of contaminants would be in use other than the typical fuels and lubricants found in vehicles and equipment, additional stormwater runoff from built-up areas would be dispersed and minor, and water needs would be limited to personal needs of the workers operating and maintaining the wind farm facilities and equipment.

3.15.6.8.1.3 Decommissioning Impacts

Decommissioning of wind farms would be expected to have impacts similar to those described in Section 3.15.6.8.1 and in more detail in Section 3.15.6.1 for common construction activities, i.e., measures would be required to manage the fuel and lubricants that would be present in equipment in a manner protective of stormwater runoff that could then reach surface waters away from the construction sites. Water demand during decommissioning would be limited to that needed for actions such as dust suppression, soil compaction, and possibly re-seeding or landscaping to put the ground back into suitable condition. Water demand would be less than for construction, would likely come from groundwater, and would not adversely impact surface water resources.

3.15.6.8.2 Optima Substation

Surface water impacts from construction of the future Optima substation would be the same as described in Section 3.15.6.2.1 for the Oklahoma Converter Station and AC Interconnection Siting Areas and the common construction impacts described in Section 3.15.6.1. There are few intermittent streams and no perennial streams or major waterbodies in the area proposed for the substation. Impacts during operation and maintenance would be expected to be similar to those described for the Oklahoma Converter Station and AC Interconnection Siting Areas in Section 3.15.6.2.1.1.

3.15.6.8.3 TVA Upgrades

Surface water impacts of concern for the required TVA upgrades, like the Project, are associated with the potential for runoff and receiving water contamination, changes to runoff rates, disturbances to surface water or drainage channels, and effects on water availability as described in Section 3.15.6.1.1. These potential impacts would be limited primarily to the construction phase of the required upgrades and, accordingly, to the construction of a new transmission line.

TVA has indicated that new TVA transmission lines constructed over the last decade have had an average of 3.4 stream crossings per mile of new line. An average of 1.2 stream crossings per mile were forested stream crossings, where forest occurred on one or both affected stream banks. Construction of the new transmission line would be expected to involve the same potential contaminants (primarily fuels and lubricants in equipment) as the Project during construction and implementation of the same type of measures to ensure those contaminants were not released. The construction would be expected to involve relatively minor changes to runoff rates and, to minimize liability and costs, TVA would take precautions to minimize disturbances to surface water and drainage features. Water needs for dust suppression, soil compaction, equipment cleaning, and concrete formulation would be relatively minor and short term. There would be little potential for impacts to surface water during upgrades involving modifications to existing facilities. A possible exception would be if replacement of structures was required as part of the upgrades to existing transmission lines. These type activities could involve new ground disturbances and potential for impacts to surface water similar to those described for typical construction. Operational impacts would be similar to those described above for the Project transmission lines.

3.15.6.9 Impacts Associated with the No Action Alternative

Under the No Action Alternative, DOE assumes for analytical purposes that the Project would not be constructed. Surface water conditions would remain as described in the affected environment descriptions of Section 3.15.5.

Figures Presented in Appendix A

3.16 Transportation

This section includes evaluation of existing roadways, railroads, river navigation, and airports/airstrips within the ROI and an evaluation of the potential impacts from specific Project components on transportation amenities. Local bus and emergency routes would be addressed in the more detailed, location-specific Transportation and Traffic Management Plan (see Section 3.16.6.1.2) to be developed prior to construction. Bus and emergency routes are not expected to be prevalent in the Project ROI because the Project traverses areas that are predominantly rural and that have low population densities. Bus and emergency routes are therefore not specifically identified in the affected environment section but are addressed qualitatively in the impacts section.

3.16.1 Regulatory Background

A variety of federal, state, and local agencies administer and regulate roadways and railways. The American Association of State Highway and Transportation Officials (AASHTO) sets standards for construction and operation of interstate and U.S. highways, which are regulated by the FHWA. State departments of transportation are responsible for state highways and routes. County and local roads are controlled by the presiding jurisdiction (cities, counties). Other roads on federal lands are managed by the applicable federal agencies (such as USFS or USACE). Railroad operations are regulated primarily by state commissions. State transportation agencies in the ROI include the Oklahoma Department of Transportation (OKDOT), the Arkansas State Highway and Transportation Department, the Texas Department of Motor Vehicles, the Texas DOT (TXDOT), and the Tennessee DOT (TNDOT). Table 3.16-1 provides a summary of regulatory entities and requirements associated with transportation resources in the area of the Project.

Table 3.16-1:
Regulatory Requirements and Authority Associated with Transportation Resources

Regulatory Entity or Requirement	Key Elements
Roadways	
Encroachment or ROW Permits	Cities, counties, and other public agencies typically require an encroachment permit or similar authorization from the applicable jurisdictional agency at locations where road construction activities would occur within or above the public road ROW. A utility permit (ROW permit or encroachment permit) for state and federal highways must be obtained from the OKDOT for all crossings or encroachment on such highways in Oklahoma, the Arkansas State Highway and Transportation Department, the TXDOT (utility installation request); and the TNDOT Right-of-Way Division Utilities Office. These roadway use permits or similar road use agreements/documents stipulate the party responsible for the repair of damage to roadways and structures caused by a project. The Applicant or its construction contractor must visually document road conditions before and after construction phase and repair road to conditions before construction started or as directed by the applicable state DOT and/or local departments of public works.
Design standards, specifications, and guidelines for roadways (interstate and U.S. highways)	In general, AASHTO and the FHWA define nationwide design standards, specifications, and guidelines for roadways (interstate and U.S. highways) to be used for design and traffic control of roadways. The specific requirements of the permit from the applicable transportation agency are individually determined based on Project and jurisdiction specifics. Permits issued by state and local jurisdictions may include the following requirements: • Identify all roadway locations where special construction techniques such as night construction would be used to minimize impacts to traffic flow. • Develop circulation and detour plans to minimize impacts to local street circulation, which may include the use of signing and flagging to guide vehicles through and/or around the construction zone. • Schedule truck trips outside of peak morning and evening commute hours.

Table 3.16-1:
Regulatory Requirements and Authority Associated with Transportation Resources

Regulatory Entity or Requirement	Key Elements
	• Limit lane closures during peak hours to the extent possible. • Install temporary traffic control devices as specified in the Manual of Uniform Traffic Control Devices for Streets and Highways (FHWA 2009). • Store construction materials only in designated areas.
Oversize and Overweight Permits	Oversize and overweight permits must be obtained from the Oklahoma Department of Public Safety (http://www.dps.state.ok.us/swp/) for roadway travel in Oklahoma, the Arkansas State Highway and Transportation Department (http://www.arkansashighways.com/) for roadway travel in Arkansas, the Texas Department of Motor Vehicles (http://www.txdmv.gov/), and the TNDOT (www.tdot.state.tn.us/). Truck load limits are presented below. Truck Weight and Size Specifications for Oversize/Overweight Vehicles (Texas, Oklahoma, Arkansas, Tennessee) Vehicle Parameters — Specifications Gross Weight — 80,000 pounds for gross vehicle weight 20,000 pounds for single axle weight 34,000 pounds for tandem axle weight[1] Length — 90 feet Width — 8 feet 6 inches Height — 13 feet, 6 inches[2] 1 The tandem axle weight limit is 40,000 pounds in Oklahoma. 2 The height limit is 14 feet in Texas. Sources: AHTD (2011), OKDPS (2014), TNDOT (2003), TXDMV (2014)
National Scenic Byways Program (23 USC § 162) through the Intermodal Surface Transportation Efficiency Act of 1991 (ISTEA) (Public Law 102-240)	The FHWA is responsible for administering the National Scenic Byways Program (23 USC § 162) through the ISTEA (Public Law 102-240). A scenic byway is a public road with special scenic, historic, recreational, cultural, archaeological, and/or natural qualities that have been recognized as such through legislation or official declaration. ROW acquisition would also be necessary for the crossing of roads that are designated as scenic byways. Federal regulations governing utility use/crossings of a highway ROW note that "[u]tilities provide an essential public service to the general public. Traditionally, as a matter of sound economic public policy and law, utilities have used public road right-of-way for transmitting and distributing their services." 23 CFR 645.209(a). Historic Route 66, Cherokee Hills Byway, Crowley's Ridge Parkway, and the Great River Road National Scenic Byways are crossed by Proposed or Alternative Routes. Additional discussion of scenic byways is included in Section 3.12.
Arkansas Scenic Highways	Arkansas has designated numerous scenic highways through legislative acts that provide a means to further administer and finance such roadways by the Arkansas State Highway and Transportation Department (AHTD 2011). Many of these highways are submitted for consideration as a federal scenic byway. Numerous scenic highways are crossed by the Applicant Proposed Route or HVDC alternative routes. However, additional requirements in terms of traffic controls, ROW acquisition, and heavy vehicle permitting are not indicated beyond what is required for other State highways. Additional discussion of Arkansas scenic highways is included in Section 3.12.
Railroads	
Railroad Operation and Operators	The Oklahoma Corporation Commission Transportation Division, the Arkansas Public Service Commission, and the TNDOT Rail Safety/Regulatory Unit (partners with the Federal Railroad Administration to enforce federal law) oversee railroad operations and operators in their respective states. These entities make public decisions involving railroad safety matters. Specific procedures and standards apply in each state for shared corridor operations and modifications of at-grade crossing. The TXDOT Railroad Division coordinates project development for any projects that affect railroad right-of-way in the state. The Federal Railroad Administration (FRA) was created by the DOT Act of 1966 and its mission is to enable the safe, reliable, and efficient movement of people and goods (FRA 2014).

Table 3.16-1:
Regulatory Requirements and Authority Associated with Transportation Resources

Regulatory Entity or Requirement	Key Elements
NESC (IEEESA 2012)	The NESC (IEEESA 2012) sets policies for practical safeguarding of persons during the installation, operation, or maintenance of electric supply and communication lines and associated equipment. Any railroad/overhead utility crossing interaction would conform to NESC requirements and applicable code requirements. Key requirements include the following four items: 1. Poles or other structures supporting power must be 50 feet from the centerline of main running tracks, centralized traffic control sidings and heavy tonnage spurs. Pole location adjacent to industry tracks must provide at least a 30-foot clearance from the centerline of track when measured at right angles. If located adjacent to curved track, then said clearance must be increased at the rate of 1.5 inches per degree of curved track. 2. Regardless of the voltage, un-guyed poles must be located a minimum distance from the centerline of any track equal to the height of the pole above the ground line plus 10 feet. If guying is required, the guys must be placed in such a manner as to keep the pole from leaning or falling in the direction of the tracks. 3. High voltage poles and structures (345kV and higher) must be located outside the railroad ROW. 4. Crossings must not be installed under or within 500 feet from the end of any railroad bridge or 300 feet from the centerline of any culvert or switch area.
National Transportation Safety Board (NTSB) Office of Railroad, Pipeline and Hazardous Materials	The National Transportation Safety Board (NTSB) Office of Railroad, Pipeline and Hazardous Materials Investigations investigates accidents involving railroads, oil and gas pipelines, and the transportation of hazardous materials (NTSB 2014). On the basis of the investigations conducted by this Office, the NTSB issues safety recommendations to federal and state regulatory agencies, industry and safety standards organizations, carriers and pipeline operators, equipment and container manufacturers, producers and shippers of hazardous materials, and emergency response organizations. The railroad division has the responsibility for railroad accident investigations involving passenger railroads, freight railroads, commuter rail transit systems and other transportation systems operating on a fixed guideway. These accidents typically involve collisions or derailments; some of these accidents lead to the release of hazardous materials.
River Navigation[1]	
USACE Memphis District	The USACE Memphis District is mandated by Congress to keep the Mississippi River open for commercial navigation by obtaining and maintaining a 9-foot-deep and 300-foot-wide channel. About 175 million tons of cargo are transported by barge through the Memphis District's reach (355 miles) of the river each year. The Memphis District is also responsible for maintenance dredging of 10 harbors on the Mississippi River. These harbors serve as vital links to rail and highway transportation systems in the region, helping to deliver products and commodities to and from global markets.
USACE Tulsa District	The USACE Tulsa District is mandated by Congress to keep the McClellan-Kerr Arkansas River Navigation System open for commercial navigation. The system crosses the state of Arkansas into Oklahoma traversing the state until it reaches the confluence of the Arkansas and Verdigris River where the navigation channel follows the Verdigris River terminating 51 miles upstream at the Port of Catoosa, near Tulsa, Oklahoma. The Tulsa District maintains a minimum 9-foot-deep and 250-foot wide channel along the Arkansas River.
Airports and Navigation Aids	
FAA Review Requirements (14 CFR 77.9)	Airports require clear zones for aviation safety. Clear zones vary according to airport activity and the types of aircraft operating at a particular airport. Large airports and military facilities have more extensive requirements than smaller airports and smaller landing strips. Clear zone requirements typically involve a three-dimensional space free of aviation obstacles. In some areas, guy wires, towers, transmission lines, tall buildings, and other possible aviation hazards are marked, lighted, and/or charted based on Federal Aviation Administration (FAA) requirements. FAA requirements also cover an airport's radar, flight control instruments, flight paths, and other fundamental aspects of airport operations and safety. Standards are applied along with customization to address actual conditions at individual airports. Locations where potential air space obstruction hazards would be constructed may require submittal of a Notice of Proposed Construction or Alteration to the FAA based on criteria contained in 14 CFR Part 77, Safe, Efficient Use, and Preservation of the Navigable Airspace. Overhead transmission lines and their

Table 3.16-1:
Regulatory Requirements and Authority Associated with Transportation Resources

Regulatory Entity or Requirement	Key Elements

	supporting structures are subject to these requirements (FAA 2014a). Pursuant to 17 CFR 77.9, any person/organization who intends to sponsor any of the following construction or alterations must file notice with the FAA:
	• Any construction or alteration exceeding 200 feet above ground level
	• Any construction or alteration:
	    o Within 20,000 feet of a public use or military airport which exceeds a 100:1 surface from any point on the runway of each airport with at least one runway more than 3,200 feet
	    o Within 10,000 feet of a public use or military airport which exceeds a 50:1 surface from any point on the runway of each airport with its longest runway no more than 3,200 feet
	    o Within 5,000 feet of a public use heliport which exceeds a 25:1 surface
	• Any highway, railroad or other traverse way whose prescribed adjusted height would exceed the above-noted standards
	• Any construction or alteration located on a public use airport or heliport regardless of height or location
	
	Other FAA requirements for notification include non-height related criteria such as proximity to a navigation facility, encroachment on the airport property, and emission of potential interference frequencies. The FAA notification criteria evaluation tool is available at the following link: https://oeaaa.faa.gov/oeaaa/external/gisTools/gisAction.jsp?action=showNoNoticeRequiredToolForm.

FAA Requirements—Landing Strips and Other Aviation Purposes (14 CFR Part 157)	The applicable FAA regulation for landing strips for agricultural and other aviation purposes is 14 CFR Part 157. These airports may or may not be shown on the FAA sectional charts.
FAA Requirements—Federal Aviation Act of 1958 (Public Law 85-726) (14 CFR Part 77)	Additional requirements are applicable at military sites and within military operating areas and military training routes. Unlike public airports, military operations often include large areas surrounding their airports and operations for testing, training, and other purposes well beyond the military airport areas' landing and takeoff boundaries. These areas are given special airspace designations linked to corresponding military operations. A Section 1101 Air Space Permit is required for air space construction clearance according to the Federal Aviation Act of 1958 (Public Law 85-726) (14 CFR Part 77). The Applicant will address any identified operations and safety issues near military airports that may create unresolved conflicts in military airspace operating areas. Incorporation of design features and implementation of BMPs are expected to lessen the extent of the safety issues to permissible levels. If not, it is currently assumed that any routes with irresolvable issues related to airports or airspace will require additional mitigation to be applied, including the possibility of suggested reroutes.
FAA Navigation Aids	Air navigation aid facilities are used for various purposes including assistance for pilot navigation. An automatic direction finder uses non-directional beacons (NDBs) on the ground to drive a display that shows the direction of the beacon from the aircraft. NDBs continue to be used as a common form of navigation in some areas with relatively few other navigational aids. Very high frequency omnidirectional range (VOR) is a more sophisticated system, and is still the primary air navigation system established for aircraft flying under instrument flight rules (IFR). Air navigation facilities have varied owners and operators including the FAA, the military services, private organizations, individual states and foreign governments. The FAA has the statutory authority via the Federal Aviation Act of 1958 to establish, operate, and maintain air navigation facilities and to prescribe standards for the operation of any of these aids which are used for instrument flight in federally controlled airspace (FAA 2014b). If large structures are in the immediate proximity of these navigation facilities, there is a potential to interfere with the ability of the facilities to transmit signals.

1 USACE river navigation requirements are also addressed in Section 3.15.

3.16.2 Data Sources

The data sources used to analyze transportation resources are described below:

- Data sources used to analyze transportation amenities for the ROI include data for major roads, public roads, roadways, and railroads (GIS Data Sources: BTS 2013; TXDOT 2013; CSA 2007; AHDT 2006a; USCB 2000).
- Annual average daily traffic (AADT) counts for points along roadways within ROIs were obtained from Clean Line (2013, 2014). These AADTs originated from the OKDOT 2012 AADT estimates (OKDOT 2012), the AHDT 2012 AADT (Annual Average Daily Traffic) estimates (AHTD 2012), the TNDOT 2012 AADT estimates (TNDOT 2012), and the TXDOT 2012 AADT estimates (TXDOT 2012).
- A traffic analysis was performed to assess potential traffic impacts during construction of the Project. Detailed data and analysis tables are provided in *Traffic Technical Report for the Plains & Eastern Clean Line* and supplement to the *Traffic Technical Report* (Clean Line 2013).
- The data sources for airports and airstrips (also referred to as airfields) are the Bureau of Transportation Statistics and GIS shape files provided by Clean Line, respectively (GIS Data Sources: BTS 2013a; Clean Line 2013b).
- The data source for navigation aids is FAA's National Flight Database (FAA 2014b).

3.16.3 Region of Influence

3.16.3.1 Region of Influence for the Project

The ROI used to define and evaluate roadway transportation resources and the effects of the Project is a 6-mile area around the Project components. For the transmission line corridors, the 6-mile-wide area extends from each side of the centerline of the Applicant Proposed Route, HVDC alternative routes, and the AC collection system routes (12 miles wide in total). This area defines the ROI surrounding the converter station and AC interconnection siting areas and ensures that local interstate highways, U.S. highways, state highways, and local roads were included in the overall impact evaluation and that the major types of public roadways that may be directly impacted by Project vehicles would be included in the traffic analysis.

Railroads were identified based on the potential encroachment within the ROI defined above. Encroachment refers to areas where railroads and railroad ROWs might be affected because the Project would cross the railroad ROW or be located in close proximity to the Project.

Airports, airstrips, and navigational aids were identified in a 4-mile-wide corridor from the HVDC transmission line and AC collection system transmission line centerlines. A distance of 4 miles is consistent with the FAA safety requirements discussed in Section 3.16.1. Specific mileage from centerlines is also provided as an indicator of the strength and likelihood of potential effects to airports, airstrips, and navigational aids.

Several route variations to the Applicant Proposed Route in Regions 2–7 were developed in response to public comments on the Draft EIS and are described in Appendix M and summarized in Sections 2.4.2.1–2.4.2.7. Assessments of the impacts related to the route variations by Project region, including accompanying HVDC alternative route adjustments, are provided below. The variations are presented graphically in Exhibit 1 of Appendix M. These variations represent minor adjustments to the Applicant Proposed Route and transportation resources would remain consistent within the ROI.

3.16.3.2 Region of Influence for Connected Actions

3.16.3.2.1 Wind Energy Generation

The ROI for evaluation of existing traffic conditions is all public roadways within 6 miles of the AC collection system route centerlines, an area that includes 85 percent of the land area within each of the WDZs. Traffic counts also were evaluated for major highways in an area approximately 12 miles around the WDZs because the WDZs are located in a rural area with low population densities. The WDZs and surrounding communities include rural areas of Oklahoma, Texas, and Kansas. The ROI in the WDZs includes Cimarron and Beaver counties in Texas and Oklahoma, respectively; Sherman, Hansford, and Ochiltree counties in Texas; and southern portions of Baca and Morton counties in Kansas.

3.16.3.2.2 Optima Substation

The transportation ROI for the future Optima Substation includes a 6-mile area surrounding the 160-acre site (Section 3.1), and is entirely included within the Project ROI for Region 1.

3.16.3.2.3 TVA Upgrades

The ROI for the direct assignment facilities (which are included in the Applicant Proposed Project) would occur within the Tennessee Converter Station Siting Area and more specifically within the Shelby Substation. The ROI for the network upgrades, and in particular TVA's future 500kV transmission line, cannot be fully determined at this time. The new 500kV line would be in western Tennessee. The upgrades to existing facilities would mostly be in western and central Tennessee. Upgrades to existing infrastructure would include upgrading terminal equipment at three existing 500kV substations and six existing 161kV substations; making appropriate upgrades to increase heights on 16 existing 161kV transmission lines to increase line ratings, and replacing the conductors on eight existing 161kV transmission lines.

3.16.4 Affected Environment

Several route variations to the Applicant Proposed Route in Regions 2–7 were developed in response to public comments on the Draft EIS and are described in Appendix M and summarized in Sections 2.4.2.1–2.4.2.7. Comparisons in affected environment between the Applicant Proposed Route and the route variations by Project region, including accompanying HVDC alternative route adjustments, are provided below. The variations are presented graphically in Exhibit 1 of Appendix M.

3.16.4.1 Roadways

The roadway network in the ROI includes interstate highways, U.S. highways, state highways, and local roads. Public roadways are classified into Class I two-lane highways, Class II two-lane highways, basic freeway segments, and multi-lane highways as defined below. Class I two-lane highways are highways on which motorists expect to travel at relatively high speeds. These highways are major intercity routes, primary connectors of major traffic generators, daily commuter routes, or major links in state or national highway networks. The roadways serve mostly long-distance trips or provide the connections between facilities that serve long-distance trips (TRB 2010).

Class II two-lane highways are highways where motorists do not necessarily expect to travel at high speeds. These highways function as access routes to Class I highways, serve as scenic or recreational routes (not primary arterials), or pass through rugged terrain where high-speed operation is not possible. These roadways most often serve relatively short trips.

Basic freeway segments are roadway segments outside the influence area of traffic merging and lane-changing caused by the presence of on-ramps and off-ramps.

Multi-lane highways have four to six lanes (including both directions) and posted speed limits that range from 40 to 65 miles per hour. They may be divided by medians, may be undivided, or may have a two-way left turn lane. These roadways are typically located in suburban areas leading to central cities or along high-volume rural corridors connecting two cities or two activity centers that generate a substantial number of daily trips.

The affected environment includes major roadways within the ROI and available information on the existing roadway level of service (LOS), a measure of the quality of service of a roadway. There are six letter designations of LOS from A to F, with LOS-A (free traffic flow with little delay) representing the best roadway operating conditions and LOS F (roadway congestion with long delays) representing the worst operating conditions (TRB 2010). The acceptable LOS for a roadway varies as defined by the federal, state, county, or local agency with jurisdiction over the roadway. According to AASHTO, a LOS-C or better is considered acceptable on rural roadways (AASHTO 2011). Within urban areas, LOS-D generally is considered the minimum acceptable LOS (AASHTO 2011). States have individual requirements and thresholds or criteria regarding decreases in LOS that might trigger the necessity for road capacity improvements for Project construction activities.

General characterization of the current LOS on existing roadways was performed in the Traffic Analysis (Clean Line 2014) for the Project and is summarized in Section 3.16.5. Overall, public roadways in the Project ROI currently operate at an acceptable LOS-C or better as depicted in Figures 3.16-1a through 1f (located in Appendix A). Exceptions are local street segments in Van Buren, Arkansas, in Region 4, and a local street in Searcy, Arkansas, in Region 5 that currently operate at LOS-D. Tables listing all the roadway segments, including local roadways, and related details (i.e., name, segment ID, class, and LOS) in the transportation ROI are provided in the *Traffic Technical Report* and supplement to the *Traffic Technical Report* (Clean Line 2013, 2014).

In addition to LOS, the roadway affected environment is presented in Section 3.16.5 in relation to state and federal roadway crossings and areas of potential ROW encroachment by region. Although the crossing of local and county roadways would also trigger permits, requirements for such crossings or encroachments are generally not as rigorous. The numerous crossings of local and county roadways by Project components are depicted in the maps included on Figure 1.0-2 in Appendix A.

3.16.4.1.1 Construction Haul Roads

Currently, it is anticipated that the materials necessary for construction of the Project would be shipped via major roadways including interstate highways, federal highways, and state highways. More specific haul routes would be identified in a Transportation and Traffic Management Plan. Because haul routes cannot be specifically identified by Project alternative at this point in the planning process, they are not used to further evaluate specific impacts. Once at the appropriate staging area, materials would be moved to designated locations along the HVDC transmission line and other Project components for assembly and installation via existing roads, overland routes, and temporary access roads. Access roads are discussed in Section 2.1.2.4. The road types and typical access road dimensions during construction and operations and maintenance are described in Table 2.1-7. The estimated length (by road type within each state) for access roads associated with HVDC and AC transmission lines (which includes those associated with the fiber optic regeneration sites) is provided in Tables 2.1-8 and 2.1-9, respectively.

The major roadways near each Project component and region are listed in Table 3.16-2. These roads could serve as haul routes during Project construction. The daily commuting routes for construction workers are expected to follow the same roads as the truck haul routes to the construction ROW or temporary staging areas for parking. Improvements to or closure of any roads, intersections, or bridges are not expected to be necessary to accommodate oversized truck deliveries to the Project components. However, if closures were necessary, their durations would be minimized as specified in Section 3.16.6.1.2, and closures would be conducted in accordance with a Transportation and Traffic Management Plan and appropriate state DOT requirements and procedures.

Table 3.16-2:
Potential Primary Haul Roads by Region

Project Region	Interstates/Turnpikes	U.S. Highways	State Highways	Local Roads
Region 1	Nearest: I-40	US-412, US-85, US-270, US-283, US-64, US-183	SH-136, SH-3, SH-23, SH-149, SH-34, SH-46	CR-202, CR-16, CR-14, CR-A
AC Collection System		US-54, US-83, US-412, US-287	SH-95, SH-3, SH-15, SH-207, SH-70, SH-23	CR-14
Oklahoma Converter Station		US-54, US-412	SH-136, SH-3	CR-33, CR-202, CR-282, CR-16
Region 2	Nearest: I-40, I-35	US-64, US-412, US-412, US-281, US-60, US-81	SH-50, SH-34, SH-15, SH-3, SH-45, SH-58, SH-51, SH-8, SH-132	None of particular note

GIS Data Sources: BTS (2013), TXDOT (2013), CSA (2007), AHTD (2006a), USCB (2000)

3.16.4.2 Railroads

Numerous railroads are located within the ROI as shown on Figures 3.16-1a through 3.16-1f in Appendix A. Railroads are more specifically discussed in Section 3.16.5 by region.

3.16.4.3 River Navigation

The Project crosses the Arkansas River between Oklahoma and Arkansas (Regions 3 and 4) and the Mississippi River between Arkansas and Tennessee (Region 7). A discussion of River Navigation is provided only for Regions 3, 4, and 7.

3.16.4.4 Airports and Navigational Aids

Airports and airstrips are shown on Figures 3.16-1a through 3.16-1f, in Appendix A and airports within the ROI are listed in Table 3.16-3. Fifty-two airports, airstrips, and heliports are located within the ROI including, 12 public airports, 13 private airports, 20 private airstrips, 3 public heliports, and 4 private heliports. These air travel facilities are more specifically discussed in Section 3.16.5 by region.

Table 3.16-3:
Airports and Airstrips within the ROI

Airport Name	County, State	Type	Private/ Public	Region	Route	Distance from Centerline (miles)
Hooker Municipal Airport	Texas County, OK	Airport	Public	1	AC Collection System Route NE-1	2.6
					AC Collection System Route NE-2	2.8

3.16.5 Regional Description

3.16.5.1 Region 1

No route variations were proposed in Region 1.

3.16.5.1.1 Roadways

Region 1 is primarily rural; small towns are scattered throughout the ROI. Communities in or near the Region 1 ROI include Guymon, Hardesty, Beaver, and Laverne, Oklahoma. Major federal and state highways in the ROI for Region 1 include US-64, US-83, US-183, US-283, US-270, and US-412 and state highways (SH)-23, SH-34, SH-46, SH-94, SH-136, SH-149, and SH-207. The tables provided in the *Traffic Technical Report* and supplement to the *Traffic Technical Report* (Clean Line 2013, 2014) list local roads in the region. Major highways within the ROI for the Oklahoma converter station include SH-136 and SH-207. Major highways in ROI for the AC collection system routes include US-54, US-56, US-64, US-83, and US-412 and SH-15, SH-70, SH-94, SH-95, SH-136, SH-192, and SH-207. Average daily traffic counts (ADTC) are estimated at a maximum of 1,100 on state highways and a maximum of

4,800 for federal and joint federal/state roadways in Region 1 for 2012 (Clean Line 2013, 2014). The major highways, as well as the local roads, in the ROI currently operate at an acceptable average daily LOS-C or better.

3.16.5.1.2 Railroads

The Burlington Northern Santa Fe Railway (BNSF) railroad parallels US 54 in Texas County, Oklahoma, in the ROI in Region 1. A majority of the 13 AC collection system routes would require crossing the railroad. No other operational railroads are located in the ROI in Region 1.

3.16.5.1.3 Airports and Navigation Aids

Three public airports are located in the ROI in Region 1 (Table 3.16-3). Laverne Municipal Airport is located within 1.23 miles of the HVDC Alternative Route 1-A centerline. Hooker Municipal Airport is located 2.56 miles from the centerlines of AC Collection System Routes NE-1 and NE-2. Guymon Municipal Airport is located 3.47 miles from the centerline of AC Collection System Route NW-1. Navigation aids are not located within the ROI in Region 1.

3.16.5.2 Region 2

3.16.5.2.1 Roadways

Region 2 is mostly rural; the largest communities are the towns of Woodward and Fairview, Oklahoma. Major highways in the ROI include US-60/281, US-81, US-183, and US-412; and SH-8, SH-34, SH-34C, SH-50, SH-50B, SH-51, SH-51A, SH-58, SH-74E, SH-132, and SH-183. ADTC are estimated at a maximum of 7,000 on state highways and a maximum of 8,200 for federal and joint federal/state federal and joint federal/state roadways in Region 2 for 2012. Major and local roadways currently operate at an acceptable average daily LOS-B or better in the ROI (Clean Line 2013, 2014). The ROI for the two route variations proposed in Region 2 is generally the same as that of the original Applicant Proposed Route. The route variations are slightly farther from local roadways (see Exhibit 1 of Appendix M).

3.16.5.2.2 Railroads

Railroads in the ROI in Region 2 include (from west to east) the BNSF Railway, the Grainbelt Corporation Railroad, and the Union Pacific Railroad (UPRR). Railroads are located along US-412 in Woodward County, Oklahoma; in a rural region of Major County, Oklahoma; and along US-81 in Garfield County, Oklahoma. The ROI for the two route variations proposed in Region 2 is generally the same as that of the original Applicant Proposed Route. The route variations do not cross railroads.

3.16.5.2.3 Airports and Navigation Aids

One private airstrip, Steinert Lakes, is located within 1 mile from the centerlines of the Applicant Proposed Route and one HVDC alternative route. Navigation aids are not located within the ROI in Region 2. The ROI for the two route variations proposed in Region 2 is generally the same as that of the original Applicant Proposed Route. Link 1, Variation 1, is approximately 0.4 mile closer to one public airport and one private airfield.

3.16.5.3 Region 3

3.16.5.3.1 Roadways

Large communities in the ROI in Region 3 include Stillwater, Cushing, Drumright, and Muskogee. Major highways in the ROI include interstates I-35, I-40 and I-44; US-62, US-64, US- 69, US-75, US-77, US-177, and US-266; SH-10,

SH-16, SH-18, SH-33, SH-48, SH-51, SH-52, SH-56, SH-64, SH-66, SH-72, SH-74, SH-86, SH-99, SH-100, SH-105, SH-108, and SH-162; and the Muskogee Turnpike. ADTC are estimated at a maximum of 16,100 on state highways and a maximum of 19,300 for federal and joint federal/state roadways in Region 3 for 2012. I-35 had a maximum ADTC of 20,300 in 2012; and I-44 had a maximum ADTC of 25,900. Major and local roadways currently operate at an acceptable average daily LOS-C or better in Region 3 (Clean Line 2013, 2014). The ROI for the five route variations proposed in Region 3 is generally the same as that of the original Applicant Proposed Route. Links 1 and 2, Variation 1, is generally farther from local section line roadways (see Exhibit 1 of Appendix M).

3.16.5.3.2 Railroads

Railroads in the ROI in Region 3 include (from west to east) the Stillwater Central Railroad, the BNSF, and the UPRR (in Muskogee County, Oklahoma). The crossings are located near US-77 in Logan County, Oklahoma; near I-44 in Creek County, Oklahoma; near US-75 in Okmulgee County, Oklahoma; and near US-69 in Muskogee County, Oklahoma (or the town of Oktaha, Oklahoma). The ROI for the five route variations proposed in Region 3 is generally the same as that of the original Applicant Proposed Route. The route variations would not cross any railroads.

3.16.5.3.3 River Navigation

The USACE Tulsa District maintains navigation along the Arkansas River at the western Project crossing within Region 3. The ROI for the five route variations proposed in Region 3 is generally the same as that of the original Applicant Proposed Route. The route variations are not located in the vicinity of the Arkansas River crossing.

3.16.5.3.4 Airports and Navigation Aids

Airports and airstrips in the ROI in Region 3 include Cushing Municipal Airport, Jones Memorial, Neversweat airstrip, Ragwind Acres airstrip, Eagle Creek airstrip, Okmulgee Regional Airport, and Davis Field. Heliports in the ROI include Richardson Regional Airport, Bristow Hospital, HSI, Cushing Regional Hospital, and Keefton Emergency Helicopter Service. Link 1, Variation 2, is not located within 1 mile of any airports or airstrips. Link 1 and 2, Variation 1, is located within 1 mile of a private airstrip. One public airport and three private airports and heliports are located in the ROI for Link 4, Variation 1. There is one public airport located in the ROI for Link 5 Variation 2, and this route variation is approximately 0.4 mile closer to this public airport than the original Applicant Proposed Route. Two operational navigation aid facilities are located in the Region 3 ROI including Cushing Non-directional Radio Beacon (CUH NDB) and Okmulgee VHF (very high frequency) Navigational Facility/UHF (ultra high frequency) Standard Distance Measuring Equipment (OKM VOR/DME). One decommissioned navigation facility—Muskogee Non-directional Radio Beacon (MKO NDB)—is located in the ROI.

3.16.5.4 Region 4

3.16.5.4.1 Roadways

Large communities in Region 4 include Sullisaw, Fort Smith, and Clarksville. Major highways in the region include these interstates: I-40 and I-540; US-59, US-60, US- 64, and US-71; SH-10, SH-21, SH-23, SH-59, SH-60, SH-71, SH-82, SH-96, SH-100, SH-101, SH-103, SH-109, SH-123, SH-162, SH-164, SH-186, SH-194, SH-215, SH-219, SH-220, SH-252, SH-255, SH-282, SH-309, SH-315, SH-348, SH-352, SH-359, and SH-924. ADTC are estimated at a maximum of 3,500 on state highways and a maximum of 12,500 for federal and joint federal/state roadways in Region 4 for 2012. I-40 had a maximum ADTC of 40,000 in 2012 in the region and I-540 had a maximum ADTC of 22,000. All public roadways in the region currently operate at an acceptable LOS-C or better except for segments along Fayetteville Road and North Highway 59 in Van Buren, Arkansas, and a segment of nearby I-40 that currently operate at LOS-D. The ROI for the seven route variations proposed in Region 4 is generally the same as that of Applicant Proposed Route Links 3 and 6. Applicant Proposed Route, Link 4, Variation 3 is closer to local roadways (see Exhibit 1 of Appendix M).

3.16.5.4.2 Railroads

Railroads in the ROI in Region 4 include (from west to east) the Kansas City Southern Railroad, the UPRR (in Sequoyah County, Oklahoma), and the Arkansas & Missouri Railroad. The crossings are located near SH-10 in Muskogee County, Oklahoma (or near the town of Marble City in Sequoyah County, Oklahoma); near the town of Sallisaw in Sequoyah County, Oklahoma; near I-540 in Crawford County, Arkansas, and near the town of Mulberry in Crawford County, Arkansas. The ROI for the seven route variations proposed in Region 4 is generally the same as that of the original Applicant Proposed Route. The route variations would not cross any railroads.

3.16.5.4.3 River Navigation

The USACE Tulsa District maintains navigation along the Arkansas River at the eastern Project crossing within Region 4. The ROI for the seven route variations proposed in Region 4 is generally the same as that of the original Applicant Proposed Route. The route variations are not located in the vicinity of the Arkansas River crossing.

3.16.5.4.4 Airports and Navigation Aids

Airports and airstrips in the ROI in Region 4 include an unnamed airstrip near Neversweat Too airstrip, Gustafson airstrip, Ozark-Franklin County Airport, and Clarksville Municipal Airport. Heliports in the ROI include Johnson Regional Medical Center, an unnamed hospital near Clarksville, and Crawford Memorial Hospital. Ozark-Franklin County Airport is less than 1 mile from the Applicant Proposed Route and HVDC Alternative Route 4-B centerlines. One private airport/heliport is located in the ROI for Link 3, Variation 2. One private airstrip is located within 1 mile of the same route variation. One private airport/heliport is located in the ROI for Link 6, Variation 1, and the route variation is slightly closer (<0.1 mile) to the airport/heliport than the original Applicant Proposed Route. One operational navigation aid facility is located in the Region 4 ROI: Clarksville Non-directional Radio Beacon (CZE NDB).

3.16.5.5 Region 5

3.16.5.5.1 Roadways

The larger communities in or near the Region 5 ROI include Dover, Russelville, Damascus, Twin Groves, Greenbriar, Guy, Rose Bud, Heber Springs, and Branch, Arkansas. Major highways in Region 5 include US-65, US-67, US-167, and US-285; SH-5, SH-7, SH-9, SH-14, SH-16, SH-17, SH-25, SH-27, SH-36, SH-87, SH-92, SH-95, SH-105, SH-107, SH-110, SH-124, SH-157, SH-164, SH-213, SH-224, SH-225, SH-247, SH-258, SH-287, SH-305, SH-310, SH-337, SH-356, and SH-367. The Arkansas convertor station and AC interconnect is located in Pope and Conway counties, Arkansas. Major highways in this area include I-40; US-64; and SH-95, SH-105, SH-124, SH-164, SH-213, SH-247, SH-326, and SH-363. ADTC are estimated to be maximums of 11,000 on state highways and 7,600 for federal and joint federal/state roadways in Region 5 for 2012. Public roadways in the region currently operate at an acceptable LOS-C or better except, for a segment along West Race Avenue in Searcy, Arkansas, and near US-67 that currently operates at LOS-D (Clean Line 2013, 2014). The ROI for the five route variations proposed in Region 5 is generally the same as that of the original Applicant Proposed Route. Link 7, Variation 1, is generally located closer to local roadways than the original Applicant Proposed Route (see Exhibit 1 of Appendix M).

3.16.5.5.2 Railroads

The UPRR is in the ROI in Region 5. The crossing is located near SH-367 in Jackson County, Arkansas. The ROI for the five route variations proposed in Region 5 is generally the same as that of the original Applicant Proposed Route. The route variations would not cross any railroads.

3.16.5.5.3 Airports and Navigation Aids

Airstrips in the ROI in Region 5 include Landers Loop airstrip, Heifer Creek Ranch airstrip, Rak airstrip, McDonald's airstrip, two unnamed airstrips, and Brown's airstrip. No public airports or heliports are located in the ROI. One unnamed private airfield is within 0.2 mile of all HVDC transmission line alternatives. One private airport/heliport is located in the ROI for Applicant Proposed Route Link 1, Variation 2. One private airport/heliport is located in the ROI for Applicant Proposed Route Links 3 and 4, Variation 2, and is approximately 0.2 mile farther from the airport/heliport. Navigation aids are not located within the ROI in Region 5.

3.16.5.6 Region 6

3.16.5.6.1 Roadways

Communities within the Region 6 ROI include Newport, Beedeville, Hickory Ridge, Harrisburg, Cherry Valley, and Marked Tree, Arkansas. Major highways in Region 6 include US-49, US-63, US-67; and SH-1, SH-14, SH-17, SH-18, SH-37, SH-42, SH-69, SH-75, SH-145, SH-149, SH-163, SH-193, SH-214, SH-224, SH-367, SH-373, SH-384, and SH-463. ADTC on state highways are estimated at a maximum of 12,000 and reach a maximum of 6,900 for federal and joint federal/state roadways in Region 6 for 2012. Major and local roadways currently operate at an acceptable average daily LOS-C or better in the Region 6 ROI (Clean Line 2013, 2014). The ROI for the single route variation proposed in Region 6 Link 2, Variation 1, is generally the same as that of the original Applicant Proposed Route (see Exhibit 1 of Appendix M).

3.16.5.6.2 Railroads

Railroads in the ROI in Region 6 include three segments of the UPRR. The crossings are located along US-49 in Poinsett County, Arkansas, and near SH-1 in Poinsett and Cross counties, Arkansas. The ROI for the single route variation proposed in Region 6, Link 2, Variation 1, is generally the same as that of the original Applicant Proposed Route. The route variation would not cross any railroads.

3.16.5.6.3 Airports and Navigation Aids

Numerous private airstrips occur in the ROI in Region 6. One private airstrip is 0.1 mile from the centerline of the Applicant Proposed Route; on private airfield is within 0.7 mile of the centerline of HVDC Alternative Route 6-C; and a temporary airstrip is within 0.7 mile of the centerlines of HVDC Alternative Route 6-A and the Applicant Proposed Route. No heliports or navigation aids are located within the ROI in Region 6. Two private airfields are in the ROI for Link 2, Variation 1, which is the same for the original Applicant Proposed Route Link 2.

The Walton Land Company private airstrip is located in Region 6 Applicant Proposed Route, Link 8, near the Region 7 border. DOE and the Applicant considered other route variations, but found no feasible alternative routes for the Project in this area. This airstrip was not previously identified in the Draft EIS.

A BMP has been added to Section 3.16.6.4 that states that the Applicant would perform mitigation to address Project structures in the vicinity of private airstrips. This BMP would require conducting specific flight plan analyses to determine whether interference with private airstrips can be avoided through micrositing within the 1,000-foot-wide corridor, to the extent practicable. If impacts are unavoidable, the Applicant would develop and implement mitigation measures and/or provide compensation in coordination with landowners. The Applicant would apply similar mitigation to private airstrips where Project structures would present a hazard within a 1:20 glide slope from each end of private airfields.

The Applicant has provided a ROW acquisition plan and a Code of Conduct for negotiations with landowners. A copy of this Code of Conduct can be found in comments submitted by the Applicant, which are included in Appendix Q. The Code of Conduct is also available on Clean Line's website at: http://www.plainsandeasterncleanline.com/site/page/code-of-conduct.

3.16.5.7 Region 7

3.16.5.7.1 Roadways

Communities in and near the Region 7 ROI include Marked Tree, Lepanto, Tyronza, Gilmore, and Osceola, Arkansas; and Munford, Gilt Edge, Millington, Atoka, Brighton, Bartlett, Memphis, Lakeland, and Arlington, Tennessee. Major highways in Region 7 include I-55; US-51, US-61, and US-63; and SH-14, SH-42, SH-75, SH-77, SH-87, SH-118, SH-119, SH-135, SH-140, SH-149, SH-181, SH-198, SH-239, SH-297, SH-308, SH-322, SH-385, and SH-463. The Tennessee Converter Station Siting Area and AC Interconnection Tie is located in Shelby County, Tennessee, where the major highways include US-51 and SH-385. ADTC are estimated at maximums of 11,000 on state highways and 23,634 for federal and joint federal/state roadways in the region. I-55 had a maximum ADTC of 19,000 in 2012 in Region 7 for 2012. Major and local roadways currently operate at an acceptable average daily LOS-C or better in the ROI (Clean Line 2013, 2014). The ROI for the three route variations proposed in Region 7 is generally the same as that of original Applicant Proposed Route. Link 1, Variation 1 would have the same general affected environment for roadways; Link 1, Variation 2, is generally located closer to area roadways (see Exhibit 1 of Appendix M); and Link 5, Variation 1, avoids an area of local roadways.

3.16.5.7.2 Railroads

Railroads in the ROI in Region 7 include (from west to east) the BNSF Railroad and the Canadian National Railroad. The crossings are located along US-63 in Poinsett County, Arkansas; along US-61 in Mississippi County, Arkansas; and near US-51 (or near SH-385) in Shelby and Tipton counties, Tennessee. The ROI for the three route variations proposed in Region 7 is generally the same as that of the original Applicant Proposed Route. The route variations would not cross any railroads.

3.16.5.7.3 River Navigation

The USACE Memphis District maintains navigation along the Mississippi River at the Project crossing within Region 7. The ROI for the three route variations proposed in Region 7 is generally the same as that of the original

Applicant Proposed Route. Link 1, Variation 2, located at the western area of the river crossing, would not cause any changes to the ROI in the vicinity of the Mississippi River crossing.

3.16.5.7.4 Airports and Navigation Aids

Airports and airstrips in the ROI in Region 7 include Marked Tree Municipal Airport, Woodbridge Field, an unnamed airstrip, Millington Regional Jetport, and Ray airport. The Marked Tree Municipal Airport is located 1 mile from the HVDC Alternative Route 7-A and Applicant Proposed Route. Ray, a private airstrip, is located 0.4 mile from the centerline of HVDC Alternative Route 7-C. No heliports are located in the ROI. One public airport and one private airport/heliport are located in the ROI for Applicant Proposed Route Link 5, Variation 1. The ROI for the original Applicant Proposed Route is generally the same in relation to the distances to airport facilities. One navigation aid facility is located in the Region 7 ROI: Millington Non-directional Radio Beacon (MIG NDB).

3.16.5.8 Connected Actions

3.16.5.8.1 Wind Energy Generation

3.16.5.8.1.1 Roadways

Table 3.16-5 provides AADT ranges for roadway segments, major highways, and communities in the ROI. Major highways in the ROI include US-56, SH-3 (Oklahoma), US-64, SH-51 (Kansas), US-54, SH-136 (Oklahoma), SH-15 (Texas), US-83, SH-70 (Texas), SH-23 (Oklahoma), and SH-95 (Oklahoma). Maximum ADTC counts in the ROI range from 400 adjacent to WDZ-G to 10,300 in WDZ-A for 2012 (Clean Line 2013, 2014). Major and local roadways currently operate at an acceptable average daily LOS-B or better in the ROI.

Table 3.16-5:
Connected Action—Roadways in WDZ and Wind Energy Generation ROI

WDZ	AADT (maximum for roadway segments in 2012)[1]	Major Federal and State Roadways	Communities
A	10,300	US-83, SH-15, SH-192, SH-143	Perryton, TX
B	2,000	SH-136, SH-207, SH-15, Hansford CR-278	Hardesty, OK
Adjacent to WDZ-B ROI[2]	1,850		Gruver, TX
C	1,500	US-54, US-287, SH-136, SH-15	None
Adjacent to WDZ-C ROI[2]	4,400		Stratford, TX
	6,200		Cactus, TX
	4,100		Sunray, TX
D	2,200	US-412, SH-3, SH-94, SH-136	Hardesty, OK
E	8,600	US-412, SH-136, US-54, SH-3, US-64	Guymon, OK, Hardesty, OK, Optima, OK
F	8,600	US-54, SH-3, US-54, US-412, SH-95, SH-136	Texhoma, TX; Texhoma, OK; Guymon, OK; Goodwell, OK
G	1,400	US-56, SH-3, SH-95, SH-27, US-412, SH-171, US-287, US-385, US-64, SH-325	Kerrick, OK
Adjacent to WDZ-G ROI[2]	5,000		Boise City, OK
	400		Keyes, OK
	2,000		Elkhart, KS
H	1,400	SH-95, SH-3	None

Table 3.16-5:
Connected Action—Roadways in WDZ and Wind Energy Generation ROI

WDZ	AADT (maximum for roadway segments in 2012)[1]	Major Federal and State Roadways	Communities
I	7,600	SH-94, Texas CR 7, US- 54, US- 64	Hooker, OK; Adams, OK; Optima, OK; Turpin, OK;
Adjacent to WDZ-I ROI[2]	6,700		Tyrone, OK
	7,340		Liberal, KS
J	3,300	US-83, SH-3, US-412	Balko, OK; Turpin, OK
Adjacent to WDZ-J ROI[2]	3,100		Beaver, OK
	7,340		Liberal, KS
K	3,300	US-83, SH-3, SH-23, US-270, SH-15	Balko, OK; Perryton TX
Adjacent to WDZ-K ROI[2]	2,900		Booker, TX
	3,100		Beaver, OK
L	4,500	SH-70, SH-15, SH-51, SH-207, SH-23, US-83	Spearman, TX; Waka, TX
Adjacent to WDZ-L ROI[2]	820		Morse, TX

1 Source: Clean Line (2014)
2 Adjacent areas are major highways outside of WDZs generally within 12 miles. Sources: TXDOT (2014), OKDOT (2014), (KSDOT) (2014)

3.16.5.8.1.2 Railroads

Railroads in the WDZ ROIs are listed in Table 3.16-6. In WDZ-A, the Southwest Railroad is located along SH-15 and SH-192 and passes through Perryton, Texas. Two BNSF lines located in WDZ-C both pass through Stratford, Texas. In WDZ-L, the Southwest Railroad is located along SH-15 and passes through Spearman, Texas, along US-287 northwest of the WDZ. In WDZ-E, a BNSF line passes through Guymon, Oklahoma, along US-54 within the ROI northwest of the WDZ. In WDZ-F, the BNSF line passes through Texhoma (Oklahoma and Texas) and Goodwell, Oklahoma, along US-54. In WDZ-G, the CVR line is located along US-56 and passes through Elkhart, Kansas, north of the WDZ boundary. In WDZ-I, the BNSF line passes through Hooker, Oklahoma, along US-54. Southwest Railroad is located 2.61 miles south of WDZ-K and runs along SH-15/SH-192.

Table 3.16-6:
Connected Action—Railroads in WDZ ROIs (within 6 miles of WDZ boundaries)

1 Distances are to closest airport feature, including runways.

3.16.5.8.2 Optima Substation

The future Optima Substation ROI is entirely included in the western area of Region 1 and transportation conditions would be similar to those described in Section 3.16.6.2.1 for the Oklahoma Converter Station Siting Area and the AC collection system routes. Major highways in these areas include US-54, US-56, US-64, US-83, and US-412 and SH-15, SH-70, SH-94, SH-95, SH-136, SH-192, and SH-207. ADTC are estimated at a maximum of 1,100 on state highways and a maximum of 4,800 for federal and joint federal/state roadways for 2012. The major highways, as well as the local roads, currently operate at an acceptable average daily LOS-C or better.

3.16.5.8.3 TVA Upgrades

The ROI for the direct assignment facilities (which are included in the Applicant Proposed Project) would occur within the Tennessee Converter Station Siting Area and more specifically within the Shelby Substation. The ROI for the network upgrades, and in particular TVA's future 500kV transmission line, cannot be fully determined at this time. The new 500kV line would be in western Tennessee. The upgrades to existing facilities would mostly be in western and central Tennessee. Upgrades to existing infrastructure would include upgrading terminal equipment at three existing 500kV substations and six existing 161kV substations, making appropriate upgrades to increase heights on 16 existing 161kV transmission lines to increase line ratings, and replacing the conductors on eight existing 161kV transmission lines. Where possible, general impacts associated with the required TVA upgrades are discussed in the impact sections that follow.

3.16.6 Impacts to Transportation

Impacts to traffic on roadways would include increased traffic during construction activities from workers commuting to the construction sites, as well as increased traffic from the hauling of materials and equipment to the construction sites. Incidental congestion and delay would be expected from the following:

- Slow-moving trucks and construction vehicles
- Vehicle turning movements where construction occurs near and parallel to roadways
- Travel delays and detours associated with transmission line installation in some locations

Temporary travel delays involving major roads (interstate highways, federal highways, and state highways) and railroads may also occur for HVDC or AC line installation at crossings. Shorter duration delays or no delays are anticipated where lines cross narrower roads with lower traffic volumes.

No improvements to public roadways are planned as part of the Applicant Proposed Project or DOE Alternatives.

3.16.6.1 Methodology

3.16.6.1.1 Traffic Impacts

3.16.6.1.1.1 Level of Service

As discussed above (Section 3.16.4.1), impacts to roadway traffic are assessed using the concept of Level of Service (LOS). A qualitative description of LOS is provided in Table 3.16-8. LOS for roadways in the ROI was calculated to assess the potential effects to roadway traffic during construction and operations of the separate components of the Project. These calculations were performed using the standard methods in the Highway Capacity Manual (TRB 2010), and results were used to assess the potential change in LOS from the Project on roadways. Details of the Traffic Analysis calculations are provided in the *Traffic Technical Report* and supplement to the *Traffic Technical Report* (Clean Line 2013, 2014).

Table 3.16-8:
General Description of LOS

LOS	General Description	Motorist Experience
A	Free flow. Traffic flows at or above the posted speed limit and motorists have complete mobility between lanes.	Motorists have a high level of physical and psychological comfort.
B	Reasonably free flow. LOS A speeds are maintained, maneuverability within the traffic stream is slightly restricted.	Motorists still have a high level of physical and psychological comfort.

Table 3.16-8:
General Description of LOS

LOS	General Description	Motorist Experience
C	Stable flow, at or near free flow. Ability to maneuver through lanes is noticeably restricted and lane changes require more driver awareness.	Most experienced drivers are comfortable, roads remain safely below but efficiently close to capacity, and posted speed is maintained.
D	Approaching unstable flow. Speeds slightly decrease as traffic volume is slightly increased.	Freedom to maneuver within the traffic stream is much more limited and driver comfort levels decrease.
E	Unstable flow, operating at capacity. Flow becomes irregular and speed varies rapidly because there are virtually no usable gaps to maneuver in the traffic stream and speeds rarely reach the posted limit.	Any incident will create serious delays. Drivers' level of comfort becomes poor.
F	Forced or breakdown flow. Every vehicle moves in lockstep with the vehicle in front of it, with frequent slowing required.	Travel time cannot be predicted and drivers' level of comfort is poor.

Source: TRB (2010)

To estimate potential changes in LOS from the Project, the Applicant provided anticipated trip generation summarized in Table 3.16-9. Workers, vehicle trips, and the duration of construction activities for the Project are discussed and presented in detail in Sections 2.1.2 and 3.13. The duration of construction for the entire Project would be approximately 36 to 42 months including the initiation of clearing and grading activities through cleanup and restoration tasks. Construction is expected to run concurrently over different areas, and construction within all areas would not occur during the same time. Activities in one segment may be parallel or staggered with activities in other segments. The duration of construction within a 140-mile construction segment is estimated to be 24 months, but disturbance at any one location would be much shorter, depending on localized construction activities and progress. The types of construction vehicles in use at any time would depend on construction activities such as grading, structure construction, access road construction, reclamation, and other activities further described in Section 2.1. Construction vehicle types are summarized in Table 3.16-10 and are broken down by construction activity in the *Traffic Technical Report for the Plains & Eastern Clean Line* and supplement to the *Traffic Technical Report* (Clean Line 2013, 2014). The table provides information on vehicles that would be on roads and also the types of equipment that might be hauled to the site. The hauling information provides information on heavy equipment hauling on roads.

Table 3.16-9:
Summary of Trips During Project Construction

Project Component	Peak Number of Total Daily Trips	Peak Personal (Worker) Trips	Peak Light Construction Vehicle Trips	Peak Heavy Construction Vehicle Trips
HVDC Transmission Line (140-mile segment multi-use areas)	273	54	86	133
AC Collection System	273	54	86	133
HVDC Converter Stations	844	132	250	462
HVDC Transmission Line (140-mile segment multi-use areas), converter station, and AC collection system (simultaneous construction)—Region 1 only	1,390	276	438	676
HVDC Transmission Line (140-mile segment multi-use areas) and converter stations (simultaneous construction) Regions 1, 5, and 7 only	1,117	212	352	553

Source: Appendix F of this EIS.

Table 3.16-10:
Summary of Construction Vehicles/Equipment

Vehicles (on-road light)	Vehicles (on-road heavy)	Vehicles (off-road, to be hauled to construction site)	Other Equipment to be Hauled to Construction Site
Pick-up truck, Truck (1-ton), Utility van, Mechanic's truck, truck (2-ton), splicing truck/van, welder truck, boom lift truck,	Dump truck, Concrete truck, Concrete Pump truck, fuel truck, crane (15-ton boom truck), crane (30-ton), crane (120- to 300-ton), articulated dump truck, road sweeper, water truck, flatbed truck, reel stand truck, steel haul truck, truck (5-ton)	Plate compactor, trencher, excavator mini, 100 Series excavator, vibratory compactor, bobcat/skid loader, forklift (telescopic), lowboy truck, loader backhoe, wheel loader (5 CY), motor grader, bulldozer (100 and 300 Series), scraper, all terrain vehicle, single-drum puller (large), trencher, wagon drill, wire reel trailer, flail mower or Bush hog, crane (rubber-tired), wire puller (small), feller buncher, loader, motor grader, roller compactor, skidder, 3-drum puller (heavy), 3-drum puller (medium), double bull-wheel tensioner (heavy), double bull-wheel tensioner (light), helicopter (small), single-drum puller (large)	Air compressor, generator, construction trailer, chipper, hydra-ax or mulcher

Source: Appendix F of this EIS.

Construction LOS was calculated for each of the roadway segments in the ROI where AADT counts were available (Clean Line 2014). Traffic count data are generally collected and available for federal and state highways, as well as other well-traveled roadways such as county roads and major local roads near communities. Traffic count data are generally not collected or available for lesser-traveled roadways. The analysis does not include the urban street segment category because of variations in how the state DOTs collect AADT data for city streets. In Oklahoma and Arkansas, AADT counts are only collected for select city streets; in Tennessee and Texas, AADT counts are not collected for any city streets. Although urban street segments have the potential to be accessed for construction purposes, major roadways in towns and urban areas throughout the Project are generally accounted for by the other roadway categories that are included in the LOS analysis. Each roadway segment corresponds to an AADT count data point with lengths delimited based on the AADT data.

The traffic analysis estimated the total arriving and departing traffic on a daily basis resulting from construction based on Project trips. The analysis includes the very conservative assumption that each roadway within the ROI could receive the full number of estimated peak daily construction trips. This assumption is implausible because the roadways cannot all receive the full number of trips. The assumption is used as a screening tool to identify roadways where potential effects would be negligible (even under the most conservative trip scenario), and thus to focus on roadway segments with greater potential for impacts. A more detailed traffic analysis is not possible at this stage of the Project because specific commuting and haul routes based on worker residences, material and equipment locations, and construction site destinations would not be identified until the design phase of the Project, when a Transportation Management Plan would be developed. Traffic from construction activities outside the ROI would be much more dispersed, and roadways outside the ROI are unlikely to receive the full number of trips.

The analysis considers simultaneous construction activities within Regions 1, 5, and 7, where the HVDC transmission line and converter stations (Oklahoma, Arkansas, and Tennessee) might be under construction during the same time. The analysis also considers simultaneous construction of the AC collection system and HVDC transmission lines for Region 1. The specific criteria used to assess the LOS for two-lane highways (both Class I and Class II), basic freeway segments, and multi-lane highways are provided in Table 3.16-11. Given the numerous roadways and associated jurisdictions traversed and affected by the Project, the AASHTO minimum LOS for rural and urban areas (C and D, respectively) have been used to evaluate impacts.

Table 3.16-11:
LOS-Criteria Summary

	2-Lane Class I (at 45 mph)	2-Lane Class I (at 45 mph)	2-Lane Class II (at 45 mph)	Basic Freeway Segments (at 70 mph)	Multi-Lane Highway Segments (at 55 mph)
LOS	Avg. Travel Speed (mph)	Percent Time Following	Percent Time Following	Density (cars/mile/lane)	Density (cars/mile/lane)
A	>55	<35	<40	<11	<11
B	>50–55	>35–50	>40–55	>11–18	>11–18
C	>45–50	>50–65	>50–70	>18–26	>18–26
D	>40–45	>65–80	>70–85	>26–35	>26–35
E	<40	>80	>85	>35-41	>35-41

Source: TRB (2010)

3.16.6.1.1.2 Bus and Emergency Routes

Construction traffic has the potential to impact bus and emergency routes for roadways near the construction areas. Public bus routes are expected to be rare in the ROI because most of the Project is located within rural areas without bus routes. Sections 3.16.6.2 and 3.16.6.3 identify more populated areas where the Project could impact bus and emergency routes. Bus and emergency routes would be specifically identified in association with a Transportation and Traffic Management Plan, which also would include measures to avoid or minimize potential impacts to bus routes and emergency vehicle traffic.

3.16.6.1.1.3 Roadway ROW and Railroad

Impacts resulting from roadway and railroad crossings are generally evaluated by identifying the interstates, federal and state highways, and railroads that would be crossed by the Project. Crossings have the potential to involve short-term traffic delays and interruptions, including temporary lane closures in some cases.

Impacts could also occur in areas where the routes are located adjacent to roadways and railroads. Construction activities that take place adjacent to major roadways have the potential to cause temporary adverse impacts to traffic from vehicles entering and leaving the roadway and could involve lane closures.

The Transportation and Traffic Management Plan would include railroad crossing protocols and construction and post-construction practices to avoid vehicle, railroad, and transmission line conflicts. Typically, stoppage of railroad traffic is not required during construction or conductor stringing and tensioning activities. Crossing activities are similar to those for road crossings and typically involve the use of guard structures. Stringing and tensioning activities would be performed in coordination with the appropriate railroad authorities as required.

An analysis of representative transmission line centerlines was performed to identify roadways within 50 feet of the centerlines (see Table 3.16-17 in Section 3.16.6.2.3). The analysis includes the following roadway categories: local, minor arterial/minor collector, principal arterial/major urban collector, county roads, state highways, federal highways, and interstates.

3.16.6.1.1.4 Airport, Airfield, and Navigation Aid

Transmission line structures and lines are a navigation issue and can become a hazard if they are located too close to airport operations or military airspace operating areas. Transmission line construction near an airport presents the potential for new flight safety issues. Effects can occur depending on the proximity between flight paths and transmission line locations, structure and conductor heights, and compliance with applicable requirements. Incorporation of design features and implementation of EPMs are expected to reduce the extent of the safety issues to permissible levels. Any routes with irresolvable issues related to airports or airspace would require FAA review and coordination with specific facilities or entities.

Airports, airfields, and navigation aids within 4 miles of the Applicant Proposed Route and the HVDC alternative routes were identified (see Table 3.16-3 for airports and airstrips). Specific mileage from the representative centerlines is provided to identify potential for conflicts, the triggering of FAA review requirements, or potential impacts to navigation aids.

3.16.6.1.1.5 Roadway Infrastructure

Roadway pavement or other infrastructure might be damaged by heavy vehicles delivering equipment and materials to the site. Specifications and haul routes for oversize/overweight vehicles and equipment would be developed for a Transportation and Traffic Management Plan. Other impacts to roadway infrastructure could include damage from temporary access points. Such damage would be repaired and restored, so the impacts would be temporary. These impacts would be generally common to all alternatives and are therefore not specifically evaluated in terms of the Applicant Proposed Route and HVDC alternative routes.

3.16.6.1.2 EPMs

The Applicant would implement EPMs to avoid or minimize potential impacts resulting from construction, operations and maintenance, and decommissioning of the Project. Prior to construction, the Applicant would develop and implement a Transportation and Traffic Management Plan that would detail the requirements, permits, plans, and mitigation procedures that would be implemented to avoid or minimize potential impacts on transportation infrastructure and traffic conditions.

The Applicant has developed a comprehensive list of EPMs that would avoid or minimize transportation impacts. Implementation of these EPMs is assumed throughout the impact analysis that follows. A complete list of EPMs for the proposed Project is provided in Appendix F*;* those EPMs that would specifically minimize the potential for transportation impacts are listed below:

- LU-2: Clean Line will minimize the frequency and duration of road closures.
- GE-26: When needed, Clean Line will use guard structures, barriers, flaggers, and other traffic controls to minimize traffic delays and road closures.
- GE-8: Access controls (e.g., cattle guards, fences, gates) will be installed, maintained, repaired, replaced, or restored as required by regulation, road authority, or as agreed to by landowner.
- LU-1: Clean Line will work with landowners and operators to ensure that access is maintained as needed to existing operations (e.g., to oil/gas wells, private lands, agricultural areas, pastures, hunting leases).
- LU-4: Clean Line will coordinate with landowners to site access roads and temporary work areas to avoid and/or minimize impacts to existing operations and structures.

- GE-1: Clean Line will train personnel on health, safety, and environmental matters. Training will include practices, techniques, and protocols required by federal and state regulations and applicable permits.
- GE-6: Clean Line will restrict vehicular travel to the ROW and other established areas within the construction, access, or maintenance easement(s).
- GE-7: Roads not otherwise needed for maintenance and operations will be restored to preconstruction conditions. Restoration practices may include decompacting, recontouring, and re-seeding. Roads needed for maintenance and operations will be retained.
- GE-16: Where required by FAA, or in certain areas to protect aviator safety, Clean Line will mark structures and/or conductors and/or shield wires with high-visibility markers (i.e., marker balls or other FAA-approved devices).
- GE-20: Clean Line will conduct construction and scheduled maintenance activities on the facilities during daylight hours, except in rare circumstances that may include, for example, to address emergency or unsafe situations, to avoid adverse environmental effects, to minimize traffic disruptions, or to comply with regulatory or permit requirements.
- GE-22: Clean Line will impose speed limits during construction for access roads (e.g., to reduce dust emissions, for safety reasons, and for protection of wildlife).
- AG-5: Clean Line will work with landowners and/or tenants to consider potential impacts to current aerial spraying or application (i.e., crop dusting) of herbicides, fungicides, pesticides, and fertilizers within or near the transmission ROW. Clean Line will avoid or minimize impacts to aerial spraying practices when routing and siting the transmission line and related infrastructure.

DOE has confirmed that the Applicant recognizes the impact heavy traffic can have on county and local roads and has agreed to minimize the impact of construction vehicles to existing road networks. The Applicant and its construction contractor will work with the state highway authority and county judges and engineers to plan road use during construction. The Applicant has committed to work with each county prior to construction to ensure repair or payment for repair of damage to county or local roads and will coordinate with the county in the event that road upgrades are needed and would pay for such upgrades and improvements. In addition to the ad valorem property tax revenues (or payment in lieu of taxes, where applicable) estimated in Section 3.13, the Applicant has committed to make an infrastructure payment to offset the potential costs of additional county services required during construction. Infrastructure payments will be based on the linear length of the HVDC transmission line constructed in the county. The infrastructure payment will be $7,500 per mile. The Applicant anticipates these one-time payments will be made to counties concurrent with or soon after the commencement of construction activities in the county and expects to make these payments pursuant to an agreement with the county that would specify these payments.

3.16.6.2 Impacts Associated with the Applicant Proposed Project

3.16.6.2.1 Converter Stations and AC Interconnection Siting Areas

Based on the traffic impact analysis (Clean Line 2014), construction of the Oklahoma converter station and AC interconnection is not predicted to result in an LOS decrease for any roadway segments.

Construction of the Tennessee Converter Station Siting area and AC Interconnection Tie (simultaneously with the HVDC transmission line) is predicted to result in a decrease from LOS-A to LOS-B for nine roadway segments; from LOS-B to LOS-C for five roadway segments; and from LOS-C to LOS-D for six roadway segments. With an LOS-B or LOS-C, impacts to roadways would be minimally noticeable to motorists and temporary during construction, and all roadways would continue to operate at an acceptable LOS-C or better. For roadways that are currently operating at LOS-C, a decrease to LOS-D might be unacceptable to specific jurisdictions. The area of the Tennessee Converter Station Siting area and AC Interconnection Tie is more densely populated and urbanized than most other portions of the proposed Project. It is important to note that the decrease from LOS-C to LOS-D is only a one-level drop in operation level and would be minimally noticeable to motorists. In addition, the assumptions made for the traffic analysis are conservative and were intended to identify where there might be potential effects to roadway segments in the ROI. The scenario that peak traffic would be distributed entirely to the roadway segments with resulting decreases to LOS-D is a worst-case scenario; actual impacts to these roadway segments are expected to be less than predicted.

Airports, airstrips, and navigation aids in relation to potential FAA requirements and review are not relevant for the converter stations, except in cases of direct property encroachment, because the converter station structures would not exceed 85 feet in height, well below the 200-foot FAA review trigger, and the direct property encroachment would be avoided. Structures for the AC interconnection tie would be relatively small (gantries or other insulated support structures) and therefore not anticipated to conflict with airports and airstrips.

3.16.6.2.1.1 Construction Impacts

3.16.6.2.1.1.1 Oklahoma Converter Station Siting Area and AC Interconnection Siting Area

All public roadways within the Oklahoma Convertor Station Siting Area currently operate at an acceptable LOS-A. An estimated 1,117 additional construction trips could occur during construction of both the converter station and HVDC transmission line; a maximum of 1,390 trips are estimated under a scenario where the convertor station, AC collection system, and HVDC transmission line are under construction at the same time (Table 3.16-9). Construction trips for the converter station alone, or in conjunction with the HVDC transmission line, are not predicted to result in an LOS decrease for any roadway segments in the siting area ROI.

It is possible that the converter station might require acquisition of Texas CR-202 roadway ROW and require permitting from the county. Based on the assessment of roadway categories where centerlines are within 50 feet of the roadway, 0.04 mile of the Oklahoma converter station AC interconnection is within 50 feet of a principal arterial/major urban collector roadway.

No railroads are located in the Oklahoma Converter Station Siting Area. No airports, airstrips, or navigation aids are located within 4 miles of the siting area.

3.16.6.2.1.1.2 Tennessee Converter Station Siting Area and AC Interconnection Tie

All public roadways within the ROI of the Converter Station Siting area and AC Interconnection Tie currently operate at an acceptable LOS-C or better. As shown in Table 3.16-12, during construction, trips generated from the converter station could result in LOS decreases as described below:

- LOS-A to LOS-B—segments of Mudville Road, Tipton Road, Tracy Road, Rosemark Road, West Union Road, Armour Road, and Sledge Road
- LOS-B to LOS-C—segments of Tipton Road, Brunswick Road, and Rosemark Road
- LOS-C to LOS-D—segments of SH-14 and local roads Munford Avenue, Atoka Idaville Road, Church Street, and Navy Road

Table 3.16-12:
Roadway Segments with LOS Decrease—Tennessee Converter Station Siting Area and AC Interconnection Tie

Roadway	Location	Map ID	Alternatives Impacted	Existing LOS	LOS with Project Construction

Source: Clean Line (2014)
TCS = Tennessee Converter Station

These impacts to roadways are centered in the areas of Munford, Atoka, and Millington, Tennessee. It is important to note that the decrease from LOS-C to LOS-D is only a one-level drop in operation level, and would be minimally noticeable to motorists. In addition, the assumptions made for the traffic analysis are conservative and were intended to identify where there might be potential effects to roadway segments in the ROI. The scenario that peak traffic would be distributed entirely to the roadway segments with resulting decreases to LOS-D is a worst-case scenario and thus, actual impacts to these roadway segments are expected to be less than predicted.

In the case of both the converter station and HVDC transmission line being under construction in Region 7 at the same time, up to 1,117 construction trips would be generated (Table 3.16-9). For this case, the LOS of four additional public roads would be affected. During construction, trips generated from this scenario are predicted to cause an additional decrease from LOS-A to LOS-B for segments of Portersville Road and Maple Hill Drive, and from B to C for segments of Atoka Idaville Road and Bethuel Road.

With LOS-B and LOS-C, impacts to roadways would be temporary during construction. Although an LOS-D would result in a measurable decrease in roadway operation, the decrease would be temporary and the decrease in operation would be limited to one LOS level. This decrease is not likely to be noticed by motorists.

No portion of the AC Interconnection Siting Area is located within this area based on the assessment of roadway categories where the area is within 50 feet of the roadway.

No railroads are located within the Converter Station Siting area and AC Interconnection Tie . Two airports are located within 4 miles of the converter station siting area—Millington Regional Jetport and Ray Airport. Equipment and buildings associated with the converter station are expected to be less than 85 feet in height and would not require consideration in regards to FAA requirements.

The Converter Station Siting area and AC Interconnection Tie is located within a populated area that might contain bus routes and where emergency routes would be essential to maintain.

3.16.6.2.1.2 Operations and Maintenance Impacts

The operations and maintenance of the converter station and AC interconnection siting areas would require employees, resulting in an incremental increase in localized vehicle trips. The converter station and AC interconnection would be inspected regularly or as necessary using fixed-wing aircraft, helicopters, ground vehicles, all-terrain vehicles, and/or through pedestrian inspection.

Incidental safety impacts could occur in relation to slow-moving Project vehicles on steep roads with limited sight distance required for operations and maintenance of the converter stations or AC interconnection lines, but the travel volumes would be far lower and more distributed over time than those associated with the construction phase These impacts would be associated with normal travel to and from the AC interconnection transmission lines for inspections and repairs.

Based on the number of trips generated during the operational period and their distribution within the roadway network, substantial capacity and congestion impacts are not anticipated. Incidental congestion and delay would be expected from the following: slow-moving trucks and service vehicles and vehicle turning movements where activities occur near and parallel to roadways. Incidental travel time delays are not expected to substantially influence emergency response times or local travel. Access roads not required for facility operations and maintenance would be closed or closed and reclaimed/restored.

Railroad impacts would involve infrequent crossings by construction vehicles and occasional inspections and repairs near railroad tracks. Impacts to railroad operations could occur were a repair needed over an active track, but this is anticipated to be a rare event.

Operations and maintenance of the converter stations or AC interconnection lines would not result in impacts to airports.

3.16.6.2.1.3 Decommissioning Impacts

Impacts during decommissioning of the converter stations and AC interconnection would be similar to those anticipated during construction. EPMs would remain applicable during the decommissioning phase of the Project. The Applicant would be responsible for the decommissioning and reclamation of access roads following abandonment in accordance with the landowner's or appropriate agency's direction. Roadway reclamation would reduce motor vehicle access and return the access road areas back to preconstruction conditions. Temporary access roads may be left intact through mutual agreement of the appropriate landowners and jurisdictional entities.

3.16.6.2.2 AC Collection System

3.16.6.2.2.1 Construction Impacts

All public roadways within 6 miles of the centerline of the ROWs for the AC collection system routes currently operate at an acceptable LOS-B or better. As shown in Table 3.16-13, during construction of the AC collection system, trips added to the ROI could result in a decrease to LOS-B from LOS-A for segments of the following Class I roadways: US-83, US-412, SH-15, and Texas County Highway 28. Impacts to roadways would be temporary during construction.

Table 3.16-13:
Roadway Segments with LOS Decrease—AC Collection System

Roadway Segment	Location	Segment Map ID	Existing LOS	LOS during Project Construction
Class I				
County Highway 28	northeast of Guymon, OK	494361171	A	B

Source: Clean Line (2014)

The AC Collection System Routes E-1, NE-2, and NW-2 would cross US-412 resulting in a decrease from LOS-A to LOS-B for segments of the following roadways: US-83, US-412, SH-15, and County Highway 28. AC Collection System Routes E-1, NE-2, and NW-2 representative centerlines would not be located within 50 feet of any of the analyzed roadway categories. AC Collection System Routes E-1 and NE-2 would not cross any railroads. The representative centerline of AC Collection System Route NE-2 is located 2.79 miles from Hooker Municipal Airport (Table 3.16-3). Transmission structures for the AC collection system would not exceed 180 feet, so given the relatively flat topography of the area, they would not require an FAA review. AC Collection System Routes NW-1 and NW-2, cross one railroad at US-54; and SE-3, and W-1 also cross one railroad. AC Collection System Route NE-1 has two railroad crossings.

AC Collection System Routes E-2 and E-3 would both cross US-83, resulting in a decrease from LOS-A to LOS-B for segments of the following roadways: US-83, US-412, SH-15 and County Highway 28. AC Collection System Route E-2 is parallel to and within 50 feet of local roadways for approximately 1 mile. AC Collection System Route E-3 would be parallel to and within 50 feet of local roadways for 5 miles, and principal arterials/major urban collector roadways for 3.4 miles.

AC Collection System Routes NE-1 and NE-2 would both cross US-412 and US-54, resulting in a decrease from LOS-A from LOS-B for segments of the following roadways: US-83, US-412, SH-15, and County Highway 28. AC Collection System Routes NE-1 and NW-1 would not be located within 50 feet of any of the analyzed roadway categories. AC Collection System Route NE-1 would cross the railroad along US-54 at two locations. This alternative centerline is located 2.56 miles from Hooker Municipal Airport. AC Collection System Route NW-1 would cross the railroad along US-54. This alternative representative centerline is located 3.47 miles from Guymon Municipal Airport. Transmission structures for AC Collection System Routes NE-1 and NW-1 would not exceed 180 feet, so given the relatively flat topography of the area they would not require an FAA review.

AC Collection System Routes SE-1 and SE-3 would both cross SH-15, resulting in a decrease from LOS-A from LOS-B for segments of the following roadways: US-83, US-412, SH-15, and County Highway 28. Under LOS-B, impacts to roadways would be temporary during construction. AC Collection System Route SE-1 would be parallel to and within 50 feet of county roadways for 3.3 miles and AC Collection System Route SE-3 would be parallel to and within 50 feet of county roadways for 12.4 miles. The close proximity to roadways might result in impacts to roadway ROW and to traffic during construction. Both alternatives cross one railroad near SH-15.

AC Collection System Routes SE-2 and SW-1 would not result in an LOS decrease for segments of any roadways in the ROI. The alternatives would not cross any federal or state highways or railroads.

AC Collection System Route SW-2 would cross SH-15, resulting in a decrease from LOS-A to LOS-B for segments of the following roadways: US-83, US-412, SH-15, SH-207, and County Highway 28. The route is parallel to and within 50 feet of county roadways for 5.7 miles.

The AC Collection System Route W-1 would cross US-54, but not result in an LOS decrease for segments of any roadways in the ROI. The alternative crosses one railroad near US-54.

3.16.6.2.2.2 Operations and Maintenance Impacts

Operations and maintenance of both the AC collection system and HVDC transmission line in Oklahoma would require a total of 32 employees. These 32 new jobs would result in a related increase in population due to family size and also have the potential to induce an additional 83 jobs in Oklahoma and Texas (see Section 3.13). The additional trips that this potential increase in population would generate, including trips from the predicted induced employment, would be negligible in terms of the existing area roadway traffic. None of the routes would result in impacts to railroads or airports/airfields as a result of operations and maintenance of the AC collection system.

Impacts to traffic, roadway capacity and congestion, and railroads would be similar as describe in Section 3.16.6.2.1. Impacts on airports would not change during the operational phase.

3.16.6.2.2.3 Decommissioning Impacts

Impacts during decommissioning would be similar to those described in Section 3.6.6.2.1.

3.16.6.2.3 HVDC Applicant Proposed Route

3.16.6.2.3.1 Construction Impacts

Descriptions of construction impacts (including impacts to LOS) associated with the Applicant Proposed Route are provided by region in the Sections below. Table 3.16-16 provides a roadway impact summary by Project region and a list of roadway and railroad crossings. LOS impacts have been evaluated to describe potential impacts, but note that these are based on conservative assumptions (Section 3.16.6.1).

Table 3.16-16:
Applicant Proposed Route Roadway Impacts and Railroad Crossings by Region

Region[1]	LOS Decrease—Number of Roadway Segments[2]	LOS Decrease to LOS-D or F[2]	Number of U.S. Highways Crossed[3]	Number of State Highways Crossed[3]	Number of Railroad Crossings[3]
1	11	0	5	1	0
2	10	0	3	3	3
3	37	0	8	5	4
4	34	12	4	12	3
5	8	1	3	13	1
6	5	0	1	7	2
7	15	10	4	5	3

Region 6	0	0	0	0.4	10.4	0.1	0
Region 7	2.1	0	0	0.7	4.4	0.4	0.1

1 The values in this table (Regions 2–7) would not be affected by the minor changes that would result from application of the minor route variations and adjustments.
GIS Data Sources: BTS (2013), TXDOT (2013), CSA (2007), AHTD (2006a), USCB (2000)

The FAA standards for tall structures in areas near airports and airstrips apply to structures above 200 feet in height. It is unlikely that any of the transmission structures would be designed to exceed 200 feet, so it is unlikely that the Applicant Proposed Route would result in such impacts to airports and airstrips. However, FAA review requirements are also triggered by proximity and topography in some cases and the potential impacts are discussed below. Construction of the Project is not expected to otherwise impact air transportation.

3.16.6.2.3.1.1 Region 1

The Applicant Proposed Route would cross the following federal and state highways: US-83, US-283, US-270, US-183, US-34, and SH-23. The proximity to roadways might result in impacts to roadway ROW and to traffic. Table 3.16-18 lists LOS impacts in Region 1 for the Applicant Proposed Route. The route does not cross any railroads and the centerline is not located within 4 miles of airports, airfields, or navigation aids.

Table 3.16-18:
Roadways with LOS Decreases for the Applicant Proposed Route—Region 1

Roadway	Location	Map ID	Existing LOS	LOS with Project Construction
Region 1				
US-270	between the SH-23 intersection and intersection with US-283	493085071	A	B
		493085100	A	B
		493085124	A	B
		493085143	A	B
		493085150	A	B
		493085171	A	B

3.16.6.2.3.1.2 Region 2

The Applicant Proposed Route would cross the following federal and state highways: SH-15, SH-58, SH-132, US-412, US-281, US-60, and US-81. The representative route centerline is parallel to and within 50 feet of 19.8 miles of local roads and 1.2 miles of principal arterials/major urban collector roads. The proximity to roadways might result in impacts to roadway ROW and to traffic. Table 3.16-19 provides a listing of LOS impacts in Region 2 for the Applicant Proposed Route. The route would cross three railroads in the area. Steinert Lakes private airport is located 3.2 mile from the route centerline (Table 3.16-3). Transmission structures for the Applicant Proposed Route are not expected to exceed 200 feet in height, and the landscape in the area is relatively flat and would not trigger the 1:50 slope ratio limitation, so FAA review requirements are not anticipated. The more populated area of Enid, Oklahoma, might have bus and emergency routes that could be impacted by construction traffic.

Table 3.16-19:
Roadways with LOS Decreases for the Applicant Proposed Route—Region 2

Roadway[1]	Location	Map ID	Existing LOS	LOS with Project Construction
Class I				
SH-51	west of Hennessey, OK	499802732	A	B
East Jack Choate Avenue	In Hennessey, OK	499803699	A	B

1 The values in this table would not be affected by the minor changes that would result from application of the minor route variations and adjustments.
Source: Clean Line (2014)

Two route variations were developed in Region 2 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.2. The variations are illustrated in Exhibit 1 of Appendix M. In comparison to the original Applicant Proposed Route, Link 1, Variation, 1 has slightly less mileage

(0.01 mile) within 50 feet of roadways, but would be within 4 miles of the Mooreland Municipal Airport. Link 2, Variation 2, would have the same mileage within 50 feet of roadways as the original Applicant Proposed Route.

3.16.6.2.3.1.3 Region 3

The Applicant Proposed Route would cross the following federal and state highways: SH-74, SH-51, SH-18, SH-99, SH-48; US-177, US-75 Alternate, US-75, US-63, US-69; I-35, I-44; and the Muskogee Turnpike. The route centerline is within 50 feet of 11.3 miles of local roads and 2.4 miles of principal arterials/major urban collector roads. Table 3.16-20 provides a list of roadway segments that are predicted to have a decrease in LOS during construction. The Applicant Proposed Route crosses four railroads in Region 3. The eastern boundary of Region 3 (with Region 4) is located at the Arkansas River crossing. There are two highway crossings within the ROI: I-40 and US-64/SH-100. US-64/SH-100 is closer to the Applicant Proposed Route crossing and provides a more direct pathway to the eastern side of the river (within Region 4). This roadway also passes through Webbers Falls and Gore, Oklahoma, where segment LOS decreases are indicated during construction. Traffic impacts to US-64/SH-100 are likely in the area of the river crossing. Although roadway segments in Webbers Falls currently operate at LOS-A, roadway segments in Gore operate at LOS-B and LOS-C.

Five route variations were developed in Region 3 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.3. The variations are illustrated in Exhibit 1 of Appendix M. In comparison to the original Applicant Proposed Route, Link 1, Variation 2, would not have any mileage within 50 feet of roadways and would have one less road crossing. Links 1 and 2, Variation 1, would have slightly more mileage (0.01 mile) within 50 feet of roadways; it should be noted that a route adjustment was made for HVDC Alternative Route 3-A to maintain an end-to-end route with this variation. Link 4, Variation 1, and Link 4, Variation 2, would have the same mileage within 50 feet of roadways and would cross one additional road. Link 5, Variation 2, would have the same mileage within 50 feet of roadways.

Source: Clean Line (2014)

Two public airfields are within 4 miles of the Applicant Proposed Route centerline: Davis Field Airport is 3.5 miles from the centerline and Cushing Municipal Airport is 0.8 mile from the representative centerline (Table 3.16-3). Four private airports or airfields are located within 4 miles of the Applicant Proposed Route centerline, and three private heliports are located within 4 miles of the centerline. Two of the private airfields or heliports are located within 1 mile of the Applicant Proposed Route centerline. However, most transmission structures for the route are not expected to exceed 200 feet in height, and the landscape in the area is relatively flat so FAA review requirements are not anticipated for those structures. The height of the Arkansas River crossing could range from approximately 130 to 200 feet on the west bank within Region 3 to maintain necessary clearance over the navigable channels. River traffic may be controlled, in coordination with the USACE, during the short time required to span the conductor across the Arkansas River. No airports are located within 4 miles of the crossing area. Three navigation aids are located within 4 miles of the representative route centerline: CUH NDB, OKMVOR/DME, and MKO NDB. All of these navigation aids are located over 1 mile from the representative route centerline, and the route is not expected to cause interference with these facilities.

The more populated areas of Stillwater and Muskogee, Oklahoma, may have bus and emergency routes that could be impacted by construction traffic.

Figure 3.16-1 in Appendix A provides additional details regarding existing roadways; railroads, and airports and airstrips within Region 3.

3.16.6.2.3.1.4 Region 4

The Applicant Proposed Route would cross the following federal and state highways: SH-10, SH-100, SH-82, SH-352, SH-164, SH-103, SH-21, SH-123, US-59, SH-59, I-40, I-540, SH-162, US-64, SH-23, and SH-219. Table 3.16-21 lists roadway segments where the LOS is predicted to decrease during. The Applicant Proposed Route would result in a decrease from LOS-C to LOS-D for several segments. Although an LOS-D would result in a measurable decrease in roadway operations, the decrease would be temporary, and because the decrease is only one LOS level, a significant incremental impact is not expected in relation to existing conditions. At the Arkansas River crossing, the structure heights could range from approximately 180 to 250 feet on the east bank located in Region 4. Region 4 would have the same impacts at the Arkansas River crossing as described above for Region 3.

1 The values in this table would not be affected by the minor changes that would result from application of the minor route variations and adjustments.
Source: Clean Line (2014)

Seven route variations were developed in Region 4 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.4. The variations are illustrated in Exhibit 1 of Appendix M. In comparison to the original Applicant Proposed Link, Link 3, Variation 1, would have the same mileage within 50 feet of roadways. 3, Variation 2, would have slightly more mileage (0.04 mile) within 50 feet of roadways and would avoid two airstrips that are within 1 mile of the original Applicant Proposed Route. This route variation is proposed along with the original Applicant Proposed Route. Link 3, Variation 3, would have 0.02 mile less mileage within 50 feet of roadways. Link 6, Variation 1, would have the same impacts on transportation as the original Applicant Proposed Route. Link 6, Variation 2, would have slightly more mileage (0.08 mile) within 50 feet of roadways. Link 6, Variation 3 would have 0.02 mile less mileage within 50 feet of roadways and would have one less road crossing. Link 9, Variation 1, would have 0.03 less mileage within 50 feet of roadways.

The Applicant Proposed Route crosses three railroads. The Applicant Proposed Route centerline is within approximately 1 mile of one public airport, Ozark-Franklin County Airport (within 0.6 mile) and 3.7 miles from Clarksville Municipal Airport. The Applicant Proposed Route centerline is within 2 miles of a private hospital heliport and within 4 miles of two private airports. However, most transmission structures are not expected to exceed 200 feet in height, and the landscape in the area is relatively flat, so they are unlikely to trigger FAA height or slope ratio limitations. The representative route centerline is 3.9 miles from the CZE NDB navigation aid and is not expected to impact the facility.

The more populated area of Van Buren, Arkansas may have bus and emergency routes that could be impacted by construction traffic.

3.16.6.2.3.1.5 Region 5

The Applicant Proposed Route would cross the following federal and state highways: US-65, US-167, US-67, SH-164, SH-105, SH-124, SH-95, SH-287, SH-107, SH-16, SH-157, SH-87, SH-367, and SH-224. Table 3.16-22 lists roadway segments where the LOS is predicted to decrease during construction. The representative centerline of the

Applicant Proposed Route is within 50 feet of 0.9 mile of state highways and 5 miles of county roads. The proximity to roadways might result in impacts to roadway ROW and traffic.

Table 3.16-22:
Roadways with LOS Decreases for the Applicant Proposed Route—Region 5

Roadway[1]	Location	Map ID	Existing LOS	LOS with Project Construction
Class I				
Little Rock Road	north of Rose Bud, AR	495086707	B	C

1 The values in this table would not be affected by the minor changes that would result from application of the minor route variations and adjustments.

Source: Clean Line (2014)

Five route variations were developed in Region 5 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.5. The variations are illustrated in Exhibit 1 of Appendix M. In comparison to the Applicant Proposed Route, Link 1, Variation 2, would have slightly more mileage (0.05 mile) within 50 feet of roadways and would have one additional road crossing. Link 2, Variation 2, would have slightly more mileage (<0.1 mile) within 50 feet of roadways and would cross 2 less roadways. Links 2 and 3, Variation 1, would have slightly more mileage (0.01 mile) within 50 feet of roadways. It should be noted that a route adjustment was made for HVDC Alternative Route 5-B to maintain continuity with the variation. Links 3 and 4, Variation 2, would have the same mileage within 50 feet of roadways and would have one additional road crossing. It should be noted that a route adjustment was made for HVDC Alternative Route 5-E to maintain continuity with the variation. Link 7, Variation 1, would have the same mileage within 50 feet of roadways.

The Applicant Proposed Route crosses one railroad near US-67. The Applicant Proposed Route centerline is located 1 to 3 miles from one private airport and two private airstrips. Transmission structures for the route are not expected to exceed 200 feet in height and slope ratios in relation to the airports would not exceed 1:50, so FAA review requirements are not anticipated.

3.16.6.2.3.1.6 Region 6

The Applicant Proposed Route would cross the following federal and state highways: US-49, SH-17, SH-145, SH-37, SH-214, SH-1, SH-163, and SH-75. The crossings would require ROW permits. Table 3.16-23 lists roadway segments where the LOS is predicted to decrease during construction. The route centerline is within 50 feet of 10.4 miles of county roads. The proximity to roadways might result in impacts to roadway ROW and traffic.

Table 3.16-23:
Roadways with LOS Decreases for the Applicant Proposed Route—Region 6

Roadway[1]	Location	Map ID	Existing LOS	LOS with Project Construction
Class I				
Highway 14 East	south of Newport, AR	41848771	A	B
SH-14	east of Marked Tree, AR	445617713	A	B

SH-14	north of Newport, AR	500360708	A	B
Class II				
SH-14	north of Newport, AR	500360708	A	B

1 The values in this table would not be affected by the minor changes that would result from application of the minor route variations and adjustments.

Source: Clean Line (2014)

One route variation was developed in Region 6 after the publication of the Draft EIS. The route variation is described in Appendix M and summarized in Section 2.4.2.6. The variation is illustrated in Exhibit 1 of Appendix M. In comparison to the original Applicant Proposed Route, Link 2, Variation 1, would have slightly less mileage (0.09 mile) within 50 feet of roadways than the original Applicant Proposed Route. It should be noted that a route adjustment was made for HVDC Alternative Route 6-A to maintain continuity with the variation.

The Applicant Proposed Route crosses two railroads: one near SH-1 and one near US-49. The Applicant Proposed Route centerline is 0.1 mile to 3.4 miles from 14 private airfields. Transmission structures for the route are not expected to exceed 200 feet in height and slope ratios in relation to the airports/airfields would not exceed 1:50, so FAA review requirements are not anticipated.

The height of the transmission structures at the Mississippi River crossing could reach approximately 350 feet on the west bank within Region 6 to maintain necessary clearance over the navigable channels.

3.16.6.2.3.1.7 Region 7

The Applicant Proposed Route would cross the following federal and state highways: US-63, US-61, US-51/SH-3, SH-149, SH-322, SH-308, SH-77, and I-55. Table 3.16-24 lists roadway segments where the LOS is predicted to decrease during construction of the proposed Project, including general locations. The route centerline is within 50 feet of 2.1 miles of local roads and 4.4 miles of county roads.

Three route variations were developed in Region 7 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.7. The variations are illustrated in Exhibit 1 of Appendix M. In comparison to the original Applicant Proposed Route, Link 1, Variation 1, would have slightly less mileage (<0.1) within 50 feet of roadways. Link 1, Variation 2, would encounter 0.06 mile less mileage within 50 feet of roadways, and would cross one additional road, but it would cross one less interstate/U.S./state highway. ,Link 5, Variation 1, would encounter the same mileage within 50 feet of roadways.

1 The values in this table would not be affected by the minor changes that would result from application of the minor route variations and adjustments.
Source: Clean Line (2014)

The Applicant Proposed Route would cross the Mississippi River in Region 7. Only two highways cross the river near the proposed Project: I-40/US-64 and I-55/US-61. These highways are located in the urban areas of West Memphis, Arkansas, on the western side of the river, and in Memphis, Tennessee, on the eastern side of the river, and they are not located in the 6-mile ROI. The AADTs on these interstate highways near the river crossing range from 54,725 to 58,389. AADTs along I-40 farther east in the city of Memphis increase to more than 80,000. The 1,117 trips associated with construction of the converter station and the HVDC transmission line (Table 3.16-9) could increase the AADT on these highways by about 2 percent. This increase would not be significant for either highway over a 24-hour period.

The Applicant Proposed Route crosses three railroads: one near US-63, one near US-61, and one near US-51. The Applicant Proposed Route is within 2.5 miles of the Marked Tree Municipal Airport. Based on a 50:1 surface extending from the runway of this airport and structure heights that are not expected to exceed 200 feet, FAA notification would not be required. The Applicant Proposed Route is within 2 miles of the Millington Regional Jetport. Based on a 100:1 surface extending from the runway of this airport and potential structure heights, transmission line structures are likely to be subject to FAA review. The Applicant has and intends to continue to coordinate with the City of Millington and the FAA in the implementation of solutions to ensure continued safe airport operations. The Applicant intends to complete and submit Form 7460-1 (Notice of Proposed Construction or Alteration) to initiate FAA review as required for all structures that meet the criteria under 17 CFR Part 77.

The transmission structure height at the Mississippi River crossing might reach 350 feet to maintain necessary clearance over the navigable channels. River traffic may be controlled, in coordination with the USACE, during the short time required to span the conductor across the Mississippi River. However, no airports are located within 4 miles of the crossing area.

The greater metropolitan area of Memphis, Tennessee, may have bus and emergency routes that could be impacted by construction traffic. Bus and emergency routes would be identified in a Transportation and Traffic Management Plan described in Section 3.16.6.1.2. The plan would also include specific measures to avoid and mitigate potential impacts to bus routes and emergency vehicle traffic.

3.16.6.2.3.2 Operations and Maintenance Impacts

Operations and maintenance of the HVDC transmission line in Arkansas would require a total of 10 employees. These 10 new jobs would result in related increased population associated with family members and have the potential to induce an additional 15 jobs (see Section 3.13) in Arkansas. The additional trips from this potential increase in population, including trips from the predicted induced employment, would be negligible in terms of the existing area roadway traffic.

The additional trips that would result from the very slight potential increase in the local population as a result of 32 new jobs over the entire state of Oklahoma (for both the AC collection system and the HVDC transmission line), 10 jobs in the state of Arkansas, and 15 jobs in the state of Tennessee during operations and maintenance of the HVDC transmission line, including trips from potential induced employment, would not be noticeable in terms of the existing area roadway traffic.

The general types of impacts to traffic, roadway capacity and congestion, and railroads would be similar to those described in Section 3.16.6.2.1.2. River traffic would not be impacted. Impacts on airports would not change during the operational phase.

3.16.6.2.3.3 Decommissioning Impacts

Impacts during decommissioning would be similar to those described in Section 3.6.6.2.1.

3.16.6.3 Impacts Associated with the DOE Alternatives

3.16.6.3.1 Arkansas Converter Station Alternative Siting Area and AC Interconnection Siting Area

3.16.6.3.1.1 Construction Impacts

All roadways currently operate at an acceptable LOS-C or better within the ROI. As shown in Table 3.16-25, during construction, trips generated from the converter station could result in a decrease to LOS-B from LOS-A for several segments of roadway. All roadways would continue to operate at an acceptable LOS-C or better in the converter station siting area.

Table 3.16-25:
Roadway Segments with LOS Decrease—Arkansas Converter Station Siting Area and AC Interconnection Siting Area

Roadway	Location	Map ID	Alternatives Impacted	Existing LOS	LOS with Project Construction
Class I					
US-64	east of Atkins, AR	496274975	ACS	A	B
US-64	east of Atkins, AR	496274975	ACS and HVDC line	A	B
SH-247	north of Atkins, AR	496275121	ACS and HVDC line	A	B
Class II					
Avenue Two Southeast	in Atkins, AR	496274854	ACS	A	B
SH-105 North	south of Hector, AR	496276184	ACS	A	B
SH-124	northeast of Russellville, AR	496275352	ACS	A	B
SH-124	northeast of Russellville, AR	496275226	ACS	A	B
SH-124	northeast of Russellville, AR	496275226	ACS and HVDC line	A	B
Avenue Two Southeast	in Atkins, AR	496274854	ACS and HVDC line	A	B

SH-124	northeast of Russellville, AR	496275352	ACS and HVDC line	A	B
SH-124	northeast of Russellville, AR	496275226	ACS and HVDC line	A	B

Source: Clean Line (2014)

SH-124 and SH-247 are located within the Arkansas Converter Station Siting Area. Based on the assessment of roadway categories where centerlines are within 50 feet of the roadway, 0.17 mile of the AC interconnect centerline is within 50 feet of a county roadway.

No railroads are located within the Arkansas Converter Station Siting Area, and no airports, airstrips, or navigation aids are located within 4 miles of the siting area.

The Arkansas converter station will require a new substation at the point where the 500kV AC interconnection line taps the existing Arkansas Nuclear One-Pleasant Hill 500kV line. The substation is expected to generate a small amount of additional local traffic during construction, and traffic impacts would be slight and temporary.

3.16.6.3.1.2 Operations and Maintenance Impacts

An estimated 15 workers would be employed that could lead to an additional overall population increase of 45 persons in the local area. The additional trips from this increase in population, including trips from the predicted induced employment of 22 persons (see Section 3.13), would be negligible in terms of the existing area roadway traffic.

3.16.6.3.1.3 Decommissioning Impacts

Impacts during decommissioning would be similar to those described in Section 3.6.6.2.1.

3.16.6.3.2 HVDC Alternative Routes

3.16.6.3.2.1 Construction Impacts

Construction impacts to the transportation system under the HVDC alternative routes are discussed below by region. LOS impacts have been evaluated to describe potential impacts, but note that these are based on conservative assumptions (Section 3.16.6.1.1).

The number of railroad crossings would generally be the same for all of the alternatives because the HVDC transmission line would generally traverse the same area in each region, although the actual crossing locations would vary somewhat by HVDC alternative route.

The FAA standards for tall structures in areas near airports and airstrips apply to structures above 200 feet in height. It is unlikely that any of the transmission structures would be designed to exceed 200 feet, so it is unlikely that any of the alternatives would result in such impacts to airports and airstrips. Potential impacts to airports and airstrips, however, are discussed below and considered conservative. Construction of the proposed Project is not expected to otherwise impact air transportation.

3.16.6.3.2.1.1 Region 1

During construction of the HVDC transmission line, trips added to the analysis area are predicted to result in an LOS decrease to LOS-B from LOS-A for segments of the following roadways: US-412, US-270, and US-283. Table 3.16-26 provides an overview of impacts to roadway segments by HVDC alternative route.

Table 3.16-26:
Roadways with LOS Decreases—Region 1

Roadway	Location	Map ID	Alternatives Impacted	Existing LOS	LOS with Project Construction
US-412	West of the SH-23 intersection	493084995	AR 1-B, 1-C	A	B
US-270	between the SH-23 intersection and intersection with US-283	493085071	AR 1-B, 1-C, 1-D, APR	A	B

Source: Clean Line (2014)

Table 3.16-27 provides a summary of potential impacts from the Region 1 HVDC alternative routes. None of the routes would cross any railroads. Although slight local variations would occur for specific alternatives, the overall impacts to traffic from the proposed Project are expected to be similar in relation to the Applicant Proposed Route.

Table 3.16-27:
HVDC Transmission Line Roadway Impacts and Railroad Crossings by HVDC Alternative Routes—Region 1

Alternative	LOS Decrease—Number of Roadway Segments[1]	LOS Decrease —Number of Segments Not Present with APR[1 2)]	Number of U.S. Highways Crossed[3]	Number of State Highways Crossed[3]	Number of Railroad Crossings[3]
1-A	10	5	4	2	0
1-B	5	3	1	0	0
1-C	7	5	1	0	0
1-D	10	0	1	0	0

1 GIS Data Sources: TXDOT (2013), CSA (2007)
2 GIS Data Sources: BTS (2013)

The LOS of five roadway segments may decrease for the HVDC alternative routes beyond the Applicant Proposed Route, so a small potential exists for increased construction impacts on LOS in comparison to the Applicant Proposed Route within this area.

While the centerline for HVDC Alternative Route 1-A is located 1.3 miles from the Laverne Municipal Airport (Table 3.16-3), its transmission structures are not expected to exceed 200 feet in height, and the landscape in the area is relatively flat, so FAA review requirements are not anticipated. HVDC Alternative Routes 1-B, 1-C, and 1-D centerlines are not located within 4 miles of airports, airfields, or navigation aids.

3.16.6.3.2.1.2 Region 2

Table 3.16-29 provides a list of roadway segments in Region 2 where there are predicted decreases in LOS related to construction. During construction of the HVDC transmission line, trips added to the ROI are indicated to result in a decrease to LOS-B from LOS-A for segments of the following federal and state roadways: US-412, US-60, and SH-51, SH-58, and SH-8.

Table 3.16-30 provides a summary overview of impacts to roadway segments by alternative. The Applicant Proposed Route crosses three railroads and HVDC route alternatives cross two railroads in Region 2. Railroads are located along US-412 in Woodward County, Oklahoma; in a rural region of Major County, Oklahoma; and along US-81 in Garfield County, Oklahoma.

Table 3.16-30:
HVDC Transmission Line Roadway Impacts and Railroad Crossings by HVDC Alternative Routes—Region 2

1 GIS Data Sources: TXDOT (2013), CSA (2007)
2 GIS Data Source: BTS (2013)

The more populated area of Enid, Oklahoma, may have bus and emergency routes that could be impacted by construction traffic.

Under LOS-B, impacts to roadways for HVDC Alternative Routes 2-A and 2-B would be temporary during construction. Although slight local variations would occur for specific HVDC alternative routes, the overall impacts to traffic from the proposed Project are expected to be similar in relation to the Applicant Proposed Route.

Mileages for HVDC Alternatives 2-A and 2-B are much less than the 17.6 miles of the corresponding Applicant Proposed Route link, so the impacts would be expected to be much less than the Applicant Proposed Route.

HVDC Alternative Route 2-A does not cross any railroads. No airports, airfields, or navigation aids are located within 4 miles of the route. HVDC Alternative Route 2-B crosses two railroads: one near EO550 Road and one near US-81. HVDC Alternative Route 2-B is located within 1 mile of the Steinert Lakes private airport (Table 3.16-3).

3.16.6.3.2.1.3 Region 3

Table 3.16-32 provides a list of roadway segments that are predicted to have a decrease in LOS during construction. During construction of the HVDC transmission line, trips added to the ROI could result in a decrease to LOS-B from LOS-A and to LOS-C from LOS-B for some segments.

1 The values in this table would not be affected by the minor changes that would result from application of the minor route variations and adjustments.
2 GIS Data Sources: TXDOT (2013), CSA (2007)
3 GIS Data Source: BTS (2013)

The more populated areas of Stillwater and Muskogee, Oklahoma, may have bus and emergency routes that could be impacted by construction traffic.

HVDC Alternative Route 3-A would not individually result in an LOS decrease for any roadway segments in Region 3. 3-B would have decreases to LOS-B from LOS-A and to LOS-C from LOS-B. 3-C would have decreases to LOS-B from LOS-A and to LOS-C from LOS-B. These decreases are similar to the roadway segment decreases predicted for the Applicant Proposed Route.

HVDC Alternative Route 3-C would result in the LOS decrease of three additional roadway segments beyond the number of roadway segments predicted for the Applicant Proposed Route in the comparable area. 3-D would result in LOS decrease for one additional roadway segment beyond the number of roadway segments predicted for the Applicant Proposed Route. 3-E would result in the LOS decrease of one additional roadway segment beyond the number of roadway segments predicted for the Applicant Proposed Route. Therefore, the potential exists for increased construction impacts with HVDC Alternative Routes 3-C, 3-D, and 3-E for decreases in LOS in comparison to the Applicant Proposed Route. However, under LOS-B and LOS-C, impacts to roadways would be temporary during construction.

The Applicant Proposed Route would be parallel to and within 50 feet of 6.1 miles of local roads. HVDC Alternative 3-A mileage would be 1.9 miles. HVDC Alternative 3-B mileage would be 2.3 miles. HVDC Alternative 3-C mileage would be 5.2 miles. HVDC Alternative Route 3-D would be 1.7 miles. HVDC Alternative 3-D mileage would be less than 1 mile. These mileages are less than or comparable to the associated Applicant Proposed Route links and the impacts would be temporary during construction.

HVDC Alternative Routes 3-C, 3-D, and 3-E transmission structures would not be expected to exceed 200 feet in height, and the landscape in the area is relatively flat, so FAA review requirements are not anticipated. The exception would be for HVDC Alternative 3-E at the Arkansas River crossing where the height on the west bank could range from approximately 130 to 200 feet to maintain necessary clearance over the navigable channels. River traffic may be controlled, in coordination with the USACE, during the short time required to span the conductor across the Arkansas River under HVDC Alternative Routes 3-C, 3-D, or 3-E, and Applicant Proposed Route Link 6. However, no airports are located within 4 miles of the crossing area.

A route adjustment was developed for HVDC Alternative Route 3-A to maintain continuity with Applicant Proposed Route Link 1, Variation 1, and Links 1 and 2, Variation 1. Compared to the original HVDC alternative route, the route adjustment would have slightly more mileage (0.01 mile) within 50 feet of roadways and the centerline is not located within 1 mile of any private airstrips or heliports. The route adjustment is illustrated in Exhibit 1 of Appendix M.

3.16.6.3.2.1.4 Region 4

Table 3.16-35 lists roadway segments where the LOS is predicted to decrease during construction of the Project. During construction of the HVDC transmission line, trips added to the ROI could result in a decrease to LOS-B from LOS-A, to LOS-C from LOS-B, and to LOS-D from LOS-C for some segments. Most of the LOS-D roadway segments are located in Clarkesville, Arkansas. Although an LOS-D would result in a decrease in roadway operation, the decrease would be temporary and would be minimally noticeable by motorists.

Table 3.16-35:
Roadways with LOS Decreases—Region 4

Roadway	Location	Map ID	Alternatives Impacted	Existing LOS	LOS with Project Construction
Class I					
SH-23	south of Ozark, AR	41455642	AR 4-E, APR	B	C
West Commercial Street	in Ozark, AR	41456033	AR 4-B, 4-E, APR	C	D
Ozark Franklin County Airport	in Ozark, AR	425748260	AR 4-B, 4-E, APR	A	B
SH-219	in Ozark, AR	425751612	AR 4-B, 4-E, APR	C	D
Highway 219	north of Ozark, AR	425753499	AR 4-B, 4-E, APR	A	B

Source: Clean Line (2014)

Table 3.16-36 provides an overview of impacts to roadway segments by alternative. Although slight local variations would occur for specific alternatives, the overall impacts to traffic from the Project are expected to be similar for all alternatives.

The more populated area of Van Buren, Arkansas, may have bus and emergency routes that could be impacted by construction traffic.

Figure 3.16-1 in Appendix A provides additional details regarding existing roadways, railroads, and airports and airstrips within Region 4. Additional discussion for individual alternatives is provided in the sections below.

Table 3.16-36:
HVDC Transmission Line Roadway Impacts and Railroad Crossings by HVDC Alternative Routes—Region 4

Alternative	LOS Decrease—Number of Roadway Segments[1]	LOS Decrease—Number of Segments Not Present with APR[1, 2]	LOS Decrease to LOS-D or F[1]	Number of U.S. Highways Crossed[3]	Number of State Highways Crossed[3]	Number of Railroads Crossed[3]
AR 4-A	8	1	0	3	6	2
AR 4-B	17	8	2	3	9	2
AR 4-C	5	0	0	0	1	0
AR 4-D	7	1	0	2	5	1
AR 4-E	13	0	8	2	6	0

1 Source: Clean Line (2014)
2 This column is based on an assessment of the comparable APR links for each HVDC alternative route and indicates where there are additional roadway segments that are predicted for a LOS decrease.
3 Source: OCGI (2012); GIS Data Sources: AHTD (2006a), TXDOT (2013), USCB (2013)

Table 3.16-37 shows the centerline mileage within 50 feet of roadways for the HVDC alternative routes and the corresponding links of the Applicant Proposed Route.

HVDC Alternative Route 4-A would result in one decrease to LOC-C greater than the roadway segment decreases predicted for the Applicant Proposed Route. HVDC Alternative Route 4-B would result in a decrease from LOS-B to LOS-C; 4-C would result in a decrease from LOS-A from LOS-B; 4-D would result in a decrease from LOS-A to LOS-B and LOS-B to LOS-C; 4-E would result in a decrease from LOS-A from LOS-B, LOS-B to LOS-C, and LOS-C to LOS-D.

Table 3.16-37:
Centerline within 50 Feet of Roadways—Region 4

Route	Local Roads[1] (miles)	Minor Arterials and Minor Collector Roads[1] (miles)	Principal Arterials and Major Urban Collectors[1] (miles)	State Highways[2] (miles)	County Roads[1] (miles)	U.S. Highways[2] (miles)	Interstates[2] (miles)
AR 4-A (Corresponds with APR Links 3, 4, 5, 6)	1.0	0	0.4	0.3	1.4	0.1	0.1
AR 4-B (Corresponds with APR Links 2, 3, 4, 5, 6, 7, 8)	0.9	0	0.3	0.4	3.9	0.2	0.1
AR 4-C (Corresponds with APR Link 5)	0	0	0	0.1	0.2	0	0
AR 4-D (Corresponds with APR Links 4, 5, 6)	0	0	0	0.2	1.4	0.1	0.1
AR 4-E (Corresponds with APR Links 8, 9)	0.2	0	0	0.4	4.2	0	0.1
APR (Link 1)	0.4	0.1	0.2	0	0	0	0
APR (Link 2)	0.2	0	0	0	0	0	0
APR (Link 3)	0.6	0.1	0.4	0	0.2	0	0
APR (Link 4)	0	0	0	0	0.1	0	0
APR (Link 5)	0	0	0	0.1	0.1	0	0
APR (Link 6)	0.2	0	0	0.2	1.8	0.1	0.4
APR (Link 7)	0	0	0	0.1	0.7	0	0
APR (Link 8)	0	0	0	0	0	0.1	0
APR (Link 9)	0	0	0	0.3	2.7	0	0

1 GIS Data Sources: AHTD (2006a), CSA (2007)
2 GIS Data Source: BTS (2013), USCB (2000)

HVDC Alternative Route 4-A mileage would be 1.0 mile on local roads and 1.4 miles on county roads. HVDC Alternative Route 4-B mileage would be 0.9 mile for local roads and 3.9 miles for county roads. HVDC Alternative Route 4-C mileage would be less than 1 mile. HVDC Alternative Route D mileage would be 1.4 miles. The mileages for HVDC Alternative Routes 4-A, 4-B, 4-C, and 4-D would be comparable to the mileage of the corresponding Applicant Proposed Route links. HVDC Alternative 4-E mileage would be 4.2 miles, and this mileage is greater than the mileage of the corresponding Applicant Proposed Route links.

HVDC Alternative Routes 4-A, 4-B would cross two railroads, one near Marble City, Oklahoma, and one near I-540, and would require easements. HVDC Alternative Route 4-C would cross one railroad near I-540. HVDC Alternative Route 4-D would cross two railroads, one near Marble City, Oklahoma, and one near I-540, and would require easements. HVDC Alternative Route 4-E would not cross any railroads.

HVDC Alternative Route 4-A centerline is not located within 4 miles of any airports, airfields, or navigation aids. HVDC Alternative Route 4-B centerline is located 3.72 miles from the Ozark-Franklin County Airport (Table 3.16-3). This distance is considerably greater than the Applicant Proposed Route. HVDC Alternative Route 4-C centerline is located 3.9 miles from a private hospital heliport (Table 3.16-3). HVDC Alternative Route 4-D centerline is not located within 4 miles of any airports, airfields, or navigation aids. HVDC Alternative Route 4-E centerline is located within about 1 mile of the Clarksville Municipal Airport and is 3.9 miles from the Ozark-Franklin County Airport and within 4 miles of two public heliports. HVDC Alternative 4-E centerline is located 1.3 miles from the CZE NDB Clarksville navigation aid and is not expected to cause interference with the facility. Transmission structures for HVDC Alternative Routes 4-B, 4-C, and 4-E are not expected to exceed 200 feet in height, and the landscape in the area is relatively flat, so FAA review requirements are not anticipated. None of the HVDC Alternative Routes in Region 4 would span the Mississippi Region.

3.16.6.3.2.1.5 Region 5

Table 3.16-38 lists roadway segments where the LOS is predicted to decrease during construction. During construction of the HVDC transmission line, trips added to the ROI are predicted to result in a decrease from LOS-A to LOS-B for segments of the following roadways: SH-14, Edgemont Road, SR 124, Highway 9, and Blackland Road. During construction of the HVDC transmission line, trips added to the ROI are predicted to result in a decrease from LOS-B to LOS-C for segments of Little Rock Road. Under LOS-B and LOS-C, impacts to roadways would be temporary during construction.

During construction of the HVDC transmission line, trips added to the analysis area are predicted to result in a decrease from LOS-C to LOS-D for segments of Heber Springs Road W located northwest of Damascus, Arkansas.

Table 3.16-38:
Roadways with LOS Decreases—Region 5

Roadway[1]	Location	Map ID	Alternatives Impacted	Existing LOS	LOS with Project Construction
Class I					
SH-14	near the intersection with US-67	444973582	AR 5-D	A	B
Little Rock Road	north of Rose Bud, AR	495086707	AR 5-B, 5-E, 5-F, APR	B	C
Edgemont Road	northeast of Quitman, AR	495087059	APR	A	B
SR 124	northeast of Russellville, AR	496275226	APR	A	B
Heber Springs Road W	south of Heber Springs, AR	515874130	APR	C	D
Highway 9	northwest of Damascus, AR	516208297	APR	A	B
Class II					
Blackland Road	in Pleasant Plains, AR	447212101	AR 5-D	A	B
Edgemont Road	northeast of Quitman, AR	495087059	APR	A	B

APR Link 4	0	0	0	0.2	0.4	0	0
APR Link 5	0	0	0	0	1.1	0	0
APR Link 6	0	0	0	0.1	0.1	0	0
APR Link 7	0	0	0	0.1	0.3	0	0

Table 3.16-40:
Centerline within 50 Feet of Roadways—Region 5

Route[1]	Local Roads[2] (miles)	Minor Arterials and Minor Collector Roads[2] (miles)	Principal Arterials and Major Urban Collectors[2] (miles)	State Highways[3] (miles)	County Roads[2] (miles)	U.S. Highways[3] (miles)	Interstates[3] (miles)
APR Link 8	0	0	0	0	0.1	0	0
APR Link 9	0	0	0	0.2	1.8	0.2	0

1 The values in this table would not be affected by the minor changes that would result from application of the minor route variations and adjustments.
2 GIS Data Sources: AHTD (2006a), USCB (2000)
3 GIS Data Source: BTS (2013)

HVDC Alternative Route 5-A would result a decrease from LOS-A to LOS-B. 5-B would result in a decrease from LOS-A to LOS-B and LOS-B to LOS-C. 5-C would not result in an LOS decrease for any roadway segments in Region 5. 5-D would result in a decrease from LOS-A to LOS-B and would also result in two LOS decreases that are not predicted for the Applicant Proposed Route, so the potential exists for this alternative to have greater effects on traffic than the Applicant Proposed Route. 5-E would result in a decrease from LOS-B to LOS-C. 5-F would result in decreases from LOS-B from LOS-C and LOS-C to LOS-D.

HVDC Alternative Route 5-A mileage would be 1 mile. 5-B would mileage would be 3.7 miles 5-C mileage would be less than 1 mile. 5-D mileage would be 1.7 miles. 5-E mileage would be 1.7 miles. 5-F mileage would be 1.4 miles. These mileages are comparable to the mileage of the corresponding Applicant Proposed Route links.

HVDC Alternative Routes 5-A, 5-B, 5-C 5-E, and 5-F do not cross any railroads. HVDC Alternative Route 5-D would cross one railroad near SH-367.

HVDC Alternative Route 5-A centerline is located 2.89 miles from a private airport (Table 3.16-3). Transmission structures for the alternative are not expected to exceed 200 feet in height and slope ratios in relation to the airport would not exceed 1:100. HVDC Alternative Route 5-B centerline is located within about 0.5 mile of two private airfields and within 1.2 to 2.8 miles of four private airports. HVDC Alternative Route 5-C centerline is located 2.7 miles from one private airfield. Transmission structures for HVDC Alternative Routes 4-B and 4-C are not expected to exceed 200 feet in height and slope ratios in relation to the airfield would not exceed 1:50. HVDC Alternative Route 5-D centerline is not located within 4 miles of any airports, airfields, or navigation aids. 5-E centerline is located within about 0.5 mile of two private airfields, and within 1.2 to 2.3 miles of 3 private airports. 5-F centerline is located within about 0.5 mile of two private airfields and within 1.2 to 1.8 miles of 2 private airports. Transmission structures for the alternative are not expected to exceed 200 feet in height and slope ratios in relation to the airports/airfields would not exceed 1:50, so FAA review requirements are not anticipated for any of these alternatives.

A route adjustment was developed for HVDC Alternative Route 5-B to maintain continuity with Applicant Proposed Route Links 2 and 3, Variation 1. The variation would have the same transportation impacts as the original HVDC alternative route. The route adjustment is illustrated in Exhibit 1 of Appendix M.

A route adjustment was developed for HVDC Alternative Route 5-E to maintain continuity with Applicant Proposed Route Links 3 and 4, Variation 2. The variation would have the same mileage within 50 feet of roadways as the original HVDC alternative route. The route adjustment is illustrated in Exhibit 1 of Appendix M.

3.16.6.3.2.1.6 Region 6

Table 3.16-41 lists roadway segments where the LOS is predicted to decrease during construction. During construction of the HVDC transmission line, trips added to the ROI are predicted to result in a decrease from LOS-A to LOS-B for segments of the following roadways: Highway 14 E, SH-14, and Air Base Road. During construction of the HVDC transmission line, trips added to the 6-mile ROI could result in a decrease from LOS-B to LOS-C for segments of Highway 1. During construction of the HVDC transmission line, there are no roadway segments predicted to result in a decrease from LOS-C to LOS-D in the 6-mile ROI for Region 6.

Table 3.16-41:
Roadways with LOS Decreases—Region 6

Roadway[1]	Location	Map ID	Alternatives Impacted	Existing LOS	LOS with Project Construction
Class I					
Highway 14 E	south of Newport, AR	41848771	AR 6-A, 6-B, APR	A	B
SH-14	east of Marked Tree, AR	445617713	AR 6-C, 6-D, APR	A	B
Highway 1	south of Cherry Valley, AR	495221858	APR	B	C
SH-14	north of Newport, AR	500360708	APR	A	B
Class II					
SH-14	north of Newport, AR	500360708	APR	A	B
Air Base Road	in Newport, AR	500363489	AR 6-B	A	B

Table 3.16-43 shows the centerline mileage within 50 feet of roadways for the HVDC alternative routes and the corresponding links of the Applicant Proposed Route.

Table 3.16-43:
Centerline within 50 Feet of Roadways—Region 6

Route[1]	Local Roads[2] (miles)	Minor Arterials and Minor Collector Roads[2] (miles)	Principal Arterials and Major Urban Collectors[2] (miles)	State Highways[3] (miles)	County Roads[2] (miles)	U.S. Highways[3] (miles)	Interstates[3] (miles)
AR 6-A (Corresponds with APR Links 2, 3, 4)	0	0	0	0.1	1.7	0.1	0
AR 6-B (Corresponds with APR Link 3)	0	0	0	1.5	1.2	0	0
AR 6-C (Corresponds with APR Links 6, 7)	0	0	0	0.2	4.3	0	0
AR 6-D (Corresponds with APR Link 7)	0	0	0	0	0.3	0	0
APR Link 1	0	0	0	0.1	0.7	0	0
APR Link 2	0	0	0	0	0.1	0	0
APR Link 3	0	0	0	0.1	3.5	0	0
APR Link 4	0	0	0	0.1	0.4	0.1	0
APR Link 5	0	0	0	0	0.3	0	0
APR Link 6	0	0	0	0.1	4.3	0	0
APR Link 7	0	0	0	0	0.8	0	0
APR Link 8	0	0	0	0.1	0.3	0	0

1 The values in this table would not be affected by the minor changes that would result from application of the minor route variations and adjustments.
2 GIS Data Sources: AHTD (2006a), USCB (2000)
3 GIS Data Source: BTS (2013)

HVDC Alternative Route 6-A would result in a decrease from LOS-A to LOS-B and LOS-C to LOS-D. HVDC Alternative Route 6-B would result in a decrease from LOS-A to LOS-B, and for this route, one LOS decrease is predicted that is not predicted for the Applicant Proposed Route. HVDC Alternative Route 6-C would result in the decrease from LOS-A to LOS-B. 6-D would result in a decrease from LOS-A to LOS-B.

HVDC Alternative Route 6-A mileage would be 1.7 miles for county roads. 6-B mileage would be 1.2 miles for county roads and 1.5 miles for state highways. HVDC Alternative Route 6-D mileage would be less than 0.3 mile for local roads (county roads) and this mileage is less than the mileage of the corresponding Applicant Proposed Route links.

HVDC Alternative Route 6-A would cross one railroad near US-49. HVDC Alternative Route 6-B does not cross any railroads. HVDC Alternative Route 6-C would cross one railroad near SH-1. HVDC Alternative Route 6-D does not cross any railroads.

The HVDC Alternative Route 6-A centerline is located from 1.3 to 4.0 miles from nine private airfields. The HVDC Alternative Route 6-B centerline is located from 1.1 to 3.7 miles from seven private airfields. The HVDC Alternative Route 6-C centerline is located from 0.7 to 3.7 miles from eight private airfields. Transmission structures for the alternative are not expected to exceed 200 feet in height and slope ratios in relation to the airports/airfields would not exceed 1:50. FAA review requirements are therefore not anticipated. The HVDC Alternative Route 6-D centerline is not located within 4 miles of any airport, airfield, or navigation aid.

A route adjustment was developed for HVDC Alternative Route 6-A to maintain continuity with Applicant Proposed Route Link 1, Variation 1, and Link 2, Variation 1. The variation would have the same transportation impacts as the original HVDC alternative route. The route adjustment is illustrated in Exhibit 1 of Appendix M.

3.16.6.3.2.1.7 Region 7

Table 3.16-44 lists roadway segments where the LOS is predicted to decrease during construction of the Project.

Table 3.16-44:
Roadways with LOS Decreases—Region 7

Roadway	Location	Map ID	Alternatives Impacted	Existing LOS	LOS with Project Construction

Table 3.16-45 provides an overview of impacts to roadway segments by alternative. Additional discussion for individual alternatives is provided in the sections below.

The greater metropolitan area of Memphis, Tennessee, may have bus and emergency routes that could be impacted by construction traffic.

Table 3.16-45:
HVDC Transmission Line Roadway Impacts and Railroad Crossings by HVDC Alternative Routes—Region 7

Alternative	LOS Decrease—Number of Roadway Segments[1]	LOS Decrease—Number of Segments Not Present with APR[1, 2]	LOS Decrease to LOS-D or F[1]	Number of U.S. Highways Crossed[3]	Number of State Highways Crossed[3]	Number of Railroads Crossed[3]

1 GIS Data Sources: AHTD (2006a), USCB (2000)
2 GIS Data Source: BTS (2013)

HVDC Alternative Route 7-A would result in a decrease from LOS-A to LOS-B and a decrease from LOS-B to LOS-C. There are two LOS decreases for this route that are not predicted for the Applicant Proposed Route. HVDC

Alternative Route 7-B would result in a decrease from LOS-A to LOS-B, from LOS-B to LOS-C, and from LOS-C to LOS-D. 7-C would result in a decrease from LOS-A to LOS-B, from LOS-B to LOS-C, and from LOS-C to LOS-D. This route has a greater number of LOS-C to LOS-D decreases than the Applicant Proposed Route. 7-D would result in a decrease from LOS-A to LOS-B, LOS-B to LOS-C, and LOS-C to LOS-D.

HVDC Alternative Route 7-A mileages would be 2.8 miles for county roads,1.1 miles for local roads, and 1.1 miles for state highways. The proximity of the route to these roadways might require roadway ROW permits and has the potential to impact traffic in these areas. 7-B mileage would be 1.5 miles for local roads and this mileage in combination is comparable to the mileage of the corresponding Applicant Proposed Route link. HVDC 7-C mileage would be 1.8 miles for local roads, and the proximity of the route to the roadway might require roadway ROW permits and has the potential to impact traffic in the roadway area during construction.

HVDC Alternative Route 7-A would cross two railroads, one near US-63 and one near US-61. 7-B would cross one railroad near US-51 North. 7-C would cross one railroad near US-51 North. 7-D would cross one railroad near US-51 North.

HVDC Alternative Route 7-A centerline would be located about 1 mile from the Marked Tree Municipal Airport and from 2 to 4 miles from a private airfield and a private airport (Table 3.16-3). Most transmission structures for the alternative are not expected to exceed 200 feet in height and slope ratios in relation to the airports/airfields would not exceed 1:50. However, the structure height at the Mississippi River crossing might reach 350 feet to maintain necessary clearance over the navigable channels and there is one private airport located approximately 3.6 miles from the south river crossing point for Route 7-A. Depending on the final design height of the transmission line, FAA review could be required for the alternative for the structures located at the river crossing. River traffic may be controlled, in coordination with the USACE, during the short time required to span the conductor across the Mississippi River under HVDC Alternative Route 7-A or Applicant Proposed Route Link 1. HVDC Alternative Route 7-B centerline is located 2.3 miles from the Millington Regional Jetport. Transmission structures for the alternative are not expected to exceed 200 feet in height and slope ratios in relation to the airports/airfields would not exceed 1:50.

HVDC Alternative Route 7-C centerline is located 2.1 miles from the Millington Regional Jetport and 3.5 miles from the Charles W. Baker Airport. The Ray private airport is located 0.4 mile from the Route 7-C centerline. Transmission structures for the alternative are not expected to exceed 200 feet in height and slope ratios in relation to the airports/airfields would not exceed 1:50. The HVDC Alternative 7-C representative centerline is located 3.4 miles from the MIG NDB Millington navigation aid and is not expected to cause interference with the facility. The 7-D centerline would be located about 2 miles from the Millington Regional Jetport and is located 0.4 mile from a private airport. Transmission structures are likely to be subject to FAA review due to their proximity to the Millington Regional Jetport.

3.16.6.3.2.2 Operations and Maintenance Impacts

Impacts during operations and maintenance would be similar to those described in Section 3.16.6.1.

3.16.6.3.2.3 Decommissioning Impacts

Impacts during decommissioning would be similar to those described in Section 3.6.6.2.1.

3.16.6.4 Best Management Practices

BMPs that could be implemented to reduce potential impacts to transportation are identified below:

- Accommodate existing and programmed, approved, and/or funded transportation facility projects to the extent practicable into the final Project design, and coordinate with appropriate jurisdictions to avoid or minimize disruptions to trails, streets, or drainage/irrigation structures.
- In identified areas of traffic impact, conflicts between the Project traffic and background traffic such as movements of normal heavy trucks (dump trucks, concrete trucks, standard size tractor-trailers or flatbeds, etc.) would be minimized by scheduling (essential deliveries only) to the extent practicable during peak traffic hours/times and scheduling remaining heavy truck trips during off-peak traffic hours/times.
- To the extent practicable, staging activities and parking of equipment and vehicles will occur primarily within private ROW on private land.
- The Applicant would implement a Communications Plan described in Section 3.1.2.

The Applicant would perform mitigation to address Project structures in the vicinity of private airstrips. This BMP would require conducting specific flight plan analyses to determine whether interference with private airstrips can be avoided through micrositing within the 1,000-foot-wide corridor to the extent practicable. If impacts are unavoidable, the Applicant would develop and implement mitigation measures and/or provide compensation, in coordination with landowners. The Applicant would apply similar mitigation to private airstrips where Project structures would present a hazard within a 1:20 glide slope from each end of private airfields.

3.16.6.5 Unavoidable Adverse Impacts

Impacts to traffic and roadway infrastructure would be avoided or minimized by meeting regulatory or jurisdictional requirements and implementing EPMs and BMPs. Despite these measures, unavoidable and temporary adverse impacts to local traffic would occur during construction on roadways where materials and equipment are hauled to construction areas. Construction activities associated with the crossing of roadways and railroads and potential encroachment along roadway ROW would also result in unavoidable temporary impacts to roadways and traffic.

3.16.6.6 Irreversible and Irretrievable Commitment of Resources

As a result of increased traffic associated with construction of the Project, a portion of the local roadway network capacity would be lost during the construction period. This loss would be irretrievable but short-term. The use of non-renewable resources and resources that cannot be recycled would occur as a result of access roadway construction. This use of these resources would be irreversible.

3.16.6.7 Relationship between Local Short-term Uses and Long-term Productivity

The Project would increase the short-term uses of the local roadway network during construction but would have no impact on long-term productivity because roadways would be returned to their original condition and travel conditions would neither improve nor deteriorate during the operational life of the Project.

3.16.6.8 Impacts from Connected Actions

3.16.6.8.1 Wind Energy Generation

3.16.6.8.1.1 Construction

Estimated trips associated with three scenarios for wind farm construction within the WDZs are provided in Table 3.16-47. These three scenarios are not intended to represent an actual construction timeframe for the wind farm, but have been created to represent a range of the most conservative conditions for the traffic analysis. The traffic analysis uses trips associated with the scenario where nineteen 100MW wind farms are constructed within 1 year. This scenario includes 2,185 trips per day during construction of the 19 wind farms as documented in Appendix F. Construction of the 19 wind farms is considered a very conservative (maximum) construction scenario for a 1-year period because the design, permitting, and land acquisition process for such construction would be expected to stagger the construction of the wind farms over a period of greater than one year. Information for the scenario in which 38 wind farms and the AC collection system are under construction within 1 year is also presented as an improbable estimate of the upper limit of traffic impacts. It is much more likely that the 38 wind farms would be constructed over a period of 2 or more years due to the individual wind farm requirements for permitting, design, and land acquisition processes.

Table 3.16-47:
Connected Action—Trip Assumptions During Construction

Wind Farm Project	Trips per Day
One 100MW Wind Farm	
Workers	95
Delivery Trucks	20
Nineteen 100MW Wind Farms Constructed in 1 year, Total Trips (workers and delivery)	2,185
Thirty-eight 100MW Wind Farms Constructed in 1 year, Total Trips (workers and delivery)	4,370
Thirty-eight 100MW Wind Farms Constructed in 1 year along with AC Collection System Construction, Total Trips	4,643

Source: Clean Line (2013)

Major and local roadways in the WDZ ROI that could be affected by wind farm construction currently operate at an average daily LOS-B or better. LOS levels for most roadway segments in the WDZs would decrease from LOS-A to LOS-B during construction of the nineteen 100MW wind farms. No roadway segments in WDZ-B, -C, -G, and -H currently operate below LOS-A, and no roadway segments in these WDZs would decrease to LOS-C during wind farm construction. Table 3.16-48 provides a list of roadway segments with LOS-B to LOS-C decreases for the nineteen 100MW wind farm scenario in Table 3.16-48. Under LOS-B and LOS-C, impacts to roadways would be temporary during construction. Two roadway segments in the area of Perryton, Texas, are predicted to decrease by two LOS levels from LOS-A to LOS-C in the area of WDZ-A and -L. One roadway segment in the area of Spearman, Texas, is predicted to decrease by two LOS levels from LOS-A to LOS-C in the area of WDZ-L.

Table 3.16-48:
Roadways with LOS Decreases with Construction of 19 Wind Farms

493084980	US Hwy 412	North of Perryton, TX	J, K	B	C

Source: Clean Line (2014)

LOS would not decrease below LOS-C even in the unlikely scenario where 38 wind farms and the AC collection system are under construction during 1 year, which further supports the conclusion that impacts during construction would be temporary.

Numerous local, state, and federal roads and highways are within the WDZs (see Table 3.16-5) and many are likely to be crossed by wind farm components including access roads, underground collection cables, and generation tie lines. Railroads are also present in the WDZs as listed in Table 3.16-6. Railroads are located within WDZ-A, -C, -F, -G, and -I. Airports and airstrips in the WDZ ROI are listed in Table 3.16-7. Airports are located in WDZ-A, -F, and -I. One navigation aid is located within WDZ-A. No airports or navigation aids are located within 4 miles of WDZ-D, -H, -J, and -K. Wind turbines, including turbine blade tips can reach a height of up to 420 feet. FAA lighting requirements would apply to the wind turbines. In addition, these heights would require careful selection of specific turbine sites to avoid potential conflicts with airports and military airspace. In some cases, FAA notification requirements might be triggered.

3.16.6.8.1.2 Operation and Maintenance

As discussed in Section 3.13, operations and maintenance of the wind capacity build-out of 4,000MW would require 177 to 303 operations workers. Assuming an average family size of 3, the full build-out scenario is expected to result in a population increase of from 530 to 909. The population is anticipated to be spread among Sherman, Hansford, and Ochiltree counties in Texas; and Cimarron, Texas, and Beaver counties in Oklahoma; as well as surrounding counties in Texas, Oklahoma, and Kansas. If these people were spread evenly across the six-county area where the wind farms would be located, 152 people could potentially reside in each county. If these 152 people generated 456 additional round trips per day (a conservative estimate of three round trips per person), based on previous construction traffic analysis results, no roadway segments would incur a LOS decrease below LOS-C. Under LOS-B and LOS-C, impacts to traffic would be minimally noticeable to motorists. In addition, such trips would occur during limited times associated with peak daily commutes to and from the wind farms by workers from their homes; sporadic equipment and material deliveries, and localized maintenance activities at each wind farm. Indirect impacts to roadways would occur with typical local residential trips and family member commuting not directly associated with the wind farm operation.

3.16.6.8.1.3 Decommissioning

Decommissioning of a wind farm would involve removal and recycling of materials from turbines, electrical infrastructure, buildings, access roads, and foundations. Traffic from these activities likely would be similar to that for construction activities. The timeframe for decommissioning of a wind farm would depend on numerous factors such as the continued functioning of the power delivery infrastructure and economic factors associated with the wind farm. Wind farms might be re-powered with new equipment over the years. A scenario where all of the wind farms would be decommissioned at the same time is unlikely; decommissioning would more likely take place over many years. Therefore impacts to transportation associated with decommissioning are anticipated to be much less than those during construction.

3.16.6.8.2 Optima Substation

Impacts to transportation resources from the future Optima Substation would be similar to those described in Section 3.16.6.2.1 for the Oklahoma Converter Station Siting Area and the AC collection system. All public roadways within 6 miles of the Oklahoma Convertor Station Siting Area currently operate at an acceptable LOS-A. The future Optima Substation would involve less than the assumed additional construction trips estimated during construction of the converter station and the AC collection system where these are being constructed at the same time. Construction trips for the converter station alone, or in conjunction with the AC collection system, are not predicted to result in an LOS decrease for any roadway segments in the siting area ROI (see the Traffic Technical Report and supplement to the *Traffic Technical Report* [Clean Line 2013, 2014]).

No railroads are located at the future Optima Substation site. No airports, airstrips, or navigation aids are located within 4 miles of the future Optima Substation site.

3.16.6.8.3 TVA Upgrades

The potential impacts to transportation from the required TVA upgrades could increase traffic as workers commute to work sites and construction vehicles haul materials and equipment, and could result in incidental congestion and delays. Construction-related traffic impacts are more likely to occur during construction of the new transmission line than during upgrades of existing substations or transmission lines. Evaluations for the Project typically resulted in a LOS decrease of one level and in some cases resulted in no decrease in LOS. The required upgrades, including construction of the new transmission line, would not be expected to result in localized changes in LOS because compared to the Project, they would involve similar though substantially reduced construction activities. The specific localized impacts to towns near the proposed TVA upgrades (including the new electric transmission line) would depend on the likely commuter and haul routes that would be taken during project construction and the existing levels of congestion on those routes.

3.16.6.9 Impacts Associated with the No Action Alternative

Under the No Action Alternative, DOE assumes for analytical purposes that the Project would not be constructed. Therefore, no impacts to transportation including impacts from additional traffic, interruption of traffic, roadway ROW encroachment, or requirements for new easement from railroads would result from the Project.

3.17 Vegetation Communities and Special Status Plant Species

3.17.1 Regulatory Background

Protection and management of vegetation communities and special status plan species occurs under a number of federal and state statutes, regulations and programs. Key legal authorities and programs of relevance to these resources are summarized in Table 3.17-1. For the purposes of this EIS, noxious weeds are considered to be a subset of the overall invasive plant species that may exist and exert an influence on economics or the environment. Weeds designated as legally noxious by federal, state, or county governments include plant species that are harmful to public health, recreational activities, agriculture, wildlife species and habitat, and properties (BLM 2010).

Table 3.17-1:
Legal Authorities and Programs Associated with Vegetation Management

Statute/Regulation/Agency	Key Elements
Federal	
Endangered Species Act (7 USC § 136; 16 USC § 1531)	The ESA is designed to protect critically imperiled species and the habitats in which they are found. The law requires federal agencies to ensure that actions they authorize, fund, or carry out are not likely to jeopardize the continued existence of listed species or result in adverse modification to designated critical habitat. Under Section 7(a)(2) of the ESA, a federal agency is required to consult with the USFWS where a proposed federal agency action is determined to likely adversely affect a listed species or designated critical habitat.
Plant Protection Act of 2000 (7 USC § 7701 *et seq.*)	Under the Plant Protection Act of 2000, which repealed and superseded the Federal Noxious Weed Act of 1974 (7 USC § 2801 *et seq.*), the federal government lists 137 regulated noxious weeds. States typically have their own noxious weed lists and county weed control boards or districts that monitor weed infestations and provide guidance on weed control.
Executive Order 13112, "Invasive Species"	EO 13112 (February 3, 1999; 2564 FR 6183, February 3, 1999) establishes the National Invasive Species Council, made up of 13 departments and agencies, to prevent the introduction of invasive species and provide for their control and to minimize the economic, ecological, and human health impacts that invasive species cause.
Oklahoma	
State of Oklahoma—Threatened and endangered plant species	The state of Oklahoma does not maintain a state list of threatened and endangered plant species with commensurate regulatory protections.
Oklahoma Noxious Weed Law and Rules—Section 3-220, Title 35, Chapter 30, Subchapter 34	A designated Oklahoma State University extension agent or the Department Agriculture determines the most appropriate treatment, control, or eradication method available to treat infestations (ODA 2000).
Oklahoma Natural Heritage Program (ONHP)	The ONHP maintains a tracking list of rare plants in the state. It includes approximately 548 species of plants. Accounts for each species include description, life history, habitat preference, distribution, causes of decline, recovery needs, field-identification characters, an illustration, and a map of current and historical sites (ONHP 2014).
Arkansas	
Plant Act of 1917 (Arkansas Statutes 77-101–77-116)	The act establishes the Arkansas State Plant Board. The Board is required to remain informed of the varieties of insect pests, diseases, and noxious weeds, the origin, locality, nature and appearance thereof, the manner in which they are disseminated, and approved methods of treatment and eradication (Arkansas Plant Board 1993).
Circular 10: Regulations on the Sale of Planting Seed in Arkansas, Arkansas State Plant Board (Arkansas Code Annotated 2-16-207 and 2-16-209)	The circular describes the requirements for licensing, reporting, and labeling of seeds, including sampling and analyzing, fees and services, and prohibitions (Arkansas Plant Board 2014a).
Arkansas State Plant Board—Noxious Weed List	The state of Arkansas maintains a list of 25 plants listed as noxious. (Arkansas Plant Board 2014b)
Arkansas Natural Heritage Commission	The ANHC maintains up-to-date and comprehensive information concerning plant species and high-quality natural communities for the state of Arkansas in a System of Natural Areas. Along

Table 3.17-1:
Legal Authorities and Programs Associated with Vegetation Management

Statute/Regulation/Agency	Key Elements
	with conservation of remnants of the original natural landscape, lands within the System of Natural Areas provide vital habitat for imperiled plant and animal species. ANHC has a tracking list for state rare plants that includes approximately 544 total species. (ANHC 2014)
Tennessee	
Tennessee Department of Agriculture (TDA) Division of Plant Industries, Pest Plant Regulations (Chapter 0080-6-24)	The regulations list 14 pest plants that are injurious to the agricultural, horticultural, silvicultural, or other interests of the state (TDA 2007).
Tennessee Department of Environment and Conservation (TDEC), Rare Plant Protection and Conservation Regulations (Chapter 0400-06-02)	These regulations provide for the implementation of The Rare Plant Protection and Conservation Act, which requires persons to obtain written permission from a landowner or manager before knowingly removing or destroying state-listed endangered plant species and requires nursery farmers to be licensed to sell state-listed endangered species (TDEC 2008).
Tennessee Natural Heritage Program (TNHP)—Rare Plant List	The Rare Plant Protection and Conservation Act of 1985 allows the Division of Natural Areas, Tennessee Natural Heritage Program to enter into agreements with other agencies to conserve rare plants. It also requires persons to obtain written permission from a landowner or manager before knowingly removing or destroying state-listed endangered plant species. The Tennessee Natural Heritage Commission website has a tracking list with approximately 531 total rare plant species for the state (TDEC 2014).
Texas	
Endangered, Threatened, and Protected Native Plants (Texas Administrative Code (TAC) 31-69.1–69.9	The regulations list laws regarding threatened and endangered native plant species.
Texas Parks and Wildlife Code, Wildlife and Plant Conservation, Chapter 88	The regulation establishes TPWD and identifies procedures for identifying, studying, and protecting endangered, threatened, or protected plants.
Texas Department of Agriculture, Noxious Weed List (TAC 4-19.300(a))	The state of Texas maintains a list of 29 plants listed as noxious (http://www.texasinvasives.org/plant_database/tda_results.php).

3.17.2 Data Sources

The data sources used for Vegetation Communities in this EIS are listed in Table 3.17-2. All sources are listed in Chapter 6.

Table 3.17-2:
Sources of Vegetation Community Data

Vegetation	Data Sources
Cover Types and Dominant Species	EPA Level I (EPA 2012) and III Ecoregions (GIS Data Source: EPA 2010) 2011 National Land Cover Database (GIS Data Source: Jin et al. 2013) NRCS Plants Database (USDA 2013) Flora of North America (eFlora 2013)

3.17.3 Region of Influence

For vegetation communities and special status plant species, the ROI for the Project and connected actions is the same as described in Section 3.1.1.

3.17.4 Affected Environment

The ROI crosses many ecosystems that support diverse vegetation communities. Section 3.17.5 describes existing vegetation communities by Project region (1 through 7), including the dominant vegetation types and dominant plant species as well as special status plant species, designated conservation or habitat protection areas, and listed noxious weed species that may occur within the ROI. Land cover is described in detail in Section 3.10 and contains tables that show land cover by Project region and component.

Several route variations to the Applicant Proposed Route in Regions 2–7 were developed in response to public comments on the Draft EIS and are described in Appendix M and summarized in Sections 2.4.2.1–2.4.2.7. The variations are presented graphically in Exhibit 1 of Appendix M.

3.17.5 Regional Description

The descriptions of vegetation presented below were developed from information provided by the EPA for the Level III and IV ecoregions and the National Land Cover Database (NLCD) (Table 3.17-3).

Project Regions 1 through 3 are located within the Great Plains Level I ecoregion. Project Regions 4 through 7 are located within the Eastern Temperate Forests Level I ecoregion (EPA 2012). Level I ecoregions are further divided into Level II, Level III, and Level IV ecoregions to describe the more defined ecosystem boundaries that are often nested within broader ecological hierarchies. Level III and Level IV ecoregions within the ROI are identified and described in Table 3.17-3. Figure 3.17-1 (located in Appendix A) is a depiction of Level IV ecoregions mapped over the entire breadth of the Project.

Table 3.17-3:
EPA Level III and IV Ecoregions by State and Region/Project Component

Level III Ecoregion	Level IV Ecoregion	State(s)	Region/Project Component
High Plains	Canadian/Cimarron High Plains	Oklahoma and Texas	Region 1, AC Collection System
Southwestern Tablelands	Canadian/Cimarron Breaks		Region 1, Oklahoma Converter Station Siting Area and AC Interconnection Siting Area
Central Great Plains	Rolling Red Hills	Oklahoma	Regions 1 and 2
	Pleistocene Sand Dunes		Regions 1 and 2
	Gypsum Hills		Region 2
	Prairie Tableland		Regions 2 and 3
	Cross Timbers Transition		Region 3
Cross Timbers	Northern Cross Timbers	Oklahoma	Region 3
Central Irregular Plains	Osage Cuestas		Region 3
Boston Mountains	Lower Boston Mountains	Oklahoma and Arkansas	Regions 3 and 4
Arkansas Valley	Arkansas Valley Plains	Oklahoma and Arkansas	Region 4
	Arkansas Valley Hills	Arkansas	Regions 4 and 5, Arkansas Converter Station Alternative Siting Area
	Arkansas River Floodplain		Region 4
Mississippi Alluvial Plain	Western Lowlands Holocene Meander Belts		Regions 5 and 6
	Western Lowlands Pleistocene Valley Trains		Region 6
	St. Francis Lowlands		Region 6
	Northern Holocene Meander Belts	Arkansas and Tennessee	Region 7
	Northern Pleistocene Valley Trains	Arkansas	Region 7
	Northern Backswamps	Arkansas	Region 7
Mississippi Valley Loess Plains	Bluff Hills	Arkansas and Tennessee	Regions 6 and 7, Tennessee Converter Station Siting Area
	Loess Plains	Tennessee	Region 7, Tennessee Converter Station Siting Area

Sources: Griffith et al. (1998, 2004), Woods et al. (2004, 2005); GIS Data Source: EPA (2010)

Annual precipitation ranges from about 16 inches in the Oklahoma Panhandle region to about 45–50 inches in eastern Oklahoma, across Arkansas to the Mississippi Valley region on the east end of the Project. The gradient of precipitation greatly influences the land cover types and vegetation in the ecoregions from the High Plains and Southwestern Tablelands in the Oklahoma and northern Texas Panhandles to the Mississippi Alluvial Plain and Mississippi Valley Loess Plains in Arkansas and Tennessee (Tyrl et. al 2002). The grassland/herbaceous cover type is dominated by shortgrass and, to a lesser extent, midgrass prairie species in the semi-arid parts of Regions 1 and 2. As precipitation increases across Oklahoma (Regions 3 and 4), the species composition changes to more mixed grass prairie (midgrasses) and then to tall grass species through central and eastern Oklahoma and across Arkansas. Shrub/scrub cover types are more common in the more semi-arid western regions of the Project and decrease in abundance across Oklahoma as forest types become more common with increased precipitation. In Region 1 and parts of Region 2, shrubland areas of sand sagebrush (*Artemisia filifolia*) and shinnery oak (*Quercus* *harvardii*) are common. Farther east in the Project area, shrubland areas may be associated with early successional stages of either human or naturally disturbed areas.

Table 3.10-3 in the Land Use section of this EIS summarizes the percentage of each USGS 2011 NLCD classification within the ROI. Forest cover types (evergreen, deciduous, and mixed) occur along the entire Project but are most abundant in higher precipitation areas in the Cross Timbers, Central Irregular Plains, Boston Mountains, Arkansas Valley, Mississippi Alluvial Plain, Mississippi Valley Loess Plains ecoregions in Regions 3 through 7. Forested areas in the western semi-arid regions are limited to deciduous forests in floodplains or small areas of upland evergreen forests of pinyon-juniper woodlands. Across central Oklahoma, forested cover types become common and are composed largely of oaks in the Cross Timbers. In eastern Oklahoma, Arkansas, and western Tennessee, the forested cover types transition to deciduous forest of oaks, hickories, and other broadleaf trees and mixed forest of deciduous trees and evergreen trees such as short-leaf pine. Smaller evergreen forest of short-leaf pine also occurs on escarpments and drier south slopes. Cultivated cover types include cultivated crops or pasture/hay. Cultivated crops also vary across the Project with the precipitation gradient. Cultivated crops in the drier, western part of the Project are most likely to be dryland farms or irrigated fields (e.g., center-pivot). As precipitation increases to the east, irrigation becomes less important. Crops vary, but typically include annual species such as corn, soybeans, rice, cotton, and wheat. Several land cover types are classified as developed with different levels of development intensity. These areas typically contain a matrix of vegetation interspersed with human development (i.e., residential, commercial, and industrial). The type of vegetation within the developed cover type would reflect the location along the precipitation gradient and the potential vegetation that could occur there based on precipitation. Wetlands cover types occur throughout the ROI and may either be woody or emergent wetlands. Woody wetlands occur where forests or shrubs grow in soils periodically saturated with or covered by water. Vegetation in emergent wetlands is dominated by perennial herbaceous species.

3.17.5.1 Region 1

3.17.5.1.1 Ecoregional Descriptions

Region 1 is referred to as the Oklahoma Panhandle Region and includes the Applicant Proposed Route and HVDC Alternative Routes 1-A through 1-D, the AC collection system, and the Oklahoma Converter Station and AC Interconnection Siting Area. Region 1 is the most arid of the Project, and annual precipitation ranges from less than 16 inches to about 24 inches. The ROI in Region 1 largely crosses areas consisting of agriculture (including center-pivot irrigation) and open pasture interspersed with well fields. The land is flat and dry, and has few narrow riparian corridors associated with streams and rivers, such as Palo Duro Creek. East of Hollow N1150 Road, topography becomes more noticeable in areas. Small plateaus are even present between Oklahoma Route 46 and U.S. Route 183. The shrub/scrub cover type consists of semi-arid species such as sand sagebrush and shinnery oak. The grassland/herbaceous cover type consists primarily of shortgrass prairie species (blue grama [*Bouteloua gracilis*], buffalograss [*Buchloë dactyloides*], fringed sage [*Artemisia frigida*]) with some midgrasses (sideoats grama [*Bouteloua curtipendula*], western wheatgrass [*Pascopyrum smithii*], little bluestem [*Schizachyrium scoparium*]) as precipitation increases to the east. Forested cover types are limited in Region 1 and typically consists of deciduous forests (plains cottonwoods [*Populus deltoides* ssp. *monolifera*] and willows, such as peach-leaved willow [*Salix amygdaloides*]) in floodplains or small areas of pinyon-juniper woodland.

No route variations were proposed in Region 1.

3.17.5.1.2 Special Status Plants

No federal or state threatened or endangered plants are known to occur in the ROI for the Applicant Proposed Route, the HVDC alternative routes, or the Oklahoma Converter Station Siting Area in Region 1 (USFWS 2013a, 2014; ODWC 2013).

3.17.5.1.3 Noxious Weeds

Region 1 is located in the states of Oklahoma and Texas. Oklahoma has three listed noxious weeds: musk thistle (*Carduus nutans*), Scotch thistle (*Onopordum acanthium*), and Canada thistle (*Cirsium arvense*). Desktop analysis has not yielded data with which to establish magnitude of occurrence for these three listed noxious weeds within the ROI (ODA 2000; CISEH 2014). In addition, field reconnaissance has not been undertaken to substantiate the actual presence or absence of these three species in the ROI.

Twenty-seven plant species are designated as noxious weeds in the state of Texas (see Texas Administrative Code Title 4, Chapter 19). Two of these noxious species are confirmed to occur within Ochiltree County, Texas (field bindweed [*Convolvulus arvensis*]) and saltcedar [*Tamarix* spp.]). Field bindweed is also confirmed from both Sherman and Hansford counties, Texas. In addition to the two listed noxious weeds, a large number of other invasive plant species are confirmed for the three county area in north Texas where various portions of the AC collection system may be sited. Desktop analysis has not yielded data with which to establish magnitude of occurrence for state listed noxious weeds confirmed in the Texas counties where the various AC collection routes have been identified (CISEH 2014). In addition, field reconnaissance has not been undertaken to substantiate the actual presence or absence of listed noxious weeds in the various ROIs for the AC collection system.

3.17.5.2 Region 2

3.17.5.2.1 Ecoregional Descriptions

Region 2 is referred to as the Oklahoma Central Great Plains Region and includes the Applicant Proposed Route and HVDC Alternative Routes 2-A and 2-B. Annual precipitation in Region 2 ranges from about 24 to 32 inches. In Region 2, the ROI largely crosses areas consisting of agriculture and open pasture interspersed with well fields. Near Mooreland, Oklahoma, lands appear wetter where they are associated with the North Canadian River. From Oklahoma Route 50 south and east to the location that the ROI passes north of Canton Lake, forested areas are interspersed with open pasturelands and well fields. Between the city of Fairview and the town of Isabella, Oklahoma, land use changes to agriculture; however, east of Isabella, lands associated with the Cimarron River and floodplain are wetter and interspersed with forested tracts. The grassland/herbaceous cover type that is common in the ROI in Region 2 contains some short grass species, but more midgrasses and tall grass species (big bluestem [*Andropogon gerardii*], switchgrass [*Panicum virgatum*], Indiangrass [*Sorghastrum nutans*], and little bluestem) are present farther east. Region 2 also contains larger areas of deciduous and evergreen forest than did the more arid Region 1, including the western part of the Cross Timbers ecoregion.

Two route variations to the Applicant Proposed Route were developed in Region 2 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.2. The variations are illustrated in Exhibit 1 of Appendix M. Link 1, Variation 1, would feature 261 acres of grassland/herbaceous land cover and 11 acres of urban/developed land. Applicant Proposed Route Link 2, Variation 2 would have 845 acres of cultivated crops and 288 acres of grassland/herbaceous land cover.

3.17.5.2.2 Special Status Plants

No federal or state threatened or endangered plants are confirmed in the ROI for the Applicant Proposed Route or the HVDC alternative routes in Region 2 (USFWS 2013a, 2014; ODWC 2013).

3.17.5.2.3 Noxious Weeds

Oklahoma has three listed noxious weeds, as discussed under Region 1. Desktop analysis has not confirmed the magnitude of occurrence for these three species in the ROI. Field reconnaissance would be required to substantiate quantities and spatial distribution of these species within the ROI for the Project.

3.17.5.3 Region 3

3.17.5.3.1 Ecoregional Descriptions

Region 3 is referred to as the Oklahoma Cross Timbers Region and includes the Applicant Proposed Route and HVDC Alternative Routes 3-A through 3-E. Annual precipitation in Region 3 ranges from 32 inches in the west to about 44 inches in Muskogee County, Oklahoma. In Region 3, the ROI crosses areas consisting of agriculture and pastureland and small forested areas associated with creeks. East of Oklahoma Route 74, the land cover becomes wetter, with multiple waterbodies, including Otter Creek and Beaver Creek, and more forested areas associated with these creeks. East of Interstate 35, the ROI becomes more interspersed with forested lands and waterbodies, with a larger tract of forested area present southwest of Stillwater, Oklahoma. The ROI traverses the Cimarron River, associated tributaries, floodplains, and wetlands. East of the Cimarron River, the ROI becomes more densely forested, though not in contiguous tracts, as the forested and riparian areas are intermixed with shrub and pasture lands, as well as developed cities such as Bristow, Beggs, and Okmulgee, Oklahoma. East of Okmulgee, to Muskogee, the ROI traverses open pasture lands interspersed with oil well pads. The Cross Timbers Region contains larger areas of oak forest (deciduous forest) interspersed with grassland/herbaceous cover that is composed of mostly tall grass prairie species such as big bluestem, switchgrass, Indiangrass, and little bluestem. These two cover types, along with cultivated crops and pasture/hay, compose much of the vegetation in Region 3.

Five route variations to the Applicant Proposed Route were developed in Region 3 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.3. The variations are illustrated in Exhibit 1 of Appendix M. Link 1, Variation 2, would feature 320 acres of grassland/herbaceous cover and 112 acres of forest cover. Links 1 and 2, Variation 1, would have 269 acres of grassland/herbaceous cover, and 28 acres of forested land. It should be noted that a route adjustment was made for HVDC Alternative Route 3-A to maintain an end-to-end route with the Links 1 and 2 variations. This route adjustment yielded 61 acres of grassland/herbaceous land cover and 3 acres of forested land. Link 4, Variation 1, would have 105 acres of grassland/herbaceous land cover type and 6 acres of forested land. Link 4, Variation 2, would have 84 acres of grassland/hay land cover plus 30 acres of forested land. Applicant Proposed Route Link 5, Variation 2, would have 128 acres of pasture/hay land cover, and 106 acres of grasslands.

3.17.5.3.2 Special Status Plants

No federal or state threatened or endangered plants are known to occur in the ROI for the Applicant Proposed Route or the HVDC alternative routes in Region 3 (USFWS 2013a, 2014; ODWC 2013).

3.17.5.3.3 Noxious Weeds

Oklahoma has three listed noxious weeds as discussed under Region 1. Musk thistle is confirmed for Payne, Lincoln, Creek, and Okmulgee counties, which the ROI traverses.

3.17.5.4 Region 4

3.17.5.4.1 Ecoregional Descriptions

Region 4 is referred to as the Arkansas River Valley Region and includes the Applicant Proposed Route, including the Lee Creek Variation, and HVDC Alternative Routes 4-A through 4-E. Average annual precipitation in Region 4 varies from 44 inches in eastern Oklahoma to about 50 inches in Arkansas. In Region 4, the ROI crosses the Arkansas and Illinois rivers in Oklahoma, both of which have extensive tracts of forested lands. Through Sequoyah County, the northern portion of the ROI traverses larger tracts of forested areas, while the southern portion traverses lightly developed areas and pasture lands.

In Arkansas, land cover in Region 4 varies from north to south, with large tracts of forest common in the north, while there are more developed areas to the south associated with the city of Fort Smith. This difference between the northern and southern portions of the ROI continues through Franklin and Johnson counties. East of Clarksville, Arkansas, the ROI becomes more densely forested as it continues into Pope County.

Forested cover types are prevalent in Region 4; deciduous forest (oak-hickory) is the most common. Evergreen forests with pines are common in some locations. Grassland/herbaceous cover types are less prevalent than in the drier regions in Oklahoma but where present contain predominately tallgrass prairie species. Pasture/hay cover types are relatively abundant in this region and contain domestic forage species and some native species.

Seven route variations to the Applicant Proposed Route were developed in Region 4 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.4. The variations are illustrated in Exhibit 1 of Appendix M. Link 3, Variation 1, would involve 217 acres of pasture/hay land cover and 27 acres of forested lands. Link 3, Variation 2, features 387 acres of pasture/hay land cover and 368 acres of forested land cover. Link 3, Variation 3, would have 96 acres of pasture/hay land cover and 298 acres of forested lands. Link 6, Variation 1, would have 60 acres of pasture/hay land cover and 74 acres of forested land cover. Link 6, Variation 2, would feature 191 acres of pasture/hay and 79 acres of cultivated crops. Link 6, Variation 3, would have 15 acres of pasture/hay land cover and 92 acres of forested land cover.

3.17.5.4.2 Special Status Plants

No federal or state threatened or endangered plants are known to occur in the ROI for the Applicant Proposed Route or the HVDC alternative routes within the portion of Region 4 within the state of Oklahoma (USFWS 2013a, 2014; ODWC 2013). Arkansas has a voluntary Endangered Species Protection Program with bulletins for each county. Special status plant species potentially occurring in the ROI for the Applicant Proposed Route and the HVDC alternative routes in Region 4 in Arkansas are listed in Table 3.17-4.

Table 3.17-4:
State and Federally Designated Threatened and Endangered Plants Potentially Occurring in the ROI in Region 4 (by County)

Common Name	Scientific Name	Listing Status	Counties of Occurrence in the Region
Alabama snow-wreath	*Neviusia alabamensis*	ST	Pope
Appalachian filmy fern	*Trichomanes boschianum*	ST	Johnson
Bicknell's sedge	*Carex opaca*	SE	Franklin
Interrupted fern	*Osmunda claytoniana*	ST	Pope
Open-ground Whitlow-grass	*Draba aprica*	ST	Pope
Ovate-leaf catchfly	*Silene ovata*	ST	Crawford, Pope
Small-head pipewort	*Eriocaulon koernickianum*	SE	Franklin, Johnson, Pope
Tinytim	*Geocarpon minimum*	FT/SE	Franklin
Whorled dropseed	*Sporobolus pyramidatus*	ST	Franklin

FT = Federally Threatened SE = State Endangered ST = State Threatened
Source: ANHC (2014b)

The federally listed species tinytim (*Geocarpon minimum*) has confirmed elemental occurrence in Franklin County, Arkansas; however, no portions of the ROI have been specifically surveyed for this species, so its presence in the ROI is not confirmed. Tinytim is also listed as state endangered. Tinytim is typically found in eroded areas in saline soil prairies, called "slicks." Slicks are bare soils that occur over sandstone, and they are naturally high in sodium and magnesium. Slicks are ephemeral and can fluctuate greatly from year to year, causing tinytim populations to increase or decrease (Pittman 1993; ANHC 2011). To date, tinytim has not been found on any sandstone glades in Arkansas. Although the Ozark Highlands of Arkansas contain many sandstone glades that appear superficially similar to the tinytim-supporting glades of Missouri, no known sandstone glades are confirmed in Arkansas with the same mode of formation and chemical composition as the Missouri channel sand glades. All of the currently known Arkansas tinytim sites occur on saline soil prairies (NatureServe 2013). Factors that cause disturbances to natural plant successional phases are contributing to this species' decline. Threats include cattle grazing in and around sandstone-glade or saline soil prairie habitat, complete conversion of saline soil prairies, and off-road vehicular traffic (DeLay et al. 1993), although the current role of erosional disturbance is debatable. Other reasons given for this species' decline are climate change and changes in site-specific hydrology (USFWS 2009).

The state-threatened species, Alabama snow-wreath (*Neviusia alabamensis)*, has confirmed elemental occurrence in Pope County in Region 4 and also Conway and Faulkner County in Region 5. Alabama snow-wreath is a 3- to 6-foot-tall deciduous, thicket-forming shrub with bright green leaves. It is a clonal species that rarely reproduces by seeds. It may be found in forested bluffs, talus slopes, and streambanks on a variety of geologic substrates, soil types, and aspects, and under open- to completely closed-canopy conditions. Most typical habitat may be within forested areas on thin soil over limestone that is moist for part of the year (seasonal streambeds, margins of sinkholes, riverbluffs) (ANHC 2014b). It is most vulnerable to timber harvesting and other forms of disturbance.

The Appalachian filmy fern (*Trichomanes boschianum*) is a state listed threatened species in Arkansas and has confirmed elemental occurrence in Johnson County in Region 4 and Cleburne County in Region 5. Its presence within the ROI for the Applicant Proposed Route or the HVDC alternative routes cannot be confirmed without species specific surveys in these areas. The Appalachian filmy fern has a very limited distribution. The habitat for this species consists of places where humidity is constantly high and temperatures tend to be moderate throughout the year. This includes deep recesses and cracks in cliffs and rock shelters, and on boulders along streams or in deep narrow hollows. Appalachian filmy fern is usually found on sandstone or conglomerate, but can be on other non-calcareous rocks (Taylor 2014).

Bicknell's sedge (*Carex opaca*) is a state listed endangered plant species that has confirmed elemental occurrence in Franklin County in Region 4, Faulkner County in Region 5, and Poinsett County in Regions 6 and 7. Its presence within the ROI for the Applicant Proposed Route or the HVDC alternative routes cannot be confirmed without species specific surveys in these areas. Bicknell's sedge is a large (3-foot-tall) perennial sedge that grows in dense clumps. Its primary habitats are moist depressions, drainages, and swales in wet or mesic prairie; it also colonizes roadside ditches and railroad ROWs and often occurs on heavy, clayey soils. Habitat conversion and alteration of hydrologic regimes are primary threats as these habitats (wet or mesic prairie) lend themselves to alternative use.

The interrupted fern (*Osmunda claytonia*) is a state threatened species in Arkansas with confirmed elemental occurrence in Pope County in Regions 4 and 5. Its presence within the ROI for the Applicant Proposed Route or the HVDC alternative routes cannot be confirmed without species specific surveys in these areas. This fern species is distributed through eastern Canada and is rare but occurs in many states in the eastern and central United States. It is ranked as critically imperiled in Arkansas, which indicates that there are five or fewer known occurrences in the state (NatureServe 2014a; Meades et al. 2000).

Open-ground Whitlow-grass (*Draba aprica*) is an Arkansas state listed threatened species with confirmed elemental occurrence in Pope County in Regions 4 and 5 and in Faulkner County in Region 5. Its presence within the ROI for the Applicant Proposed Route or the HVDC Alternative Routes cannot be confirmed without species specific surveys in these areas. Open-ground Whitlow-grass is an annual, herbaceous plant, up to one foot tall, with dense clusters of small, white flowers. In Arkansas, populations tend to occur in barrens or glades on very thin soil (approximately 1.5-inch-tall), often on rocky glade/barren margins; sites include shale barrens. Loss of glade habitat is a threat to the species.

The ovate-leaf catchfly (*Silene ovata*) is an Arkansas state threatened plant species that has confirmed elemental occurrence from Crawford and Pope counties in Region 4 of the Project and Pope, Conway, Van Buren, and Cleburne counties in Region 5. Its presence within the ROI for the Applicant Proposed Route or the HVDC alternative routes cannot be confirmed without species specific surveys in these areas. The ovate-leaf catchfly is a state listed endangered species in Tennessee and is reported from Shelby County in Region 7. Ovate-leaf catchfly is a perennial herb approximately 2 to 6 inches tall, with opposite leaves that are rare throughout its range. It occurs in a variety of open or forested sandy or pebbly habitats including floodplains. Threats include logging, grazing (deer and feral hogs), trampling, road construction, and ROW maintenance. Soil disturbance is likely to have a negative effect on this species due to the resultant erosion.

The small-head pipewort (*Eriocaulon koernickianum*) is a state-listed endangered plant species. It is a small annual with a leafless flowering stem, approximately 2 to 3 inches tall, arising from a tuft of grass-like leaves. It has confirmed elemental occurrence in Arkansas in Franklin, Johnson, and Pope counties in Region 4 and Pope, Conway, and Van Buren counties in Region 5. Its presence within the ROI for the Applicant Proposed Route or the HVDC alternative routes cannot be confirmed without species specific surveys in these areas. In the western part of its range, including Arkansas, the small-head pipewort is found in or near sandy, permanently moist to wet acidic seepage areas, particularly upland sandstone glade seeps and sandy hillside seeps; in hillside seepage bogs, particularly the less densely vegetated, sandy bog margins; and (rarely) in wet prairies. Plants tend to occur in sparsely vegetated areas rather than among dense vegetation; the species is considered intolerant of shade and is probably early successional. Habitat loss resulting from wetland draining is a serious threat. Natural disturbances, such as periodic fire, are necessary to ensure this species' persistence via removal of competing vegetation.

Whorled dropseed (*Sporobolus pyramidatus*) is a grass species listed as threatened in the state of Arkansas. It has confirmed elemental occurrence from Franklin County in Region 4. Its presence within the ROI for the Applicant Proposed Route or the HVDC alternative routes cannot be confirmed without species specific surveys in these areas. Whorled dropseed is a warm season, tufted perennial grass typically growing from 4–19 inches in height. It grows in open, disturbed sites on sandy, saline and alkaline soil types. Its distribution includes Kansas to Colorado, south Texas, Louisiana, and Arizona, and in southern Florida (NRCS 2014). Whorled dropseed has a conservation rank in Arkansas of S2, which means the species is thought to have 6 to 20 element occurrences within the state (NatureServe 2014b; Kartesz 1999).

American ginseng (*Panax quinquefolius*) is not listed as federally threatened or endangered under the Endangered Species Act (ESA), nor is it a state-listed threatened or endangered species in Arkansas. However, this species does have commercial value, and as such, the state of Arkansas does require licensing and regulation for persons engaged in harvesting the plant. Additionally, the USFWS regulates the export of American ginseng under the Convention on International Trade in Endangered Species of Wild Fauna and Flora (USFWS 2015).

3.17.5.4.3 Noxious Weeds

Region 4 straddles the border between Oklahoma and Arkansas. Oklahoma has three listed noxious weeds, as discussed under Region 1, of which only musk thistle is confirmed in Sequoyah County, Oklahoma (Region 4). The ROI does traverse this county.

Thirty-eight noxious weeds are listed for Arkansas. Seventeen of the state-listed noxious weeds are confirmed in the four counties crossed by the ROI in Region 4 (Table 3.17-5).

Table 3.17-5:
Arkansas Listed Noxious Weeds-Region 4 (by County crossed within the ROI)

Common Name	Scientific Name	Crawford	Franklin	Johnson	Pope
Balloonvine	*Cardiospermum halicacabum*	X

3.17.5.5 Region 5

3.17.5.5.1 Ecoregional Descriptions

Region 5 is referred to as the Central Arkansas Region and includes the Applicant Proposed Route and HVDC Alternative Routes 5-A through 5-F. Annual precipitation in Region 5 is approximately 50 inches. Forested cover types are common in Region 5 and include deciduous (oak-hickory), mixed (oak-pine), and evergreen (pine). The pasture/hay cover type also is prevalent throughout the ROI. Grassland/herbaceous land cover types are not as common in Region 5 but comprise mostly tall grass species. In Region 5, the ROI traverses forested areas that are interspersed with waterways, such as the Illinois Bayou, and open pasture lands. From Route 105 to Route 95, the ROI traverses large tracts of forested lands and riparian corridors. As Region 5 continues through Conway, Van Buren, Faulkner, Cleburne, and White counties, the ROI consists of an evenly distributed mosaic of forested lands and open lands. In White County, the ROI crosses the Little Red River and its relatively wide riparian corridor. As the ROI continues northeast and into Jackson County, there are large contiguous tracts of forested lands, as well as areas of agriculture and pasture land. An abrupt change in land cover is evident near U.S. Route 67. To the west of U.S. Route 67, lands are largely forested, while to the east, as the ROI enters the floodplain of the White River, land use shifts to agricultural uses, with sparse forested areas that are associated with small creeks.

Five route variations to the Applicant Proposed Route were developed in Region 5 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.5. The variations are illustrated in Exhibit 1 of Appendix M. Link 1, Variation 2, would have 36 acres of pasture/hay and 295 acres of forest. Link 2, Variation 2, would have 58 acres of forest land and 8 acres of total agricultural and open lands, and more forested land than the ROI for Applicant Proposed Route Link 2. Links 2 and 3, Variation 1, would have 10 acres of grassland/herbaceous cover and 237 acres of forest. It should be noted that a route adjustment was made for HVDC Alternative Route 5-B to maintain an end-to-end route with Links 2 and 3, Variation 1. The route adjustment for HVDC Alternative Route 5-B features 18 acres of pasture/hay and 105 acres of forested lands. Links 3 and 4, Variation 2, would have 91 acres of pasture/hay and 362 acres of forest lands. It should be noted that a route adjustment was made for HVDC Alternative Route 5-E to maintain an end-to-end route with this proposed variation. The HVDC route adjustment for Alternative Route 5-E would have 16 acres of pasture/hay and 58 acres of forested land. Link 7, Variation 1, would feature 59 acres of pasture/hay and 52 acres of forest.

3.17.5.5.2 Special Status Plants

Special status plant species potentially occurring in the ROI in Region 5 in Arkansas are listed in Table 3.17-6.

Table 3.17-6:
State and Federally Designated Threatened and Endangered Plants Potentially Occurring in the ROI in Region 5 (by County)

Common Name	Scientific Name	Listing Status	Counties of Occurrence in the Region
Alabama snow-wreath	*Neviusia alabamensis*	ST	Pope, Faulkner
Appalachian filmy fern	*Trichomanes boschianum*	ST	Cleburne
Bicknell's sedge	*Carex opaca*	SE	Faulkner
Dwarf bristle fern	*Trichomanes petersii*	ST	Pope, Conway
French's shooting-star	*Primula frenchii*	ST	Cleburne
Interrupted fern	*Osmunda claytoniana*	ST	Pope
Open-ground Whitlow-grass	*Draba aprica*	ST	Pope, Faulkner
Ovate-leaf catchfly	*Silene ovata*	ST	Pope, Conway, Van Buren, Cleburne
Pondberry	*Lindera melissifolia*	FE/SE	Jackson, Poinsett
Purple fringeless orchid	*Platanthera peramoena*	ST	Faulkner, White
Small-head pipewort	*Eriocaulon koernickianum*	SE	Pope, Conway, Van Buren
Southern tubercled orchid	*Platanthera flava*	ST	Conway
Tall cinquefoil	*Drymocallis arguta*	ST	Faulkner

Key: FE = Federally Endangered SE = State Endangered ST = State Threatened
Source: ANHC (2014b)

Many of the Arkansas state listed plant species that occur in Region 5 also occur in Region 4. Those species are discussed in Section 3.17.5.4 under Region 4 special status plants. The species that do not occur in the regions previously discussed are described here.

The federally endangered plant species pondberry (*Lindera melissifolia*) has confirmed element occurrence in Jackson and Poinsett counties, Arkansas, but no species-specific surveys have been undertaken to document the presence or absence within the ROI in Regions 5, 6, or 7. Pondberry is a strongly aromatic shrub that grows in seasonally flooded wetlands and along the margins of ponds, depressions, and bogs (eFlora 2013; Devall et al. 2001). Exact census counts of this species are lacking; however, Arkansas has confirmed 10 populations (DeLay et al. 1993). The state of Arkansas has protected areas, known as "Natural Areas," for pondberry within two counties crossed by the ROI. Swifton Sand Ponds Natural Area is located in Jackson County, and St. Francis Sunken Lands Natural Area is located in Poinsett County (ANHC 2009). Neither of these locations, however, is within the ROI.

Some populations of pondberry can appear quite large, but they may in fact be groupings of clones that produce numerous stems (Devall et al. 2001); this characteristic could add to the pondberry's vulnerability. Pondberry has been rarely confirmed historically. This plant has been adversely affected by logging, wetland drainage, road construction, and habitat conversion (Pittman 1993). Other threats include over-spray of herbicides from adjacent agricultural operations and pollution of ponds by pesticides and fertilizers associated with farming practices (LDWF 2013).

Dwarf bristle fern (*Trichomanes petersii*), listed by the state of Arkansas as threatened, is a rare mat-forming fern resembling a moss with leaves that vary in size from approximately 0.2 inch to 1 inch in length. The dwarf bristle fern inhabits moist, sheltered rocks, predominantly sandstones, where the surrounding air is perpetually moist. In Region 5, the dwarf bristle fern is known from Pope and Conway counties.

French's shooting-star (*Primula frenchii*) is a state listed threatened plant species in Arkansas that occurs in Cleburne County in Region 5. French's shooting-star is a perennial herbaceous species that typically grows as a pioneer species, protected beneath sandstone overhangs, preferring north and east-facing exposures. The species grows in habitats that yield little competition from other plant species, often growing alone in bare soil. In Arkansas, it is found occasionally in large numbers in areas that have not been impacted by timber management. Removal of large shade trees negatively affects the species.

The purple fringeless orchid (*Platanthera peramoena*) is listed as threatened in the state of Arkansas and occurs in Faulkner and White counties in Region 5. It grows in moist forests, woodlands, meadows, and thickets, as well as in marshes and swamps. The purple fringeless orchid appears to benefit from natural disturbances that reduce overhead tree canopies and results in more light. The species has a restricted habitat, making it especially vulnerable to land-use conversion, habitat fragmentation, and forest management practices.

The southern tubercled orchid (*Platanthera flava*) is a state threatened species in Arkansas and occurs in Conway County in Region 5. The southern tubercled orchid occurs on sandy silt alluvium and rotting logs in bottomland (floodplain) forest and wet thickets. It also occurs in wet-mesic prairies and wet meadows. This species is threatened by habitat loss, especially in floodplain forests and wet prairies. The primary threat to the southern tubercled orchid is the destruction of wetland habitat through development, logging, drainage, beaver activity, and other hydrologic alterations. Also threatening to this species are over-collection of orchids, excessive grazing, and successional overgrowth of habitats by woody species.

Tall cinquefoil (*Drymocallis arguta*) is member of the rose family that is listed as threatened by the state of Arkansas. The species is reported from Faulkner County in Region 5. The herbaceous species can reach 3 feet in height. Little information is available for tall cinquefoil in Arkansas but in other locations is considered a prairie species on well-developed soils. Habitat conversion and disturbance is a potential threat.

American ginseng (*Panax quinquefolius*) is not listed as federally threatened or endangered under the Endangered Species Act (ESA), nor is it a state-listed threatened or endangered species in Arkansas. However, this species does have commercial value, and as such, the state of Arkansas does require licensing and regulation for persons engaged in harvesting the plant. Additionally, the USFWS regulates the export of American ginseng under the Convention on International Trade in Endangered Species of Wild Fauna and Flora (USFWS 2015).

3.17.5.5.3 Noxious Weeds

Arkansas has 43 listed noxious weeds. Sixteen of the 43 state-listed noxious weeds are confirmed to occur in the seven counties crossed by the ROI in Region 5 (Table 3.17-7).

Table 3.17-7:
Arkansas-Listed Noxious Weeds-Region 5 (by County Crossed within the ROI)

Sources: Arkansas Plant Board (2014b), CISEH (2013)

3.17.5.6 Region 6

3.17.5.6.1 Ecoregional Descriptions

Region 6 is referred to as the Cache River and Crowley's Ridge Region and includes the Applicant Proposed Route and HVDC Alternative Routes 6-A through 6-D. Annual precipitation in Region 6 is approximately 50 inches. Region 6 occurs almost entirely within the Mississippi Alluvial Plain ecoregion. This ecoregion is fairly level and therefore provides good agricultural land. Agricultural crops (e.g., rice [*Oryza sativa*], soybeans [*Glycine max*], cotton [*Gossypium* spp.], corn [*Zea mays*], and wheat [*Triticum aestivum*]) represent a major cover type with Region 6. Because of the high precipitation levels, forest types that are present include deciduous and mixed types interspersed among the agricultural land or along riparian corridors. The western portion of the ROI is similar to the eastern end and consists of agriculture land with sloughs and narrow riparian corridors that continue to Route 37. In Region 6, the ROI traverses the Cache River, including its densely forested riparian corridor and associated wetlands. Immediately after traversing the forested areas of the Cache River, land use abruptly changes to agriculture and pasture lands and transitions to small forested areas that intersect Crowley's Ridge, which is densely forested with deciduous species (oak-hickory). Crowley's Ridge is a remnant elevated plain covered in loess soils and is part of the Mississippi Valley Loess Plains ecoregion. East of Crowley's Ridge, the ROI consists of agriculture and open land. Because Region 6 is located in the Mississippi Alluvial Plain ecoregion with a relatively high water table, woody wetlands, areas dominated by hydrophytic tree species with periodically saturated soils or standing water, also are more common.

One route variation was developed to the Applicant Proposed Route in Region 6 in response to public comments on the Draft EIS. The route variation is described in Appendix M and summarized in Section 2.4.2.6. The variation is illustrated in Exhibit 1 of Appendix M. These variations represent minor adjustments to land cover within the ROI. Link 2, Variation 1, would have 274 acres of cultivated crop lands and 6 acres of urban/developed lands. It should be noted that a route adjustment was made for HVDC Alternative Route 6-A to maintain an end-to-end route with Link 2, Variation 1. The route adjustment for HVDC Alternative Route 6-A would have 1,574 acres of cultivated crops and 62 acres of urban/developed lands compared with the original HVDC Alternative Route 6-A.

3.17.5.6.2 Special Status Plants

Bicknells's sedge and pondberry, described under Regions 4 and 5 respectively, have documented element occurrence in Jackson and Poinsett counties, Arkansas (Table 3.17-8). No species-specific surveys have been conducted for these two species within the Applicant Proposed Route or the HVDC alternative routes in the ROI in Region 6. These two species also have documented element occurrence in previously discussed regions of the Project.

Table 3.17-8:
State and Federally Designated Threatened and Endangered Plants Potentially Occurring in the ROI in Region 6 (by County)

Common Name	Scientific Name	Listing Status	Counties of Occurrence in the Region
Bicknell's sedge	*Carex opaca*	SE	Poinsett
Pondberry	*Lindera melissifolia*	FE/SE	Jackson, Poinsett

Key: FE = Federally Endangered SE = State Endangered
Source: ANHC (2014a)

American ginseng (*Panax quinquefolius*) is not listed as federally threatened or endangered under the Endangered Species Act (ESA), nor is it a state-listed threatened or endangered species in Arkansas. However, this species does have commercial value, and as such, the state of Arkansas does require licensing and regulation for persons engaged in harvesting the plant. Additionally, the USFWS regulates the export of American ginseng under the Convention on International Trade in Endangered Species of Wild Fauna and Flora (USFWS 2015).

3.17.5.6.3 Noxious Weeds

Arkansas has 43 designated noxious weeds. Fifteen of the 43 state-listed noxious weeds are confirmed to occur in the three counties crossed by the ROI in Region 6 (Table 3.17-9).

Table 3.17-9:
Arkansas-Listed Noxious Weeds—Region 6 (by County crossed within the ROI)

Common Name	Scientific Name	Poinsett	Mississippi	Cross

3.17.5.7 Region 7

3.17.5.7.1 Ecoregional Descriptions

Region 7 is referred to as the Arkansas Mississippi River Delta and Tennessee Region and includes the Applicant Proposed Route, HVDC Alternative Routes 7-A through 7-D, and the Tennessee Converter Station Siting Area and AC Interconnection Tie. The majority of the ROI in Arkansas consists of Mississippi River floodplain (Mississippi Alluvial Plain ecoregion), which is predominantly used for agricultural crops (e.g., rice, soybeans, and cotton). Annual precipitation is about 50 inches. The Project crosses the Mississippi River in Region 7. Immediately adjacent to the river is riparian forest. Woody wetlands are also relatively common in the region because of the high water table and precipitation, but they are patchy in distribution, so the routes may vary in the amount of wetlands within the ROI. Shrub/scrub cover types also may be more prevalent in Region 7 and in many cases may represent woody successional communities in areas that have been disturbed by human activities or periodic flooding. The eastern end of Region 7, where the Project terminates, is in Tennessee and occurs in the Mississippi Valley Loess Plains ecoregion. Vegetation is a mixture of cultivated land (crops and pasture/hay) and forests (deciduous and mixed).

Three route variations to the Applicant Proposed Route were developed in Region 7 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.7. The variations are illustrated in Exhibit 1 of Appendix M. Link 1, Variation 1, would feature 98 acres of cultivated crops. Link 1, Variation 2, would have 402 acres of cultivated crop lands and 21 acres of urban/developed lands Link 5, Variation 1, would have 56 acres of cultivated crops and 27 acres of forested lands.

3.17.5.7.2 Special Status Plants

Two special status plant species, Bicknell's sedge and pondberry, have documented element occurrence in Poinsett County in Arkansas (Table 3.17-10). Pondberry was discussed in detail in Region 5 and Bicknell's sedge was discussed in Section 3.17.5.4 for Region 4.

Table 3.17-10:
State and Federally Designated Threatened and Endangered Plants Potentially Occurring in the ROI in Region 7—Arkansas

Common Name	Scientific Name	Listing Status	Counties of Occurrence in the Region
Bicknell's sedge	*Carex opaca*	SE	Poinsett
Pondberry	*Lindera melissifolia*	FE/SE	Poinsett

FE = Federally Endangered SE = State Endangered
Source: ANHC (2014a)

No plants designated as threatened or endangered under the ESA occur in the portion of the ROI for the Applicant Proposed Route or the HVDC alternative routes in Region 7 in Tennessee (USFWS 2013a, 2013b, 2013c, 2014). State-designated plant species have been confirmed in Shelby and Tipton counties, Tennessee (TDEC 2014). Table 3.17-11 identifies these special status plant species and documents the counties in Tennessee in which they occur.

Table 3.17-11:
State-Listed Threatened and Endangered Plants Potentially Occurring in the ROI in Region 7—Tennessee

Common Name	Scientific Name	Listing Status	Shelby County	Tipton County

Earleaved false-foxglove	*Agalinis auriculata*	SE		X
Nodding rattlesnake-root	*Prenanathes crepidinea*	SE	X	X
Ovate-leaf catchfly	*Silene ovata*	SE	X	
Red starvine	*Schisandra glabra*	ST	X	X
Sweetbay magnolia	*Magnolia virginiana*	ST	X	

SE = State Endangered, ST = State Threatened
Source: TDEC (2014)

No species-specific field surveys for pondberry or any state-listed species in Arkansas or Tennessee have been undertaken to date within the ROI for the Applicant Proposed Route or the HVDC alternative routes in Region 7.

Copper iris (*Iris fulva*) is a state threatened species in Tennessee and has documented element occurrence in Shelby County, Tennessee. The copper iris is a perennial plant that grows from a rhizome. Habitats include wetlands and bottomland forests. Primary threats include habitat conversions and alteration of wetland hydrology.

The earleaved false-foxglove (*Agalinis auriculata*) is an annual herbaceous plant up to approximately 36 inches tall. It occurs primarily in mesic to dry prairies, fallow fields, tallgrass prairies, prairie-like glades and barrens. It is listed as endangered by the state of Tennessee and has been reported in Tipton County in Region 7 of the Project. Tennessee's Rare Plant Protection and Conservation Act requires persons to obtain written permission from a landowner or manager before knowingly removing or destroying state-listed endangered plant species. Primary threats for this species include habitat conversion, repeated mowing, and succession to woody species.

Nodding rattlesnake-root (*Prenanathes crepidinea*) is considered a state endangered plant species in Tennessee and reported from Shelby County in Region 7. It is a herbaceous perennial plant that is associated with wooded floodplains. Primary threats include changes to stream hydrology, logging of floodplain forests, and conversion to agriculture.

Red starvine (*Schisandra glabra*) is a twining, woody vine with deciduous leaves and occurs in locations in western Tennessee along loess bluffs in counties bordering the Mississippi River, including Shelby County in Region 7 of the Project. Red starvine is considered a threatened species by the state of Tennessee. Primary habitat includes moist woods in bottomlands or in the bluffs along creeks and rivers in sandy-silt-loam soils. Threats include competition from non-native invasive species such as Japanese honeysuckle, land use conversions, and forest management practices.

The sweetbay magnolia (*Magnolia virginiana*) is classified as a threatened species by the state of Tennessee, although it is relatively common in other regions in the eastern and southern United States. It is typically a shrub or small tree, evergreen to partly deciduous. The sweetbay magnolia has been reported in Shelby County in Region 7. The species is most common in wet woods, swamps, bogs, and floodplains. Primary threats include land use conversions and alteration of hydrology regimes.

American ginseng (*Panax quinquefolius*) is not listed as federally threatened or endangered under the Endangered Species Act (ESA), nor is it a state-listed threatened or endangered species in Tennessee. However, this species does have commercial value, and as such, the state of Tennessee does require licensing and regulation for persons engaged in harvesting the plant. Additionally, the USFWS regulates the export of American ginseng under the Convention on International Trade in Endangered Species of Wild Fauna and Flora (USFWS 2015).

3.17.5.7.3 Noxious Weeds

Tennessee has 14 designated noxious weed species (TDA 2007). Of this total, seven species are confirmed from counties crossed by the ROI (CISEH 2014). Table 3.17-12 presents the Tennessee noxious weed county occurrences.

Table 3.17-12:
Tennessee-Listed Noxious Weeds-Region 7 (by County crossed within the ROI)

Common Name	Scientific Name	Tipton	Shelby
Amur honeysuckle	*Lonicera maackii*		X
Autumn olive	*Elaeagnus umbellata*		X
Chinese privet	*Ligustrum sinense*	X	X
European privet	*Ligustrum vulgare*		X

Multiflora rose	*Rosa multiflora*	X	X
Thorny olive	*Elaeagnus pungens*		X

Sources: TDA (2007), CISEH (2014)

3.17.5.8 Connected Actions

3.17.5.8.1 Wind Energy Generation

The land cover in each WDZ is summarized in Section 3.10. The ecoregional description and dominant vegetation types within the WDZs are the same as that of Region 1.

3.17.5.8.2 Optima Substation

The future Optima Substation would be constructed on approximately 160 acres partially within the area identified on Figure 2.1-3 in Appendix A as the AC Interconnection Siting Area. The land cover in the future Optima substation location is primarily grassland herbaceous, with some shrub/scrub and developed, open space. There are no structures or existing infrastructure on the 160-acre site, although there are roads and an operating wind farm nearby. Irrigated cropland is also in the vicinity.

3.17.5.8.3 TVA Upgrades

The ROI for the direct assignment facilities (which are included in the Applicant Proposed Project) would occur within the Tennessee Converter Station Siting Area and more specifically within the Shelby Substation. The ROI for the network upgrades, and in particular TVA's future 500kV transmission line, cannot be fully determined at this time. The new 500kV line would be in western Tennessee. The upgrades to existing facilities would mostly be in western and central Tennessee. Upgrades to existing infrastructure would include upgrading terminal equipment at three existing 500kV substations and six 161kV substations, making appropriate upgrades to increase heights on 16 existing 161kV transmission lines to increase line ratings, and replacing the conductors on eight existing 161kV transmission lines. Where possible, general impacts associated with the required TVA upgrades are discussed in the sections that follow.

3.17.6 Impacts to Vegetation Communities and Special Status Plant Species

3.17.6.1 Methodology

3.17.6.1.1 Impact Calculations

Vegetation communities and special status plant species are assessed for impacts based upon the current understanding of Project construction detail, standard operations and maintenance details, and possible scenarios for decommissioning. This assessment quantifies impacts to vegetation resources using estimated facility dimensions and associated land requirements by Project component as defined in Chapter 2 and Appendix F. The analysis conservatively assumes that the typical width of the ROW—200 feet—would be cleared of existing vegetation during the construction of the transmission line. All values for acreage of impacts have been rounded to the nearest tenth of an acre.

3.17.6.1.2 Construction Impacts

Construction-related impacts to vegetation communities and special status plant species may be temporary, short-term, or long-term. The elements of the construction process that may cause impacts to vegetation communities and special status plant species include, but are not necessarily limited to, the following activities:

- Clearing and grading
- Placement of structural foundations
- Access road construction
- Excavation for grounding wires, fiber optic regeneration cables, and transmission line structural foundations
- Blasting
- Herbicide use
- Hazardous materials handling

In terms of duration of impacts, the potential for temporary or short-term impacts to vegetation communities and special status plant species from construction activities include:

- The mechanical damage to vegetation by heavy machinery.
- The compaction of soils on temporary construction laydown yards or temporary access roads, thereby reducing the soil's water-holding capacity and inhibiting plant growth.
- The alteration of hydrology from access road construction, which could affect plant growth. Impacts could be positive or negative depending on the type and duration of alteration.
- The contamination of vegetation from herbicide drift or runoff, and from accidental spills of hazardous substances, such as fuels and lubricants. These impacts may stunt plant growth or inhibit the onset of growth.

The potential long-term impacts to vegetation communities and special status plant species from Project construction include:

- Removal of vegetation by excavation for structure foundations.
- Removal of vegetation during construction of access roads.
- Long-term conversion of forests and shrublands to herbaceous cover type within the transmission ROW; this impact includes the effects of habitat fragmentation such as reduced gene flow, susceptibility to blow-down, and competition by invasive species.
- Introduction of invasive species from construction equipment or spread of existing invasive species on newly cleared land. Invasive species can compete with native vegetation and could result in long-term change to vegetation community diversity and structure.

A more detailed discussion of the potential impacts to vegetation communities and special status plant species from specific construction activities and the corresponding proposed avoidance and minimization measures are discussed in the following sections. Unless otherwise specified, the discussion of impacts provided below is common to all components of the Project, including converter stations and AC interconnections, the HVDC transmission line, AC collection system transmission lines, access roads, multi-use construction yards and other temporary construction areas, and communications sites. In cases where a specific component's impact may vary, additional detail is provided to distinguish between components.

3.17.6.1.2.1 Clearing and Grading

The analysis conservatively assumes that construction within the typical width of the ROW—200 feet—would disturb existing vegetation either by removing it or by causing mechanical damage to it during the construction process. Grading, on the other hand, is expected to be much more focused in scope. Grading activities would likely take place at specific construction sites for structure foundations along some portion of the Project access road system, and at the converter station sites. Direct impacts would include removal of vegetation, mechanical damage to vegetation, the potential modification of plant community structure (e.g., removal of trees or shrubs and conversion to grassland/herbaceous land cover), and indirect impacts from compaction of soils and the resulting potential for increased erosion. Specific impacts are discussed below.

3.17.6.1.2.1.1 Removal of Vegetation

The removal of vegetation, as described in this section, includes blading or digging to physically remove plants, and also mechanical damage to plants that results in loss of vigor or death (e.g., crushing of above- and belowground biomass as heavy machinery or other equipment moves over the surface or is stored on the surface). Removal of vegetation can be either direct short-term or long-term impacts, depending on the vegetation cleared, and it would occur during clearing and grading activities. Removal of vegetation may be partial (e.g., aboveground tissue only) or complete. Vegetation removal can impact community structure and composition as well as alter soil moisture content and nutrient chemistry; however, impacts depend on the type and amount of vegetation removed and the rate of regeneration after construction. To reduce impacts from vegetation removal, the Applicant would minimize clearing of vegetation within the ROW (EPM GE-3) and would clearly demarcate (EPM FVW-3) and avoid or minimize impacts to environmentally sensitive vegetation (EPM FVW-1).

The greatest amount of localized vegetation removal would occur at the converter station sites, which would be long term in duration. Desktop analysis has not confirmed any special status plant species within the Oklahoma Converter Station Siting Area. The Oklahoma Converter Station Siting Area is predominately introduced vegetation. Similarly, the Tennessee Converter Station Siting Area is half cultivated cropland and half wooded areas, and no confirmed special status plant species are within this siting area based on desktop analysis. The ROI for the Arkansas Converter Station Alternative Siting Area includes the Cherokee WMA, but this WMA would not be considered a candidate for converter station siting. Wooded areas are present within the Arkansas Converter Station Alternative Siting Area, but much of the area has been cleared for pasture. Therefore, with the implementation of EPMs GE-6, FVW-1, and FVW-3, impacts from vegetation clearing at the converter station sites would be limited in size and would not involve the removal of environmentally sensitive plant species.

In contrast to the more localized vegetation removal at the converter station siting areas, vegetation removal at HVDC or AC structure footprints, along access roads, and in conjunction with temporary workspaces would be dispersed over a larger area. Although vegetation removal at structure footprints and along access roads would likely be long-term, vegetation along the remainder of the ROW and temporary access roads would be allowed to grow back to within certain parameters (i.e., height thresholds for transmission line safety). Conversion of forest along the transmission line ROWs would be considered a long-term impact, while clearing of forested areas for temporary work spaces would be considered a long-term impact. Where access occurs using overland driving instead of via existing improved or constructed roads, vegetation could be crushed, and although root materials would remain intact, allowing the vegetation to regenerate, this could also lead to the spread of invasive plants and noxious weed species, as discussed below. Therefore, the Applicant would restrict vehicular travel to the ROW and other established areas (EPM GE-6) to reduce this impact. Considering the dispersal of impacts over a larger region, these long-term impacts are considered to be minor.

3.17.6.1.2.1.1.1 Erosion

Removal of vegetation exposes topsoil to water and wind erosion. Removal of vegetation during Project construction could result in local erosion. Erosion can then cause increase runoff that removes downgradient vegetation or that causes sediment deposition over existing downgradient vegetation. Additionally, erosion could alter existing drainage patterns and affect vegetation resources that are not normally located in areas of flow. Minimizing vegetation removal, per EPM GE-3, would reduce the extent of erosion. In addition, the Applicant would develop and implement an SWPPP to ensure that both direct and indirect impacts related to erosion are minimized.

3.17.6.1.2.1.1.2 Fragmentation

Removal of vegetation during construction of the Project could result in habitat fragmentation. Habitat fragmentation is the physical separation of larger blocks of habitat into smaller blocks with newly created edge exposed. This fragmentation effect can occur naturally, or it can result from manmade actions. There is some degree of existing habitat fragmentation created by previous development that includes roads, oil and gas pipelines, and transmission lines that are already influencing the landscapes over which this Project would be built. Impacts resulting from vegetation removal within grassland and shrub communities, outside the footprint of the Project facilities and structures, would be short-term and less likely to contribute to long-term habitat loss, fragmentation, and degradation because these communities would be allowed to reestablish themselves following construction.

Habitat fragmentation in forested ecosystems is more visible, and its impact may be more pronounced. The construction of ROW corridors through forested tracts would create new, long edge habitats, susceptible to invasion by noxious weeds and other non-native vegetation species. As previously stated, the Applicant would minimize clearing of vegetation (EPM GE-3); however, if overstory vegetation were removed within forested ecosystems, these areas would not be allowed to reestablish following construction within the ROW due to the need to maintain the ROW for operational safety and system reliability, which would contribute to long-term habitat loss, fragmentation, and degradation. Forested vegetation could also be removed during construction in select tensioning and pulling sites, at temporary workspaces, and for temporary access roads. This vegetation would be allowed to reestablish following construction, but the recovery time would likely result in this activity being a long-term impact to vegetation resources.

3.17.6.1.2.1.1.3 Edge Effects

As described in the previous subsection, vegetation removal during the construction phase may result in habitat fragmentation, which exposes or creates new “edge” habitat, especially pronounced in forested areas. The creation of edge effects could increase competition among plant species due to changes in microclimate (e.g., increased light levels, decreased humidity, increased wind effects, etc.). This indirect impact would be long-term; however, per EPM FVW-1, the Applicant would avoid and/or minimize impacts on environmentally sensitive vegetation such that edge effects would be reduced.

3.17.6.1.2.1.1.4 Noxious Weeds

Invasive plant species and state listed noxious weeds occur within many counties in the ROI. The direct impact of removing vegetation can lead to the indirect impact of establishment of invasive plant species and listed noxious weeds, which can impact habitat quality by replacing native species. Replacement of native species, in turn, can lead to increased erosion, changes in soil nutrients, and lowering of existing wildlife habitat values.

Vegetation removal and soil disturbance during the construction phase of the Project would create disturbed substrates ideally suited to noxious weed establishment. EPMs GE-3 and FVW-2 (minimization of the spread of invasive species and noxious weeds) would reduce this impact. Additionally, construction vehicles and materials could disperse invasive plant seeds, resulting in their spreading and/or establishment in areas that may not have previously contained any invasive species. However, as stated above, restricting vehicular travel to the ROW and other established areas, per EPM GE-6, would also help to reduce this impact.

The Applicant would identify and implement measures to control and minimize the spread of non-native invasive species and noxious weeds based upon EPM FVW-2.

3.17.6.1.2.1.1.5 Soil Compaction

Construction of the Project would require the use of heavy equipment, which could cause soil compaction within the ROW and along access roads. Soil compaction could occur throughout the entire ROW for the ROI. Compaction of soils reduces pore space and soil aeration, decreasing soil permeability, thereby increasing runoff and altering water flow. This can alter vegetative communities and their ability to reestablish following construction. The Applicant would minimize compaction through appropriate use of construction equipment (EPM GE-27) and would develop and implement a restoration plan that would describe post-construction activities to reclaim disturbed areas not required for the operations and maintenance activities.

3.17.6.1.2.1.1.6 Herbicide Use

The Applicant would likely apply herbicides selectively to stumps and low-growing brush during clearing of the ROW. There would be mortality of targeted plant species that need to be removed. There would also be the potential for this type of activity to include accidental herbicide overspray and drift. Such an occurrence may cause adverse toxic effects to non-targeted terrestrial and aquatic vegetation, depending upon the type of herbicide used and the concentration. Impacts to non-targeted individual plants may be severe enough to cause mortality, whereas overall plant community impact may be localized and much less severe. To minimize potential impacts during construction, the Applicant would apply herbicides according to all label instructions and any federal, state, and local regulations (EPM GE-5).

3.17.6.1.2.1.1.7 Fuel and Lubricant Handling

Accidental spills of harmful fuels and lubricants used during construction could have unintended direct impacts on vegetation. Materials present during construction that could harm or cause mortality to vegetation include fuels, lubricants, antifreeze, detergents, paints, solvents, herbicides, and potentially other toxic fluids. In addition to the direct impact to the vegetation, cleanup of spills could also require the removal and disposal of vegetation. The Applicant would develop and implement an SPCCP to prevent, control, and clean up spills. The Applicant would keep emergency and spill response equipment on hand during construction (EPM GE-13) and would restrict the refueling and maintenance of vehicles and the storage of fuels and hazardous chemicals from within at least 100 feet of wetlands and waterbodies (EPM GE-14). These measures would ensure that any inadvertent spills would be cleaned up promptly and that impacts, including the potential for loss of vigor or mortality to plants, would be kept to a minimum.

3.17.6.1.2.2 Vegetation Cover Types of Special Concern

This section specifically discusses potential impacts from the Project’s construction phase to vegetation cover types of special concern, including vegetation communities in designated conservation areas or sensitive habitats identified in the ROI. The potential impacts to vegetation in wetlands and riparian areas are discussed in Section 3.19.

In general, the potential Project impacts from construction of the HVDC and AC transmission lines to special vegetation cover types would be similar to those discussed for general vegetation cover types. While the siting area for the Arkansas Converter Station Alternative does include the Cherokee WMA, the Applicant would specifically site this station outside the boundary of the WMA. Neither the Oklahoma nor the Tennessee converter station siting areas contain vegetation of special concern. As a result, no impacts to special status plant species are anticipated. Discussion of the potential construction impacts to vegetation communities within CRP lands are described under agricultural resources (Section 3.2).

3.17.6.1.2.2.1 Special Status Plant Species

Special status plant species are provided with special protection due to their rarity, uniqueness, and/or sensitivity. The USFWS has identified two federally protected plant species with potential to occur in the ROI. These two species are tinytim, which is federally listed as threatened, and pondberry, which is federally listed as endangered. Additional state-recognized special status plants may occur along the HVDC transmission line in Arkansas and Tennessee (as described for special status plants within Section 3.17.5).

Potential impacts to special status plant species from construction of the Project may include direct impacts from crushing by equipment or removal of federally or state-listed threatened or endangered plant species when clearing vegetation, and indirect impacts resulting from soil compaction from heavy construction equipment, which could inhibit water absorption and indirectly impact plant species survival. There may also be an increased potential for invasive plants and noxious weeds to encroach upon areas with special status plant species, causing short- and potentially long-term impacts to the plant communities in which the special status plants live. The use of herbicides to control noxious weed species could have the unwanted side effect of loss of non-target species, such as special status plants. Some potential for habitat fragmentation and edge effects exists in some plant communities in which special status plants may be found. Habitat fragmentation can lead to reduced gene flow within and between plant populations, reducing reproductive success for special status plants. Edge effects associated with habitat fragmentation can lead to special status plant species being outcompeted by early seral-stage plants that thrive in the edge environments. The edge position may also expose special status plants to more harsh or adverse microclimate conditions, reducing vigor or causing mortality.

The Applicant would plan and carry out special status plant surveys prior to any construction activities as necessary and appropriate. The Applicant would (EPMs FVW-1 and FVW-3) identify and clearly mark special status plant species such that impacts would be avoided and/or minimized to the maximum extent possible. The Applicant's Revegetation Plan would address the details of revegetating plant communities identified to contain special status plant species (EPMs FVW-1 and FVW-3).

3.17.6.1.3 Environmental Protection Measures

The Applicant has developed a comprehensive list of EPMs that would cover the measures necessary to avoid and minimize impacts to vegetation communities. Implementation of these EPMs is assumed throughout the impact analysis that follows for the Project. A complete list of EPMs for the Project is provided in Appendix F; those EPMs that would specifically minimize the potential for impact on vegetation and special status plant species are list below:

General EPMs relating to vegetation resources include the following:

- GE-3: Clean Line will minimize clearing vegetation within the ROW, consistent with a Transmission Vegetation Management Plan (TVMP) filed with NERC, and applicable federal, state, and local regulations. The TVMP may require additional analysis under NEPA depending on whether and under what conditions DOE decides to participate in the Project.
- GE-4: Vegetation removed during clearing will be disposed of according to federal, state, and local regulations.
- GE-5: Any herbicides used during construction and operations and maintenance will be applied according to label instructions and any federal, state, and local regulations.
- GE-6: Clean Line will restrict vehicular travel to the ROW and other established areas within the construction, access or maintenance easement(s).
- GE-7: Roads not otherwise needed for maintenance and operations will be restored to preconstruction conditions. Restoration practices may include decompacting, recontouring, and re-seeding. Roads needed for maintenance and operations will be retained.

Vegetation-specific EPMs included the following:

- FVW-1: Clean Line will identify environmentally sensitive vegetation (e.g., wetlands, protected plant species, riparian areas, large contiguous tracts of native prairie) and avoid and/or minimize impacts to these areas.
- FVW-2: Clean Line will identify and implement measures to control and minimize the spread of non-native invasive species and noxious weeds.
- FVW-3: Clean Line will clearly demarcate boundaries of environmentally sensitive areas during construction to increase visibility to construction crews.
- FVW-5: If construction occurs during important time periods (e.g., breeding, migration, etc.) or at close distances to environmentally sensitive areas with vegetation, wildlife, or aquatic resources, Clean Line will consult with USFWS and/or other resource agencies for guidance on seasonal and/or spatial restrictions designed to avoid and/or minimize adverse effects.

The Applicant would also develop and implement the following plans to avoid or minimize impacts to vegetation resources from construction, operations and maintenance, and/or decommissioning, as appropriate:

- Restoration Plan: This plan would describe post-construction activities to reclaim disturbed areas. This plan should include information on integrated weed management to identify current noxious weed infestations, treat those areas during construction, and periodically monitor and continue treatment of infestations as needed.
- Transmission Vegetation Management Plan (TVMP): This plan would describe how the Applicant would conduct work on its ROW to prevent outages due to vegetation. The TVMP may require additional analysis under NEPA depending on whether and under what conditions DOE decides to participate in the Project.

3.17.6.1.4 Operations and Maintenance Impacts

This section discusses potential impacts to vegetation resources associated with the operations and maintenance of Project converter stations and interconnects, HVDC and AC transmission lines, access roads, and fiber optic regeneration stations.

Operations and maintenance activities could impact vegetation resources, including special vegetation cover types, special status plant species, and noxious weeds. Potential impacts would include periodic maintenance of vegetation, soil compaction, introduction or spread of noxious weeds, and fire risk.

3.17.6.1.4.1 Vegetation Maintenance

The Applicant would maintain a 150- to 200-foot-wide typical ROW during operations and maintenance. Trees and brush would be periodically trimmed or removed within the ROW. Vegetation in the transmission ROW would be limited to low-growing vegetation to prevent interference with or damage to transmission lines. Vegetation management would be conducted as necessary to ensure compliance with NESC clearance requirements. The frequency of vegetation maintenance relates to the growth rates of the vegetation found within and near the ROW. More rapidly growing vegetation would require more frequent maintenance. In addition to vegetation maintenance of the ROW, minor trimming of woody vegetation may be required along access roads that are maintained for operations and maintenance activities. Maintenance activities are likely to result in periodic trampling of herbaceous vegetation. Maintenance vehicles would utilize established access roads to the extent practicable. Limited vegetation clearing could occur during Project operations and maintenance for any necessary repairs required for Project components. Impacts from vegetation clearing would be similar to those outlined for the construction phase.

Pursuant to NERC Reliability Standard FAC-003-2, prior to operation, the Applicant would create and implement a documented vegetation management strategy for the Project's permanent ROW to prevent vegetation-caused outages on the transmission system. The Applicant would develop a Vegetation Management Program (Vegetation Program) that will provide the framework for implementing treatments prescribed in the Project's Transmission Vegetation Management Plan (TVMP). The TVMP may require additional analysis under NEPA depending on whether and under what conditions DOE decides to participate in the Project.

The Vegetation Program will be based on established principles of Integrated Vegetation Management (IVM) for promoting and managing sustainable plant communities within transmission line ROWs that are compatible with safe, reliable operations and maintenance of the Project. The Project Description (Section 4.4 of Appendix F) describes how the Applicant will use management objectives described in the Vegetation Program to inform the Project's TVMP. The TVMP will define site-specific standards and action thresholds, measurable objectives and metrics; and prescribe controls or treatment options to achieve defined management objectives that support the Vegetation Program's overall goals of maintaining desirable plant communities and system reliability.

During development of the TVMP, the Applicant would solicit input from landowners or tenants (or other land managers as appropriate) as a key step when evaluating and selecting site-specific control methods for the TVMP. To accomplish this, the Applicant will utilize information obtained from landowners, tenants, and/or managers about specific land uses within their parcels to select control methods that best achieve the ROW management objectives at a specific site and address landowners' concerns. The Applicant would also work with landowners to clarify expectations for management objectives and to communicate the need for, benefits of, and scientific principles of IVM.

The Vegetation Program's goals, broad management objectives, and periodic progress reports are intended to be available and accessible to the general public or interested stakeholders upon request and/or through a project or corporate website. Opportunities for accessing these resources may include public or community education materials focused on IVM's objectives and its benefits. Consistent with common utility practice, the TVMP is a detailed plan and living document that will contain site-specific treatment measures that will be coordinated with a landowner. The TVMP may contain sensitive information that could be considered Critical Energy Infrastructure Information (as defined by FERC Order 630) and or personally-identifiable Information (such as name, address, or property maps) for landowners, and therefore general circulation may be limited in whole or in part.

3.17.6.1.4.2 Soil Compaction

Soil compaction during operations and maintenance of the Project could occur from inspection and maintenance vehicles. Impacts from soil compaction would be similar in nature, but less likely to occur in the same volume when compared to those outlined for the construction phase. Maintenance vehicles would stay on established access roads to the extent practicable, thereby minimizing additional soil compaction. The Applicant would minimize compaction of soils and rutting (EPM GE-27).

3.17.6.1.4.3 Introduction/Spread of Noxious Weeds

The periodic use of maintenance and inspection vehicles over a period of many years would increase the likelihood of introduction and spread of invasive plant species, including noxious weeds. This potential would be heightened after the initial construction phase when habitats such as forested tracts are newly fragmented and susceptible to invasion by noxious weeds. The threat would be lessened during operations through careful adherence to EPMs, including FVW-2.

3.17.6.1.4.4 Fire Risk

The operations and maintenance of an active electric transmission system presents an inherent fire risk. The greatest potential would result from uncontrolled growth of vegetation either within the ROW under live wires, or vegetation outside of the ROW, that could fall into energized lines. Uncontrolled wildfire could cause mortality to both the vegetation adjacent to the ROW and to vegetation resources located at greater distances, depending on several variables. Wildfires are a threat to all vegetation cover types, but especially damaging to forested ecosystems. The duration, intensity, and spatial extent of the impacts would vary according to the ambient conditions of local climate and of the vegetation itself.

Vegetation management would be conducted as necessary to ensure compliance with NERC clearance requirements. The frequency of vegetation maintenance relates to the growth rates of vegetation found within and near the ROW. More rapidly growing vegetation requires more frequent maintenance. The Applicant would develop and implement a TVMP describing vegetation maintenance schemes that specifically seek to minimize fire risk. The TVMP may require additional analysis under NEPA depending on whether and under what conditions DOE decides to participate in the Project.

3.17.6.1.5 Decommissioning Impacts

There is potential for the decommissioning of the Project to impact vegetation communities and special status plant species. Prior to any decommissioning activities, the Applicant would develop a Decommissioning Plan, for review and approval by appropriate state and federal resource agencies.

The Applicant would follow the same general and resource-specific EPMs during decommissioning that would be implemented during the construction and operations and maintenance phases of the Project. These measures would help to avoid and/or minimize impacts on vegetation communities and special status plant species.

At the end of the useful life of the facilities, decommissioning activities may include replacement of vegetation lost during construction. Potential impacts to vegetation communities and special status plant species during decommissioning are estimated to be similar to, but of less duration and severity, compared with the construction phase of the Project. It is assumed that the ROW would be allowed to revert back to pre-construction conditions, relieving the effects of habitat fragmentation, reducing or eliminating vehicle traffic and the issue of soil compaction, and reducing the threat of wildfire caused by transmission lines or maintenance vehicles in the ROW.

3.17.6.2 Impacts Associated with the Applicant Proposed Project

This section describes the potential impacts from the Project that would be common to the converter stations, AC interconnection, AC collection system, and Applicant Proposed Route. Impacts from the construction, operations and maintenance, and decommissioning phases of the Project are discussed separately by Project component.

3.17.6.2.1 Converter Stations and AC Interconnection Siting Areas

3.17.6.2.1.1 Construction Impacts

3.17.6.2.1.1.1 Oklahoma Converter Station Siting Area and Associated AC Interconnection Siting Area

The dominant vegetation for the siting area for the Oklahoma converter station is grassland and herbaceous cover (605 acres). Construction impacts for the Oklahoma Converter Station Siting Area and Associated AC Interconnection Siting Area were calculated using estimated facility dimensions and associated land requirements as described in Section 3.17.6.1. Construction of a single converter station is estimated to take 32 months. It is yet to be determined how many tubular (impact of 0.001 acre each), H-frame (impact of 0.002 acre each), and fiber optic (impact of 0.009 acre per control building) structures and how many tensioning areas outside the ROW (impact of 2.58 acres each) would be needed. The discussion below focuses on impacts related to the transmission lines; the lattice structures, which are assumed to be the primary structures used; and the tensioning area inside the 200-foot-wide representative ROW.

Forty-five to 60 acres of land would be cleared and graded for the station facility footprint, plus an additional 5 to 10 acres of land for the overall construction. The clearing and grading of the 45–60 acres would produce a long-term impact and the clearing, grading, and use of the additional 5–10 acres would produce a short-term impact. The latter would be revegetated using guidance within the Project's Restoration Plan. In addition, one 35-foot-wide by 1-mile-long all weather access road would be needed. Clearing and grading activities for the road would cause approximately 4 acres of long-term impact to current vegetation.

A maximum 200-foot-wide by 3-mile-long interconnection ROW would result in approximately 65.5 acres of long-term impacts, including the initial clearing of the existing vegetation. The structural footprint for the lattice structures would be 28 feet by 28 feet, equaling 784 square feet (0.02 acre) of vegetation removal. The maximum number of lattice structures would be 21, or less than 1 acre of long-term impact to vegetation.

Approximately four tensioning or pulling sites, 150 feet wide by 600 feet long, also would be required within the ROW, although it is estimated that 1 acre of the total will be located outside the ROW (2.0 acres each, minus 1 acre, for a total of 7 acres). Tensioning or pulling sites would be located partially outside the ROW at locations where the line turns more than 8 degrees, estimated at 1 acre.

Approximately 74 acres would be required for the Oklahoma converter station (including access road) and approximately 19 acres would be required for the Oklahoma AC interconnection during construction.

3.17.6.2.1.1.2 Tennessee Converter Station Siting Area and AC Interconnection Tie

The dominant vegetation for the 218 acre siting area for the Tennessee converter station includes cultivated crop lands (71 acres or 33 percent), pasture/hay (67 acres or 31 percent), and cultivated crops (44 acres or 20 percent).

Approximately 74 acres would be required for the Tennessee converter station (including access road). This acreage would be cleared and graded for the station facility. The clearing and grading of the 74 acres would produce a long-term impact. It is anticipated that any temporary construction areas would be contained within the footprint of the Tennessee converter station and the Shelby Substation. Any temporary impacts would be revegetated using guidance within the Project's Restoration Plan.

The AC interconnection tie to the Shelby Substation would be contained entirely within the converter station footprint and the Shelby Substation footprint and therefore not impact any additional vegetation.

3.17.6.2.1.2 Operations and Maintenance Impacts

3.17.6.2.1.2.1 Oklahoma Converter Station Siting Area and Associated AC Interconnection Siting Area

Vegetation removed during the construction of the converter station would not be replaced during the operations phase of the Project. Similarly, vegetation removed during the construction of the converter station access road would not be replaced during the operations and maintenance phase of the Project. Vegetation within the ROW of the AC interconnection would be maintained during the operations and maintenance phase of the Project in compliance with the TVMP. The TVMP may require additional analysis under NEPA depending on whether and under what conditions DOE decides to participate in the Project. The projected acreage of vegetation to maintain in the ROW is 65.5 acres.

3.17.6.2.1.2.2 Tennessee Converter Station Siting Area and Associated AC Interconnection Tie

Vegetation removed during the construction of the converter station would not be replaced during the operations phase of the Project. Similarly, vegetation removed during the construction of the converter station access road would not be replaced during the operations and maintenance phase of the Project.

3.17.6.2.1.3 Decommissioning Impacts

The decommissioning impacts related to the Project would be similar in nature to the set of temporary impacts resulting from initial construction of the Project. These temporary impacts would involve use of construction machinery at each of the two converter stations (i.e., Oklahoma and Tennessee). The specific acreages for the footprints of the two converter stations total a projected maximum of 120 acres that would be reclaimed and revegetated according to the details that would be written into the Decommissioning Plan. The total ROW acreage projected to be temporarily impacted again during decommissioning of the two sites would equal a maximum value of 70.3 acres. It is likely these temporary impacts would only be crushing or matting of some portion of the overall ROW at each of the two sites, and the vegetation would naturally recover. For those areas that are more severely impacted, reseeding with native vegetation species may be required according to the Decommissioning Plan.

3.17.6.2.2 AC Collection System

3.17.6.2.2.1 Construction Impacts

The AC collection system would consist of four to six 345kV lines, each extending up to 40 miles from the Oklahoma Converter Station. Within the 150–200-foot-wide ROW for each transmission line, an assembly area for the pole structures (whether lattice, tubular, or H frame, the assembly area footprint is the same) would be required. Each assembly area would be 150 feet wide by 150 feet long (0.5 acre) and five to seven assembly areas per mile would be required. Assuming 30 miles of AC collection lines, the total acreage of assembly areas would range between 765 and 1,071 acres. Total disturbance from the construction of access roads (inside and outside the ROW) for the AC collection system would be approximately 301 miles, or 669 acres.

Approximately six fiber optic regeneration sites would be required for the AC collection system. Each fiber optic regeneration site would be approximately 100 feet by 100 feet, with a fenced area of approximately 75 feet by 75 feet. The regeneration equipment would be enclosed in a small control building made of either metal or concrete, approximately 12 feet by 32 feet by 9 feet tall. An access road and power supply to the site would be required, but the same road would be used to access the transmission line, so those access road impacts are included in the impacts for the transmission line. Typically, these sites would be adjacent to or within 750 feet of the ROW. A total of approximately 3 acres of undeveloped land would be converted to a utility use for the six fiber optic regeneration sites anticipated to be required for the entire AC collection system.

Temporary work areas that would be required during construction include wire splicing sites and tensioning or pulling sites. One wire splicing site 100 feet by 100 feet (0.2 acre) would be required every 2 miles; assuming 150 sites, these would total 30 acres. A tensioning or pulling site 150 feet wide by 600 feet long (2 acres) would be required at least every 18,000 feet; assuming a total of 200 sites and 25 percent of these (50 sites) are located within the ROW, these would total 100 acres.

Assuming that the remaining 75 percent (150) of the tensioning or pulling sites would be located outside the ROW, they would add an additional 300 acres.

Additional temporary construction areas that would be required outside the ROW include multi-use construction yards and fly yards.

Multi-use construction yards would each be approximately 25 acres in size and would be located approximately 25 miles apart and typically within 10 miles of the ROW. Assuming the AC collection system requires approximately 15 multi-use construction yards, the total footprint would be 375 acres for all 15 yards. Fly yards would each require 10 to 15 acres each and would be located at approximately 5-mile intervals along the ROW and typically within 10 miles of the ROW. Assuming a total of 60 fly yards, 15 of which would be located within multi-use construction yards, 45 fly yards would have a total footprint of 450 to 675 acres. In total, approximately 3,223 acres would be required for the construction of the AC collection system, although construction would only occur in particular construction segments for a limited time.

Impacts would include temporary mowing and long-term removal of vegetation. Additional impacts to vegetation would be consistent with those described in Section 3.17.6.1.3. The duration of construction for the complete AC collection system will be approximately 24 months from mobilization to restoration. The land cover in the AC collection system representative ROW, by route, is summarized in Table 3.17-13. For each route, it is assumed that the entire acreage within the ROW would be temporarily disturbed during construction, although construction would not occur along the entire length of a route at the same time.

This page intentionally left blank.

Table 3.17-13:
Land Cover in the AC Collection System Representative ROW by Route

		Barren Land (Rock/Sand/Clay)	Cultivated Crops	Developed, High Intensity	Developed, Low Intensity	Developed, Medium Intensity	Developed, Open Space	Emergent Herbaceous Wetlands	Grassland/ Herbaceous	Open Water	Shrub/ Scrub	Woody Wetlands	Total

This page intentionally left blank.

3.17.6.2.2.2 Operations and Maintenance Impacts

3.17.6.2.2.2.1 Route E-1

The ROW for AC Collection System Route E-1 is dominated by grassland/herbaceous land cover (542.7 acres). This route does not feature any forested cover types in the ROW, but does cross 50.9 acres of shrub/scrub land cover. The operations and maintenance for AC Collection System Route E-1 may involve some degree of trimming and/or mowing in the ROW, but with no real change to the dominant cover types. The TVMP would govern the degree of maintenance that is required in the shrub-scrub cover type.

3.17.6.2.2.2.2 Route E-2

Grassland/herbaceous land cover is the dominant land cover type (574.2 acres) in the ROW for AC Collection System Route E-2. There are also 298.6 acres of cultivated crops land cover in the ROW. Both land cover types may have some trimming or mowing impacts from operations and maintenance of the Project with no change to the dominant cover type. No forested cover type is present in the 200-foot-wide ROW for AC Collection System Route E-2. There are 74.5 acres of shrub/scrub cover in the ROW that may require trimming and/or mowing over the operational life of the Project. This impact would not likely cause a change to cover type.

3.17.6.2.2.2.3 Route E-3

The ROW for AC Collection System Route E-3 is dominated by grassland/herbaceous land cover type (650.3 acres). It is unlikely that the operations or maintenance of the line would impact this land cover type or cause other adverse effects. No forested land cover is present in the ROW for AC Collection System Route E-3. Shrub/scrub land cover equals approximately 47.1 acres in the ROW and may require some degree of trimming or mowing during operations and maintenance with no change likely to the dominant cover type.

3.17.6.2.2.2.4 Route NE-1

AC Collection System Route NE-1 is almost equally dominated by cultivated crops (247.2 acres) and by grassland/herbaceous land cover (291.1 acres) in the ROW. Both land cover types may have impacts from trimming or mowing during operations and maintenance of the Project ROW with no change to the dominant cover type. No forested land cover is present in the ROW for AC Collection System Route NE-1. There are approximately 40.7 acres of shrub-scrub land cover in the ROW that may require trimming and/or mowing over the operational life of the Project. This impact would not likely cause a change to cover type.

3.17.6.2.2.2.5 Route NE-2

Grassland/herbaceous land cover is the dominant land cover type (450.2 acres) in the ROW for AC Collection System Route NE-2. The grassland/herbaceous land cover may have trimming and mowing impacts during operations and maintenance of the Project with no change to the dominant cover type. There is no forested land cover in the ROW for AC Collection System Route NE-2. There are 32.1 acres of shrub/scrub that may require trimming and/or mowing over the operational life of the Project. This impact would not likely cause a change to cover type.

3.17.6.2.2.2.6 Route NW-1

Grassland/herbaceous land cover is the dominant land cover type (609.5 acres) in the ROW for AC Collection System Route NW-1. There are also 540.2 acres of developed open space land cover in the ROW. The grassland/herbaceous land cover may have trimming and mowing impacts during operations and maintenance of the Project with no change to the dominant cover type. No forested land cover is present in the ROW for AC Collection System Route NW-1. There are 15.6 acres of shrub/scrub vegetation that may require trimming and/or mowing over the operational life of the Project. This impact would not likely result in a change to cover type.

3.17.6.2.2.2.7 Route NW-2

Grassland/herbaceous land cover (629.3 acres) is the dominant land cover type in the ROW for AC Collection System Route NW-2. There are also 410.9 acres of cultivated crops land cover in the ROI. Both the grassland/herbaceous and cultivated crop land cover may have trimming and mowing impacts during operations and maintenance of the Project with no change to the dominant cover type. No forested land cover is present in the ROW for AC Collection System Route NW-2. There are approximately 26.1 acres of shrub/scrub land cover that may require trimming and/or mowing over the operational life of the Project. This impact would not likely result in a change to cover type.

3.17.6.2.2.2.8 Route SE-1

Grassland/herbaceous land cover is the dominant land cover type (513.2 acres) in the ROW for AC Collection System Route SE-1. There are also 340.0 acres of cultivated crops land cover in the ROW. Both the grassland/herbaceous and cultivated crop land cover may have trimming and mowing impacts during operations and maintenance of the Project with no change to the dominant cover type. No forested land cover is present in the ROW for AC Collection System Route SE-1. Fifty-nine acres of shrub/scrub land cover located within the ROW may require trimming and/or mowing over the operational life of the Project. This impact would not likely result in a change to cover type.

3.17.6.2.2.2.9 Route SE-2

Grassland/herbaceous land cover is the dominant land cover type (169.9 acres) in the ROW for AC Collection System Route SE-2. There are also 130.6 acres of cultivated crops land cover in the ROW. Both the grassland/herbaceous and cultivated crops land cover may have trimming and mowing impacts during operations and maintenance of the Project with no change to the dominant cover type. No forested land cover is present in the ROW for AC Collection System Route SE-2. There are approximately 4.4 acres of shrub/scrub land cover that may require trimming and/or mowing over the operational life of the Project. This impact would not likely result in a change to cover type.

3.17.6.2.2.2.10 Route SE-3

Grassland/herbaceous land cover is the dominant land cover type (565.7 acres) in the ROW for AC Collection System Route SE-3. There are also 483.9 acres of cultivated crops land cover in the ROW. Both the grassland/herbaceous and cultivated crop land cover may have trimming and mowing impacts during operations and maintenance of the Project with no change to the dominant cover type. No forested land cover is present in the ROW for AC Collection System Route SE-3. There are 59.6 acres of shrub/scrub land cover that may require trimming and/or mowing over the operational life of the Project. This impact would not likely result in a change to cover type. Approximately 14 acres of wetlands may be present in the ROW for AC Collection System Route SE-3.

3.17.6.2.2.2.11 Route SW-1

Grassland/herbaceous land cover is the dominant land cover type (312.8 acres) in the ROW for AC Collection System Route SW-1. This land cover may have trimming and mowing impacts during operations and maintenance of the Project with no change to the dominant cover type. No forested land cover is present in the ROW for AC Collection System Route SW-1. There are 2.6 acres of shrub/scrub land cover that may require trimming and/or mowing over the operational life of the Project. This impact would not likely result in a change to cover type.

3.17.6.2.2.2.12 Route SW-2

Grassland/herbaceous land cover is the dominant land cover type (733.0 acres) in the ROW for AC Collection System Route SW-2. There are also 122.7 acres of developed open space in the ROW. Both the grassland/herbaceous and the open space land cover may have trimming and mowing impacts during operations and maintenance of the Project with no change to the dominant cover type. No forested land cover is present in the ROW for AC Collection System Route SW-2. There are approximately 10.6 acres of shrub/scrub land cover that may require trimming and/or mowing over the operational life of the Project. This impact would not likely result in a change to cover type.

3.17.6.2.2.2.13 Route W-1

Grassland/herbaceous land cover is the dominant land cover type (377.0 acres) in the ROW for AC Collection System Route W-1. The grassland/herbaceous land cover may have trimming and mowing impacts during operations and maintenance of the Project with no change to the dominant cover type. No forested land cover is present in the ROW for AC Collection System Route W-1. There are approximately 11.5 acres of shrub/scrub land cover that may require trimming and/or mowing over the operational life of the Project. This impact would not likely result in a change to cover type.

3.17.6.2.2.3 Decommissioning Impacts

The decommissioning impacts related to the AC collection system would be similar in nature to the set of temporary impacts resulting from initial construction. These temporary impacts would result from use of construction machinery at the various alternative AC collection system sites of infrastructure (e.g., the lattice structures, tubular structures, H-frame structures, and fiber optic infrastructure) to remove aboveground material, and foundation material where required. Use of construction machinery would have the potential to crush or remove vegetation (primarily in grasslands or croplands), but these areas would be reseeded following removal of infrastructure. No long-term effects are judged to be likely from the decommissioning phase of the AC collection system. Revegetation would be guided by the Project's Decommissioning Plan.

3.17.6.2.3 HVDC Applicant Proposed Route

3.17.6.2.3.1 Construction Impacts

Construction impacts for the Applicant Proposed Route were calculated using estimated facility dimensions and associated land requirements as described in Section 3.17.6.1, Chapter 2, and Appendix F. It is yet to be determined how many lattice crossing (impact of 0.11 acre each), monopole (impact of 0.001 acre each), guyed (impact of 0.001 acre each), and fiber optic (impact of 0.009 acre per control building) structures and how many tensioning areas outside the ROW (impact of 3.44 acres each) would be needed. The discussion below focuses on impacts related to the representative 200-foot-wide ROW for the transmission lines. These impacts would result from initial clearing of the ROW. This would include both potential removal of vegetation and mechanical damage to vegetation. There would be placement of foundations for the lattice structures (which are assumed to be the primary structures used) and which would involve approximately six structures per mile on average, with 0.02 acres of impact per structural foundation set. This impact would be long-term in duration. Additional impacts to vegetation in the ROW would be consistent with those described in Section 3.17.6.1.2.The placement of the transmission line would involve tensioning areas inside the 200-foot-wide representative ROW (average of one tensioning site per two miles of transmission line). Tensioning impacts are estimated to be temporary in duration and might include trimming or mowing of vegetation, and/or crushing of existing vegetation by heavy machinery. The land requirements for the Applicant Proposed Route in Regions 1–7 are summarized in Table 3.17-14. Changes to impacts due to route variations and adjustments developed in response to public comments on the Draft EIS are described at the end of applicable sections.

Table 3.17-14:
Total Temporary and Long-Term Construction Impact Acreage for the Applicant Proposed Route—200-Foot-Wide Representative ROW

Regional Description	Potential Impact Acreage Within ROW
Region 1	
Initial ROW Clearing (115.5 miles in length)	2,825.2 acres
Lattice Structural Foundations/693 structures	13.9 acres
Region 2	
Initial ROW Clearing (106 miles in length)	2,588.1 acres
Lattice Structural Foundations (636 structures)	13 acres
Region 3	
Initial ROW Clearing (161.7 miles in length)	3,949.1 acres
Lattice Structural Foundations (970 structures)	19.4 acres
Region 4	
Initial ROW Clearing (126.3 miles in length)	3,087.6 acres
Lattice Structural Foundations (758 structures)	15.2 acres
Lee Creek Variation in Region 4	
Initial ROW Clearing (3.4 miles in length)	84.4 acres
Lattice Structural Foundations (20 structures)	0.4 acres
Region 5	
Initial ROW Clearing (112.8 miles in length)	2,759.5 acres
Lattice Structural Foundations (677 structures)	13.5 acres
Region 6	
Initial ROW Clearing (54.4 miles in length)	1,331.9 acres
Lattice Structural Foundations (326 structures)	6.5 acres
Region 7	
Initial ROW Clearing (42.8 miles in length)	1,048.0 acres
Lattice Structural Foundations (256 structures)	5.1 acres

The duration of construction is expected to be approximately 36 to 42 months for the entire Project, although the duration of construction for a single HVDC segment is anticipated to be approximately 24 months from mobilization to restoration.

Acreages of land cover types, by region (1 through 7), are included in Tables 3.10-15 through 3.10-21 Section 3.10 of the EIS. Additionally, descriptions of route variations to the Applicant Proposed Route, and the associated acreages of land cover types in those route variations, are described in detail in Sections 3.10.6.2.3.1.1 through 3.10.6.2.3.1.7.

3.17.6.2.3.2 Operations and Maintenance Impacts

Impacts from operations and maintenance of the Applicant Proposed Route would be similar to those from the AC collection system routes (see Section 3.17.6.2). These impacts may result from some degree of trimming and/or mowing in the ROW, with no real change to the dominant cover types. Within the transmission line ROW (200 feet wide by 720 miles long), only the transmission structures, fiber optic regeneration sites, and access roads would remain. For lattice structures, the operational footprint would be four to six structures per mile, and each foundation would measure 28 feet by 28 feet (less than 0.02 acre). Assuming 720 miles of lattice structures, the operational footprint would be 86 acres. Each structure would be 120 to 200 feet tall. For monopole structures, the operational footprint would be five to seven structures per mile, each with a foundation of 7 feet by 7 feet (approximately 0.001 acre), up to 5 acres total. Each structure would be 120 to 160 feet tall. Lattice crossing structures, which would be required in limited situations, would each have a structural footprint of 55 feet by 55 feet (approximately 0.07 acre) and each structure would be 200 to 300 feet tall. Guyed structures would also be required in limited situations, and would each have a structural footprint (not including guy wires) of 7 feet by 7 feet (0.001 acre) and each structure would be 120 to 200 feet tall.

The estimated four fiber optic regeneration sites would remain, each consisting of a fenced area 75 feet wide by 75 feet long (0.13 acre) including a control building 12 feet by 32 feet. The estimated operational footprint for all four sites is 0.8 acre. A permanent access road to the fenced area, a power supply to the control building, and a backup power generator and fuel supply would also remain.

It is anticipated that all existing roads and existing roads with repairs/improvements would be retained for operations and maintenance of the Project. It is estimated that approximately 75 percent of the new overland roads with no improvements and 90 percent of the new overland roads with clearing and new bladed roads would be retained for operations and maintenance access. New overland roads that are utilized for operations and maintenance would result in long-term removal of vegetation. These roads would be up to 20 feet wide and would total an estimated 1,851 acres. Access roads that are not needed for operations and maintenance of the Project would be restored (EPM GE-7).

In total, approximately 1,938 acres would be required for the operation of the HVDC transmission line, including 86 acres for the structures, 1,851 acres for the roads, and 0.8 acre for the fiber optic regeneration sites. All other land in the ROW would be allowed to recover and return to its previously dominant vegetation types, with the exception of forested lands and shrublands, which would be maintained according to the TVMP. Vegetation within the wire zone would be limited to low-growing herbaceous vegetation including grasses, forbs, and short-stature shrubs in those locations where the conductor is 50 feet or less from the ground. Tall shrubs and short trees would be permitted in the border zone (i.e., to the edge of the ROW). Tree-trimming and brush removal would be conducted as needed to maintain the vegetation within the ROW.

During operations and maintenance of the Applicant Proposed Route, the transmission line would be inspected regularly and as necessary using fixed-wing aircraft, helicopters, ground vehicles, and/or personnel on foot. Maintenance would be performed as needed. Maintenance activities would generally be smaller in scale and more localized than construction activities. Maintenance activities would cause long-term impacts to forested land cover, and may cause temporary impacts within the ROW to crops and other vegetation; the areas of impacts are summarized in Table 3.17-15.

Table 3.17-15:
Total Long-Term Operations and Maintenance Impact Areas for the Applicant Proposed Route—200-Foot-Wide Representative ROW

Applicant Proposed Route	Total Length of Route/Acres of Potential Vegetation Impact Within the ROW	Forested Land Cover Within ROW
Region 1		
APR Links 1–5	115.5 miles/2,825.2 acres	< 1 acre
Region 2		
APR Links 1–3	106.0 miles/2,588.1 acres	252.9 acres
Region 3		
APR Links 1–6	161.7 miles/3,949.1 acres	1,145.4 acres
Region 4		
APR Links 1–9	126.3 miles/3,087.6 acres	1,333.5 acres
Region 5		
APR Links 1–9	112.8 miles/2,759.5 acres	1,556.2 acres
Region 6		
APR Links 1–8	54.4 miles/1,331.9 acres	96.5 acres
Region 7		
APR Links 1–5	42.8 miles/1,048.0 acres	81.8 acres
Totals	719.5 miles/17,589.4 acres	4,466.3 acres

3.17.6.2.3.2.1 Region 1

The majority of land cover within the ROW for Region 1 is grassland/herbaceous (1,742.3 acres) and cultivated crops (748.8 acres). Less than 1 acre of the ROW for the Applicant Proposed Route in Region 1 contains forested lands, so very little trimming of trees is anticipated.

3.17.6.2.3.2.2 Region 2

Region 2 is dominated by grassland/herbaceous land cover (1,299.9 acres) and cultivated crop land cover (788.0 acres) within the ROW. Forested lands account for approximately 252.9 acres of cover within the ROW for this region, including evergreen, deciduous, and mixed forest types. The routine operations and maintenance for the Project would result in long-term impacts to some portion of these forested lands as governed by the TVMP.

3.17.6.2.3.2.3 Region 3

Region 3 operations and maintenance would occur in a ROW dominated by grassland/herbaceous vegetation (1,339.5 acres) and 1,145.4 acres of deciduous and evergreen land cover types. The routine operations and maintenance for the Project would result in long-term impacts to some portion of these forested lands as governed by the TVMP.

3.17.6.2.3.2.4 Region 4

Region 4 is dominated by pasture/hay land cover type (1,436.1 acres). This land cover type would likely require very little vegetation maintenance during the operational life of the Project. However, there are 1,333.5 acres of deciduous, evergreen, and mixed forest cover types in the ROW of Region 4. The routine operations and maintenance for the Project would result in long-term impacts to some portion of these forested lands as governed by the TVMP.

3.17.6.2.3.2.5 Region 5

Region 5 operations and maintenance would occur on lands dominated by deciduous forest (810.8 acres in the ROW) land cover. There are 1,556.2 total acres of deciduous, evergreen, and mixed forest cover types in the Region 5 ROW. The routine operations and maintenance for the Project would result in long-term impacts to some portion of these forested lands as governed by the TVMP.

3.17.6.2.3.2.6 Region 6

Region 6 operations and maintenance would occur on lands dominated by cultivated crops (1,056.5 acres) land cover. Very little impact is anticipated from operations and maintenance activities with regard to this cover type. Forested lands within the ROW for Region 6 are limited to 88.8 acres of deciduous forest and 7.7 acres of mixed forest land cover. The routine operations and maintenance for the Project would result in long-term impacts to some portion of these forested lands as governed by the TVMP.

3.17.6.2.3.2.7 Region 7

Region 7 operations and maintenance would occur on lands dominated by cultivated crops (691.8 acres). Little to no impact would result from operations and maintenance of the Project on this land cover type. The ROW for Region 7 has approximately 81.8 acres of deciduous, evergreen, and mixed forest land cover types. The routine operations and maintenance for the Project would result in long-term impacts to some portion of these forested lands as governed by the TVMP.

3.17.6.2.3.3 Decommissioning Impacts

The decommissioning impacts related to the Applicant Proposed Route would be similar in nature to the set of temporary impacts resulting from initial construction of the HVDC transmission line. These temporary impacts would result from use of construction machinery at the various sites of infrastructure (e.g., the lattice structures, lattice crossing structures, monopole structures, guyed structures, and fiber optic infrastructure) to remove aboveground material, and foundation material where required. Use of construction machinery would have the potential to crush or remove vegetation, but no long-term effects are judged to be likely from the decommissioning phase of the Project. Revegetation would be guided by the Project's Decommissioning Plan.

3.17.6.3 Impacts Associated with the DOE Alternatives

3.17.6.3.1 Arkansas Converter Station Alternative Siting Area and AC Interconnection Siting Area

3.17.6.3.1.1 Construction Impacts

Construction impacts for the Arkansas Converter Station Siting Area and associated AC Interconnection Siting Area were calculated using estimated facility dimensions and associated land requirements as described in Chapter 2 and Appendix F. The dominant land cover types at the Arkansas Converter Station Siting Area are deciduous forest (71 acres), followed by pasture/hay lands (67 acres), and cultivated crops (44 acres). There are also 12 acres of woody wetlands within the siting area.

Twenty to 35 acres of land would be cleared and graded for the station facility footprint, plus an additional 5 to 10 acres of land for the overall construction. The clearing and grading of the 20–35 acres would produce a long-term impact and the clearing, grading, and use of the additional 5–10 acres would produce a short-term impact. The latter would be revegetated using guidance within the Project's Restoration Plan. In addition, one 35-foot-wide by 1-mile-long all weather access road would be needed. Clearing and grading activities for the road would cause approximately 4 acres of removal of current vegetation.

Construction of the related Project facilities for the Arkansas converter station and interconnection facility would result in the following impacts to vegetation:

- Transmission line ROW: A maximum 200-foot-wide by 5-mile-long ROW would result in 121 acres of long-term impacts to vegetation via clearing and grading activities. The AC Interconnection Siting Area contains 72 percent (478 acres) hay and pastureland and 11 percent (76 acres) evergreen forest.
- Lattice Structures: The maximum number of lattice structures would be 35, and this would equal approximately 1 acre of long-term impact to vegetation.
- Tubular Pole Structures: The maximum number of tubular pole structures would be 35, and this would equal less than 1 acre of long-term impact to vegetation.
- Substation Site: A 25–35-acre site would be required to construct a substation for the interconnection to an existing 500kV transmission line. An additional 5-acre area would be required during construction, resulting in a potential for 45 total acres of impact. The substation site is mostly grassland with some forested areas.

3.17.6.3.1.2 Operations and Maintenance Impacts

Vegetation removed during the construction of the converter station would not be replaced during the operations phase of the Project. Similarly, vegetation removed during the construction of the converter station access road would not be replaced during the operations and maintenance phase of the Project. Vegetation within the ROW of the AC interconnection would be maintained during the operations and maintenance phase of this Project in compliance with the TVMP. The projected acreage of vegetation to maintain in the ROW is 121 acres. Vegetation removed for the substation site would not be replaced except for about 5 acres required only during construction.

3.17.6.3.1.3 Decommissioning Impacts

The decommissioning impacts related to the Arkansas converter station and associated facilities would be similar in nature to the set of temporary impacts resulting from initial construction. These temporary impacts would involve use of construction machinery at the converter station site, as well as the ROW area that would have been used for AC interconnection. The specific acreage for the footprint of the converter station totals a projected maximum of 60 acres which would be reclaimed and revegetated according to the details that would be written into the Decommissioning Plan.

3.17.6.3.2 HVDC Alternative Routes

3.17.6.3.2.1 Construction Impacts

Construction impacts for the HVDC alternative routes were calculated using estimated facility dimensions and associated land requirements as described in Chapter 2 and Appendix F. It is yet to be determined how many lattice structures (impact of 0.11 acre each), monopoles (impact of 0.001 acre each), guyed structures (impact of 0.001 acre each), and fiber optic (impact of 0.009 acre per control building) structures, and how many tensioning areas outside the ROW (impact of 3.44 acres each) would be needed. Predicted impacts to vegetation in the ROW would be consistent with those described in Section 3.17.6.1.2. The land requirements for the HVDC alternative routes and the Applicant Proposed Route in Regions 1–7 are summarized in Table 3.17-16. The table also includes the acreage of potential vegetation impacts in the ROW, and the acres of potential forest impacts within the ROW.

Table 3.17-16:
Land Requirements for the HVDC Alternative Routes and the Applicant Proposed Route in Regions 1–7

Alternative	Length of Route/Acres of Potential Vegetation Impact Within ROW/Predominant Land Cover/Acres of Potential Forest Impact Within ROW[1]	# of Lattice Structures/Acres of Potential Vegetation Impact Within ROW
Region 1		
AR 1-A	123.0 miles/3,003.1 acres/grassland and herbaceous cover/4.7 acres	738 structures/14.8 acres
APR Links 2–5	113.6 miles/2,777.7 acres/grassland and herbaceous cover/0.1 acres	682 structures/13.6 acres
AR 1-B	51.8 miles/1,268.4 acres/grassland and herbaceous cover/0.0 acres	311 structures/6.2 acres
APR Links 2–3	53.8 miles/1,316.0 acres/grassland and herbaceous cover/0.0 acres	323 structures/6.5 acres
AR 1-C	52.0 miles/1,272.5 acres/grassland and herbaceous cover/0.0 acres	312 structures/6.2 acres
APR Links 2–3	53.8 miles/1,316.0 acres/grassland and herbaceous cover/0.0 acres	323 structures/6.5 acres
AR 1-D	33.5 miles/819.2 acres grassland and herbaceous cover/0.0 acres	201 structures/4.0 acres
APR Links 3-4	33.6 miles/822.8 acres grassland and herbaceous cover/0.0 acres	202 structures/4.0 acres
Region 2		
AR 2-A	57.2 miles/1,396.3 acres/grassland and cultivated crops/144.5 acres	343 structures/6.9 acres
APR Link 2	54.4 miles/1,330.7 acres/grassland and cultivated crops/231.5 acres	326 structures/6.5 acres
AR 2-B	29.8 miles/727.7 acres/cultivated crops and grassland/16.6 acres	179 structures/3.6 acres
APR Link 3	31.2 miles/763.6 acres/cultivated crops and grassland/15.9 acres	187 structures/3.7 acres
Region 3		
AR 3-A	37.6 miles/919.1 acres/grassland, deciduous forest, and cultivated crops/194.3 acres	226 structures/4.5 acres
APR Link 1	40.0 miles/977.1 acres/grassland, deciduous forest, and cultivated crops/236.5 acres	240 structures/4.8 acres
AR 3-B	47.7 miles/1,166.6 acres/grassland, deciduous forest, and cultivated crops/229.0 acres	286 structures/5.7 acres
APR Links 1–3	49.9 miles/1,220.6 acres/grassland, deciduous forest, and cultivated crops/293.7 acres	299 structures/6.0 acres
AR 3-C	121.6 miles/2,967.5 acres/grassland, deciduous forest, and pasture/hay/878.3 acres	730 structures/14.6 acres
APR Links 3–6	118.6 miles/2,895.2 acres/pasture/hay, deciduous forest, and grassland/901.9 acres	712 structures/14.2 acres
AR 3-D	39.3 miles/958.8 acres/pasture/hay, deciduous forest, and grassland/185.0 acres	236 structures/4.7 acres
APR Links 5, 6	35.1 miles/856.8 acres/pasture/hay, grassland, and deciduous forest/167.4 acres	211 structures/4.2 acres
AR 3-E	8.5 miles/207.8 acres/pasture/hay, deciduous forest, and grassland/74.1 acres	51 structures/1.0 acre
APR Link 6	7.7 miles/189.7 acres/deciduous forest, pasture/hay, and grassland/80.8 acres	46 structures/0.9 acre
Region 4		
AR 4-A	58.4 miles/1,426.1 acres/deciduous forest and pasture/hay/749.1 acres	350 structures/7.0 acres
APR Links 3–6	60.4 miles/1,475.7 acres/pasture/hay and deciduous forest/521.6 acres	362 structures/7.2 acres
AR 4-B	78.6 miles/1,919.8 acres/deciduous forest and pasture/hay/1,239.4 acres	472 structures/9.4 acres
APR Links 2–8	81.3 miles/1,987.9 acres/pasture/hay and deciduous forest/758.4 acres	488 structures/9.8 acres
AR 4-C	3.4 miles/82.6 acres/deciduous forest and pasture/hay/56.8 acres	20 structures/0.4 acre
APR Link 5	2.2 miles/53.4 acres/deciduous forest and pasture/hay/35.1 acres	13 structures/0.3 acre
AR 4-D	25.3 miles/617.6 acres/pasture/hay and deciduous forest/276.6 acres	152 structures/3.0 acres
APR Links 4–6	25.4 miles/619.1 acres/pasture/hay and deciduous forest/157.1 acres	152 structures/3.0 acres

Table 3.17-16:
Land Requirements for the HVDC Alternative Routes and the Applicant Proposed Route in Regions 1–7

Alternative	Length of Route/Acres of Potential Vegetation Impact Within ROW/Predominant Land Cover/Acres of Potential Forest Impact Within ROW[1]	# of Lattice Structures/Acres of Potential Vegetation Impact Within ROW
AR 4-E	36.7 miles/897.2 acres/pasture/hay and evergreen and deciduous forest/394.1 acres	220 structures/4.4 acres
APR Links 8–9	38.7 miles/946.7 acres/pasture/hay and evergreen and deciduous forest/464.6 acres	232 structures/4.6 acres
Region 5		
AR 5-A	12.6 miles/308.5 acres/evergreen and deciduous forest/226.6 acres	76 structures/1.5 acres
APR Link 1	12.3 miles/300.1 acres/evergreen and deciduous forest/224.0 acres	74 structures/1.5 acre

1 The values in the table do not reflect the minor changes that would result from application of the minor route variations and adjustments

Descriptions of route adjustments to HVDC Alternative Routes 3A, 5B, 5E, and 6A, with their associated acreages of land cover types crossed by the adjustment, are described in detail in Section 3.10.6.3.2.1.3.1, Section 3.10.6.3.2.1.5.2, Section 3.10.6.3.2.1.5.5, and Section 3.10.6.3.2.1.6.1, respectively.

3.17.6.3.2.2 Operations and Maintenance Impacts

Impacts from operations and maintenance of the HVDC alternative routes would be similar to those from the Applicant Proposed Route (see Section 3.17.6.2.3). No long-term impacts are described for access roads because the location of access roads has not yet been determined. Maintenance activities would cause long-term impacts to pre-construction forested land cover. Some forested lands (including evergreen forests, hardwood forests, and mixed forests) would need to be cut and maintained according to the TVMP and would not be allowed to regrow for line safety and integrity reasons. There may also be temporary impacts within the ROW to crops and other vegetation. Grasslands/herbaceous, cultivated crops, and other low-profile land covers may have trimming and mowing impacts during operations and maintenance of the Project. The land area for long-term impacts to forested land cover are summarized in the Table 3.17-16, including a comparison of impacts to the Applicant Proposed Route, by region. These long-term impacts may include the pruning or removal of shrubs and trees, where necessary according to the TVMP. In the table, total forested land cover includes the sum of deciduous, evergreen, and mixed forest cover types.

3.17.6.3.2.3 Decommissioning Impacts

The decommissioning impacts relative to the alternative routes would be similar in nature to the set of temporary impacts resulting from initial construction. These temporary impacts would result from use of construction machinery at the various sites of infrastructure (e.g., the lattice structures, lattice crossing structures, monopole structures, guyed structures, and fiber optic infrastructure) to remove aboveground material, and foundation material where required. Use of construction machinery would have the potential to crush or remove vegetation, but no long-term effects are judged to be likely from the decommissioning phase of the Project. Revegetation would be guided by the Project’s Decommissioning Plan.

3.17.6.4 Best Management Practices

A complete list of EPMs for the Project is provided in Appendix F; those EPMs that would specifically lead to the avoidance or minimization of potential impacts on vegetation communities are summarized in Section 3.17.6.1. The Applicant would consider the development of site-specific BMPs that may be necessary after consultation with appropriate federal and state agencies.

3.17.6.5 Unavoidable Adverse Impacts

Unavoidable adverse impacts to vegetation and special status plant species from the Project may include the following:

- Removal of vegetation in the footprints of new transmission line support structures, access roads, regulator stations, and other associated infrastructure
- Conversion of structural types of vegetation (e.g., forest conversion to grassland or forest to low-stature shrublands)
- Changes to plant species diversity with the general trend likely to be a diminishment of vegetation species diversity in disturbed areas
- Potential lower yields in croplands that are disturbed during construction and operations and maintenance

3.17.6.6 Irreversible and Irretrievable Commitment of Resources

A commitment of resources is irreversible when its primary and secondary impacts limit the future options for a resource. An irretrievable commitment refers to the use or consumption of a resource that is neither renewable nor recoverable for use by future generations.

Both short- and long-term disturbance to vegetation would be minimized through appropriate application of the Project's Restoration Plan. Once the Project has been decommissioned, there is potential for all of the approximately 2,598 acres of vegetation to be recovered. Therefore, it is predicted that there would be no irreversible or irretrievable commitment of vegetation resources.

3.17.6.7 Relationship Between Local Short-term Uses and Long-Term Productivity

Removal of vegetation, mechanical damage to vegetation, and reduced plant water availability due to compaction of soils are all potential local short-term use effects on vegetation that could result from construction of the Project. The short-term impacts would be minimized through the use of multiple EPMs incorporated into the Project. The impact of short-term uses on long-term productivity to vegetation resources would be limited to those areas where (1) structural foundations are left in place until decommissioning, or (2) instances where vegetation structure is altered from forested to herbaceous structural types. In this second specific case, the functions of wildlife habitat maintenance, biodiversity, and recreational opportunities could be diminished. The EPMs listed in Section 3.19.6.1 should limit these changes in long-term productivity.

3.17.6.8 Impacts from Connected Actions

3.17.6.8.1 Wind Energy Generation

Although site-specific layouts of wind energy generation facilities in the 12 WDZs have yet to be designed or proposed, impacts from these potential wind energy generation facilities on vegetation communities were evaluated using the methodology described in Section 3.17.6.1.

Based on the maximum capacity of the Project and information from wind energy developers, it is estimated that 20-30 percent of the potentially suitable land, or between 216,400 and 324,600 acres, would actually be developed for wind energy facilities using transmission capacity from the Project.

It is estimated that during the construction phase approximately 2 percent of land within a wind energy facility is affected (Denholm et al. 2009). Assuming up to 30 percent build-out of the WDZs, up to 6,492 acres would be temporarily disturbed during construction. This would include the construction of access roads, turbine pads and foundations, underground collection lines, collector substation, and often a generation tie line. An operations and maintenance building and at least one or two meteorological towers are also typically included.

During the operations and maintenance phase of wind energy facilities, approximately 1 percent or less of the land would be affected. Once construction has been completed, temporary construction areas would revert to their previous uses. Only turbines, access roads, generation tie-lines (if necessary), substations, and operations and maintenance buildings would remain. This would equate to approximately 3,246 acres. Existing land uses, including agricultural croplands, would be expected to return to almost all areas of the facilities, unless deemed incompatible with the operations of a wind farm.

Temporary impacts during construction may result from increased dust entrainment that can settle on surrounding vegetation causing a reduction in photosynthetic capability of plants. It is also likely that there would be mowing or potential removal of vegetation in ROWs for generation tie-lines, access roads, and electrical collection lines that are placed underground. Long-term impacts may result to vegetation where it is removed to facilitate construction of substation facilities.

Impacts to pasture and cultivated crops may also occur during construction in the WDZs. Construction may temporarily prevent the existing uses in the construction area, including growing crops. Wind energy developers typically coordinate with landowners to minimize impacts to agricultural operations, such as timing construction to begin after crops are harvested; and specifying types of seed to use during revegetation. The land cover distribution for the 12 WDZs is presented in Table 3.10-12 in Section 3.10.

Wind lease agreements typically include provisions to minimize the losses, including minimizing soil compaction and revegetating temporary work areas. In addition, the agreements typically stipulate compensation for landowners for any losses of crops, landscaping, and trees. Once construction has been completed, agricultural operations would be able to continue in most of the wind farm. Agricultural activities such as cultivating crops are generally permitted up to the wind turbine pads, so only a very minimal area of existing agricultural land would be removed from production. Access roads may change the configuration of fields for crops.

3.17.6.8.2 Optima Substation

The future Optima Substation is anticipated to be constructed on 160 acres of currently undeveloped land near an operating wind energy facility. The land cover of the site is primarily grassland/herbaceous. Vegetation within this area would be expected to be removed for the construction of the substation. Impacts associated with removal of vegetation are described in Section 3.17.6.1.2. No special status plant species have documented elemental occurrences within the substation site.

3.17.6.8.3 TVA Upgrades

Much of the following discussion is relevant for the new 500kV transmission line, or for certain upgrades associated with the 161kV transmission lines. The required TVA upgrades to existing facilities (including existing transmission lines and existing substations) should have minimal impact on vegetation resources and, except for potential access roads, would not involve vegetation removal outside existing ROWs or developed substation sites. The construction, operation, and maintenance of the new 500kV transmission line would have impacts similar to the Project although on a smaller scale. These impacts may include mechanical damage and/or removal of vegetation by heavy machinery, reduced water-holding capacity and inhibition of plant growth, due to compaction of soils, introduction of invasive species from construction equipment or spread of existing invasive species on newly cleared land, alteration of hydrology during road construction, which could affect plant growth, long-term conversion of forested and shrublands to herbaceous cover type within ROWs, and contamination from herbicide drift or runoff or from accidental spills of fuels or lubricants that could stunt plant growth or inhibit the onset of growth.

Many construction-related impacts would be short-term, but vegetation loss in areas of new structures and access roads would be long-term. On average, the construction of new TVA transmission lines during the last decade has resulted in the removal of 5.6 acres of forest per mile of new line. During operations, vegetation would reestablish on most disturbed areas; in ROWs for the new electric transmission line vegetation would be managed so maintenance activities would not be affected, especially in any forested areas where trees could restrict access or affect operations if allowed to reestablish. Depending on the locations of the required TVA upgrades, federally protected plant species and state-recognized special status plants may occur. Special status plant species could be impacted the same as other vegetation unless, as is planned for the Project, plant surveys are carried out prior to construction activities and TVA marks special status species and avoid them as practicable.

3.17.6.9 Impacts Associated with the No Action Alternative

Under the No Action Alternative, DOE assumes for analytical purposes that the Project would not be constructed. No impacts on vegetation or special status plant species on private, federal, state, or tribal lands, or their corresponding land management policies and regulations would occur. The existing diversity, structure, and function of vegetation within the ROW would be expected to continue to evolve under the influence of natural processes such as succession and as a result of other human-related disturbances.

3.18 Visual Resources

This section describes the affected environment and assesses the impact of the Project on visual resources, which are defined as visible features of the landscape (e.g., land, water, vegetation, animals, structures, and other features) (BLM 2010).

The methodology used to identify and assess the potential impacts of the Project on visual resources is based on the Bureau of Land Management (BLM) Visual Resource Management (VRM) inventory and contrast rating systems although the Project does not cross lands administered by the BLM. The BLM VRM system provides a systematic approach for evaluating the potential changes to visual resources that may result from the Project. The major concepts of the BLM VRM methodologies that this visual resource analysis follows are described below:

- Establish an understanding of the existing visual character and qualities of the landscape environment of the Project area
- Determine areas from which the Project would be visible
- Estimate the visual expectations and response of the viewers to visual changes resulting from the Project
- Identify the visual contrast resulting from changes to the existing landscape character and qualities in the Project area as a result of the Project

The overall visual resource assessment methodology is graphically shown in a flowchart in Figure 3.18-1 (located in Appendix A). The methodologies for conducting the visual resources inventory and impact assessment are described in more detail in Sections 3.18.4 and Section 3.18.6, respectively.

3.18.1 Regulatory Background

Goals, objectives, policies, implementation strategies, and guidance for visual resources are typically contained in resource management plans, and comprehensive plans. Regulations and guidance documents that focused the analysis presented in this section are identified in Table 3.18-1.

Table 3.18-1:
Visual Laws and Regulations Applicable to the Project

Statute/Regulation	Agency	Applicability to the Project
Federal		
National Environmental Policy Act of 1969, as amended (NEPA)	Council of Environmental Quality (CEQ)	The CEQ implementing regulations for NEPA require that EISs (including DEISs) discuss the environmental consequences to aesthetic resources (40 CFR 1508.8). Aesthetic resources under NEPA include park lands, wild and scenic rivers and other ecologically critical areas that may be affected by major federal actions that may include activities entirely or partially financed, assisted, conducted, or approved by federal agencies. NEPA's focus is on the environment of the area(s) to be affected by the alternatives under consideration. In December 2012, DOE published the NOI to prepare an EIS to analyze the potential environmental impacts of the Project. Several of the scoping comments received in response to this NOI addressed potential effects of the Project on specific aesthetic resources including impacts on scenic vistas such as Gloss Mountain and the Mississippi River, Ozark Mountains, Ozark National Forest, Trail of Tears, Honey Springs Battlefield/State Park, scenic highways, and National Scenic Byways.

Table 3.18-1:
Visual Laws and Regulations Applicable to the Project

Statute/Regulation	Agency	Applicability to the Project
Federal Land Policy and Management Act of 1976 (FLPMA) (43 USC § 1701 et. seq.)	National Forest Service (NFS)	FLPMA was enacted for the purpose of establishing a unified, comprehensive, and systematic approach to managing and preserving public lands in way that protects "the quality of scientific, scenic, historical, ecological, environmental, air and atmospheric, water resource, and archaeological values." In the context of FLPMA, public lands consist of federally-owned lands (i.e., BLM, NPS, and USFS lands). The following sections of FLPMA are applicable to visual resources: Section 102 (a)(8). States that "…the public lands be managed in a manner that will protect the quality of the …scenic…values…" Section 103(c). Identifies "scenic values" as one of the resources for which public land should be managed. Section 505(a). Requires that "Each right-of-way shall contain terms and conditions which will…minimize damage to the scenic and aesthetic values…" HVDC Alternative Route 4-B crosses the Ozark-St. Francis National Forest (Figure 3.10-1 in Appendix A). The Ozark-St. Francis National Forests Revised Land and Resource Management Plan was updated in 2005 to provide a framework for managing the forests' natural resources by establishing long-range goals and management areas with specific objectives. The Land and Resource Management Plan identifies the following scenery management priorities (USFS 2005a): • Maintain or enhance the visual character of the forests by using the USFS Scenery Management System (SMS) to achieve Scenic Integrity Objectives (SIO) • Manage landscapes and built elements in order to achieve scenic integrity objectives • Promote the planning and improvement of infrastructure along scenic travel routes. Use the best environmental design practices to harmonize changes in the landscape and to advance environmentally sustainable design solutions • Restore landscapes to reduce visual effects of nonconforming features • Manage scenic restoration to be consistent with other management area objectives • Maintain the integrity of the expansive, natural landscapes, and traditional cultural features that provide the distinctive character of places Maintain the character of key places in order to maintain their valued attributes.
National Historic Preservation Act of 1966, as amended (NHPA) (16 USC § 470 et seq.) (implementing regulations at 36 CFR 800.5)		The NHPA includes language protecting the visual integrity of sites listed or eligible for the NRHP: "Examples of adverse effects…include…introduction of visual, atmospheric, or audible elements that diminish the integrity of the property's significant historic features…" (36 CFR 800.5). Visual resources protected by the NHPA are discussed in Section 3.9.6.
The National Trails System Act (16 USC § 1241)	National Park Service (NPS)	National Trails were established under the National Trail System Act of 1968 (16 USC §§ 1241–51), designating and protecting national scenic trails, national historic trails, and national recreational trails. National trails are administered by the BLM, NPS, and USFS. These agencies provide coordination and oversight for the entire length of a trail. However, because these trails traverse both public and private lands as well as lands controlled by various agencies, on-site management activities are performed by the jurisdictional agency, the state, or the landowner (16 USC §§ 1241–51, as amended 2009). Portions of the Applicant Proposed Route and HVDC Alternative Routes 4-A, 4-B, 4-C, 4-D, 4-E, and 7-A in Regions 4 and 7 cross the Trail of Tears. The Trail of Tears in Region 4 is a multi-branched linear resource management corridor and was used during the forced relocation of Native American peoples indigenous to the

Table 3.18-1:
Visual Laws and Regulations Applicable to the Project

Statute/Regulation	Agency	Applicability to the Project
		southeastern United States to Indian Territory (now Oklahoma) in the 1830s. Greatly expanded in 2009, the Trail of Tears National Historic Trail consists of several separate branches that cross, and in one case terminate in, Arkansas. The ROI for the Project (see Section 3.18.3) intersects the branch of the Trail of Tears now called the Bell-Drane Route between western Crawford County and south-central Johnson County. Generally following the old Little Rock-to-Fort Gibson Road up the northern side of the Arkansas Valley as far west as Fort Smith, this trail segment is typically described as approximating the present route of U.S. Route 64. From the vicinity of Fort Smith, the Bell-Drane Route turns north and approximates State Route 59 to Evansville, in southwestern Washington County near the Arkansas-Oklahoma line. The NPS does not exercise regulatory authority over any portion of Trail of Tears crossed by the Project. The role of the NPS is to lead a group of federal, state, local, non-governmental, and private stakeholders with interests in the identification, preservation, interpretation, and promotion of the Trail of Tears National Historic Trail and associated properties.
National Scenic Byways Program (23 USC § 162) Intermodal Surface Transportation Efficiency Act of 1991 (ISTEA; Public Law 102-240).	The Federal Highway Administration (FHA)	A scenic byway is a public road with special scenic, historic, recreational, cultural, archaeological, and/or natural qualities that have been recognized as such through legislation or official declaration. Easements associated with scenic byway ROWs may prohibit construction of transmission structures or other structures that degrade the scenic quality of the road. The National Scenic Byways Program establishes the framework for identifying and managing highways that have "outstanding scenic, historic, cultural, natural, recreational, and archaeological qualities." Additionally, the FHWA's May 18, 1995, interim policy (60 FR 26759, May 18, 1995 [FHWA Docket No. 95-15]) sets forth the procedures for the designation of certain roads as National Scenic Byways or All-American Roads by the U.S. Secretary of Transportation. The interim policy also requires the preparation of a corridor management plan to provide guidance for the conservation and enhancement of the byways' intrinsic qualities.
State		
Oklahoma Scenic Rivers Act (Oklahoma Statute 82-1451–1471)	Oklahoma Water Resources Board (OWRB)	In Oklahoma, state scenic rivers were established under the Oklahoma Scenic Rivers Act designating certain free-flowing rivers that possess unique natural scenic beauty and outdoor recreational values for the benefit of present and future inhabitants of the state. The intent of this act is to preserve state-designated scenic rivers in their natural scenic state. There are five streams protected under the program in Oklahoma, including Lee Creek and Little Lee Creek. No other rivers designated under the Oklahoma Scenic Rivers Act occur within the ROI.
Arkansas Natural and Scenic Rivers Act (Arkansas Code Annotated 15-23-301)	Arkansas	In Arkansas, state scenic rivers are established under the Arkansas Natural and Scenic Rivers System Act, designating certain rivers of the state that possess "outstanding natural, scenic, educational, geological, recreational, historical, fish and wildlife, scientific, and cultural values of great present and future benefit to the people". The intent of this act is to balance the alterations of man and the protection of the natural landscape along certain rivers. The act establishes a process for designating and managing state-designated scenic rivers.
Scenic Highway Designations (Arkansas Code Annotated 27-67-203)	Arkansas Highway Commission	State-designated scenic highways are established under the Arkansas Code Title 27-67-203. Byways are nominated for scenic status and are officially designated by the State General Assembly (AHTD 2007). For a highway to be declared scenic, a group interested in preserving the scenic, cultural, recreational, and historic qualities of the route must be created. Once a scenic highway has been designated, the Arkansas State Highway, Transportation Department, and respective counties must place appropriate signs indicating these highways have been designated; however, the state does not identify additional regulations for protecting state-designated scenic highways.

Table 3.18-1:
Visual Laws and Regulations Applicable to the Project

Statute/Regulation	Agency	Applicability to the Project
Tennessee Scenic Rivers Act (Tennessee Administrative Code 11-13)	Tennessee Department of Environment and Conservation—Division of Natural Areas	In Tennessee, state scenic rivers are established under the Tennessee Scenic Rivers Act of 1968, designating certain rivers that “possess outstanding scenic, recreational, geological, fish and wildlife, botanical, historical, archaeological, and other scientific values of great present and future benefit to the people” as scenic rivers. This act establishes three classes of scenic rivers and the management requirements for each classification, including permitted land uses. The intent of this act is to protect scenic, historic, archaeological, and scientific features of state-designated scenic rivers, regardless of classification.
Tennessee Scenic Highway System Act of 1971 (Tennessee Administrative Code 54-17)	Tennessee Department of Transportation (TNDOT)	The Tennessee Scenic Highway System Act of 1971 establishes the criteria to designate, recover, and conserve natural scenic beauty along designated scenic highways, and preserve routes of historical significance. This act recommends designation of specific highways, and provides strategies for promoting the scenic highway system.

3.18.2 Data Sources

Potential visual resources were identified through a desktop analysis of readily available information, research, and reports; information received directly from regulatory agencies and other stakeholders during the DOE scoping process and stakeholder outreach; and data obtained through GIS databases. Table 3.18-2 lists the GIS databases that were used to compile visual resource data. GIS source data included federal, state, and municipal governments, and non-governmental organizations.

Table 3.18-2:
Summary of GIS Data Sources

Information/Resources	Data Sources	Region of Influence Extent of Data Collection[1]

National Register of Historic Places Sites	GIS Data Source: NPS (2013)	Within 3 miles
Residential Structures	GIS Data Sources: Tetra Tech (2014), Clean Line (2013a, 2013b)	Within 0.5 mile on either side of the referenced centerline of the Applicant Proposed Route and HVDC Alternative Routes).

1 Measured from representative centerlines of transmission line routes or the boundary of the converter station siting areas.

Structures within 0.5 mile of the transmission line routes were digitized and categorized from aerial photography, and a structure data layer was created (GIS Data Sources: Clean Line 2013a, 2013b; Tetra Tech 2014a). These data were field verified and updated accordingly. Aerial reconnaissance was also conducted following development of the Applicant Proposed Route and HVDC alternative routes.to verify the feasibility of the routes. Additional structures noted during the aerial reconnaissance were also included in the structure inventory.

In addition to the desktop research and initial field reconnaissance, field investigation at Key Observation Point (KOP) locations was conducted in February and March 2014 to assess contrast and visual impacts and provide photographs for visual simulations.

3.18.3 Region of Influence

3.18.3.1 Region of Influence for the Project

The ROI for visual resources was established through a combination of field reconnaissance and in consideration of the BLM distance zones. For the purpose of this analysis, a 1,000-foot-wide corridor was identified by Clean Line (Clean Line 2013). A representative ROW (a 200-foot-wide corridor associated with the transmission lines) was created within this 1,000-foot-wide corridor. Although theoretically the transmission line and associated ROW could be located anywhere within these corridors, it would be difficult to assess the transmission line from an infinite number of possibilities. Assessment of the line from the center of the corridors (referenced centerline), therefore, provides consistency throughout the assessment. The ROI for visual resources for the transmission line is defined as 6 miles (3 miles on either side of the referenced centerline of the Applicant Proposed Route, HVDC alternative routes, AC interconnection lines, and AC collection system). The reference centerlines are located within the 1,000-foot-wide corridor (which is the “standard” ROI for the Applicant Proposed Route and HVDC alternative routes) and within the center of each corridor identified for the AC interconnection routes and AC collection system. The ROI for visual resources also includes the converter station siting areas and the interconnection siting areas and a 3-mile buffer from the boundaries of those siting areas.

These visual resource ROIs encompass the 3 miles on either side of the reference centerline for the transmission lines and from the boundary of the converter station siting areas, encompasses the foreground/middleground (FG/MG) as defined by the BLM VRM system. In the FG/MG, Project components might be viewed in detail. Some viewing locations may occur outside the defined ROI (between 3 and 15 miles) and may include areas such as communities, scenic vistas from a national or state park, trails, etc. that were identified during agency consultation and/or the public scoping process.

Based on the foregoing, the ROI for visual resources is as follows:

- Applicant Proposed Project
  - Oklahoma Converter Station Siting Area: A 620-acre siting area and a 3-mile buffer from the boundary of the siting area in Texas County, Oklahoma.
  - Texas County AC Interconnection Siting Area: A 3-mile buffer from the boundary of an approximate 870-acre corridor.
  - AC Collection System Corridors: Six miles (3 miles either side) of the referenced centerline (explained above). The referenced centerlines for the AC Collection System are located in the center of thirteen 2-mile-wide corridors in Oklahoma (Beaver, Cimarron, and Texas counties) and Texas (Hansford, Ochiltree, and Sherman counties).
  - Tennessee Converter Station Siting Area: A 220-acre siting area and a 3-mile buffer from the boundary of the siting area in Shelby County, Tennessee.
  - Applicant Proposed Route: Six miles (3 miles either side) of the referenced centerline (explained above).
- DOE Alternatives
  - Arkansas Converter Station Alternative Siting Area: A 20,000-acre siting area and a 3-mile buffer from the boundary of the siting area in Pope County, Arkansas.
  - Arkansas Converter Station Alternative AC Interconnection Siting Area: Six miles (3 miles either side) of the referenced centerline. The referenced centerline is located in the center of a 2-mile-wide corridor.

- o HVDC alternative routes: Six miles (3 miles either side) of the referenced centerline (explained above).
  Region of Influence for Connected Actions

3.18.3.1.1 Wind Energy Generation

The WDZs are areas that have been identified within a 40-mile radius of the Oklahoma Converter Station Siting Area with adequate wind resources and within which future development of wind energy facilities could occur. The ROI for wind energy generation has been set at 30 miles from the boundary of each WDZ. The ROI for wind energy generation includes approximately 1,700 square miles, or 1,385,000 acres in Oklahoma (Beaver, Cimarron, and Texas counties) and Texas (Hansford, Ochiltree, and Sherman counties). Sensitive visual resources in the ROI for WDZs G, H, and I also include communities in Kansas.

3.18.3.1.2 Optima Substation

The ROI for the future Optima Substation includes a 3-mile buffer around the boundary of the substation site. The future Optima Substation would be constructed within 160 acres and is located approximately 2.3 miles east of the Oklahoma Converter Station Siting Area in Texas County, Oklahoma.

3.18.3.1.3 TVA Upgrades

The ROI for the direct assignment facilities (which are included in the Applicant Proposed Project) would occur within the Tennessee Converter Station Siting Area and more specifically within the Shelby Substation. The ROI for the network upgrades, and in particular TVA's future 500kV transmission line, cannot be fully determined at this time. The new 500kV line would be constructed in western Tennessee. The upgrades to existing facilities would mostly be in western and central Tennessee. Upgrades to existing infrastructure would include upgrading terminal equipment at three existing 500kV substations and six existing 161kV substations, making appropriate upgrades to increase heights on 16 existing 161kV transmission lines to increase line ratings, and replacing the conductors on eight existing 161kV transmission lines. The new 500kV transmission line would be in the Mississippi Valley Loess Plains region described in Section 3.18.4.8.

3.18.4 Affected Environment

The affected environment includes the visual resources described for the ROI in Regions 1 through 7. The methodology for conducting the visual resources inventory is graphically shown in a flowchart in Figure 3.18-2 in Appendix A.

To inventory and characterize the affected environment for visual resources, scenery and viewing locations, including KOPs, were considered. The following tasks were undertaken to inventory visual resources in the ROI:

- Documentation of existing landform, vegetation, and water features (scenery) at the regional scale (see the ecoregion description in Sections 3.18.4.1 through 3.18.4.10) and at the Project-specific scale (see regional description Sections 3.18.5.1 through 3.18.5.7)
- Identification of viewing locations including KOPs (viewing locations)

Scenery

Scenery is the aggregate of features that give character to the landscape (BLM 1984). Landscapes encompass varying levels of landform, vegetation, existence of water, color, scarcity, adjacent scenery, and cultural modifications. Cultural modifications are defined as human modifications to the landscape. All of these elements combine to form landscape character (BLM 2010). The existing landscape character provides the context for assessing the effects of changes to the landscape caused by the Project. Regional-level landscape character creates a sense of place and describes the generalized visual image of a specific geographic area. To assess impacts to the landscape's visual character, it is important to establish the context for the visual environment at both a regional level and at a project-specific level.

Regional Level Scenery

EPA Level III ecoregions were used to develop a description of the existing landscape character in Regions 1 through 7 (EPA 2012). Ecoregions provide an appropriate foundation for describing visual character at the regional level because they are defined based on elements similar to those used in the BLM's VRM for inventorying and assessing scenic quality (BLM 2010). These factors include physiographic elements of landform, vegetation, water, and cultural modifications. Level III ecoregions that cross the Project ROI include the Arkansas Valley, Boston Mountains, Central Great Plains, Central Irregular Plains, Cross Timbers, High Plains, Mississippi Alluvial Plain, Mississippi Valley Loess Plains, Ozark Highlands, and Southwestern Tablelands. Level III ecoregions are depicted in Figure 3.17-1 in Appendix A and detailed descriptions are provided in Sections 3.18.4.1 through 3.18.4.10.

Project-Specific Level Scenery

An inventory of the existing landscape character within the ROI was conducted to provide the context for assessing the effects of changes to the landscape at a level of detail consistent with the scale and dimensions of the Project and gain a broad understanding of the types of landscapes potentially crossed by the Project. The factors used to describe the visual character of the Level III ecoregions (topography, vegetation, water, and cultural modifications) were reviewed in further detail within the ROI and mapped using GIS. The factors were ranked and combined into 3 categories that were determined based on the frequency of occurrence of the factor in the Project area and the anticipated impacts to each type:

- Distinct—Landscapes where characteristic features of landform, water, and vegetation are distinctive or unique in the context of the surrounding areas. These features occur infrequently within the ROI and are typically associated with intact natural landscapes with minimal cultural modifications.
- Common—Landscapes where characteristic features of landform, water, and vegetation occur frequently within the ROI. These features are typically associated with croplands and rangelands with cultural modifications limited primarily to rural residential structures and ancillary facilities associated with farms (e.g., barns, silos, fences).
- Developed—Landscapes with a greater occurrence of cultural modifications than the surrounding areas. Cultural modifications in the landscape include roads, buildings (residential, commercial, industrial), utility lines, and other infrastructure and are typically associated with villages, towns, and cities.

To map the three categories within the ROI the landscape factors (topography, vegetation, water, and cultural modifications) were assigned a numeric value based on the criteria included in Table 3.18-3.

Table 3.18-3:
Landscape Category Inventory and Evaluation Rating

Landscape Inventory Factor	Rating Criteria and Score		
Landform	Terrain with slopes 26 percent or greater. High vertical relief as expressed in prominent hills, mountains, cliffs, or rock outcrops; or severe surface variation or highly eroded formations. Terrain features which are dominant or are exceptional. Score 5	Terrain with slopes ranging from 11-25 percent. Hills, canyons, ravines, or terrain with interesting erosional patterns. Terrain features that are interesting but not dominant or exceptional. Score 3	Terrain with slopes ranging from 0 to 10 percent. Flat gently rolling terrain with few or no interesting landscape features. Score 1
Vegetation	Forests, wetlands and National Forest lands. Exhibit a variety of vegetation types and are relatively untouched, natural/intact landscapes. Score 5	Crops/pasturelands. Vegetation types which occur most often in the landscape. Variety of vegetation is limited to only one or two major types. Score 3	Developed and barren land. Vegetation is either absent due to development or little or no variety of vegetation types. Score 1
Water	Lakes, reservoirs, and rivers. Features that are present and are a dominant factor in the landscape. Score 8 (derived from combination of landform, vegetation, and cultural modification rankings)	None	None
Cultural Modifications	Protected/scenic lands, parks, and trails. Cultural modifications add favorably to visual variety while promoting visual harmony. Cultural modifications may include picnic areas, trailheads, boat launches, trails and trail signage. Score 2	Cultural modifications add little or no visual variety to the area; and introduce no discordant elements. Score 0	Developed lands. Cultural modifications dominate the landscape; and may include moderate and high-density residential, commercial and/or industrial development or infrastructure such as roadways and utilities. Score -4

The sum of the numeric values for these factors determines the landscape category. Lands categorized as Distinct received a score of 9 or more, lands categorized as Common received a score of 3 to 8, and Developed lands received a score of 2 or less. Landscape categories are depicted in Figure 3.18-3 in Appendix A.

KOPs are viewing locations that are representative of visually sensitive areas used to assess visual impacts. The description of landscape categories from each KOP focuses on the view from the KOP out over the landscape; therefore, a KOP may be located within a certain landscape category but the view might be towards another. For example, a KOP located in a town would be in a landscape categorized as Developed, but the view from the KOP could be a landscape categorized as Common. Descriptions of the landscape category for each KOP are included in Sections 3.18.5.1 through 3.18.5.7.

Visual Sensitivity

BLM defines visual sensitivity as a measure of viewer concern for the scenic resource and potential changes to the resource. The level of viewer concern relates to the importance of maintaining the scenic quality or viewshed from a specific viewing location; and varies for different viewers or groups of viewers depending on viewer activities (Clean

Line 2014). For example, scenic routes are typically associated with viewers who have a high degree of concern for maintaining the scenic quality or viewshed because the landscape setting is a key component to the scenic designation. In contrast, viewing locations associated with a state route would have a lower sensitivity because viewers travel at a higher rate of speed and concern for aesthetics is generally secondary to commuting.

Viewing locations are defined as public and private areas (including KOPs) within the landscape where the Project could be visible, and where concern for changes to the landscape exists. Viewing locations are typically associated with residences, travel routes, and recreation areas; however, other viewers can have concern for changes to the landscape and include public facilities, such as schools and religious institutions and resorts. DOE and Clean Line identified viewing locations within the ROI through a desktop analysis of relevant, publicly available information and GIS databases. Additional viewing locations were identified outside the ROI and included viewing locations identified during agency consultation, stakeholder meetings, or public scoping (Clean Line 2014). These additional viewing locations were included in the visual analysis.

Visual sensitivity for each identified viewing location was based on the following factors: (1) volume of use, (2) frequency of views (i.e., how often the view is experienced), and (3) viewing duration.

Key Observation Points

KOPs represent a critical or representative viewpoint within or along an identified viewing location, used to assess visual impacts of a proposed project. A process for ranking all potential visual resources was developed to help select the most appropriate KOPs to complete the visual impact analysis. The process for ranking visual resources to identify KOPs involved the following steps:

- Identifying all visual resources in the ROI.
- Ranking visual resources using the KOP ranking criteria and formula described below, including resources identified through agency consultation, public scoping, or stakeholder outreach (Clean Line 2014).
- Selecting visual resources with values ranging from moderate high to high (Clean Line 2014).
- Reviewing Google Earth aerial imagery in combination with Google Earth Streetview and line-of-site tools (i.e., using .kmz files) to identify more precise locations of the selected visual resources, evaluate their potential visibility, and identify the best typical or representative views, as well as views from sensitive resources. Using these tools and professional judgment, the list of resources was narrowed to identify the best potential KOPs for field investigations (Clean Line 2014).

DOE and Clean Line identified KOPs for the Project from the list of visual resources by applying the following selection criteria:

- Visibility: If any portion of the Project is potentially visible from the KOP based on terrain.
- Distance: If the Project would potentially be visible within FG or MG distance zones (i.e., within 3 miles) of the KOP. The Project may be visible in the BG distance zone for some unique KOPs that receive high use and have high visual sensitivity and/or were identified during scoping or public or stakeholder outreach (e.g., an overlook at a state park within 15 miles of the Project).
- Visual Sensitivity: If the KOP is identified to have moderate–high visual sensitivity (Clean Line 2014).

KOPs are depicted in Figures 3.18-3 in Appendix A. To document the existing conditions of the landscape viewed from the selected KOPs consistently, inventory forms were used for KOPs on federal, state, and private lands (see Visual Contrast Rating Worksheets in Appendix K).

3.18.4.1 Arkansas Valley

The Arkansas Valley ecoregion is characterized by undulating plains with scattered hills, open low mountains, ridges, cuesta, and level to undulating floodplains and terraces associated with the Arkansas River. The broad floodplain valley of the Arkansas River includes low terraces, meander scars, oxbows, swales and natural levees. This ecoregion also contains perennial and intermittent streams and several large reservoirs and lakes. Elevations range from 100 to 1,500 feet AMSL. Vegetation types consist of oak savanna and oak-hickory-pine forests with maple, beech, elm and red cedar in upland areas. Dense deciduous forests occupy broad areas along streams and within floodplains and consist largely of bottomland oaks, sycamore, sweetgum, willow, eastern cottonwood, green ash and elm. Cultural features in this ecoregion consist primarily of croplands and pasturelands. Cropland occurs extensively in floodplain areas and consists largely of soybeans, grain sorghum, wheat, alfalfa, and corn. Poultry and livestock farming also occur within this ecoregion. Other cultural modifications include coal mining, natural gas production facilities, distribution and high-voltage transmission lines, paved and unpaved roadways, scattered rural residences, and farms and associated appurtenances (e.g., barns, silos, fences, other out buildings, etc.).

The ROI in Regions 4 and 5 crosses the Arkansas Valley ecoregion (Figure 3.17-1 in Appendix A).

3.18.4.2 Boston Mountains

The Boston Mountains ecoregion is characterized by low rugged mountains typically capped by sandstone, high rounded hills, and deeply dissected mountainous plateaus. Outcrops are common within this ecoregion. The area contains a high density of intermittent and perennial streams, several of which are designated as wild and scenic. Elevations range from 475 to 1,700 feet AMSL. Vegetation types consist primarily of oak-hickory forests with shortleaf pine and red cedar found in many lower areas. On north-facing slopes and in ravines, dominant vegetation includes sugar maple, beech, red oak, basswood and hickory. Bottomlands contain riparian hardwood forests dominated by birch, sycamore, cottonwood, elm, and willow. This region is sparsely populated and recreation and forestry are the primary land uses. The Ozark National Forest occupies much of this ecoregion and logging and recreation are common activities. Livestock farming, pastures and hayland occupy some of the flatter areas. Croplands are rare within this ecoregion. Other cultural modifications include electric distribution lines, paved and unpaved roads, and rural residences.

The ROI in Regions 4 and 5 crosses the Boston Mountains ecoregion (Figure 3.17-1 in Appendix A).

3.18.4.3 Central Great Plains

The Central Great Plains ecoregion is characterized by broad alluvial valleys, level to gently rolling plains, dissected gently to steeply rolling hills, ravines, low escarpments, and some sand dunes. Water is generally limited to ephemeral and intermittent streams, often with incised channels, that occur in the area. Some larger rivers with braided sandy channels also cross the ecoregion including Beaver River/North Canadian River and Cimarron River. Elevations range from 750 to 2,700 feet AMSL. Much of the vegetation within this ecoregion has been converted to croplands. Natural vegetation that occurs within the ecoregion includes scattered grasslands consisting of short-, mixed-, and tallgrass prairie; oak savanna and eastern red cedar in some upland areas; and cottonwood, willow, walnut, ash, and elm in scattered riparian areas. Cultural features in this ecoregion consist mostly of dryland and irrigated croplands, including corn, grain sorghum, alfalfa, and cotton. Other cultural modifications common to this ecoregion include natural gas and oil fields, distribution and high-voltage transmission lines, paved and unpaved roadways, scattered rural residences, and farms and associated appurtenances.

The ROI in Regions 1, 2, and 3 crosses the Central Great Plains ecoregion (Figure 3.17-1 in Appendix A).

3.18.4.4 Central Irregular Plains

The Central Irregular Plains ecoregion is characterized by rolling and irregular plains with intermittent low hills and cuestas, which are ridges with a steep face on one side (usually on the eastern side) and a gentle slope on the other. Perennial streams are common within this ecoregion and in some areas many are channelized. Some larger streams, reservoirs, and rivers, such as the Arkansas River, occur in this ecoregion. Elevations range from 500 to 1,050 feet AMSL. Vegetation types consist of tall grass prairie with oak-hickory woodlands in upland and more rugged areas. Wooded riparian areas occur in wet bottomlands and consist largely of box elder, maple, oak, cottonwood, willow, walnut, pecan, hackberry, elm, and sycamore. Cultural features in this ecoregion consist of a mosaic of cropland, woodland, and grassland. Croplands consist largely of wheat, soybeans, grain sorghum, and alfalfa. Other cultural modifications include oil and gas and coal mining production facilities, distribution and high-voltage transmission lines, paved and unpaved roadways, scattered rural residences, and farms and associated appurtenances.

The ROI in Region 3 crosses the Central Irregular Plains ecoregion (Figure 3.17-1 in Appendix A).

3.18.4.5 Cross Timbers

The Cross Timbers ecoregion is characterized by gently rolling hills with some ridges and ledges. Small perennial streams are common and in some areas many are channelized. Some larger streams, reservoirs, and lakes also occur within this ecoregion. Elevations range from 600 to 1,300 feet AMSL. Vegetation types consist of oak savanna, oak-hickory woodlands, and eastern red cedar interspersed with openings of tall grass prairie in upland areas. Scattered riparian areas consist of cottonwood, willow, walnut, ash, elm, and sycamore. Cultural features in this ecoregion consist primarily of rangeland and pastureland with some croplands. Where cropland occurs, it consists largely of corn, soybeans, hay, and grain sorghum. Other cultural modifications include natural gas and oil fields with associated facilities, distribution and high-voltage transmission lines, paved and unpaved roadways, scattered rural residences, and farms and associated appurtenances.

The ROI in Region 3 crosses the Cross Timbers ecoregion (Figure 3.17-1 in Appendix A).

3.18.4.6 High Plains

The High Plains ecoregion is characterized by nearly level gently rolling terrain, with some sand plains and hills and scattered playa depressions. Playas are flat-bottom depressions typically found in arid and semiarid regions that are seasonally covered by water. In addition to playas, other water sources that occur within this ecoregion primarily include intermittent and ephemeral streams. Elevations range from 2,400 to 4,800 feet AMSL. Vegetation types are mostly short and midgrass prairie, with other types of vegetation including Harvard shin oak, fourwing saltbush, sand sagebush, and yucca. Riparian vegetation such as cottonwood and willow can be found scattered along riparian areas. Cultural features in this ecoregion include cropland and grazing land. Croplands largely consist of winter wheat and grain sorghum. Center-pivot irrigation is widely used. Concentrated hog feeding operations and natural gas and oil development facilities are common within this ecoregion. Other cultural modifications include distribution and high-voltage transmission lines, wind farms, paved and unpaved roadways, scattered rural residences, and farms and associated appurtenances.

The ROI in Region 1 crosses the High Plains ecoregion (Figure 3.17-1 in Appendix A).

3.18.4.7 Mississippi Alluvial Plain

The Mississippi Alluvial Plain ecoregion is characterized primarily by broad, flat to nearly flat floodplains and river terraces threaded with numerous drainages. Several large streams and rivers flow and wind generally south, including the White, Cache, and Mississippi rivers. Many of the waterways have been channelized and several flood-control levees installed. Elevations range from 100 to 275 feet AMSL. Vegetation consist primarily deciduous hardwood forest, forested wetlands, and wetlands. Forests are comprised of hickory, maple, oak, ash and bald cypress, tupelo, sweetgum, sycamore in wetter areas. Cropland occurs extensively in floodplain areas and consists largely of soybeans, rice, grain sorghum, corn, cotton, and wheat. Other cultural modifications include distribution and high-voltage transmission lines, paved and unpaved roads, scattered rural residences, and farms and associated appurtenances, and commercial catfish and crawfish farms.

The ROI in Regions 5, 6, and 7 crosses the Mississippi Alluvial Plain ecoregion (Figure 3.17-1 in Appendix A).

3.18.4.8 Mississippi Valley Loess Plains

The Mississippi Valley Loess Plains ecoregion is characterized primarily by low, steeply to gently sloping ridges and low terraces dissected by numerous small ravines and intermittent streams. Few lakes occur within this ecoregion. Elevations range from 200 to 500 feet AMSL. Vegetation types consist of mixed deciduous forests consisting of oaks, hickories and loblolly and shortleaf pines. Crops include soybeans, cotton, corn, and wheat. Other cultural modifications that occur within this ecoregion include distribution and high-voltage transmission lines, paved and unpaved roads, rural residences, and farms and associated appurtenances.

The ROI in Regions 6 and 7 crosses the Mississippi Valley Loess Plains ecoregion (Figure 3.17-1 in Appendix A).

3.18.4.9 Ozark Highlands

The Ozark Highlands ecoregion is characterized by gently rolling plains to moderate and highly dissected hilly plateaus, small steep valley, and sharp narrow ridges. Perennial and intermittent streams are common in this ecoregion as are ponds, lakes, and reservoirs. Elevations range from 300 to 1,850 feet AMSL. Vegetation types consist of upland forest dominated by oak, hickory, and pine. Forests are most common and dense on north-facing slopes and ravines. Cultural modifications in this ecoregion include pasturelands, typically found in flatter areas at the periphery of the ecoregion. Grazing, logging and recreation are common activities in this ecoregion. Croplands are not prevalent in this ecoregion. Other cultural modifications include mining facilities, distribution and high-voltage transmission lines, paved and unpaved roads, and scattered rural residences.

The ROI in Region 4 crosses the Ozark Highlands ecoregion (Figure 3.17-1 in Appendix A).

3.18.4.10 Southwestern Tablelands

The Southwestern Tablelands ecoregion is characterized by broad, flat elevated tablelands with red-hued shallow canyons, mesas, badlands, gorges, and dissected river breaks. Water is generally scarce, limited mostly to ephemeral and intermittent streams. Elevations range from 1,900 to 3,450 feet AMSL. Vegetation types consist mostly of shortgrass prairie, wheat grass, western wheatgrass, bluestem, and dropseed, with some occurrences of sagebrush, yucca, and cholla. Juniper-pinyon woodlands occur in some areas. Scattered riparian areas consist of cottonwoods, willow, elm, and hackberry. Cultural features in this ecoregion consists mostly of semiarid range land with some cropland areas. Croplands largely consist of winter wheat, grain sorghum, corn, and alfalfa. Other cultural modifications include natural gas and oil fields with associated facilities such as pump jacks, storage tanks, and piping, wind farms, distribution and high-voltage transmission lines, paved and unpaved roadways, scattered rural residences, and farms and associated appurtenances.

The ROI in Region 1 crosses the Southwestern Tablelands ecoregion (Figure 3.17-1 in Appendix A).

3.18.5 Regional Description

Several route variations to the Applicant Proposed Route in Regions 2–7 were developed in response to public comments on the Draft EIS, which are described in Appendix M and summarized in Sections 2.4.2.1–2.4.2.7. Assessments of the impacts related to the route variations by Project region, including accompanying HVDC alternative route adjustments, are provided below. The variations are presented graphically in Exhibit 1 of Appendix M. No route variations were proposed in Region 1.

3.18.5.1 Region 1

Region 1 is referred to as the Oklahoma Panhandle Region and includes the Applicant Proposed Route Links 1 through 5, HVDC Alternative Routes I-A through I-D, Oklahoma converter station siting area and associated AC interconnection siting area, and AC collection system. The ROI in Region 1 crosses the following Level III ecoregions: High Plains, found within the western portion of the region; Southwestern Tablelands, found in the central and eastern portion; and Central Great Plains, found in the far eastern portion of the region. The landscape character within the ROI is predominantly agricultural and rural with open rangeland, grassland, and some cropland. The flat, open terrain allows for expansive views across the landscape (GIS Data Sources: Clean Line 2013a, 2013b; Tetra Tech 2014a). Other topographic features found within the ROI include small canyons, ravines, low escarpments, bluffs and rocky outcrops; however these features are scarce. The ROI traverses the Beaver River/North Canadian River and several intermittent streams, creeks, and dry washes. Vegetation consists primarily of grasses with riparian species found along rivers and other drainageways and in wetland areas. In addition, trees associated with residential development are common within the landscape and can be seen clustered around rural residential homes and along fields and roads. Cultural modifications include agriculture and croplands, farms and associated appurtenances, local roads and highways, wind farms, and high-voltage transmission lines. Several small communities are located within and/or adjacent to the ROI including the towns of Hardesty, Laverne, May, and Fort Supply, and the communities of Balko, Bryans Corner, and Elmwood.

Visual resources identified in the ROI include rural residences and residential areas associated with the towns and other small communities, Lake Schultz State Park, Beaver Dune State Park, several NWRs, Palo Duro and Kiowa creeks and Beaver River/North Canadian River, and historic landmarks.

3.18.5.1.1 Landscape Character Description by KOP

Fort Supply WMA Recreation Area Applicant Proposed Route (identified as Proposed Route [PR] in Appendix K). This KOP represents views from recreational users near the northern edge of the Fort Supply Reservoir. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from a community recreation area. The strong concern refers to the public concern for the state of the environment as defined in environmental aesthetic philosophy. The landscape viewed from this KOP is characterized by gently rolling terrain and dense deciduous and evergreen forest. In addition, a large reservoir dominates many views from within the recreation area. Given the variation in vegetation and the dominant water feature, this landscape is categorized as Distinct. Cultural modifications include recreational facilities associated with the Fort Supply WMA Recreation Area, including playground equipment and picnic shelters.

Hardesty Alternative Route (AR). This KOP represents views from residential areas along the southern boundary of Hardesty, Oklahoma. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from residential areas. The landscape viewed from this KOP consists primarily of grasslands and cultivated croplands with scattered rural residences; and was therefore categorized as Common. Cultural modifications include chain-link fences and electric distribution lines associated with scattered rural residences.

Lake Schultz State Park AR. This KOP represents views to the north from recreational users near the west entrance to the Lake Schultz State Park and WMA. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from a public park and WMA. The landscape viewed from this KOP consists of level to gently rolling terrain, sloping down towards Shultz Lake, a shallow depression in the landscape. Vegetation includes low grasses and shrubs, including Yucca, with dense stands of trees concentrated in the bottom of the depression. Water is not present year round within the lake. Given the variation in vegetation, presence of water and the State Park designation, this landscape is categorized as Distinct. Cultural modifications that are visible to the north include scattered rural residential structures in the BG.

Lake Schultz State Park PR. This KOP represents views to the south from recreational users near the west entrance to the Lake Schultz State Park and WMA. Similar to the Lake Schultz State Park AR KOP, visual sensitivity at this KOP is also high and was categorized as Distinct given the variation in vegetation, presence of water, and the State Park designation. Cultural modifications that are visible from this KOP include fences and a high-voltage transmission line in the FG/MG.

Laverne AR. This KOP represents views from a residential neighborhood in Laverne, Oklahoma. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from residential areas. The landscape viewed from this KOP is characterized by flat terrain with vegetation consisting primarily of low grasses. Vegetation includes trees planted along roadways and around rural residential structures. Croplands and grasslands are typical within the region; therefore, this landscape is categorized as Common. Cultural modifications include light poles, electric distribution lines, and residential structures.

Local Historical Marker AR/PR. This KOP represents views to the south from a local historical marker located on the northern side of Route 3/270. Visual sensitivity at this KOP is moderate because of the low level of use and short viewing durations and the fact that, besides the historical markers, there are no other facilities. The landscape viewed from this KOP is characterized by relatively level to gently rolling terrain covered primarily with grasses and scattered trees; therefore, this landscape is categorized as Common. Cultural modifications visible from this KOP include low wire fences, unpaved roads, and distribution and high voltage transmission lines. The lack of variation in terrain allows panoramic views of the surrounding landscape to the south Cultural modifications visible from this KOP include electric distribution lines.

May PR. This KOP represents residential views to the south from the community of May, Oklahoma. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from residential areas. The landscape viewed from this KOP is characterized by relatively level to gently rolling terrain with stands of deciduous trees clustered around rural residential structures or dense stands within open fields. Grasslands and scattered rural residential developments are typical within the region; therefore, this landscape is categorized as Common. Cultural modifications include scattered residential structures, sheds and storage buildings, low fences, and electric distribution lines.

Optima NWR AR. This KOP represents views from the southern edge of the Optima NWR, which primarily serves as an access point for hunters. Visual sensitivity at this KOP is high because of the long viewing durations from a National Wildlife Refuge. The landscape viewed from this KOP is characterized as gently rolling to low hills with vegetation consisting primarily of grasses. Although there is some variation in the terrain, there is very little variation in vegetation and the area is primarily grasslands that are typical within the region; therefore, this landscape is categorized as Common. Cultural modifications include multiple electric distribution lines in the FG/MG.

3.18.5.2 Region 2

Region 2 is referred to as the Oklahoma Central Great Plains Region and includes the Applicant Proposed Route Links 1 through 3 and HVDC Alternative Routes 2-A and 2-B. The ROI in Region 2 traverses Woodward, Major, and Garfield counties in Oklahoma. The ROI crosses only one Level III ecoregion, Central Great Plains. The landscape character within the ROI in Region 2 is predominantly rangeland and cropland. The relatively flat to gently rolling terrain allows for expansive views across much of the landscape (GIS Data Sources: Clean Line 2013a, 2013b; Tetra Tech 2014a). Other topographic features found within the ROI include low escarpments, terraced buttes, ravines, sand dunes, and rocky outcrops, although these features are scarce. The Cimarron River and Turkey Creek traverse the ROI along with several smaller creeks, drainages, and washes. Several man-made impoundment ponds occur along drainages in the ROI. Vegetation consists primarily of grasses, low shrubs, oak savanna, and riparian species scattered along streams, washes, and other drainageways and wetlands. In addition, trees associated with residential development are common within the landscape and can be seen clustered around rural residential homes and along fields and roads. Cultural modifications include agriculture, croplands, farms and associated appurtenances, wind farms, natural gas and oil facilities, hog and poultry operations, feed lots, roads, highways, high-voltage transmission lines, and rural residences. Several communities are located within and/or adjacent to the ROI including the cities of Fairview and Woodward; the towns of Ames, Cleo Springs, and Mooreland; and the communities of Bison and Waukomis.

Visual resources identified in the ROI include rural residences and residences associated with cities, towns, and other small communities; Gloss Mountain State Park; Boiling Springs State Park; several State Conservation Areas; and Cimarron River and Turkey Creek.

Two route variations to the Applicant Proposed Route were developed in Region 2 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.2. The variations are illustrated in Exhibit 1 of Appendix M. These variations represent minor adjustments to the Applicant

Proposed Route and the landscape setting and visual resources would remain consistent within the ROI. Applicant Proposed Route Link 1, Variation 1, would avoid crossing a wooded area crossed by the original Applicant Proposed Route and would be located farther from Boiling Springs State Park. However, this variation would be closer to more residences and structures. Applicant Proposed Route Link 2, Variation 2, crosses a similar landscape setting as the original Applicant Proposed Route including grasslands and cultivated crops. Although this variation would be located further from some residences, it would be located closer to others.

3.18.5.2.1 Landscape Character Description by KOP

Ames PR/AR. The Ames KOP represents residential views in Ames, Oklahoma, as well as representative views from the historic Cimarron River Branch Cattle Trail. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from residential areas and the historical designation and long viewing duration of visitors and tourists engaged in leisure activities of the trail. The landscape viewed from this KOP is characterized by nearly level to low rolling hills covered with grasses and with scattered trees and grasses in the FG/MG and denser stands of trees in the BG. Grasslands are typical within the region; therefore, this landscape is categorized as Common. Cultural modifications include electric distribution lines.

Bison AR. This Bison AR KOP is located on the northern side of Bison, Oklahoma and represents typical residential views. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from residential areas. The landscape viewed from this KOP is categorized as Developed in the FG because of cultural modifications associated with Bison and the landscape in the MG is characterized as Common because of the level terrain and lack of vegetation. Cultural modifications include fences, residential structures, storage sheds, silos, street lights and electric distribution lines.

Bison PR. This Bison AR KOP is located on the southern side of Bison, Oklahoma and represents typical residential views. The landscape viewed from this KOP is categorized as Developed in the FG because of cultural modifications associated with Bison and the landscape in the MG is categorized as Common because it consists of grasslands and croplands with scattered rural residences typical within the region. Cultural modifications include fences and residential structures, storage structures, and electric distribution lines.

Boiling Springs State Park PR. This KOP represents views from the Boiling Springs State Park recreation area. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from a state park recreation area. The landscape viewed from this KOP consists of level to gently rolling terrain with grasses and scattered areas of dense trees and shrubs. Small lakes occur within the park but are not dominant features. Given the variation in vegetation, presence of water and the State Park designation, this landscape is categorized as Unique.

Canton WMA and Lake Recreation Area PR. This KOP represents views from a Canton Lake. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from a community recreation area. The landscape viewed from this KOP is characterized by level terrain in the immediate FG, a large expansive lake in the FG/MG, and dense vegetation along the northern edge of the lake in the BG. Given the dominance of the water feature and variation in vegetation around the lake, this landscape is categorized as Distinct. Cultural modifications include recreational elements associated with Canton Lake Recreation Area.

Cimarron River Crossing AR. This KOP represents the crossing of a major river. Visual sensitivity at this KOP is moderate because a concern for aesthetics is generally secondary to commuting from this location, even though it represents a major water body. The landscape viewed from this KOP consists of level terrain sloping down to a wide, flat sandy river bottom. Water meanders along the sandy bottom creating a braided pattern. Dense stands of riparian species occur along the banks of the river. Due to the dense stands and variety of vegetation and presence of water, this landscape is categorized as Distinct. Cultural modifications include a bridge and guard rails, fences and a distribution line in the FG and a transmission line in the MG.

Cimarron River Crossing PR. This KOP represents views of the Cimarron River crossing from a local road. Visual sensitivity at this KOP is moderate because a concern for aesthetics is generally secondary to commuting from this location, even though it represents a major water body. The landscape viewed from this KOP consists of a wide, flat sandy river bottom. When the river is not flowing full, water meanders along the sandy bottom creating a braided pattern. Dense stands of riparian vegetation occur along the banks of the river. Cultural modifications are limited to the road and bridge crossing the river, guardrails and road signs. Due to the presence of water, the variety of vegetation and lack of cultural modifications, this landscape is categorized as Distinct.

Cleo Springs AR. This KOP represents views to the south from residential areas along the southern boundary of Cleo Springs, Oklahoma. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from residential areas. From this KOP the landscape in the FG is categorized as Developed because of cultural modifications associated with Cleo Springs, and the landscape in the MG is categorized as Common because it consists primarily of grasslands, rural residences, and scattered stands of trees. Cultural modifications include residential structures, outbuildings (e.g., sheds, barns) associated with farms, communications structures, and transmission lines.

Fairview PR. This KOP represents a view looking south from along the southern boundary of Fairview, Oklahoma. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from residential areas and a public park. From this KOP, the landscape in the FG is categorized as Developed because of cultural modifications associated with Fairview, and the landscape in the MG is categorized as Common because it consists primarily of croplands, rural residences, and scattered stands of trees. Cultural modifications include ball fields, fences, light poles, and electric distribution lines in the FG and residential structures, electric distribution lines, and a communication tower in the MG.

Gloss Mountain State Park AR. This KOP is representative of the view looking northeast from the north overlook at Gloss Mountain State Park. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from a state park. The landscape viewed from this KOP consists of mesas, with steep slopes and flat tops surrounded by level to gently rolling terrain. Erosion over time has caused the sides of the mesas to erode, leaving v-shaped slopes that are deep red/rust in color. Vegetation is limited to grasses and shrubs on the mesas and the adjacent area. Dense stands of trees are visible in the MG/BG and are associated with the Cimarron River to the north. This landscape is categorized as Distinct due to the tall, steep rugged landforms and color, which are not typical features in the region. Cultural modifications include scattered oil and gas facilities and transmission structures.

Gloss Mountain State Park APR. This KOP is representative of the view looking southwest from an overlook in Gloss Mountain State Park. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from a state park. The landscape viewed from this KOP consists of mesas, with steep slopes and flat tops surrounded by level to gently rolling terrain. Erosion over time has caused the sides of the mesas to erode, leaving v-shaped slopes that are deep red/rust in color. Vegetation is limited to grasses on the mesas; the surrounding plains are covered with grasses and scattered shrubs and trees. This landscape is categorized as Distinct. Cultural modifications are limited to primarily roads within the FG/MG.

Mooreland PR. This KOP is representative of the view from a ball field on the southern edge of the community of Mooreland, Oklahoma. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from a community park and residential areas. The landscape viewed from this KOP is characterized by gently rolling terrain with grasses and scattered evergreen and deciduous trees. This landscape is categorized as Developed because of cultural modifications associated with Mooreland including fences, light poles, structures associated with the ball field, and residential structures. The rolling terrain and vegetation surrounding the ball field obstructs views beyond the MG.

State Road (SR) 60 West of Fairview PR. This KOP represents views from along eastbound SR 60 west of Fairview, Oklahoma. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from residential areas along the roadway and because it was identified as an important resource during public scoping (Clean Line 2014). This landscape is characterized by gently rolling terrain, grasslands, and large fields cleared for agricultural activities, with evergreen and deciduous trees clustered around rural residences. This type of landscape is typical within the region and was therefore categorized as Common. Cultural modifications visible from this KOP include residential structures and outbuildings associated with an adjacent farm, wood H-frame transmission structures, a distribution line that parallels the southern side of SR 60, and a communication tower in the BG. Views of the surrounding landscape are open due to the lack of variation in terrain and vegetation.

Waukomis AR. This KOP represents typical views from a residential area along the southern edge of Waukomis, Oklahoma. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from residential areas. The landscape viewed from this KOP consists primarily of cultivated croplands with evergreen and deciduous trees clustered around rural residences; therefore this landscape was categorized as Common. Cultural modifications include short wire fences around fields, a distribution line and residential structure in the FG and a communication tower and transmission lines in the MG.

3.18.5.3 Region 3

Region 3 is referred to as the Oklahoma Cross Timbers Region and includes the Applicant Proposed Route Links 1 through 6 and HVDC Alternative Routes 3-A through 3-E. The ROI in Region 3 traverses Garfield, Kingfisher, Logan, Payne, Lincoln, Creek, Okmulgee, and Muskogee counties in Oklahoma. The ROI crosses three Level III ecoregions: Central Irregular Plains, found within the western portion of the region; Cross Timbers, found in the central portion; and Central Great Plains, found within the eastern portion of the region. The landscape character within the ROI is predominantly rangeland, cropland, and pastureland with some woodland and grassland areas. The relatively flat to gently rolling terrain found primarily in the western portion of the region allows for expansive views across much of the landscape (GIS Data Sources: Clean Line 2013a, 2013b; Tetra Tech 2014a). The terrain transitions to more steeply rolling hills interspersed with ravines, low escarpments, sand dunes, and cuestas in the central and eastern portion of the ROI. In these areas, the varied terrain and forested areas limit distant views. The ROI traverses the Cimarron and Arkansas rivers and several small ephemeral streams. Other surface waters in the region include wetlands, impoundment ponds, reservoirs, and lakes (i.e., Lake Carl Blackwell, Lake McMurtry, Lake Perry, Okmulgee Lake, and Lake Cushing). Vegetation consists primarily of grasses and shrubs, oak savanna, oak-hickory woodland, eastern red cedar, and riparian species along streams, at the edges of lakes and reservoirs and in wetland areas. In addition, rows of trees along fields and roadways are common within this region. Cultural modifications include agriculture, croplands, farms and associated appurtenances, wind farms, natural gas and oil facilities, hog and poultry operations, feed lots, roads, highways, high-voltage transmission lines, and rural residences. Several large and small communities occur within and/or adjacent to the ROI including the cities of Crescent, Stillwater, Perkins, Cushing, Drumright, Bristow, Stroud, Beggs, Okmulgee, and Muskogee and the towns of Marshall, Ripley, Shamrock, Winchester, Haskell, Wainwright, Oktaha, Summit, Rentiesville, and Webbers Fall.

Visual resources identified in the ROI include rural residences and residences associated with towns and cities, several state and National Wildlife Conservation areas, Robert S. Kerr Reservoir, Cimarron and Arkansas rivers, and several historic landmarks, such as Tank Farm Loop Route 66 Roadbed, Irvings Castle, and Little Deep Fork Creek Bridge.

Five route variations to the Applicant Proposed Route were developed in Region 3 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.3. The variations are illustrated in Exhibit 1 of Appendix M. These variations represent minor adjustments to the Applicant Proposed Route and the landscape setting and visual resources would remain consistent within the ROI. Applicant Proposed Route Link 1, Variation 2, crosses a landscape setting that is similar to the Applicant Proposed Route, including grasslands and wooded areas; however, this variation would avoid crossing an agricultural field crossed by the original Applicant Proposed Route. Although this variation would be located further from some residences, it would be located closer to others. Applicant Proposed Route Links 1 and 2, Variation 1, crosses a similar landscape setting as the original Applicant Proposed Route and would be located farther from some residences and closer to others. It should be noted that a route adjustment was made for HVDC Alternative Route 3-A to maintain an end-to-end route with the Links 1 and 2 variations. Applicant Proposed Link 4, Variation 1, would avoid crossing a quarry operation crossed by the Applicant Proposed Route; however, this variation would be closer to more residences and structures. Applicant Proposed Route Link 4, Variation 2, crosses a landscape setting that is similar to the original Applicant Proposed Route, including woodlands and grasslands, and would be located further from residences. Applicant Proposed Route Link 5, Variation 2, would cross more wooded areas than the Applicant Proposed Route, and the eastern portion of Variation 2 would parallel an existing 500kV transmission line for approximately 0.6 mile. However, this variation would be located closer to more residences and structures.

3.18.5.3.1 Landscape Character Description by KOP

Agra AR. This KOP represents views from a residential area near the southern boundary of Agro, Oklahoma. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from residential areas. The landscape viewed from this KOP is characterized by gently rolling terrain with grasses and dense stands of evergreen and deciduous trees. This landscape is categorized as Developed because of cultural modifications associated with Agra including wood and chain-link fences, light poles, electric distribution lines and commercial structures.

Beggs AR. This KOP represents residential views from the southern edge of the Beggs, Oklahoma. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from residential areas. The landscape viewed from this KOP is characterized by gently to moderately rolling terrain in the FG with larger, steeper hills in the MG. Large dense stands of evergreen and deciduous trees cover the landscape in the FG and

MG. Given the variation in terrain and vegetation, this KOP is categorized as Distinct. Cultural modifications include residential structures, low wire fences and a distribution line. Views from this KOP are limited by the rolling terrain and dense stands of trees.

Beggs PR. This KOP represents views from a school and an environmental education facility located near the northern boundary of Beggs, Oklahoma. Visual sensitivity at this KOP is moderate because of the low level of use and activities are directed inward to the wetlands features within the environmental education facility. The view from this KOP consists of grasslands with dense stands of evergreen and deciduous trees clustered around rural residences and man-made retention ponds. Grasslands are typical within the region, so this landscape was categorized as Common. Cultural modifications include a boardwalk and picnic pavilion associated with the environmental interpretive center and a chain-link fence around the facility in the FG and residential structures in the MG.

Boynton AR. Views from this KOP represent residential views from the western edge of Boynton, Oklahoma. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from residential areas. The landscape viewed from this KOP is categorized as Common because it consists of grasslands and croplands with scattered rural residences with deciduous and evergreen trees clustered around residences and along roadways. Cultural modifications include residential structures, low wire fences, and a distribution line. The level terrain allows for open views of the MG/BG; however, views may be limited by dense stands of trees.

Bristow and Route 66 AR. This KOP represents views from residences located along the southern edge of the town of Bristow, Oklahoma. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from residential areas. The view from this KOP is categorized as Common within the FG because it consists of grasslands with pockets of wooded areas interspersed around cleared fields typical within the region. Cultural modifications include electric distribution lines and existing wood H-frame transmission line structures. Views from this KOP are limited by a dense wooded area within the FG.

Cimarron River Crossing PR. This KOP represents the crossing of a major river from a local roadway. Visual sensitivity at this KOP is moderate because from this route, concern for aesthetics is generally secondary to commuting. The landscape viewed from this KOP consists of a wide flat sandy river bottom with riparian vegetation along the banks of the river in the FG and grasslands with scattered trees and small pockets of wooded areas in the MG. Due to the presence of water and variety of vegetation, this landscape is categorized as Distinct. Cultural modifications include a transmission line in the FG (crossing the river) and the MG, and structures associated with agricultural activities. Views from along this roadway are partially limited by the dense riparian vegetation along the banks of the river.

Council Hill AR. This KOP represents views to the north from a residential area along the northern boundary of Council Hill, Oklahoma. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from residential areas. From this KOP, the landscape in the immediate FG is categorized as Developed because of cultural modifications associated with Council Hill, and the landscape in the MG is categorized as Common because it consists primarily of grasslands with small pockets of wooded areas. Cultural modifications include fences, barn structures and a distribution line. Views are limited due to the small wooded areas and vegetation along roadways.

Cushing PR. This KOP represents views from a rural residential area northwest of Cushing, Oklahoma. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from residential areas. The view from this KOP is characterized as gently to moderately rolling grasslands and croplands with pockets of wooded areas and small man-made retention areas typical within this region, so this landscape is categorized as Common. Cultural modifications include fences, residential structures, out structures associated with farms (e.g., barns, sheds, corrals), in the FG and a communication tower and transmission line in the MG.

Depew and Route 66 AR. This KOP represents views to the northeast from a rural residential area near the northern boundary of Depew, Oklahoma. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from residential areas. From this KOP the landscape in the immediate FG is categorized as Developed because of cultural modifications associated with Depew, and the landscape in the MG is categorized as Common because it consists of grasslands/agricultural fields, rolling hills, and pockets of wooded areas. Cultural modifications include residential and commercial buildings. Vegetation screens much of the view past the immediate FG from this KOP, with intermittent views of the MG.

Heyburn Lake PR. This KOP represents views to the southwest from recreational users on the northern side of Heyburn Lake. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from a public park and recreational area. The landscape viewed from this KOP is characterized by a large lake surrounded by riparian vegetation along the edge of the lake. Given the variation in vegetation and the dominant water feature, this landscape is categorized as Distinct. Cultural modifications include recreational facilities associated with the recreation area, including playground equipment and picnic and camping areas. Views from this KOP are limited by the dense vegetation along the southern side of the lake.

Honey Springs Battlefield Historic Site and Rentiesville AR South. This KOP represents views north from the southern boundary of the historic Honey Springs Battlefield site. Visual sensitivity at this KOP is high due to the historic designation of the site. The landscape viewed from this KOP is characterized by level terrain—open fields with pockets of wooded areas. There is a small, narrow stream that meanders through the landscape; however, this water feature does not dominate the landscape. This type of landscape is typical within this region, so this landscape is categorized as Common. Cultural modifications include structures associated with the interpretive facilities including a small bridge, rock interpretive shelter and several stone monuments, and a distribution line.

Honey Springs Battlefield Historic Site AR North. This KOP represents views north from the northern boundary of the historic Honey Springs Battlefield site. Visual sensitivity at this KOP is high due to the historic designation of the site. The landscape viewed from this KOP is characterized by level open fields with pockets of wooded areas around the fields typical within this region, so this landscape is categorized as Common. Cultural modifications include small interpretive signs and a transmission line.

Lake Carl Blackwell AR. This KOP represents views south from the southern side of Lake Carl Blackwell. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from a recreational area. The landscape viewed from this KOP is characterized by level to gently rolling terrain and a large lake with dense stands of riparian vegetation along the banks. Given the variation in vegetation and the dominant water feature, this landscape is categorized as Distinct. Cultural modifications include recreational facilities associated with the recreation area, including picnic shelters, campers, and docks; and a communication tower, cell phone tower and transmission line in the MG.

Marshall AR. This KOP represents a view looking north from a residential area near the northern edge of Marshall, Oklahoma. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from residential areas. The view from this KOP is characterized as flat croplands with vegetation along the edge of fields and clustered around residential development typical within this region, so this landscape is categorized as Common. Cultural modifications include small wire fences, residential structures, and a distribution line.

Marshall PR. This KOP represents a view southwest from the southern edge of Marshall, Oklahoma. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from residential areas. The view from this KOP is characterized as level to gently rolling terrain and croplands with vegetation along the edge of fields and clustered around residential structures and along small streams that traverse the landscape. Croplands and rural residences are typical within this region, so this landscape is categorized as Common. Cultural modifications consist of residential structures, electric distribution lines, and oil and gas features (i.e., tanks and pump jacks) in the MG and a communication tower in the BG.

McLain AR. This KOP represents the view south from a rural country road near the community of McLain, Oklahoma. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from residential areas. The view from this KOP is characterized as level to gently rolling terrain in the FG transitioning to larger hills in the MG. Vegetation includes evergreen and deciduous trees along the edge of fields and clustered around residential structures. The landscape is categorized as Common because it consists primarily of grasslands with small pockets of wooded areas, typical within the region. Cultural modifications include wire fences, residential structures and storage sheds, and a wood H-frame transmission line.

McLain PR. This KOP represents a view east from a rural country road near the community of McLain, Oklahoma. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from a residential area. The view from this KOP is characterized as moderately rolling terrain with open fields and patches of wooded areas typical in the region, so this landscape is categorized as Common. Cultural modifications include wire fences, residential structures, a distribution line paralleling the road and a high-voltage transmission line.

Mehan AR. This KOP represents views north from the eastern edge of Mehan, Oklahoma. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from residential areas. The landscape viewed from this KOP is categorized as Common as it consists of open and agricultural fields with pockets of wooded areas and vegetation clustered around rural residences. Cultural modifications include rural residential structures, oil rigs, and transmission lines in the MG.

Mehan PR. This KOP represents views south from the eastern edge of Mehan, Oklahoma. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from residential areas. The landscape viewed from this KOP is categorized as Common, because it consists of open and agricultural fields with pockets of wooded areas and vegetation clustered around rural residences. In addition there is a small man-made retention pond. Cultural modifications include rural residential structures, oil rigs and tanks, and a distribution line.

Mulhall AR. This KOP represents views north from the center of Mulhall on the main road through town (Highway 77). Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from residences in and near the town center. The landscape viewed from this KOP is categorized as Developed because of the cultural modifications associated with Mulhall, including commercial and residential structures, light poles, a railroad, and distribution line. Views are limited to the FG by the existing buildings and vegetation in and around the town center.

Mulhall PR. This KOP represents views south-southwest from the southern edge of Mulhall, Oklahoma. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from a residential area. The landscape viewed from this KOP is categorized as Common because it consists of gently to moderately rolling grasslands/croplands with pockets of wooded areas, typical within the region. Cultural modifications include short wire fences, residential structures, and structures associated with farming (e.g., barns, storage sheds), and a distribution line.

Okmulgee AR. This KOP represents views to the north from the northern edge of Okmulgee, Oklahoma. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from residential areas. The landscape viewed from this KOP is characterized by level terrain in the immediate FG transitioning to moderately rolling in the MG. Agricultural fields with trees lined around the perimeter are visible in the FG and forested hills are visible in the MG. This landscape is typical within the region, so it is categorized as Common. Cultural modifications include low wire fences, gas and oil facilities (pumps and tanks), and a distribution line.

Oktaha School AR. This KOP represents views southeast from a school and baseball field located on the eastern edge of Oktaha, Oklahoma. Visual sensitivity at this KOP is moderate because concern for aesthetics is not the primary focus of viewers associated with the school or ball field, where activities are focused more internally in the park. The landscape viewed from this KOP is categorized as Common because it consists of open grassy fields with small pockets of wooded area and vegetation along drainageways. Cultural modifications include a low wire fence, light poles, gravel parking area, and a transmission line.

Orlando AR. This KOP represents views looking south from the southern edge of Orlando, Oklahoma. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from residential areas. Views from this KOP are open due to the level terrain and lack of vegetation. The landscape is categorized as Common because it consists of open fields and croplands with vegetation occurring along roadways and clustered along drainageways; which is typical within the region. Cultural modifications include low wire fences around fields, residential structures, and electric distribution lines in the FG and a transmission line in the MG.

Perkins AR. This KOP represents views looking east from the southeastern edge of Perkins, Oklahoma. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from residential areas. The landscape viewed from this KOP is characterized by level open fields in the FG transitioning to moderately rolling wooded hills in the MG. This landscape is typical within the region, so it is categorized as Common. Cultural modifications include low wire fences around fields, residential structures, and electric distribution lines.

Preston AR. This KOP represents views south from the Jim Waller Sports Complex in Preston, Oklahoma. Visual sensitivity at this KOP is moderate because concern for aesthetics is not the primary focus of viewers associated with the sports complex, where activities are focused internally within the complex. The landscape viewed from this KOP is characterized by open fields and small pockets of wooded areas, typical within the region, so this landscape is categorized as Common. Cultural modifications include low fences, residential structures, sheds, and electric distribution lines.

Ripley PR. This KOP represents a view looking northeast from the eastern edge of Ripley, Oklahoma. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from residential areas. The landscape viewed from this KOP is characterized by level rangelands and scattered trees in the FG and rolling forested hills in the MG, typical within the region, so this landscape is categorized as Common. Cultural modifications include low fences around rangelands and a distribution line. Views from this KOP are open due to the level terrain and lack of vegetation in the FG.

Shamrock AR. This KOP represents views to the southwest from the western edge of Shamrock, Oklahoma. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from residential areas. The landscape from this view is characterized by open fields and scattered trees in the FG and dense wooded areas in the MG. Typical of the region, this landscape setting is categorized as Common. Cultural modifications include low wire fences, residential structures, and electric distribution lines. Views from this KOP are open due to the level terrain and lack of vegetation in the FG.

Shamrock PR. This KOP represents views to the northwest from the western edge of Shamrock, Oklahoma. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from residential areas. The landscape from this view is characterized by open fields and scattered trees in the FG and dense wooded areas in the MG. Typical to the region, this landscape setting is categorized as Common. Cultural modifications include low fences. Views from this KOP are open due to the level terrain and lack of vegetation in the FG.

Stillwater PR/AR. This KOP represents views looking south from a residential subdivision in the southern portion of Stillwater, Oklahoma. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from a residential area. From this KOP the landscape is categorized as Developed because of cultural modifications associated with Stillwater. Cultural modifications include residential structures and a communication tower. Views from this KOP are limited because of the dense vegetation surrounding the residential development in the FG.

Summit PR. This KOP represents views southwest from the southern edge of Summit, Oklahoma. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from a residential area. The landscape viewed from this KOP is characterized by open fields and scattered trees, which are typical in this region, so this landscape setting is categorized as Common. Cultural modifications include low wire fences around fields, residential structures, storage buildings, and a transmission line that is a dominant feature in the immediate FG. Views from this KOP are open due to the level terrain and lack of vegetation in the FG.

Taft PR. This KOP represents views south from the southern edge of Taft, Oklahoma. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from a residential area. From this KOP, the landscape is categorized as Developed because of cultural modifications associated with Taft, including a church, commercial and residential structures, light poles, and electric distribution lines. Views from this KOP are limited to the immediate FG by dense wooded areas along the southern edge of the community.

Webbers Falls Reservoir PR/AR. This KOP represents views looking south from the southern side of the Webbers Falls Reservoir. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from a recreation area. The landscape viewed from this KOP is characterized by level terrain and a portion of the reservoir and is surrounded by dense vegetation. Because of variation in vegetation and the presence of the reservoir, this landscape is categorized as Distinct. Cultural modifications are limited to features associated with the recreation area including a playground, road and shelters. Views from this KOP are limited by the dense vegetation in the immediate FG.

3.18.5.4 Region 4

Region 4 is referred to as the Arkansas River Valley Region and includes the Applicant Proposed Route Links 1 through 9 and HVDC Alternative Routes 4-A through 4-E as well as the Lee Creek Variation. The ROI in Region 4 traverses Muskogee and Sequoyah counties in Oklahoma and Crawford, Franklin, Johnson, and Pope counties in Arkansas. The ROI crosses three Level III ecoregions: Arkansas Valley, found primarily along the southern portion of the region; Boston Mountains, found primarily along the northern portion; and a small portion of the Ozark Highlands, located within the northwestern portion of the region. The landscape character within the ROI is predominantly rugged natural areas, mountains, and forested land in the northern portion, which transitions to undulating plains, terraces, cuestas and floodplains associated with the Arkansas River in the southern portion. The rugged hills, mountains, rolling hills, and forested landscapes in the northern portion of the ROI limit distant views, whereas in the southern portion of the ROI the less varied terrain and lack of vegetation allow for expansive view across the landscape (GIS Data Sources: Clean Line 2013a, 2013b; Tetra Tech 2014a). The ROI traverses the Arkansas and Illinois rivers and intermittent and perennial streams such as Little Lee Creek, Lee Creek, Frog Bayou, Illinois Bayou, Mulberry River and Big Penny Creek. Other surface waters in the region include wetlands, impoundment ponds, reservoirs, and several lakes (i.e., Tenkiller Lake, Marble City Lake, Brushy Lake, Reagan Lake, and Ozark Lake). Vegetation consists primarily of oak-hickory forests in the hills to the north and oak-hickory forest, dense deciduous hardwood riparian forest, and scattered prairies in the bottomlands to the south. Cultural modifications include agriculture, croplands, farms and associated appurtenances, natural gas and oil facilities, mining operations, poultry and livestock operations, recreation development, roads, highways, high-voltage transmission lines, and rural residences. Several communities occur within and/or adjacent to the ROI including the towns of Gore and Vain and cities of Marble City and Sallisaw in Oklahoma, the town of Dyer, and the cities of Cedarville, Van Buren, Alma, Kibler, Mulberry, Ozark, Wiederkehr Village, Clarksville, and Lamar in Arkansas.

Visual resources identified in the ROI include rural residences and residences associated with towns and cities, Tenkiller Ferry and Pine Creek Cove State Parks, Sallisaw State Park, Ozark National Forest, Trail of Tears, Arkansas River, Mulberry and Big Piney Creek (both designated as an Arkansas Wild and Scenic River), Little Lee Creek and Lee Creek (both designated as an Oklahoma Scenic River), scenic byways (i.e., Route 21, 23, 71, and 220, State Routes 59 and 282, and Interstates 40 and 540), and several state and national wildlife conservation areas, local and municipal parks, and historic landmarks. Other recreation areas identified within this region include Frog Bayou, Illinois Bayou, Robert S. Kerr, Webbers Fall and Brushy Creek reservoirs, and Marble, Brushy, and Tenkiller lakes.

Seven route variations to the Applicant Proposed Route were developed in Region 4 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.4. The variations are illustrated in Exhibit 1 of Appendix M. These variations represent minor adjustments to the Applicant

Proposed Route and the land setting and visual resources would remain consistent within the ROI. Applicant Proposed Route Link 3, Variations 1, 2, and 3, would all cross a similar landscape setting as the Applicant Proposed Route, including grasslands, wooded areas, and croplands. Link 3, Variation 1, would be located approximately 0.1 mile north of the original Applicant Proposed Route, and although this variation would be located further from some residences and a cemetery, it would be located closer to other residences. Link 3, Variation 2, would be located approximately 0.8 to 1.4 miles north of the original Applicant Proposed Route and would be located farther away from a greater number of residences than it would be moved closer to. Link 3, Variation 3, would be located 0.75 mile north of the original Applicant Proposed Route and would be located farther from the Lee Creek (Scenic River) KOP.

Applicant Proposed Route Link 6, Variations 1, 2, and 3, would all cross a landscape setting similar to the original Applicant Proposed Route, including grasslands, wooded areas, and croplands. Each of these variations would only shift the original Applicant Proposed Route approximately 500 feet. Applicant Proposed Route Link 9, Variation 1, would cross a landscape setting similar to the original Applicant Proposed Route, including Big Piney Creek, wooded areas, grasslands and cultivated croplands. This variation would be located approximately 300 feet from the original Applicant Proposed Route.

3.18.5.4.1 Landscape Character Description by KOP

Alma AR. This KOP represents views to the southwest from residences in Alma, Arkansas. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from residential areas. The landscape viewed from this location includes wood power poles, wetlands, scattered trees, and a low ridge with dense forest in the distance. Because of the vegetation and terrain visible from this location, this landscape is categorized as Common.

Arkansas River at Gore PR/AR. This KOP is the view northwest from a historic ferry crossing and boat launch ramp at Summers Ferry Park Historical Site on the eastern side of the Arkansas River. Visual sensitivity at this KOP is high due to the extended viewing times associated with the historic site and recreational use of the river. Nearby cultural modifications include a picnic and recreation area, parking lot, and boat launch. Looking across the river the dense vegetation along the river banks can be seen as well as a low ridge in the distance. Because the landscape presents unobstructed views of open water, and because of the historic designation and recreational use of the area, this landscape is categorized as Distinct.

Arkansas River PR/AR. This KOP represents the view from the east bank for the Arkansas River west of Gore. The visual sensitivity at this KOP is moderate because, while it represents a major water body, the landscape has already been heavily impacted by cultural modifications. Looking across the river, dense vegetation is visible on the other side with a low bluff in the BG. Cultural modifications in this view include several large existing transmission structures in view. While the river itself has high scenic integrity, due to the proximity to cultural modifications such as nearby dam and existing transmission structures in view, this area is categorized as Common.

Aux Arc Park PR. This KOP represents the view from Aux Arc Park and campground along the southwestern edge of the Arkansas River. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from a public park. The landscape viewed from this location includes open water with low hills and ridges and dense tree growth along the river bank. Cultural modifications include numerous buildings and other structures are visible on the far shore. Open water is dominant from this view and since this represents a scarce resource in the area this landscape is categorized as Distinct.

Big Piney Creek PR. This KOP represents the view looking northeast from a recreation and access point at Big Piney Creek just downstream from the Highway 164 crossing. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from a public recreation area. The landscape viewed from this KOP consists of open water and dense vegetation on either side of the river with a low ridgeline in the distance. From this view, the bridge where Highway 164 crosses Big Piney Creek is also visible, but the landscape is generally free of cultural modifications. Because this area has been primarily left in its natural form and water is a dominant element in view, this landscape is categorized as Distinct.

Bluff Hole Park PR/AR. This KOP represents views looking north from the entrance to Bluff Hole park and picnic area. The visual sensitivity at this KOP is considered high because of the concern for aesthetics and generally long viewing durations associated with a public park and recreation area. While the surrounding park is relatively natural, the landscape being viewed at this KOP contains cultural modifications including various signs and fences as well as both wood and metal power poles with an elevated roadway in the MG. Although this is a recreation area, this particular view contains several cultural modifications and is categorized as Common.

Boys and Girls Camp AR. This KOP represents the view looking north from a youth camp. Since this is a recreation area, the visual sensitivity is high because of the concern for aesthetics and long viewing durations associated with this type of use. The landscape viewed from this location consists of an open field with tall grasses bordered by dense forest. Cultural modifications in view include an existing transmission line and low barbed-wire fence. Because of the vegetation in the area and existing cultural modifications, this landscape is categorized as Common.

Brushy Creek Reservoir and Sallisaw State Park PR/AR. This KOP represents the view from the recreational area at Brushy Creek Reservoir. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from a recreation area. The FG view contains picnic benches and grills along the shore of the reservoir. The MG consists of open water bordered by a low ridge with dense trees in the BG. This area has a relatively low amount of cultural modifications, and because water is present and the area is used recreationally, it is categorized as a Distinct landscape.

Cedarville AR. This KOP represents views looking southeast from a partially developed subdivision in Cedarville, Arkansas. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations associated with residences. The view from this KOP is of a small open field in the FG enclosed by rolling hills with dense vegetation in the MG and BG. This KOP is located near developed land, but looks out to a more typical landscape for the region, so the landscape at this KOP is classified as Common.

City Park/Ball Fields and Rudy PR/AR. This KOP is representative of views from a community ball field in Rudy, Arkansas. Visual sensitivity is high from this KOP because of the long viewing durations associated with a public park and recreation area. Looking north, the FG landscape consists of a small open field with several residential structures, garages and utility poles. Large trees are mixed in with the residential area in the MG. Looking southwest from this KOP, the FG views are dominated by various structures and cultural modifications associated with the park. Because this area contains numerous cultural modifications and residential structures, the landscape is classified as Developed.

Clarksville PR/AR. This KOP represents the view looking southeast from the northern edge of the community of Clarksville, Arkansas. Visual sensitivity is high from this KOP because of the long viewing durations associated with residential areas. The landscape viewed from this KOP includes open grassy fields and barbed wire fences in the FG. The MG and BG consist primarily of low, rolling hills with scattered residences. Additional cultural modifications visible on the landscape include several existing transmission structures. Because of vegetation and the agricultural nature of the landscape at this KOP, it is categorized as Common.

Clear Creek Park PR. This KOP represents views from the Clear Creek Park and boat launch area. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from a recreation area. The view looking to the north and northeast looks out across a parking lot in the FG with open water, scattered trees and shrubs in the MG. Beyond that, a dense line of trees can be seen on the far side of the stream bank. Although there are cultural modifications such as picnic areas, signs, and light poles, the surrounding area is in its natural state. These modifications, combined with the presence of a large body of water, resulted in a classification of Distinct.

Coal Hill AR. The KOP at Coal Hill represents views from the northern edge of the community. Visual sensitivity is high from this KOP because of the long viewing durations associated with residential areas to the north. The FG views contain cultural modifications including wood power poles, several residences and outbuildings, and a school bus parking area. In the MG and BG, the landscape consists of rolling hills with scattered trees and residences. The landscape in this area contains some cultural modifications in the FG, but the MG and BG landscape is typical of the area, so it is categorized as Common.

Dyer PR. This KOP represents views from the southeastern edge of the town of Dyer, Arkansas. Visual sensitivity is high from this KOP because of the concern for aesthetics and typically long viewing durations associated with residential areas. This view is looking out over a large, open agricultural field with a dense line of trees and forested ridge in the distance. Also in the vicinity of the KOP are single–family residences. The rural landscape free of heavy cultural modification visible from this KOP is typical of the area and categorized as Common.

East Side City Park PR. This KOP represents views from a community park on the bank of a small body of water. Visual sensitivity is high from this KOP because of the concern for aesthetics and long viewing durations associated with a community park. Standing on the bank, the view of the landscape consists of open water in the FG and residences and densely forested banks in the MG. Cultural modifications in view include metal power poles and residential structures. There are cultural modifications in view, but because of the presence of water and natural surroundings of the area, the landscape is classified as Distinct.

Field of Dreams PR/AR. This KOP represents views from the Field of Dreams ball field. Visual sensitivity is high from this KOP because of the concern for aesthetics and long viewing durations associated with a recreation area. In the FG view, the landscape contains multiple fences and tall metal light poles are visible along with wood H-frame transmission structures. Also present are wood shelters and structures associated with the baseball fields. This is a heavily modified area and is categorized as Developed.

Fire Tower Lookout AR. This KOP is representative of views from a recreational area in a National Forest. Visual sensitivity is high from this KOP because of the concern for aesthetics and long viewing durations associated with a National Forest and recreation area. Looking out from here the landscape consists of a small field surrounded by dense vegetation and varied terrain creating very enclosed views. Because this area is free of cultural modifications and in an area designated as National Forest, it is categorized as Distinct.

Frog Bayou Creek AR. This KOP represents the view looking west from Highway 282, overlooking Frog Bayou Creek. Visual sensitivity is high at this location because it represents a major water body being viewed from a scenic byway. Looking out from an elevated viewing location, the landscape is primarily rolling hills covered in dense trees in the BG, and dense riparian vegetation in the FG/MG. In the MG is a creek that winds through open fields with very few cultural modifications. Because of the elevated viewing location, views are nearly panoramic and bordered by rolling hills covered in dense trees. Immediately behind this viewpoint is Interstate 540, a designated scenic byway. The landscape in this area has been left mostly natural; combined with the presence of a major water body, it is categorized as Distinct.

Hagarville PR/AR. This KOP represents views from the southern edge of Hagarville, Arkansas. Visual sensitivity is high from this KOP because of the concern for aesthetics and long viewing durations associated with a residential area. The landscape viewed from this location consists of an open field in the FG with multiple large metal buildings and scattered residences. In the MG and BG the landscape turns to high, rolling hills covered in dense vegetation. Because the landscape in this area is not highly developed and contains vegetation and terrain typical for the region, it is categorized as Common.

Highway 10 PR. This KOP is representative of views from a well-traveled highway used by recreationists travelling to and from recreation areas along the Arkansas River. Visual sensitivity is moderate from this location because of the relatively short viewing durations associated with traveling along a highway. Looking to the northwest, the landscape consists of open fields with rolling hills covered in dense trees. The landscape being viewed from this location contains vegetation and landform typical to the area and is categorized as Common. Visible cultural modifications are limited to wood transmission poles and the paved road.

Highway 21 Scenic Byway AR. This KOP represents views from Highway 21. Visual sensitivity at this KOP is moderate because from this route, concern for aesthetics is generally secondary to commuting. The landscape viewed to the south/southwest consists of a tall chain-link fence, wood power poles lining the road, and nearby residences in the FG. The MG contains large stands of trees transitioning to rolling hills covered in dense vegetation. The landscape viewed from this location contains typical terrain and vegetation for the area and few cultural modifications and is categorized as Common. It should be noted that this particular section of Highway 21 is not designated as a Scenic Byway.

Highway 82 PR/AR. This KOP represents the views from a highway that is well travelled by recreationist traveling to and from Tenkiller Reservoir and nearby parks. Visual sensitivity at this KOP is moderate because from this route, concern for aesthetics is generally secondary to travelling to a destination. The landscape viewed from this KOP consists of dense vegetation on either side of the highway that traverses the rolling hills. Vegetation and terrain is consistent with the region and this landscape is categorized as Common.

Highway 82 AR 4-B. This KOP represents the views from a highway that is well travelled by recreationalists traveling to and from Tenkiller Reservoir and nearby parks. Visual sensitivity at this KOP is moderate because from this route, concern for aesthetics is generally secondary to travelling to a destination. The landscape viewed from this KOP consists of dense vegetation on either side of the highway that traverses the rolling hills. The landscape viewed in the BG consists of low rolling hills covered in dense tree growth. Vegetation and terrain is consistent with the region and this landscape is categorized as Common. Cultural modifications consist of rural residences and wood power poles.

Horsehead Lake Recreation Area PR. This KOP is representative of the view looking south near the boundary of the Ozark National Forest. Visual sensitivity is high from this KOP because of the concern for aesthetics and long viewing durations associated with a recreational area in a national forest. The landscape viewed from this location is rolling hills in the MG and a meandering stream surrounded by riparian vegetation in the FG. Because this is national forest land and has been left in its natural state is categorized as Distinct.

Hunt PR. This KOP represents the view looking southeast from the town of Hunt, Arkansas. Visual sensitivity is high from this KOP because of the concern for aesthetics and long viewing durations associated with a residential area. The landscape being viewed from this location consists of single family residences in the FG and rolling hills with tall stands of trees in the MG and BG. The only cultural modifications in view are the residential structures and the terrain and vegetation is consistent with the region, so the landscape at this KOP is categorized as Common.

Interstate 40 (Scenic Highway) Rest Stop PR. This KOP represents the view looking north from a developed rest stop on westbound Interstate 40, which is a state-designated scenic highway. The visual sensitivity at this KOP is moderate due to the relatively short viewing duration associated with a highway rest area and associated travel. In the FG, the landscape being viewed is a large, open grassy field enclosed in the MG by tall trees. Because the vegetation and landform at this KOP is typical for the region, the landscape is categorized as Common.

Lake Ludwig PR. This KOP represents the view looking south from a recreation area at Lake Ludwig. Visual sensitivity is high from this KOP because of the concern for aesthetics and long viewing durations associated with a recreation area. The immediate FG includes open water surrounded by dense tree growth that rises to low densely vegetated trees in the MG. Because the view from this KOP is free from any cultural modifications combined with the presence of a large body of water, the landscape is categorized as Distinct.

Lamar AR. This KOP represents a view near the southern edge of the community of Lamar, Arkansas. Visual sensitivity is high from this KOP because of the concern for aesthetics and long viewing durations associated with a residential area. The landscape in the FG of this view is of agricultural fields with scattered trees and residential structures and barns. Other cultural modifications in the FG are a small church and metal sheds. The BG of this view is rolling hills with dense trees. Although there are some cultural modifications present in view, the landscape is primarily agricultural fields with grasses and pockets of wooded areas and is therefore categorized as Common.

Lee Creek PR. This KOP represents the view from a boat launch and fishing pier at a lake on Lee Creek. Visual sensitivity is high from this KOP because of the concern for aesthetics and long viewing durations associated with a recreation area. Looking to the north, the landscape consists of open water with a dock leading to a parking lot in the FG surrounded by dense forest creating enclosed views in the MG. Several cultural modifications are present including a dock, light poles and a restroom facility, but because this area is adjacent to open water, which is a unique landscape feature in the area, the landscape is categorized as Distinct.

Little Lee Creek (Scenic River) AR. This KOP represents a view looking northeast from a bridge crossing Little Lee Creek, a designated scenic river. Visual sensitivity from this KOP is high because of long viewing durations associated with the viewing of a scenic river. The landscape viewed from here consists of the river and riparian vegetation covering the banks on either side. In the BG, a ridgeline covered in dense trees is visible. The landscape in this area is in its natural state and the presence of water represents a scarce resource; therefore, the landscape is categorized as Distinct.

Marble City AR. This KOP represents a view from the edge of Marble City, Oklahoma. Visual sensitivity is high from this KOP because of the concern for aesthetics and long viewing durations associated with a residential area. Looking to the southeast, the FG view consists of single family residences surrounded by open fields with scattered trees in the FG. The MG and BG views consist of rolling hills covered in dense vegetation. Because the landscape being viewed from this KOP consists of vegetation and terrain typical for the region and does not contain cultural modifications other than a few residential structures, the landscape is categorized as Common.

Mulberry. This KOP represents views looking west from a park in Mulberry, Arkansas. Visual sensitivity is high from this KOP because of the concern for aesthetics and long viewing durations associated with a public park and recreation area. The immediate FG contains playground equipment and an open field bordered by a line of scattered trees. Beyond the trees is an open agricultural field with a line of dense tree growth in the distance. This landscape is categorized as Common because it consists of vegetation and terrain consistent with the region and is free of cultural modifications other than park equipment.

Mulberry River and Trail of Tears PR/AR. This KOP represents views of the Mulberry River from the Trail of Tears. Visual sensitivity at this KOP is high because of the strong concern for aesthetics due to the historical designation. The landscape in the FG view consists of a rocky bank sloping down into open water bordered by riparian vegetation on either side. Looking out to the MG is an open field bordered by a dense line of trees with low rolling hills covered in dense trees. Cultural modifications are limited to a transmission line that crosses the river in the MG. Because the water that is dominant in view represents a scarce resource combined with the lack of cultural modification, the landscape in this area is categorized as Distinct.

Mulberry River AR. This KOP represents a view from the east bank of the Mulberry River. Visual sensitivity is high from this KOP because of the concern for aesthetics and long viewing durations associated with a public recreation area. The view is dominated by open water in the FG with banks covered in dense trees on either side. A low ridge covered in dense trees is visible in the MG/BG. This is an area free of cultural modification with views of open water and interesting terrain and is therefore categorized as Distinct.

Ozark City Boat Launch PR. This KOP represents the view from the boat launch ramp at the northwestern corner of Ozark City Lake. Visual sensitivity is high from this KOP because of the concern for aesthetics and long viewing durations associated with a public recreation area. The FG of the landscape being viewed is dominated by open water with the vegetated berm of the dam clearly visible. Across the lake the terrain rises into a low ridge covered in dense trees. This landscape is categorized as Distinct because of the presence of open water and varied vegetation.

Ozark AR. This KOP represents views from the northern edge of the community of Ozark, Arkansas. Visual sensitivity is high from this KOP because of the concern for aesthetics and long viewing durations associated with a residential area. The landscape being viewed consists of agricultural land in the FG with low forested hills in the MG and BG. Cultural modifications in view are a rural dirt road bordered by wood power poles and scattered rural residences. This landscape consists of agricultural land and vegetation consistent with the region, so it is categorized as Common.

Robert S. Kerr Reservoir PR. This KOP represents views from the Sallisaw Creek Public Use Area at the Robert S. Kerr Reservoir. Visual sensitivity is high from this KOP because of the concern for aesthetics and long viewing durations associated with a public recreation area. The landscape viewed from the KOP includes picnic structures and scattered trees in the FG. Beyond that, the terrain slopes down slightly to the edge of the water, providing views across open water to forested hills in the MG. Because this landscape is in an area free of major cultural modification and adjacent to a major water body, it is classified as Distinct.

Route 21 (Scenic Byway). This KOP represents views along the scenic byway of Route 21. Visual sensitivity is high from this KOP because of the concern for aesthetics associated with a scenic byway. Looking north, the landscape being viewed from this point consists of a rural road with a few single family residences and small power poles paralleling the road. Dense trees line the road as it transitions to densely vegetated rolling hills in the MG and BG. This landscape is classified as Distinct because it consists of varied terrain and vegetation and has a low number of cultural modifications. Route 21 is also a scenic byway that is used to access a National Forest.

Route 71 (Scenic Byway) AR. This KOP represents views along the scenic byway of Route 71. Visual sensitivity is high from this KOP because of the concern for aesthetics associated with a scenic byway. The landscape being viewed looking south is an agricultural landscape with groupings of trees and slightly rolling terrain. Cultural modifications in the area include wood power poles and scattered residences with surrounding agricultural use buildings. Because this landscape contains vegetation, terrain, and cultural modifications consistent with the region, it is categorized as Common.

Route 220 (Scenic Byway) AR. This KOP represents views looking north along the Route 220 scenic byway. Visual sensitivity is high from this KOP because of the concern for aesthetics associated with a scenic byway. In the FG, a rural road winds through a dense forest with views of rolling hills in the BG. The dense vegetation and rolling terrain create enclosed views of the landscape. Because this landscape consists of a variety of vegetation and interesting terrain with few cultural modifications, it is categorized as Distinct.

Sallisaw PR. This KOP represents the view looking north-northeast along Highway 59 in the community of Sallisaw. Visual sensitivity is high from this KOP because of the concern for aesthetics and long viewing durations associated with a residential area. The landscape being viewed from here consists of gently rolling terrain with open fields and agricultural lands scattered with groupings of large trees in the FG and MG. In the BG, the landscape consists of rolling hills covered in dense vegetation. Cultural modifications in view include wood power poles, small fences and scattered residences. Because the landscape and vegetation features at this KOP are consistent with the region, it is categorized as Common.

Scott Farm AR. This KOP represents a view from the Scott Farm subdivision near Highway 59. Visual sensitivity is high from this KOP because of the concern for aesthetics and long viewing durations associated with a residential area. The landscape being viewed to the south consists of gently rolling grassy terrain with cultural modifications including a large wrought iron fence and several residences in the FG and MG. In the BG, a high bluff covered in dense vegetation is visible. Although there are several cultural modifications in view from this KOP, the terrain is somewhat unique to the region, so the landscape is categorized as Common.

Scott Farm PR. This KOP represents a view from the Scott Farm subdivision near Highway 59. Visual sensitivity is high from this KOP because of the concern for aesthetics and long viewing durations associated with a residential area. The landscape being viewed to the north consists of gently rolling grassy terrain with cultural modifications including a large wrought iron fence and several residences in the FG and MG. In the BG, the landscape consists of rolling hills covered in tall trees. Cultural modifications including communications towers and residences are also visible. Although there are several cultural modifications in view from this KOP, the terrain is somewhat unique to the region, so the landscape is categorized as Common.

Sequoyah NWR Boat Launch PR. This KOP represents views from the boat launch area at the Sequoyah National Wildlife Refuge. Visual sensitivity is high from this KOP because of the concern for aesthetics and long viewing durations associated with a wildlife refuge. Looking to the north, the landscape being viewed includes open grasslands, wetlands and agricultural fields bordered by dense trees in the BG. This area contains few cultural modifications and the vegetation and terrain are consistent with the region, so the landscape is categorized as Common.

Sequoyah's Cabin. This KOP represents the view looking to the south from Sequoyah's Cabin historic site. Visual sensitivity is high from this KOP because of the concern for aesthetics and long viewing durations associated with a historic site. The grounds contain interpretive exhibits and historic features including a historic cabin, offices, classrooms, information and gift center and picnic facilities. The view beyond the FG is mostly screened by large trees. Because of the sensitive nature of a historic site, this landscape is categorized as Distinct.

Tenkiller State Park PR/AR. This KOP is located in the southern end of Tenkiller State Park near the water's edge. Visual sensitivity is high from this KOP because of the concern for aesthetics and long viewing durations associated with a state park and recreation area. Looking out over the open water in the FG, low ridges with dense vegetation are visible in the distance. There are no noticeable cultural modifications in view. Because of the lack of cultural modifications to the landscape, the unique presence of water in the region, and the state park designation, this landscape is categorized as Distinct.

Trail of Tears (Highway 352) PR/AR. This KOP represents views from Highway 352 and the Trail of Tears. Visual sensitivity is high from this KOP because of the sensitive nature of the Trail of Tears. The landscape being viewed includes open agricultural fields and scattered groupings of trees. The landscape in the BG consists of rolling hills covered in dense vegetation. Crossing the road in the FG is an existing wood H-frame transmission line. The rural agricultural nature of this landscape combined with few cultural modifications categorizes this landscape as Common.

Trail of Tears (Route 59) AR. This KOP is representative of the Trail of Tears along Route 59. Visual sensitivity is high from this KOP because of the sensitive nature of the Trail of Tears. Looking north, the landscape consists of open fields with groupings of dense trees in the FG. Densely forested hills rise up in the BG. Cultural modifications present are limited to wood power poles and the highway. The landscape here contains few modifications and has a variety of vegetation and interesting terrain features and is therefore categorized as Distinct.

Trail of Tears and Scenic Highway 220 AR. This KOP represents views from Scenic Highway 220. Visual sensitivity is high from this KOP because of the concern for aesthetics associated with a scenic highway. The landscape being viewed consists of agricultural fields in the FG bordered by a line of dense trees. Cultural modifications include a low fence and wood power poles. In the MG and BG, the landscape consists of rolling hills covered in tall dense trees. Because the terrain and vegetation in view are consistent with the region, the landscape is categorized as Common.

Trail of Tears Route 100 PR. This KOP represents views from the Trail of Tears along SR 100. Visual sensitivity is high from this KOP because of the concern for aesthetics associated with a scenic highway and historic trail. The view from here is dominated by a road lined with dense trees and wood power poles. There are limited cultural modifications to the landscape and the terrain and vegetation are consistent with the region, so the landscape is categorized as Common.

Trail of Tears Wire Road PR. This KOP represents views from the Trail of Tears along Wire Road. Visual sensitivity is high from this KOP because of the concern for aesthetics associated with an historic trail. The landscape being viewed from this KOP consists of open agricultural fields bordered by scattered trees. Cultural modifications present are limited to wood power poles and rural residences and associated agricultural buildings. Because the landscape is made up of elements typical of the region, it is categorized as Common.

Uniontown Highway (Scenic Highway) AR. This KOP is representative of views looking south from Uniontown Highway. Visual sensitivity is high from this KOP because of the concern for aesthetics associated with a scenic highway. The landscape being viewed in this area is of open agricultural fields with scattered trees in the FG transitioning into rolling hills covered in dense vegetation in the MG. The vegetation and terrain at this KOP is typical to the region and cultural modifications visible are limited to a low fence, so the landscape is categorized as Common.

Van Buren PR/AR. This KOP represents views looking northwest from nearby residences in the community of Van Buren, Arkansas. Visual sensitivity is high from this KOP because of the concern for aesthetics and long viewing durations associated with a residential area. The landscape viewed from this location consists of grassy fields bordered by stands of tall deciduous trees. Cultural modifications include wood power poles and scattered residences and associated outbuildings. Because the landscape elements in this area are typical to the region, the landscape is categorized as Common.

Vian AR. This KOP represents views looking north and northeast from the edge to the community of Vian, Oklahoma. Visual sensitivity is high from this KOP because of the concern for aesthetics and long viewing durations associated with a residential area. The landscape being viewed in the FG consists of open agricultural fields with scattered trees and low shrubs. In the BG, the landscape consists of low rolling hills covered in dense vegetation. Cultural modifications present include low, barbed wire fences and wood H-frame transmission structures. Because the agricultural landscape in this area is typical of the region, it is categorized as Common.

Vian Lake PR. This KOP represents views from the western edge of Vian Lake. Visual sensitivity is high from this KOP because of the concern for aesthetics and long viewing durations associated with a recreation area. Looking to the northeast, views are of open water with densely vegetated rolling hills on the opposite side. Cultural modifications present on the landscape include a lattice structure transmission line. The presence of water in this region represents a scarce resource, so this landscape is categorized as Distinct.

Vine Prairie Park PR. This KOP represents views from a park and boat launch area. Visual sensitivity is high from this KOP because of the concern for aesthetics and long viewing durations associated with a recreation area. The FG view includes a parking area and open water with tall trees and riparian vegetation bordering the banks. In the MG and BG are low, rolling hills covered in dense tree growth. This area is free from cultural modifications other than those associated with the park and the presence of water is a scarce resource, so the landscape is categorized as Distinct.

West Side City Park APR. This KOP represents the view from West Side City Park in Ozark. Visual sensitivity is high from this KOP because of the concern for aesthetics and long viewing durations associated with a public park and recreation area. Looking north, the FG landscape consists of an open, grassy field bordered by tall coniferous and deciduous trees. Cultural modifications in view include a small shed, metal bleachers and a wood H-frame transmission line. The landscape at this KOP is typical for the region and is therefore categorized as Common.

White Oak AR. This KOP represents views from a small rural road running between the communities of Cravens and White Oak, Arkansas. Visual sensitivity is high from this KOP because of the concern for aesthetics and long viewing durations associated with a residential area. Looking north, the landscape consists of an open field in the FG bordered by tall trees in the MG and BG. Cultural modifications present consist of a few small structures and a low barbed-wire fence. Because the vegetation, landform, and cultural modifications are typical of the region, this landscape is categorized as Common.

White Oak PR. This KOP represents views from a small rural road running between the communities of Cravens and White Oak, Arkansas. Visual sensitivity is high from this KOP because of the concern for aesthetics and long viewing durations associated with a residential area. Looking south, views are enclosed by large trees in the FG. Cultural modifications present consist of a few small structures visible through the trees. Because the vegetation, landform, and cultural modifications are typical of the region, this landscape is categorized as Common.

White Oak Park PR. This KOP represents views from the edge of a lake. Visual sensitivity is high from this KOP because of the concern for aesthetics and long viewing durations associated with a public park and recreation area. The landscape being viewed in the FG consists of a small dock leading out into a large, open water body. In the MG, the lake is bordered by dense tree growth. The BG landscape consists of low, rolling hills with dense vegetation. Because this area represents a recreation area and water body and is free of heavy cultural modification, it is categorized as Distinct.

Wiederkehr Village and Highway 186 PR/AR. This KOP represents the view along Highway 186 looking northwest. Visual sensitivity is high from this KOP because of the concern for aesthetics and long viewing durations associated with a residential area. The landscape viewed consists of an open, agricultural field in the FG. In the MG, there are residential and agricultural structures with scattered trees. The BG landscape consists of rolling hills with dense vegetation. The landscape and vegetation features at this KOP are typical for the region, so the landscape is categorized as Common.

3.18.5.5 Region 5

Region 5 is referred to as the Central Arkansas Region and includes the Applicant Proposed Route Links 1 through 9, HVDC Alternative Routes 5-A through 5-F, and the Arkansas Converter Station Alternative Siting Area and AC interconnection and substation siting area. The ROI in Region 5 traverses Pope, Conway, Van Buren, Faulkner, Cleburne, White, and Jackson counties in Arkansas. The ROI crosses three Level III ecoregions: Arkansas Valley, which covers the majority of the region; Boston Mountains, which covers a small portion of the region in the north; and a small portion of the Mississippi Alluvial Plain, which covers the southeastern portion of the region. The landscape character within the ROI consists of varied terrain with low rugged hills, mountains, and benches in the northern portion transitioning to undulating plains, terraces, cuestas, and floodplains associated with the Arkansas River in the south. Generally, views are restricted in the northern portion of the ROI because of the rugged terrain and forested landscapes. In the southern portion of the ROI, the level to nearly level floodplains and pastureland and agricultural fields allow more expansive views in some areas. Views are limited primarily by rows of trees planted along fields and roads and riparian vegetation along waterways and drainages (GIS Data Sources: Clean Line 2013a, 2013b; Tetra Tech 2014a). The southwestern portion of the ROI crosses the Arkansas River, and the eastern portion of the ROI crosses the Little Red River and White River along with several smaller rivers and creeks such as Illinois Bayou and Cadron Creek. Other surface waters in the region include wetlands, impoundment ponds, and some small lakes and reservoirs, and the larger Greers Ferry Lake to the north. Vegetation consists primarily of oak-hickory forests, dense deciduous hardwood riparian forest, and scattered prairies and oaks in the south. Cultural modifications include croplands, poultry and livestock operations, farms and associated appurtenances, recreation development, natural gas facilities, logging and mining operations, roads and highways, electric distribution lines and several high-voltage transmission lines, and rural residences and suburban residential developments. Several communities occur within and/or adjacent to the ROI including the towns of Dover, Hector, Damascus, Guy, Twin Groves, Rose Bud, and Letona and the cities of Quitman and Bradford.

Visual resources identified in the ROI include rural residences and residences associated with towns and cities, Ozark National Forest, Woody Hollow State Park, Bald Knob NWR, Greers Ferry Lake, scenic byways (i.e., Applicant Proposed Route Links 5, 7, 9, 16, 25, 27, and 65), several state wildlife conservation areas, local and municipal parks, and historic landmarks.

Five route variations to the Applicant Proposed Route were developed in Region 5 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.5. The variations are illustrated in Exhibit 1 of Appendix M. These variations represent minor adjustments to the Applicant Proposed Route and the landscape setting and visual resources would remain consistent within the ROI. Applicant Proposed Route Link 1, Variation 2, crosses a landscape setting similar to the original Applicant Proposed Route, which is primarily wooded. Although the variation would shift the Applicant Proposed Route to the south by approximately 1,800 feet to avoid residences, the variation would be closer to other residences in the area. Applicant Proposed Route Link 2, Variation 2, crosses a landscape setting similar to the original Applicant Proposed Route, which is primarily wooded. The variation would shift the Applicant Proposed Route to the west by between 0.7 mile and 1 mile and would be located farther from residences and structures. Applicant Proposed Route Links 2 and 3, Variation 1, crosses a landscape setting similar to the original Applicant Proposed Route, which is primarily wooded. The variation would shift the Applicant Proposed Route to the west and south by less than 1,000 feet and would be located farther from residences. It should be noted that a route adjustment was made for HVDC Alternative Route 5-B to maintain an end-to-end route with the Links 2 and 3, Variation 1. Applicant Proposed Route Links 3 and 4, Variation 2, would cross a similar landscape setting and would be located approximately 0.25 mile from the original Applicant Proposed Route. Although the variation would be located farther from an existing homestead, it would be located closer to other residences. A route adjustment was made for HVDC Alternative Route 5-E to maintain an end-to-end route with the Links 3 and 4, Variation 2. Applicant Proposed Route Link 7, Variation 1, crosses a landscape setting similar to the original Applicant Proposed Route. The variation would no longer parallel an existing high-voltage transmission line, and although it would be located farther from two residences, it would be located closer to several others.

3.18.5.5.1 Landscape Character Description by KOP

Boy Scout Campground PR/AR. This KOP represents the view from the eastern side of a Boy Scout campground. Visual sensitivity is high from this KOP because of the concern for aesthetics and long viewing durations associated with a public park and recreation area. The landscape in this area is a mostly natural area with rolling terrain and dense trees. Views are enclosed due to the dense vegetation in the FG. Nearby cultural modifications include a campground and recreational facilities associated with the Boy Scout camp. This landscape consists of vegetation and terrain features typical to the region and is categorized as Common.

Bradford. This KOP represents views looking northwest from a residential area north of the community of Bradford, Arkansas. Visual sensitivity is high from this KOP because of the concern for aesthetics and long viewing durations associated with a residential area. The landscape being viewed from this KOP consists of grassy open areas with scattered trees and residential structures in the FG and groupings of dense trees in the MG and BG. Because the vegetation and cultural modifications at this KOP consist of vegetation and terrain typical for the region, it is categorized as Common.

Damascus AR. This KOP is representative of views from a residential area near the southern edge of the community of Damascus, Arkansas. Visual sensitivity is high from this KOP because of the concern for aesthetics and long viewing durations associated with a residential area. Looking to the southwest, views of the landscape consist of open fields with groupings of dense tree growth and scattered rural, single family homes. The terrain and vegetation is consistent with the region, so the landscape is categorized as Common.

Damascus PR. This KOP is representative of views from a residential area near southern edge of the community of Damascus, Arkansas. Visual sensitivity is high from this KOP because of the concern for aesthetics and long viewing durations associated with a residential area. Looking to the north/northwest, views of the landscape consist of open agricultural fields in the FG with scattered trees and rural, single family homes. The BG landscape consists of rolling hills covered in dense vegetation. The terrain and vegetation is consistent with the region, so the landscape is categorized as Common.

Dover and J.P. Lovelady Ball Park PR/AR. This KOP represents views from a park on the northern side of the rural community of Dover. Visual sensitivity is high from this KOP because of the concern for aesthetics and long viewing durations associated with a public park and recreation area. The landscape viewed in the FG includes agricultural fields with groupings of trees. Cultural modifications to the landscape include residences, wood power poles, fences, and a roadway. In the BG are low, forested ridges. Since the vegetation, landform and cultural modifications in view from this KOP are typical to the region, the landscape is categorized as Common.

Guy PR/AR. This KOP represents typical views from the north central part of the community of Guy, Arkansas. Visual sensitivity is high from this KOP because of the concern for aesthetics and long viewing durations associated with a residential area. The landscape viewed consists of rolling hills with dense trees and multiple residences. Cultural modifications include wood power poles and residential structures. The vegetation and landform in this area is consistent with the region, so the landscape is categorized as Common.

Hector PR/AR. This KOP represents views from a residential area on the southern edge of Hector, Arkansas. Visual sensitivity is high from this KOP because of the concern for aesthetics and long viewing durations associated with a residential area. The landscape viewed from this KOP consists of a road lined with tall, densely growing trees.

Cultural modifications in view include wood power poles and scattered residential and commercial structures. The landscape in this area contains landform and vegetation typical of the region and so is categorized as Common.

Highway 7 (Scenic Byway) AR. This KOP represents the view looking north from the Highway 7 Scenic Byway. Visual sensitivity is high from this KOP because of the high level of concern for aesthetics associated with a Scenic Byway. Views are of scattered rural residences surrounded by small agricultural fields and rolling hills with dense trees. Cultural modifications to the landscape include small power poles, barbed-wire fences, and scattered residential homes. The landscape at this KOP consists of vegetation and landform consistent with the region and is categorized as Common.

Highway 7 (Scenic Byway) PR. This KOP represents the view looking north from the Highway 7 Scenic Byway. Visual sensitivity is high from this KOP because of the high level of concern for aesthetics associated with a Scenic Byway. The landscape being viewed consists of a rural highway lined with tall trees and dense vegetation. The views are mostly enclosed, but a low ridgeline can be seen in the distance through breaks in the trees. Because the vegetation, landform and cultural modifications are consistent with the region, this landscape is categorized as Common.

Highway 9 (Scenic Highway) AR. This KOP represents the view looking south from the Highway 9 Scenic Highway. Visual sensitivity is high from this KOP because of the high level of concern for aesthetics associated with a scenic highway. Views are of low rolling terrain consisting of open agricultural fields and scattered groupings of trees with a forested ridge in the BG. Cultural modifications visible include scattered residences, barns, sheds and commercial business structures. The landscape viewed from this KOP consists of vegetation and terrain typical to the region and without extensive cultural modification, and is therefore categorized as Common.

Highway 9 (Scenic Highway) PR. This KOP represents the view looking south from the Highway 9 Scenic Highway. Visual sensitivity is high from this KOP because of the high level of concern for aesthetics associated with a scenic highway. Views are of low rolling terrain consisting of open agricultural fields with groupings of dense trees. Cultural modifications are limited to a low fence and wood power poles. The landscape viewed from this KOP consists of vegetation and terrain typical to the region without extensive cultural modification, and is therefore categorized as Common.

Highway 16 (Scenic Highway) AR. This KOP represents a view looking south from the Highway 16 Scenic Highway. Visual sensitivity is high from this KOP because of the high level of concern for aesthetics associated with a scenic highway. Views are of flat, open agricultural fields with dense patches of trees. This landscape has vegetation and terrain typical to the region and so is categorized as Common.

Highway 16 (Scenic Highway) AR/PR. This KOP represents views looking south from the Highway 16 scenic highway. Visual sensitivity is high from this KOP because of the high level of concern for aesthetics associated with a scenic highway. Views include a rural landscape with rolling hills, low ridges, open fields, and dense trees. Cultural modifications include residential structures and metal barns visible in the FG. The landscape viewed from this KOP consists of vegetation and terrain typical of the region without extensive cultural modification, and is therefore categorized as Common.

Highway 25 Scenic Highway. This KOP represents views looking south from Highway 25. Visual sensitivity is high from this KOP because of the high level of concern for aesthetics associated with a scenic highway. The landscape viewed from this KOP contains cultural modifications including scattered residences and commercial buildings in the FG. Vegetation in the FG consists of scattered trees and a low ridgeline with dense trees is visible in the BG. Because the landscape elements are typical for the region, this landscape is categorized as Common.

Letona PR. This KOP represents views looking from the community of Letona, Arkansas. Visual sensitivity is high from this KOP because of the concern for aesthetics and long viewing durations associated with a residential area. In the FG view are numerous cultural modifications including scattered residences, roads, and wood power poles. Vegetation in the FG consists primarily of scattered trees. In the MG/BG, dense trees and ridgelines are visible. The landscape in this area has considerable cultural modifications when compared to the rest of the region and so is categorized as Developed.

Pope County Residential Cluster PR/AR. This KOP represents views looking north/northwest from a cluster of residences in Pope County, Arkansas. Visual sensitivity is high from this KOP because of the concern for aesthetics and long viewing durations associated with a residential area. Views are of a small open field with groupings of trees in the FG bordered by residences and a small church. In the MG, there is a high ridge covered in dense trees. Because the landscape being viewed from this KOP contains interesting terrain features and a low number of cultural modifications, it is categorized as Distinct.

Quitman PR/AR. This KOP is the view looking south from the southern edge of the community of Quitman, Arkansas. Visual sensitivity is high from this KOP because of the concern for aesthetics and long viewing durations associated with a residential area. The landscape being viewed in the FG consists of an open agricultural field and a road lined with wood power poles. In the MG, several residences and scattered trees are visible. The landscape in the BG is low hills covered in dense vegetation. Because the landform and vegetation are typical for this region, the landscape is categorized as Common.

Rose Bud City Park PR/AR. This KOP represents the view looking north from a city park near the southern edge of the community of Rose Bud, Arkansas. Visual sensitivity is high from this KOP because of the concern for aesthetics and long viewing durations associated with a public park and recreation area. The landscape in view consists of an open field with scattered trees and contains cultural modifications including a small picnic pavilion and a chain-link fence. Beyond the park in the MG, residential and commercial structures with scattered trees and shrubs are visible. The views are enclosed in the BG by a line of dense trees. The landscape at this KOP contains a high number of cultural modifications not typical in this region and is categorized as Developed.

Steprock PR/AR. This KOP represents views looking south-southeast from the community of Steprock, Arkansas. Visual sensitivity is high from this KOP because of the concern for aesthetics and long viewing durations associated with a residential area. The FG views consist of gently rolling terrain with scattered groupings of trees. Cultural modifications in view include several residences, sheds, and an existing high-voltage 500kV lattice structure transmission line. Because of the existing cultural modifications, this landscape is characterized as Developed.

Twin Groves PR/AR. This KOP represents views from rural residences near the edge of the community of Twin Groves, Arkansas. Visual sensitivity is high from this KOP because of the concern for aesthetics and long viewing durations associated with a residential area. The views from this location are enclosed by dense trees that line a small road. Cultural modifications are limited to street signage and wood power poles. This type of terrain and vegetation is typical of the region and so is characterized as Common.

White River AR. This KOP represents views looking northeast from the south bank of the White River, near Jackson Road 177. Visual sensitivity is high from this KOP because of the concern for aesthetics associated with a scarce resource such as a major water body. The FG view is dominated by open water with dense riparian vegetation lining each bank. This is a major water body and is not typical for this region. Because of the uniqueness of the vegetation and the presence of water, combined with no cultural modifications in view, this landscape is categorized as Distinct.

White River PR. This KOP is representative of views looking southeast from the Highway 67 bridge crossing the White River. Visual sensitivity is high from this KOP because of the concern for aesthetics associated with a scarce resource such as a major water body. Views are of a flat landscape with open water bordered by a mix of low vegetation and trees. In the MG, an open field is visible with a row of dense trees in the BG. Because water represents a unique landscape in this region, and the area is free of cultural modifications, this landscape is categorized as Distinct.

Wonderview School AR. This KOP represents the view looking south-southwest from the school and nearby residences. Visual sensitivity is high from this KOP because of the concern for aesthetics and long viewing durations associated with a residential area. Views of the BG include dense trees and gently rolling hills with scattered residences. The view includes open agricultural fields in the FG with scattered groupings of trees. Cultural modifications in view include wood power poles, street signs, and structures associated with rural residences. The terrain and vegetation viewed from this KOP are typical of the region and it is categorized as Common.

Wonderview School PR. This KOP represents views looking north from the school and nearby residences. Visual sensitivity is high from this KOP because of the concern for aesthetics and long viewing durations associated with a residential area. The view from this KOP consists of a row of tall trees in the FG that provide some screening, but looking through the trees gives views of a broad valley in the MG with rolling hills and dense trees. In the BG, the landscape consists of rolling hills covered in dense vegetation. The variety of vegetation and somewhat unique terrain for the region, combined with the low number of cultural modifications, gives this landscape the categorization of Distinct.

3.18.5.6 Region 6

Region 6 is referred to as the Cache River and Crowley's Ridge Region and includes the Applicant Proposed Route Links 1 through 8 and HVDC Alternative Routes 6-A through 6-D. The ROI in Region 6 traverses Jackson, Cross, and Poinsett counties in Arkansas. The ROI crosses two Level III ecoregions: Mississippi Alluvial Plain, which covers the majority of the region, and Mississippi Valley Loess Plains, which run north and south through the central portion of the ROI and are associated with the South Francis River. The landscape character within the ROI is predominately agricultural, croplands, and natural areas including riparian woodlands and wetlands. The terrain is relatively flat to gently undulating with several meandering streams, branching channels, and other drainages. Views are generally open given the level terrain, although wooded areas and trees planted along the edges of field and roadways can limit expansive views in some areas (GIS Data Sources: Clean Line 2013a, 2013b; Tetra Tech 2014a). In the western portion of the region, the ROI crosses the White and Cache rivers, and in the east, the ROI crosses the Little River. The ROI crosses other surface waters including oxbow lakes, wetlands, impoundment ponds, lakes, reservoirs, and several small intermittent and perennial streams. Many of the streams are channelized and flood-control structures are common in this region. Vegetation consists of oak-hickory forests in the northern portion of the ROI and deciduous hardwood riparian forest and tall grass prairies and oaks to the south. Cultural modifications include croplands, poultry and livestock operations, farms and associated appurtenances, residential and commercial development, natural gas facilities, logging and mining operations, roads and highways, electric distribution lines and several high-voltage transmission lines, and rural residences and suburban residential developments. Several communities occur within and/or adjacent to the ROI including the towns of Fisher, Weldon, and Amagon and the cities of Cherry Valley and Marked Tree.

Visual resources identified in the ROI include rural residences and residences associated with towns and cities, Lake Poinsett State Park, Cache River NWR, Crowley's Ridge Parkway National Scenic Byway (State Route 163), and several state conservation areas and historic landmarks.

One route variation to the Applicant Proposed Route was developed in Region 5 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.5. This route variation would parallel more parcel boundaries to minimize impacts to agricultural operations and is shown in Exhibit 1 of Appendix M. The variation represents a minor adjustment to the Applicant Proposed Route and the landscape setting and visual resources would remain consistent with those described for the original Applicant Proposed Route. Applicant Proposed Route Link 2, Variation 1, crosses a landscape setting similar to the original Applicant Proposed Route, including primarily croplands. The variation would be approximately the same distance to residences as the original Applicant Proposed Route. It should be noted that a route adjustment was made for HVDC Alternative Route 6-A to maintain an end-to-end route with Link 2, Variation 1.

3.18.5.6.1 Landscape Character Description by KOP

Amagon AR. This KOP represents views west and southwest from the center of Amagon, Arkansas. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from commercial and residences in and near the town center. The landscape viewed from this KOP is categorized as Developed because of cultural modifications associated with Amagon, including commercial buildings and residential structures, light poles, and electric distribution lines. Views are limited to the FG by the existing buildings and vegetation in and around the town center.

Cherry Valley PR. This KOP represents views north from the northern edge of Cherry Valley, Arkansas. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from a residential area. From this KOP, the landscape is categorized as Common because it consists of agricultural fields lined with deciduous trees, typical within the region. Cultural modifications include storage buildings associated with agricultural lands and electric distribution lines.

Crowley's Ridge Scenic Byway AR. This KOP represents views southeast from Crowley's Ridge Scenic Byway (southbound). Visual sensitivity at this KOP is high due to the road's scenic designation. The landscape viewed from this KOP is categorized as Common because it consists of open fields lined with vegetation and pockets of wooded areas (such as the one that borders the roadway to the west), typical within the region. Cultural modifications include electric distribution lines. Views to the east and southeast from this KOP are open in the FG/MG due to the level terrain and lack of vegetation; views are limited to the west due to the dense wooded area in the immediate FG.

Crowley's Ridge Scenic Byway PR. This KOP represents the view looking north from the Crowley's Ridge Scenic Byway. Visual sensitivity at this KOP is high due to the road's scenic designation. The roadway is adjacent to a ridge and winds through dense forests on both sides. The landscape viewed from this KOP is not typical within the area; therefore it is categorized as Distinct. Cultural modifications include a distribution line. Views in this area are enclosed and limited to the immediate FG due to the terrain and dense vegetation.

Fisher and Park AR. This KOP represents views looking south from the entrance of a community park near the southern edge of Fisher, Arkansas. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from residences. The landscape viewed in the immediate FG from this KOP is categorized as Developed because of cultural modifications associated with Fisher; views in the MG are categorized as Common because they consist of open fields and pockets of wooded areas. Cultural modifications include residential structures, light poles, and electric distribution lines.

Fisher and Park PR. This KOP represents views looking east from the entrance of a community park near the southern edge of Fisher, Arkansas. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from residences. The landscape viewed from this KOP is categorized as Developed because of cultural modifications associated with Fisher. Cultural modifications include residential and commercial structures, storage structures, chain-link fences, a playground, and electric distribution lines.

Highway 14 Scenic Highway AR. This KOP represents the view looking east along Highway 14 west of Amagon, Arkansas. Visual sensitivity at this KOP is high due to the roads scenic designation. The landscape viewed from this KOP is categorized as Common because it consists of open fields and scattered rural residences and wooded areas typical within the region. Cultural modifications include residential structures and electric distribution lines in the FG/MG, and a communication tower in the BG. Views are open due to the level terrain and lack of vegetation in the FG.

Weldon PR/AR. The Weldon KOP represents views looking north from Highway 17 near the northern edge of Weldon, Arkansas. The view consists primarily of flat agricultural land with few cultural modifications such as wood power poles and an existing steel monopole transmission line. Scattered trees dot the landscape with a row of dense trees in the distance. This landscape has some modification and is categorized as Developed.

3.18.5.7 Region 7

Region 7 is referred to as the Arkansas Mississippi River Delta and Tennessee Region and includes the Applicant Proposed Route Links 1 through 5, HVDC Alternative Routes 7-A through 7-D, and the Tennessee converter station siting area. The ROI in Region 7 traverses Poinsett and Mississippi counties in Arkansas and Tipton and Shelby counties in Tennessee. The ROI crosses two Level III ecoregions: Mississippi Alluvial Plain, which covers the eastern portion of the region, and Mississippi Valley Loess Plains, which cover the western portion of the region. The landscape character within the ROI is predominantly agricultural and natural with some developed areas in Tennessee. The terrain primarily consists of flat, level floodplains associated with the Mississippi River in the western and central portion of the ROI that transition to gently undulating plains and low hills in the eastern portion of the ROI. Although the terrain is primarily flat within this region, views are typically limited given the numerous forested areas, vegetation associated with surface waters, waterways, drainages, wetlands, and trees planted along agricultural fields and along roadways (GIS Data Sources: Clean Line 2013a, 2013b; Tetra Tech 2014a). The ROI traverses the Mississippi River and its tributaries from north to south. The ROI crosses other surface waters including wetlands, several small streams, levees, drainage channels, and impoundment ponds. Vegetation consists primarily of riparian woodland and wetland species with smaller patches of hardwood forests dispersed throughout the region. Cultural modifications include croplands, pastures, agricultural operations, roads and highways, electric distribution lines and several high-voltage transmission lines, and rural residences and suburban residential developments. Dispersed rural residence and several small communities in Arkansas occur within and adjacent to the ROI in the western and eastern portion of Region 7 including towns of Tyronza, Dyess, Bassett, Birdsong, Marie, and Wilson and the cities of Joiner and Marked Tree. In the eastern portion of the ROI in Tennessee, larger communities are concentrated closer to one another and there is more dense mixed development including the town of Atoka and Tipton and cities of Millington and Munford. In addition, large private estates are common in the eastern portion of the ROI. The Naval Air Station Memphis at Millington is also located within the eastern portion of the ROI.

Visual resources identified in the ROI include rural residences and residences associated with towns and cities, Hampson-Archeological Museum State Park, Meeman-Shelby Forest State Park, Mississippi River (including a scenic trail), St. Francis River, Lower Hatchie NWR, Trail of Tears, Scenic Route 61, Scenic Byway 63, and several state wildlife conservation areas and municipal parks.

Three route variations to the Applicant Proposed Route were developed in Region 7 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.7. The variations are illustrated in Exhibit 1 of Appendix M. Applicant Proposed Route Link 1, Variation 1; Link 1, Variation 2; and Link 5, Variation 1, all cross landscape settings similar to the original Applicant Proposed Route. Applicant Proposed Route Link 1, Variation 1, would be located closer to a residence and Applicant Proposed Route Link 1, Variation 2, and Applicant Proposed Route Link 5, Variation 1, would be located approximately the same distances to residences as the original links of the Applicant Proposed Route.

3.18.5.7.1 Landscape Character Description by KOP

Atoka PR/AR. This KOP represents views from the edge of a residential neighborhood in Atoka, Tennessee. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from residences. The landscape viewed from this KOP is categorized as Common because it consists of agricultural fields surrounded by wooded areas, typical within the region. Cultural modifications include a lattice communication tower in the MG.

Atoka Community Park PR/AR. This KOP represents views from a community park and recreation area in Atoka, Tennessee. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from a community recreation area and nearby residences. From this KOP, the landscape in the FG is categorized as Developed because of cultural modifications associated with the recreation facility. Cultural modifications include ball fields, light poles, fences, and covered picnic areas, and a playground. Views from this KOP are limited to the immediate FG due to the dense wooded area surrounding the park.

Aycock Park and Millington AR. This KOP represents views from a community park and recreation area in Millington, Tennessee. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from a community recreation area and nearby residences. The landscape viewed from this KOP is categorized as Developed because of the cultural modifications associated with Millington. Cultural modifications include ball fields and backstops, playground fences, electric distribution lines, light poles, a church, and a highway. Views from this KOP are limited to the immediate FG because a dense wooded area surrounds the park.

Birdsong PR. This KOP represents views from the northern edge of the small rural community of Birdsong, Arkansas. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from a residential area. The landscape viewed from this KOP is characterized by agricultural fields lined with trees and pockets of wooded areas. This type of landscape is typical within the region and was therefore categorized as Common. Cultural modifications are limited to residential structures and electric distribution lines.

Dyess AR. This KOP represents views looking south from the southern edge Dyess, Arkansas. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from a residential area. The landscape viewed from this KOP is characterized by agricultural fields lined with trees and scattered residences. This type of landscape is typical within the region and was therefore categorized as Common. Cultural modifications include residential structures and electric distribution lines. Views from this KOP are open due to lack of vegetation in the FG/MG.

Edmund Orgill Park PR/AR. This KOP represents views from the southern edge of a lake in Edmund Orgill Park. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from a community park and recreation area. The landscape viewed from this KOP is characterized by level terrain in the immediate FG and a large expansive lake in the FG/MG and dense vegetation along the northern edge of the lake. Given the dominance of the water feature and the variation in vegetation around the lake, this landscape is categorized as Distinct. Cultural modifications include recreational elements associated with the park, including a boat launch, a small picnic shelter and low wood fences.

Harold Park and Millington AR. This KOP represents views west from a park in the town of Millington, Tennessee. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from a community park and residential area. The landscape viewed from this KOP is categorized as Developed because of cultural modifications associated with Millington. Cultural modifications include residential structures and electric distribution lines. Views from this KOP are limited to the FG by the vegetation that surrounds residences and wooded areas in the MG.

Harold Park and Millington PR/AR. This KOP represents views north from a park in the town of Millington, Tennessee. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from a community park and residential area. The landscape viewed from this KOP is categorized as Developed because of cultural modifications associated with Millington. Views are similar to those described from the Harold Park and Millington AR KOP above.

Highway 61 (Scenic Byway) PR. This KOP represents views looking northeast from Highway 61 Scenic Byway near the northern edge of Frenchmans Bayou, Arkansas. Visual sensitivity at this KOP is high due to the scenic designation of the roadway. The landscape viewed from this KOP is categorized as Common, as the area consists of agricultural fields surrounded by trees, rural residents, and small pockets of wooded areas. Cultural modifications include residential structures and electric distribution lines.

Johnny Cash Home AR. This KOP represents the view looking south from Johnny Cash's childhood home near Dyess, Arkansas. The house is an Arkansas State University Heritage site. Visual sensitivity at this KOP is high due to the historic designation. The landscape viewed from this KOP is categorized as Common, as the area consists of agricultural fields surrounded by trees and small pockets of wooded areas. Cultural modifications include the historic home and electric distribution lines. Views from this KOP are open due to the lack of vegetation in the FG/MG.

Joiner PR. This KOP represents views looking south from the southern edge of Joiner, Arkansas. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from a residential area. The landscape viewed from this KOP is categorized as Common, as the area consists of agricultural fields surrounded by trees and small pockets of wooded areas. Cultural modifications include residential structures and electric distribution lines. Views from this KOP are open due to the lack of vegetation in the FG/MG.

Lower Hatchie NWR AR. This KOP represents views to the southeast from the Lower Hatchie NWR just east of the Mississippi River in Tennessee. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from national wildlife refuge. The landscape viewed from this KOP is characterized by gently to moderately rolling terrain and small ponds in the FG, wooded areas in the MG, and low forested hills in the BG. Given the variation in vegetation, landform, and the presence of water; this landscape is categorized as Distinct. Views are open due to limited vegetation in the FG/MG.

Marked Tree PR/AR. This KOP represents views from a municipal park in the community of Marked Tree, Arkansas. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from a community park and nearby residential area. The landscape viewed from this KOP is categorized as Developed because of cultural modifications associated with Marked Tree. Cultural modifications include residential and commercial structures, ball fields, chain-link fences, light poles, and electric distribution lines. Views from this KOP are limited by development and vegetation in the immediate FG.

McGavock-Grider Park AR. This KOP represents the view from a small memorial park on State Route 61 south of Osceola, Arkansas. Visual sensitivity at this KOP is moderate because this is a small park with no recreational facilities; viewing durations are not anticipated to be very long. The landscape viewed from this KOP is categorized as Common, because the area consists of agricultural fields surrounded by trees and wooded areas. Cultural modifications include electric distribution lines and transmission lines in the MG. Views are generally open due to the lack of vegetation in the FG/MG.

Millington East AR. This KOP represents views looking southeast from the edge of a residential neighborhood in Millington, Tennessee. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from residential areas. The landscape viewed from this KOP is categorized as Common because it consists of agricultural fields surrounded by trees and small pockets of wooded areas. Cultural modifications include a transmission line in the MG. Views are typically limited to the FG due to the dense vegetation around agricultural fields.

Millington USA Baseball Stadium AR. This KOP represents views south and west from a large baseball park complex in Millington, Tennessee. Visual sensitivity at this KOP is moderate because concern for aesthetics is not the primary focus of viewers associated with the ball field, where activities are focused inside the park. The landscape viewed from this KOP is categorized as Developed because of cultural modifications associated with Millington. Cultural modifications include ball fields, dugouts, restroom facilities, light poles, chain-link fences, commercial and residential structures, and electric distribution lines; a communication tower is visible in the MG.

Views from this KOP are limited to the FG due to development, dense wooded areas to the south and vegetation surrounding residential homes to the west.

Mississippi River and Trail of Tears AR. This KOP represents views from the southern bank of the Mississippi River looking northeast. Visual sensitivity at this KOP is high as it represents a view from a scenic recreation area and national historic trail. The landscape viewed from this KOP consists of the Mississippi River, a dominant water feature in the landscape, bordered by dense vegetation along the northern bank. Due to the presence of water, the variety of vegetation this landscape is categorized as Distinct. Cultural modifications include a transmission line that crosses the river.

Mississippi River and Trail of Tears PR. This KOP represents views looking northwest from a local road near the Mississippi River and Trail of Tears. Visual sensitivity at this KOP is high as it represents a view from a scenic recreation area and historic trail. The view is dominated by open agricultural fields bordered by wooded areas, typical within the region, so this landscape is categorized as Common. The Mississippi River is visible in the distance but is not a dominant feature in the landscape. Cultural modifications include irrigation equipment silos and storage garage for farming equipment. Views from this KOP are open due to the lack of vegetation in the FG/MG.

Munford PR/AR. This KOP represents views southwest from a mixed residential and commercial area in southern Munford, Tennessee. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from residents in the area. The landscape viewed from this KOP is categorized as Developed because of cultural modifications associated with Munford including residential and commercial structures, chain-link fences, electric distribution lines and a transmission line. Views from this KOP are limited to the FG due to dense wooded areas surrounding the community.

Rhodes Estates AR. This KOP represents views northeast from a residential area near Tipton, Tennessee. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from residents in the area. The landscape viewed from this KOP is categorized as Developed because of cultural modifications associated with Rhodes Estates including residential structures, wooden fences, electric distribution lines and a transmission line. Views from this KOP are limited due to trees clustered around residences and wooded areas in the MG.

Rhodes Estates PR. This KOP represents views southeast from a residential area near Tipton, Tennessee. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from residents in the area. The landscape viewed from this KOP is similar to the landscape viewed for the Rhodes Estates AR KOP in that it is categorized as Developed because of cultural modifications associated with Rhodes Estates including residential structures, wooden fences, and electric distribution lines. Views from this KOP are also limited due to trees clustered around residences and wooded areas in the MG.

Rockyford Park AR. This KOP represents views from a neighborhood park in a residential area in northern Bartlett, Arkansas. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from residents and park users. The landscape viewed from this KOP is categorized as Developed because of cultural modifications associated with the Rockyford subdivision including a man-made pond, residential structures, benches, signs, a trail, light poles, and electric distribution lines. Views from this KOP are limited to the FG due to residential structures, scattered trees and wooded areas surrounding the subdivision.

Tyronza AR. This KOP represents views looking northwest from the western edge of Tyronza, Arkansas. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from a residential area. The view from this KOP consists of croplands with vegetation along the edge of fields and wooded areas. Croplands are typical within this region, so this landscape is categorized as Common. Cultural modifications include electric distribution lines. Views from this KOP are open due to the level terrain and lack of vegetation in the FG/MG.

Tyronza PR. This KOP represents views looking northwest from the western edge of Tyronza, Arkansas. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from a residential area. The landscape viewed from this KOP is categorized as Developed because of cultural modifications associated Tyronza, including residential and commercial structures, fence posts, chain-link fences, and electric distribution lines. Views are open due to open fields and the lack of vegetation in the immediate FG.

Wilkinsville AR. This KOP represents views south-southeast from the southern edge of Wilkinsville, Tennessee. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from residential areas. The landscape viewed from this KOP is categorized as Common, because the area consists of agricultural fields with pockets of wooded areas in the MG. Cultural modifications include irrigation equipment. Views from this KOP are open due to lack of vegetation in the immediate FG.

Wilkinsville AR. This KOP represents views southeast from the eastern edge of Wilkinsville, Tennessee. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from residential areas. The landscape viewed from this KOP is categorized as Common, because the area consists of agricultural fields with small clumps of vegetation in the FG and pockets of wooded areas in the MG. Cultural modifications include residential structures, irrigation equipment, electric distribution lines and communication towers. Views are partially obstructed due to scattered vegetation in the immediate FG.

Wilson Park AR. This KOP represents views from Hudson Wren Memorial Park near the northwestern edge of Wilson, Arkansas. Visual sensitivity at this KOP is high because of the strong concern for aesthetics and long viewing durations from nearby residential areas and this public park. The landscape viewed from this KOP is categorized as Common, as the area consists of agricultural fields with pockets of wooded areas in the MG/BG and vegetation concentrated around scattered rural residences. Cultural modifications include electric distribution lines and residential structures in the MG. Views from this KOP are open due to the lack of vegetation in the FG.

3.18.5.8 Connected Actions

3.18.5.8.1 Wind Energy Generation

Wind energy development is a connected action to the Project. To assist in evaluating the potential environmental impacts of that wind energy development, the Applicant attempted to identify the likely locations of the wind energy development that would utilize the capacity on the HVDC transmission line. The Applicant identified thirteen WDZs, each within a 40-mile-radius of the Oklahoma County Converter Station Siting Area with adequate wind resource and within which future development of wind energy facilities could occur (see Figure 3.17-1 in Appendix A). The WDZs include approximately 1,700 square miles, or 1,082,000 acres in Oklahoma (Beaver, Cimarron, and Texas counties) and Texas (Hansford, Ochiltree, and Sherman counties). According to the BLM sponsored study “Wind Turbine Visibility and Visual Impact Threshold Distances in Western Landscapes” (Sullivan et al. 2011), given the right conditions, wind turbines can be visible at more than 36 miles and may be noticeable to the casual observer at distances up to 20 miles. Because of these findings, the ROI for the wind energy generation has been set at 30 miles from the boundary of each WDZ. Consistent with the Project, EPA Level III ecoregions were used to develop a description of the existing landscape character.

3.18.5.8.1.1 WDZ-A

WDZ-A falls primarily within the High Plains ecoregion. This ecoregion is characterized by gently rolling terrain with occasional sand plains and hills along with scattered playa depressions. Vegetation is primarily short and midgrass prairie scattered with other types of vegetation including Harvard shin oak, fourwing saltbush, sand sagebrush, and yucca. The generally flat, open landscape provides largely unobstructed panoramic views and the horizontal lines of the landform are occasionally interrupted with vertical elements such as grain silos, transmission structures, and scattered rural residences and farms, which can be visible from long distances.

The far western portion of WDZ-A transitions in the Southwestern Tablelands ecoregion and is characterized by broad, elevated tablelands with shallow canyons, mesas, badlands, gorges, and dissected river breaks. Vegetation in the region consists primarily of shortgrass prairie with some scattered riparian areas. The open landscape of this ecoregion offers broad panoramic views with strong horizontal lines and provides typical views similar to the High Plains ecoregion.

Cultural modifications within the ROI are primarily cropland and grazing land with associated buildings and that is occasionally interrupted with paved and unpaved roads. In addition, livestock feeding operations and oil and natural gas facilities are common.

Sensitive visual resources in the ROI include Perryton, Texas; Spearman, Texas; Hardesty Oklahoma and other small communities, Optima NWR, Schultz WMA, Lake Schultz State Park, as well as various local parks and recreation areas.

3.18.5.8.1.2 WDZ-B

WDZ-B is characterized primarily by the High Plains ecoregion transitioning into the Southwestern Tablelands ecoregion on the eastern edge and has similar landscape and vegetation characteristics as WDZ-A. The open landscape of both ecoregions offers largely unobstructed panoramic views and the horizontal lines of the landform are occasionally interrupted with vertical elements such as grain silos, transmission structures, and scattered rural residences and farms, which can be visible from long distances.

Cultural modifications within the ROI are primarily cropland and grazing land with associated buildings and large areas utilizing center pivot irrigation and scattered paved and unpaved roads. In addition, livestock feeding operations and oil and natural gas facilities are common.

Sensitive visual resources in the ROI include Gruver Texas; Perryton, Texas; Spearman, Texas; Hardesty, Oklahoma and other small communities, Optima NWR, Schultz WMA as well as various local parks and recreation areas.

3.18.5.8.1.3 WDZ-C

WDZ-C is characterized primarily by the High Plains ecoregion transitioning into the Southwestern Tablelands ecoregion and has similar landscape and vegetation characteristics as the previous WDZs. As described previously, the open landscape of both of these ecoregions offers largely unobstructed panoramic views and the horizontal lines of the landform are occasionally interrupted with vertical elements such as grain silos, center pivots, transmission structures, and scattered rural residences and farms, which can be visible from long distances.

Cultural modifications within the ROI are primarily cropland and grazing land with associated buildings and large areas utilizing center pivot irrigation. Scattered paved and unpaved roads, concentrated livestock feeding operations, and oil and natural gas facilities are common.

Sensitive visual resources in the ROI include Rita Blanca National Grassland (administered by Cibola National Forest), Lake Schultz State Park, Shultz Wildlife Management area, Optima NWR, local parks and recreation areas, and the towns of Cactus, Texas; Goodwell, Oklahoma; Guymon, Oklahoma; Hardesty, Oklahoma; Sunray, Texas and Texahoma, Oklahoma.

3.18.5.8.1.4 WDZ-D

WDZ-D falls within the Southwestern Tablelands ecoregion and is characterized by broad, elevated tablelands with shallow canyons, mesas, badlands, gorges, and dissected river breaks. Vegetation in the region consists primarily of shortgrass prairie with some scattered riparian areas. The open landscape offers largely unobstructed panoramic views and the horizontal lines of the landform are occasionally interrupted with vertical elements such as wind turbines, steel and wood transmission and distribution structures, center pivots, and scattered rural residences and farms, which can be visible from long distances.

Cultural modifications within the ROI are primarily cropland and grazing land with associated buildings, scattered paved and unpaved roads, livestock feeding operations, and oil and natural gas facilities are common and groupings of wind turbines can be found the southwestern area of the ROI.

Sensitive visual resources in the ROI include Hardesty, Texas; Goodwell, Oklahoma; Guymon, Oklahoma; Optima, Oklahoma; Lake Schultz State Park, Optima NWR, Optima WMA, Schultz WMA and local parks and recreation areas.

3.18.5.8.1.5 WDZ-E

WDZ-E is primarily within the High Plains ecoregion transitioning to Southwestern Tablelands along the southern and northeastern edges. Vegetation and landscape characteristics are as described in WDZ-A, and similar to the previously described WDZs the open landscape offers largely unobstructed panoramic views and the horizontal lines of the landform are occasionally interrupted with vertical elements such as center pivots, transmission structures, scattered rural residences and farms, as well as wind turbines, which can be visible from long distances.

Cultural modifications within the ROI are primarily grazing land and cropland with center pivot irrigation and associated buildings, scattered paved and unpaved roads, livestock feeding operations, oil and natural gas facilities are common and groupings of wind turbines can be found the southern portion of the WDZ.

Sensitive visual resources in the ROI include Guymon, Texas; Hardesty, Texas; Optima, Oklahoma; Goodwell Oklahoma, Hooker, Oklahoma; Optima NWR, Optima WMA, Lake Schultz State Park, Schultz WMA, Rita Blanca National Grassland (administered by Cibola National Forest), Cimarron National Grassland, local parks and recreation areas.

3.18.5.8.1.6 WDZ-F

WDZ-F is primarily within the High Plains ecoregion transitioning to Southwestern Tablelands along the boundary of the WDZ. Vegetation and landscape characteristics are as described in WDZ-A, and similar to the previously described WDZs the gently rolling terrain and open landscape offers largely unobstructed panoramic views and the horizontal lines of the landform are occasionally interrupted with vertical elements such as center pivots, transmission structures, and scattered rural residences and farms, which can be visible from long distances.

Cultural modifications within the ROI are primarily grazing land and cropland with center pivot irrigation and associated buildings, scattered paved and unpaved roads, transmission structures, livestock feeding operations, and oil and natural gas facilities are common.

Sensitive visual resources in the ROI include Goodwell, Oklahoma; Guymon Texas; Texhoma, Oklahoma; Optima, Oklahoma, Optima NWR, Rita Blanca National Grassland (administered by Cibola National Forest), and Cimarron National Grassland and local parks and recreation areas.

3.18.5.8.1.7 WDZ-G

WDZ-G is characterized primarily by the High Plains ecoregion which is characterized by gently rolling terrain with occasional sand plains and hills along with scattered playa depressions. Vegetation is primarily short and midgrass prairie scattered with other types of vegetation including Harvard shin oak, fourwing saltbush, sand sagebrush, and yucca. The generally flat, open landscape provides largely unobstructed panoramic views and the horizontal lines of the landform is intermixed with occasional vertical elements such as transmission structures, grain silos, and scattered rural residences and farms, which can be visible from long distances.

Cultural modifications within the ROI are primarily grazing land and cropland with associated buildings, scattered paved and unpaved roads, transmission structures, livestock feeding operations, and oil and natural gas facilities are common.

Sensitive visual resources in the ROI include Cimarron National Grassland, Comanche National Grassland, Rita Blanca National Grassland (administered by Cibola National Forest), and the communities of Elkhart, Kansas; Keyes, Oklahoma; Boise City, Oklahoma; and local parks and recreation areas.

3.18.5.8.1.8 WDZ-H

WDZ-H consists of the High Plains ecoregion transitioning into the Southwestern Tablelands ecoregion near the southeastern and northern borders and has similar landscape and vegetation characteristics as previously described WDZs. The open landscape of both of these ecoregions offers largely unobstructed panoramic views and the horizontal lines of the landform are mixed with vertical elements such as grain silos, transmission structures, and scattered rural residences and farms, which can be visible from long distances.

Cultural modifications within the ROI are primarily cropland and grazing land with associated buildings and large areas utilizing center pivot irrigation and scattered paved and unpaved roads. In addition, livestock feeding operations and oil and natural gas facilities are common.

Sensitive visual resources in the ROI include Rita Blanca National Grassland (administered by Cibola National Forest), Cimarron National Grassland, Comanche National Grassland, local parks and recreation areas, and the communities of Elkhart, Kansas; Goodwell, Oklahoma; Guymon, Oklahoma; and Texhoma, Oklahoma.

3.18.5.8.1.9 WDZ-I

WDZ-I is characterized primarily by the High Plains ecoregion which is characterized by gently rolling terrain with occasional sand plains and hills along with scattered playa depressions. Vegetation is primarily short and midgrass prairie scattered with other types of vegetation including Harvard shin oak, fourwing saltbush, sand sagebrush, and yucca. The generally level, open landscape provides unobstructed panoramic views and the horizontal lines of the landform is intermixed with occasional vertical elements such as transmission structures, grain silos, and scattered rural residences and farms, which can be visible from long distances.

Cultural modifications within the ROI are primarily grazing land and cropland with associated buildings, scattered paved and unpaved roads, transmission structures, livestock feeding operations, and oil and natural gas facilities are common.

Sensitive visual resources in the ROI include with the communities of Hooker, Texas; Optima, Oklahoma; Hardesty, Oklahoma; Liberal, Kansas; Tyrone, Oklahoma; Optima NWR, Optima WMA, Beaver River WMA, Lake Schultz State Park, Schultz WMA, and Rita Blanca National Grassland (administered by Cibola National Forest), and local parks and recreation areas.

3.18.5.8.1.10 WDZ-J

WDZ-J is characterized by the Southwestern Tablelands ecoregion in the west and the High Plains ecoregion to the east. The landscape and vegetation in these regions is similar to that described in previous WDZs. The open landscape of both of these ecoregions offers unobstructed panoramic views and the horizontal lines of the landform are occasionally interrupted with vertical elements such as grain silos, transmission structures, and scattered rural residences and farms, which are visible from long distances.

Cultural modifications within the ROI are primarily grazing land and cropland with associated buildings, scattered paved and unpaved roads, transmission structures, livestock feeding operations, and oil and natural gas facilities are common.

Sensitive visual resources in the ROI include the Beaver River WMA, Lake Schultz State Park, Schultz WMA, Beaver Dunes State Park, Optima WMA, Optima NWR, local parks and recreation areas, and the communities of Beaver, Oklahoma; Forgan, Oklahoma; and Perryton, Texas.

3.18.5.8.1.11 WDZ-K

WDZ-K is characterized by the Southwestern Tablelands ecoregion in the southern portion and transitioning to the High Plains ecoregion in the north. The landscape and vegetation in these regions is similar to that described in previous WDZs. The open landscape of both of these ecoregions offers unobstructed panoramic views and the horizontal lines of the landform are occasionally interrupted with vertical elements such as grain silos, transmission structures, and scattered rural residences and farms, which are visible from long distances.

Cultural modifications within the ROI are primarily grazing land and cropland with associated buildings, scattered paved and unpaved roads, transmission structures, livestock feeding operations, and oil and natural gas facilities are common.

Sensitive visual resources in the ROI include the communities of Booker, Texas; Beaver, Oklahoma; Darrouzett, Texas; Perryton, Texas; Beaver Dunes State Park, Beaver River WMA, and local parks and recreation areas.

3.18.5.8.1.12 WDZ-L

WDZ-L falls within the High Plains ecoregion to the west, transitioning into the Southwestern Tablelands ecoregion on towards the eastern border of the WDZ, and has similar landscape and vegetation characteristics as WDZ-A. The open landscape of both of these ecoregions offers largely unobstructed panoramic views and the horizontal lines of the landform are occasionally interrupted with vertical elements such as grain silos, transmission structures, and scattered rural residences and farms, which can be visible from long distances.

Cultural modifications within the ROI are primarily cropland and grazing land with associated buildings and large areas utilizing center pivot irrigation and scattered paved and unpaved roads. In addition, livestock feeding operations and oil and natural gas facilities are common.

Sensitive visual resources in the ROI include with the communities of Spearman, Texas; Gruver, Texas; Perryton, Texas; Booker, Texas; Borger, Texas; Canadian, Texas; Darrouzett, Texas; Stinnet, Texas, Gene Howe WMA. Pat Murphy Unit, Lake Meredith National Recreation Area, Lake Schultz State Park, Optima NWR, Optima WMA, Schultz WMA, Lake Fryer/Wolf Creek Park and various local parks and recreation areas.

3.18.5.8.2 Optima Substation

The ROI for the future Optima Substation is located entirely within the Southwestern Tablelands ecoregion and is characterized by relatively flat terrain that is bisected by drainages in the northern portion of the ROI, causing the landscape to appear gently rolling. Vegetation consists primarily of grasses and low shrubs with some scattered riparian vegetation occurring along drainages in the northern portion of the ROI and croplands in the southern portion. The level terrain and low vegetation allows for unobstructed panoramic views across the landscape.

Cultural modifications within the ROI for the future Optima Substation are primarily cropland and grazing land with associated buildings, paved and unpaved roads, oil and natural gas facilities, transmission lines, electric distribution lines, and several turbines located in the southwestern portion of the ROI.

Sensitive visual resources within the ROI include travelers along Highway 207 and local roads; however, visual sensitivity is low because concern for aesthetics is generally secondary to commuting to and from work or work activities. No other sensitive visual resources are identified with the ROI. The closest sensitive visual resource with moderate or high sensitivity includes recreational users associated with the Optima National Wildlife Refuge, located approximately 2.5 miles northeast of the substation ROI.

3.18.5.8.3 TVA Upgrades

The ROI for the direct assignment facilities (which are included in the Applicant Proposed Project) would occur within the Tennessee Converter Station Siting Area and more specifically within the Shelby Substation. The ROI for the network upgrades, and in particular TVA's future 500kV transmission line, cannot be fully determined at this time.

The new 500kV line would be constructed in western Tennessee. Upgrades to existing infrastructure would include upgrading terminal equipment at three existing 500kV substations and six existing 161kV substations, making appropriate upgrades to increase heights on 16 existing 161kV transmission lines to increase line ratings, and replacing the conductors on eight existing 161kV transmission lines.

3.18.6 Impacts to Visual Resources

3.18.6.1 Methodology

This section describes the methods used to assess impacts to visual resources as a result of the construction and operations and maintenance of the Project. The methodology for assessing impacts is graphically shown in a flowchart in Figure 3.18-4 in Appendix A.

Regulations or guidance for managing visual resources that is applicable to all lands (federal, state, and municipal) within the ROI were not found during initial research efforts. Therefore, the visual impact assessment methodology was developed using concepts from the BLM VRM system. The BLM VRM system outlines a systematic process for analyzing potential visual impacts of proposed projects and activities by analyzing the visual contrast created between the existing landscape without the Project, and the same landscape after a proposed project has been implemented (BLM 1986). The concept of contrast, the process for analyzing contrast, and the methodology employed to identify impacts to visual resources are described in the subsequent section.

To conduct the impact assessment for visual resources, information collected in the inventory process (see Section 3.18.4 and Figure 3.18.1 in Appendix A) was used to perform a contrast analysis for the Project and identify initial impacts to scenery and viewers from KOPs.

3.18.6.1.1 Assessing Contrast

Contrast is the degree of visual change that occurs in the landscape due to the construction and operations and maintenance of a project (BLM 1986). Visual contrast introduced by the Project would result from (1) landform modifications that are necessary to prepare ROWs for construction, (2) removal of vegetation to construct and maintain transmission lines, roads, and converter stations, (3) construction of temporary and permanent access roads required to erect and maintain transmission lines and converter stations, and (4) introduction of transmission lines and converter station facilities into the landscape setting. Contrast in the landscape is determined by comparing visual elements (form, line, color, and texture) of the existing landscape with the visual elements of the Project (i.e., transmission structures, converter stations, access road, etc.). The following are descriptions of each of the visual elements:

- Form—the shape and mass of landforms or structures which appear unified
- Line—the edge of shapes or masses in the landscape (edges, bands, silhouettes)
- Color—the property of reflecting light of a particular intensity and wavelength that the eye can see
- Texture—the aggregation of small forms or color mixture into a continuous surface pattern

Using this method for each KOP, Project components (transmission line alternatives and converter station siting areas) were assigned one of the following five contrast levels:

- Strong—contrast demands attention and is dominant in the landscape

- Moderate-Strong—contrast begins to demand attention and is still moderately dominant in the landscape
- Moderate—contrast attracts attention but is co-dominant in the landscape
- Moderate-Weak—contrast begins to attract attention and is moderately subordinate in the landscape
- Weak—contrast can be seen but does not attract attention

Modified BLM Contrast Rating Worksheets (Form 8400-4) were used to document and assess the existing conditions, the proposed changes, and potential impacts for each KOP (Appendix K). The contrast level was then used when considering impacts to scenery and viewers depending on the distance of the viewer from the Project (FG, MG, or BG distance zones).

Impacts were identified based on the Project description and the associated EPMs (Appendix F). The primary effects to visual resources that are described throughout this section are assessed and disclosed based on the assumption that the EPMs would be implemented and over time they would reduce impacts to scenery and viewers.

Environmental Protection Measures applicable to minimizing impacts on visual resources were identified in the Visual Resource Technical Report (Clean Line 2014) and include the following:

- GE-3: Clean Line will minimize clearing vegetation within the ROW, consistent with a Transmission Vegetation Management Plan (TVMP) filed with the NERC and applicable federal, state, and local regulations. The TVMP may require additional analysis under NEPA depending on whether and under what conditions DOE decides to participate in the Project.
- GE-6: Clean Line will restrict vehicular travel to the ROW and other established areas within the construction, access, or maintenance easement(s).
- GE-7: Roads not otherwise needed for maintenance and operations will be restored to preconstruction conditions. Restoration practices may include decompacting, recontouring, and re-seeding. Roads needed for maintenance and operations will be retained.
- GE-10: Clean Line will work with landowners to repair damage caused by construction, operation, or maintenance activities of the Project. Repairs will take place in a timely manner, weather and landowner permitting.
- GE-11: Clean Line will conduct construction, operation, and maintenance activities to minimize the creation of dust. This may include measures such as limitations on equipment, speed, and/or travel routes utilized. Water, dust palliative, gravel, combinations of these, or similar control measures may be used. Clean Line will implement measures to minimize the transfer of mud onto public roads.
- LU-3: Clean Line will work with landowners to avoid and minimize impacts to residential landscaping.
- LU-4: Clean Line will coordinate with landowners to site access roads and temporary work areas to avoid and/or minimize impacts to existing operations and structures.
- LU-5: Clean Line will make reasonable efforts, consistent with design criteria, to accommodate requests from individual landowners to adjust the siting of the ROW on their properties. These adjustments may include consideration of routes along or parallel to existing divisions of land (e.g., agricultural fields and parcel boundaries) and existing compatible linear infrastructure (e.g., roads, transmission lines, and pipelines), with the intent of reducing the impact of the ROW on private properties.

The anticipated visual impacts that would result from construction and operation of the Project are described as follows:

- High Impacts—Where Project components are dominant or readily apparent from KOPs. Project components would introduce form, line, color, and texture changes that are inconsistent with the existing landscape.
- Moderate Impacts—Where Project components are co-dominant with existing landscape features, and moderately apparent from viewing KOPs. Project components would mimic form, line, color, and texture of similar features within the existing landscape.
- Low Impacts—Project components are subordinate in the landscape and not readily apparent from KOPs. Project components would parallel existing high-voltage transmission lines or features with similar form, line, color, and texture.

3.18.6.1.2 Impacts to Scenery

Impacts to scenery were determined based on the comparison of the contrast associated with the Project (e.g., transmission lines, converter stations, access roads, etc.) and the factors that compose the existing landscape (e.g., vegetation, landform, water, and cultural modifications) as described in section 3.18.4. Impacts to the existing landscape were assessed by reviewing the landscape category (Distinct, Common, Developed) combined with the anticipated Project contrast. It is anticipated that Distinct or Common landscapes that would be substantially altered by the Project (i.e., where similar facilities do not exist in the landscape) would result in high impacts. Moderate–low impacts are anticipated in Common or Developed landscapes where similar features may be present and the introduction of Project features would result in low levels of modification to the existing landscape. Landscape Scenery Impact ratings are shown in Table 3.18-4.

Table 3.18-4:
Landscape Scenery Impacts Matrix

Landscape Category	Project Contrast				
	Strong	Moderate–Strong	Moderate	Moderate–Weak	Weak
Distinct	High	High	Moderate–High	Moderate	Moderate
Common	High	Moderate–High	Moderate	Moderate	Moderate–Low
Developed	Moderate	Moderate	Moderate–Low	Low	Low

3.18.6.1.3 Impacts to Sensitive Viewers

Impacts to sensitive viewers were determined based on an assessment of contrast, user concern level (moderate or high), distance from the Project (0 to 0.5 mile, 0.5 to 3 miles, greater than 3 miles), and visibility of the Project. Table 3.18-5 summarizes how user concern impacts were assessed and demonstrates how concern levels vary depending on how close the viewer is to the Project. High impacts are anticipated to occur where the Project is dominant within a view and highly noticeable by the casual observer, or where the Project introduces a high level of contrast to the existing landscape. Low impacts are anticipated to occur in the BG distance zone where, because of the distance of the viewer from the Project, Project components would be subordinate in the landscape and not readily apparent to the casual observer.

Table 3.18-5:
Viewer Concern Impacts Matrix

Viewer Concern Level	Distance Zones: Foreground (FG) (0–0.5 mile) Contrast Level			Middleground (MG) (0.5–3 miles) Contrast Level			Background(BG) (3–15 miles) Contrast Level		
	Strong	Moderate	Weak	Strong	Moderate	Weak	Strong	Moderate	Weak
High	High	Moderate–High	Moderate	Moderate–High	Moderate	Low	Moderate–High	Moderate	Low
Moderate	Moderate–High	Moderate	Moderate–Low	Moderate	Moderate–Low	Low	Moderate	Moderate–Low	Low
Low	Moderate	Moderate–Low	Low	Low	Low	Low	Low	Low	Low

3.18.6.1.4 Overall Project Impacts

The landscape scenery impacts were combined with the viewer concern impacts, resulting in overall Project impact. Table 3.18-6 summarizes how the overall impacts from the Project were assessed. Overall Project impacts are described for each KOP in Sections 3.18.6.2 and 3.18.6.3.

Table 3.18-6:
Overall Project Impacts Matrix

Landscape Scenery Impacts	Viewer Concern Impacts: High	Moderate–High	Moderate	Moderate–Low	Low
High	High	High	Moderate–High	Moderate	Moderate
Moderate–High	High	Moderate–High	Moderate–High	Moderate	Moderate
Moderate	Moderate–High	Moderate–High	Moderate	Moderate–Low	Moderate–Low
Moderate-Low	Moderate	Moderate	Moderate–Low	Moderate–Low	Low
Low	Moderate	Moderate	Moderate–Low	Low	Low

It should be noted that in some instances, the overall impacts described for each KOP in Sections 3.18.6.2 and 3.18.6.3 differ from the impacts included in the corresponding Contrast Rating Worksheets in Appendix K. These differences are a result of different visual methodologies used by the DOE in preparing this EIS and by Clean Line in preparing the Contrast Rating Worksheets. Overall, impacts described in the KOPs are similar to those noted on the Contrast Rating Worksheets. In instances where there are differences, the impact ratings are close (i.e., low vs. moderate–low or moderate vs. moderate-high).When visual assessment was conducted, structures were conservatively assumed to be a typical 200-foot-tall lattice structure, which would be the tallest typical structure used. The impacts described for each KOP in subsequent sections and the Contrast Rating Worksheets in Appendix K, were based upon this assumption. However, preliminary engineering indicates that when using a lattice structure, most structures would be less than 160 feet tall, and less than 140 feet tall when using monopole structures. For KOPs representing unobstructed views across open landscapes towards the Project, the 40-foot change in tower height (from 200 feet to 160 feet for lattice structures) would most likely not be discernible to the casual observer and the overall impacts would not change from the impacts disclosed in this assessment. However, impacts may be affected for KOPs that represent views where only the top portions of the transmission structures are visible—for example, when they extend above tree line—where a lower structure height would reduce the amount of the structures visible. In these instances, it is anticipated that a lower structure height would result in lower overall visual impacts. In these site-specific incidences, the KOP analysis and corresponding Contrast Rating Worksheet (Appendix K) were not updated to reflect this change.

3.18.6.1.5 Photographic Simulations

Photographic simulations were created to depict impacts resulting from the Project at specific viewing locations. DOE and Clean Line selected 56 KOPs to represent each viewing location type (residences, recreation areas, and travel routes), associated concern level, and distance from the Project. Photographic simulations were developed to support the contrast rating and impact analysis by simulating changes associated with the Project and to disclose anticipated representative effects of the Project. Photographic simulations are included in Appendix K.

The photographic simulations that are included in Appendix K demonstrate the views of lattice and monopole structures (that range between 120 and 200 feet in height) for each selected KOP. The photographic simulations were not updated to reflect the changes in structure height based on preliminary engineering as discussed in 3.18.6.1.4.

3.18.6.2 Impacts Associated with the Applicant Proposed Project

3.18.6.2.1 Converter Stations and AC Interconnection Siting Areas

3.18.6.2.1.1 Construction Impacts

Construction would result in the short-term visual intrusion of construction vehicles, equipment, materials, and a work force in staging areas, and final converter station location. Vehicles, heavy equipment, structure components, ancillary facility components and materials, and workers would be visible during converter station construction and modification, clearing and grading, structure erection, and cleanup and restoration would create short-term and local contrast within the areas of the ROW for the AC interconnection where construction is taking place. It should also be noted that lighting of construction yards and work areas would create temporary visual impacts to night skies where construction is taking place. Affected viewers would be aware of the temporary nature of the Project construction impacts, which should decrease their concern about the impact.

3.18.6.2.1.2 Operations and Maintenance Impacts

3.18.6.2.1.2.1 Oklahoma Converter Station Siting Area and AC Interconnection Siting Area

The Oklahoma Converter Station Siting Area would be located southwest of Hardesty. The surrounding area is primarily flat, open agricultural lands that offer panoramic views. The converter station and associated structures would contrast the rural landscape and be visible on the horizon from large distances. This area is already impacted by numerous vertical structures such as wind turbines and existing transmission lines, and there are no notable visual resources, so visual concern is low. The converter station and associated structures would add additional contrast to the landscape, but in this area overall visual impacts would be low due to existing modification to the landscape and low number of sensitive viewers.

3.18.6.2.1.2.2 Tennessee Converter Station Siting Area and AC Interconnection Tie

The Tennessee Converter Station Siting Area would be located adjacent to the existing Shelby substation. The area is primarily rural and undeveloped in nature with flat to rolling terrain and areas of dense vegetation. Most of the existing development is residential, and the residents in the developments would represent most of the sensitive viewers. While the region is largely undeveloped, there is an existing substation in close proximity that would reduce the overall visual contrast and impacts of the Project. Two KOPs were identified for this converter station, Shelby 1 and Shelby 2, as described below and detailed in Table 3.18-7.

Table 3.18-7:
Visual Impact Summary of KOPS—Tennessee Converter Station Siting Area

KOP	Converter Station	Distance (Miles)	Viewer Sensitivity	Landscape Category	Visibility	Viewer Concern Impact	Contrast	Overall Impact
Shelby 1	TN	0.2	High	Developed	Yes	High	Strong	Moderate–High
Shelby 2	TN	0.5	High	Common	Yes	High	Moderate	Moderate – High

Shelby 1. Looking southwest from this KOP, the Tennessee converter station would be located 0.2 mile away in the FG. Strong contrast would be created by Project components in the FG distance zone for high sensitive residential viewers represented by this KOP; therefore, viewer concern impacts would be high. Vegetation may screen portions of the converter station, but at this distance it would become a dominant feature on the landscape. The form and line of the converter station would be similar to the existing substation, but appearing at a larger scale because it is closer to the viewer. The Project would result in strong contrast at this location; however, due to the existing substation, which has introduced similar modifications to the landscape setting, the overall visual impact would be moderate-high.

Shelby 2. The Tennessee converter station would be located adjacent to the existing Shelby substation and would therefore be located approximately 0.3 to 0.4 mile to the north of this location. Moderate contrast would be created by Project components in the FG distance zone for high sensitive residential viewers represented by this KOP; therefore, viewer concern impacts would be moderate–high. The broad profile of the substation would be visible in the FG and contrast with the existing environment. Views of the substation from some residences may be unobstructed and for some residences, some elements of the substation may be visible above the tree line and silhouetted against the sky. In either case, the substation would appear similar to the Shelby Substation in form. The Project would result in moderate contrast and moderate–high overall visual impacts at this location.

3.18.6.2.1.3 Decommissioning Impacts

Project facilities would be removed at the end of the operational life of the converter station. Structures and related facilities would be removed and foundations removed to below the ground surface level. There would be residual visual impacts for many years after the Project has been decommissioned and structures removed such as vegetative cutbacks, cut-and-fill scars from construction activities, and access roads, all of which would have added to the visual impact, though these impacts would be at ground level. There would also be temporary visual impacts during decommissioning. These impacts would diminish over time as vegetation returned to the ROW or as redevelopment occurred.

3.18.6.2.2 AC Collection System

3.18.6.2.2.1 Construction Impacts

Construction would result in the short-term visual intrusion of construction vehicles, equipment, materials, and a work force in staging areas, along access roads, and along the new transmission line ROW. Vehicles, heavy equipment, structure components, and workers would be visible during transmission line construction and modification, access and spur road clearing and grading, structure erection, conductor stringing, and cleanup and restoration. However, disturbance from construction activities would be transient and of short duration as activities progress along the transmission line route. Affected viewers would be aware of the temporary nature of Project construction impacts, which may decrease their concern to the impact. The structures and cables (transmission lines) would cause the major long-term change in scenery.

3.18.6.2.2.2 Operations and Maintenance Impacts

The AC collection system routes are located in a sparsely populated area in a landscape that is primarily flat agricultural lands offering open panoramic views. The region does not contain a high number of sensitive viewers or sensitive resources, so impacts would be expected to be low-moderate. The AC collection system routes are located in a largely open and undeveloped landscape, and the introduction of large vertical elements such as a transmission line, would have the potential to affect viewers over a large viewing area. Thirteen viewing locations/KOPs were identified for the AC collection system routes as summarized in Table 3.18-8.

Table 3.18-8:
Visual Impact Summary of KOPS—AC Collection System Routes

KOP	Route	Distance (Miles)	Viewer Concern	Landscape Category	Visibility	Viewer Concern Impact	Contrast	Overall Impact
Farnsworth	SE-3	4	High	Common	Yes	Low	Weak	Low
Goodwell	W-1	1.3	High	Common	Yes	Moderate	Moderate	Moderate
Guymon East	NE-1, NW-2	3.7	High	Developed	Yes	Low	Weak	Low
Guymon West	NW-1	3.2	High	Common	Yes	Low	Weak	Low
Hardesty	E-1	0.5	High	Common	Yes	Moderate –High	Moderate	Moderate–High
Hooker	NE-1, NE-2	2.5	High	Developed	Yes	Low	Weak	Low
Lake Schultz State Park	E-3	1.2	High	Distinct	Yes	Moderate –High	Strong	High
Lake Schultz State Park South	E-2, SE-1, SE-3	1	High	Distinct	Yes	Moderate	Moderate	Moderate–High
Optima	NE-1, NW-2	2.4	High	Developed	Yes	Low	Weak	Low
Optima NWR	E-1	1.3	High	Common	Yes	Moderate	Moderate	Moderate
Perryton-Leatherman Park	SE-3	5	High	Common	Yes	Low	Weak	Low
Spearman	SE-1	5.6	High	Developed	Yes	Low	Weak	Low
Waka	SE-1	2	High	Common	Yes	Low	Weak	Low

Farnsworth. This KOP is located on the southeastern edge of the community of Farnsworth, Texas. Looking east, AC Collection System Route SE-3 would be located 4 miles away in the BG distance zone. Because weak contrast would be introduced by the Project in the BG distance zone for high sensitive residential viewers represented by this KOP, viewer concern impacts would be low. The transmission line would be faintly visible and would appear as a pattern of vertical elements spaced across the horizon. The transmission line structures would result in weak contrast at this location and the overall visual impact would be low.

Goodwell. AC Collection System Route W-1 would be located 1.3 miles south of this KOP. Moderate contrast would be created by the introduction of Project components in the MG distance zone for high sensitive residential viewers represented by this KOP; therefore, viewer concern impacts would be moderate. The landscape in this area is open, providing panoramic views and the transmission line structures would appear as vertical objects on the horizon, when not screened by FG trees and elements. At this distance, the structures would appear small, but there is not a lot of development in this area, so the introduction of additional vertical elements on the landscape would result in moderate visual contrast and Moderate overall visual impact.

Guymon East. AC Collection System Routes NE-1 and NW-2 would be located 3.7 miles to the east of this KOP. Weak contrast would be created by Project components in the BG distance zone for high sensitive residential and recreational viewers represented by this KOP; therefore, viewer concern impacts would be low. Transmission line Structures may be visible on the horizon, but at this distance they would appear as small objects on the horizon and would add to the irregular line of the horizon, resulting in weak contrast and low overall visual impacts.

Guymon West. AC Collection System Route NW-1 would be located 3.2 miles to the southwest of this KOP. Weak contrast would be created by Project components in the BG distance zone for high sensitive residential viewers represented by this KOP; therefore, viewer concern would be low. At this distance, the structures would appear as small vertical objects on the horizon and would have a similar impact as the existing structures in view, resulting in weak visual contrast and low overall visual impacts.

Hardesty. AC Collection System Route E-1 would be located 0.5 mile to the northwest of this KOP. Moderate contrast would be created by Project components in the FG distance zone for high sensitive residential viewers represented by this KOP; therefore, viewer concern impacts would be moderate–high. The structures in the open field would be visible and introduce a repeating pattern of tall vertical elements on the landscape. The structures would be a dominant feature on the open landscape and visual contrast would be moderate. The overall visual impact would be moderate–high.

Hooker. AC Collection System Route NE-1 and NE-2 would be located 2.5 miles south of the town of Hooker. Weak contrast would be created by Project components in the MG distance zone for high sensitive residential viewers represented by this KOP; therefore, viewer concern impacts would be low. Transmission line structures would be visible on the horizon and appear as vertical elements similar to existing structures in view. The overall visual contrast would be weak and overall visual impact low.

Lake Schultz State Park. AC Collection System Route E-3 would be located 1.2 miles to the northwest of Lake Schultz State Park. Strong contrast would be created by Project components in the MG distance zone for high sensitive recreational viewers represented by this KOP; therefore, viewer concern impacts would be moderate–high. The transmission line structures would introduce vertical elements to the landscape that is currently very natural and intact. At this distance, they would not be a dominate feature, but they would result in strong contrast and high overall visual impact because of the existing scenic integrity of the area.

Lake Schultz State Park South. AC Collection System Routes E-2, SE-1, and SE-3 would be located 1 mile to the south of this KOP. Moderate contrast would be created by Project components in the MG distance zone for high sensitive recreational viewers represented by this KOP; therefore, viewer concern impacts would be moderate. The transmission line structure would be parallel to the existing 345kV line and would introduce additional vertical structures to the environment. The proposed structures would be slightly larger in scale than the existing and would result in moderate visual contrast and moderate-high overall visual impact.

Optima. From the Optima KOP, AC Collection System Routes NE-1 and NW-2 would be located 2.4 miles to the west. The transmission line structures would appear on the horizon as a row of vertical objects, but would not attract attention at this distance, resulting in weak contrast. Weak contrast would be created by Project components in the MG distance zone for high sensitive residential viewers represented by this KOP; therefore, viewer concern impacts would be low. AC Collection System Route NE-2 would be located 3.5 miles to the east and have similar visual impacts.

Optima NWR. AC Collection System Route E-1 would be located 1.3 miles southwest of the Optima NWR. Moderate contrast would be created by Project components in the MG distance zone for high sensitive recreational viewers represented by this KOP; therefore, viewer concern impacts would be moderate. The transmission line structures would be visible on the open landscape and add additional vertical structures to the existing transmission line in view. The addition of these structures would add moderate visual contrast and result in moderate overall visual impact.

Perryton-Leatherman Park. AC Collection System Route SE-3 would be 5 miles to the west of this KOP. Weak contrast would be created by Project components in the BG distance zone for high sensitive recreational and residential viewers represented by this KOP; therefore, viewer concern impacts would be low. At this distance, the transmission line structures would be barely visible and would not be distinguishable as structures, but they would add to the irregular line of the horizon and existing vertical elements and resulting in weak contrast and low visual impact.

Spearman. AC Collection System Route SE-1 would be located 5.6 miles to the east. Weak contrast would be created by Project components in the BG distance zone for high sensitive residential viewers represented by this KOP; therefore, viewer concern impacts would be low. The transmission line structures would add small vertical elements to the horizon line similar to existing structures resulting in weak contrast and low visual impact.

Waka. AC Collection System Route SE-1 would be located 2 miles to the west of this KOP. Weak contrast would be created by Project components in the MG distance zone for high sensitive residential viewers represented by this KOP; therefore, viewer concern impacts would be low. The transmission line structures would appear as vertical objects on the horizon that add to the existing elements in view and resulting in weak contrast. The overall visual impact at this location would be low.

3.18.6.2.2.3 Decommissioning Impacts

Project facilities would be removed at the end of the operational life of the transmission line. Conductors, structures, and related facilities would be removed. Foundations would be removed to below the ground surface level. There would be residual visual impacts for many years after the Project has been decommissioned and structures removed such as vegetative cutbacks, cut and fill scars from construction activities, and access roads, which all add to the visual impact, though these impacts would be at ground level. These areas would be apparent after the removal of structures but are expected to diminish over time as vegetation returns to the ROW.

3.18.6.2.3 HVDC Applicant Proposed Route

3.18.6.2.3.1 Construction Impacts

Construction would result in the short-term visual intrusion of construction vehicles, equipment, materials, and a work force in staging areas, along access roads, and along the new transmission line ROW. Vehicles, heavy equipment, structure components, and workers would be visible during transmission line construction and modification, access and spur road clearing and grading, structure erection, conductor stringing, and cleanup and restoration. However, disturbance from construction activities would be transient and of short duration as activities progress along the transmission line route. Affected viewers would be aware of the temporary nature of Project construction impacts as well as existing structures in the area adjacent to the Project, which may decrease their concern to the impact. It should be noted that there would be short term impacts during the decommissioning of the Project which are similar in nature to the construction impacts described above.

3.18.6.2.3.2 Operations and Maintenance Impacts

3.18.6.2.3.2.1 Region 1

The landscape category in Region 1 is primarily Common, categorized by agricultural and grasslands and broad panoramic views. A portion of the Applicant Proposed Route in this region would parallel an existing 345kV transmission line, a 138kV transmission line, and several small electric distribution lines in other areas. The tall vertical geometric form of the proposed structures would result in strong contrast with the horizontal lines of the relatively flat landscape. Contrast would be reduced in areas where the Applicant Proposed Route would parallel or be seen in context with existing transmission and electric distribution lines; the level of contrast would depend on the form, line, color and texture of the existing structures and the distance the existing structures are from the Applicant Proposed Route. In addition, transmission lines in this landscape category are typically visible for long distances because the terrain lacks variation and dense stands of trees and the structures are silhouetted against the sky. Changes to the landscape and vegetation due to construction of access roads and ROW clearing may be visible, but changes would generally not be noticeable in the MG and BG; changes may, however, be noticeable to viewers where the Applicant Proposed Route is located in the FG and where the line crosses areas of varied terrain or dense vegetation. Contrast could be reduced in areas where existing access roads would be used and where the Applicant Proposed Route would parallel an existing transmission line corridor where vegetation clearing has previously occurred.

The visual impacts for the Region 1 KOPs are listed in Table 3.18-9 described below.

Table 3.18-9:
Visual Impact Summary of KOPs—Applicant Proposed Route—Region 1

KOP	APR Link	Distance (Miles)	Viewer Concern	Landscape Category	Visibility	Viewer Concern Impact	Contrast	Overall Impact
Lake Schultz State Park PR	2	1	High	Distinct	Yes	Moderate	Moderate	Moderate–High
Local Historical Marker PR	4	0.6	Moderate	Common	Yes	Low	Moderate	Moderate–Low
Fort Supply WMA Recreation Area	5	6.4	High	Distinct	No	Low	No Contrast/ Not Visible	No Impact
May	5	0.6	High	Common	Yes	Moderate	Moderate	Moderate

3.18.6.2.3.2.1.1 Applicant Proposed Route Link 2

Lake Schultz State Park. Applicant Proposed Route Link 2 would be located 1 mile to the south and would appear in the MG just beyond the nearest tree line. Moderate contrast would be created by Project components in the MG distance zone for high sensitive recreational viewers represented by this KOP; therefore, viewer concern impacts would be moderate. Applicant Proposed Route Link 2 would be seen in the context of the existing Hitchland to Woodward 345kV transmission line, which would parallel the Applicant Proposed Route Link 2. Proposed structures would appear wider and taller than existing structures; however, since the existing transmission line has already introduced vertical elements similar in form, line, color, and texture into the landscape setting contrast would be moderate. Overall visual impacts to high sensitivity viewers associated with this KOP would be moderate-high.

3.18.6.2.3.2.1.2 Applicant Proposed Route Link 4

Local Historical Marker. Applicant Proposed Route Link 4 would be located 0.6 mile to the south. Moderate contrast would be created by Project components in the MG distance zone for moderate sensitive recreational viewers represented by this KOP; therefore, viewer concern impacts would be low. The transmission structures would parallel an existing 345kV transmission line. Although the existing transmission line has introduced vertical elements into the landscape setting, the taller, wider lattice structures of the Applicant Proposed Route Link 4 would result in moderate contrast in form, line, and texture to the existing structures. Overall impacts to moderate sensitive viewers associated with this KOP would be moderate–low.

3.18.6.2.3.2.1.3 Applicant Proposed Route Link 5

Fort Supply WMA Recreation Area. Applicant Proposed Route Link 5 would be located 6.4 miles north of this KOP. Overall visual impacts are not anticipated at this location because the Project would be completely screened by terrain and vegetation.

May. The Applicant Proposed Route Link 5 would be located 0.6 mile to the south. Moderate contrast would be created by Project components in the MG distance zone for high sensitive residential viewers represented by this KOP; therefore, viewer concern impacts would be moderate. The transmission structures would appear on the horizon as a row of vertical elements. Applicant Proposed Route Link 5 would be seen in the context of existing electric distribution lines in the FG and transmission lines in the BG, which have already introduced vertical elements into the landscape setting. However, the taller, wider lattice structures of the Applicant Proposed Route Link 5 would result in moderate contrast in form, line, and texture to the existing structures, creating moderate contrast. Moderate contrast to high sensitivity viewers associated with this KOP would result in moderate impacts.

3.18.6.2.3.2.2 Region 1 Conclusion

Region 1 contains a low density of sensitive viewers and is primarily associated with small rural communities and scattered rural residences. Visual impacts are anticipated to be mostly moderate to moderate-low for high sensitivity viewers where the Project is visible in the MG or BG and would be seen in the context of existing vertical structures. Moderate–high impacts are anticipated for high sensitivity viewers associated with Lake Schultz State Park where the Applicant Proposed Route would cross a landscape categorized as Distinct in the MG.

3.18.6.2.3.2.3 Region 2

The landscape category in Region 2 is primarily Common, and similar to Region 1, is characterized by agricultural and grasslands and broad panoramic views. In Region 2, the Applicant Proposed Route is located near several existing transmission lines near Mooreland and Boiling Springs State Park. In addition, the Applicant Proposed Route would parallel 30 miles of the existing Okeene to Mooreland 115kV transmission line. The contrast introduced by the Applicant Proposed Route and visibility are similar to those described in Region 1 (see Section 3.18.6.2.3.2). The visual impacts for the Region 2 KOPs are listed in Table 3.18-10 and described below.

Table 3.18-10:
Visual Impact Summary of KOPs—Applicant Proposed Route—Region 2

KOP	Link	Distance (Miles)	Viewer Concern	Landscape Category	Visibility	Viewer Concern Impact	Contrast	Overall Impact
Boiling Springs State Park	1	0.9	High	Distinct	Yes	Moderate	Moderate	Moderate–High
Mooreland	1	1.8	High	Developed	No	Moderate	No Contrast/ Not Visible	No Impact
Canton WMA and Lake Recreation Area	2	6.5	High	Distinct	No	Low	No Contrast/ Not Visible	No Impact
Cimarron River Crossing	2	0	Moderate	Distinct	Yes	Moderate–High	Strong	High
Fairview	2	3.3	High	Common	Yes	Low	Weak	Low
Gloss Mountain State Park	2	11	High	Distinct	No	Low	No Contrast/ Not Visible	No Impact
SR 60 West of Fairview	2	1	High	Common	Yes	Moderate–High	Strong	High
Ames	3	2.5	High	Common	Yes	Low	Weak	Moderate–Low
Bison	3	1.4	High	Common	Yes	Low	Weak	Low

3.18.6.2.3.2.3.1 Applicant Proposed Route Link 1

Boiling Springs State Park. Applicant Proposed Route Link 1 would be located 0.9 mile to the northeast. Moderate contrast would be created by Project components in the MG distance zone for high sensitive recreational viewers represented by this KOP; therefore, viewer concern impacts would be moderate. The rolling terrain and vegetation in the area would only offer visitors to the park sporadic views of the transmission line structures through breaks in the vegetation. There are existing vertical elements in the landscape, and the additional transmission line structures would result in moderate contrast. Because Boiling Springs is a state park, it is considered a sensitive area, so the overall visual impact would be moderate-high.

Mooreland. Applicant Proposed Route Link 1 would be located 1.8 miles to the north, but terrain would block potential views from this location, so there would be no contrast and no overall visual impact would occur at this location.

3.18.6.2.3.2.3.2 Applicant Proposed Route Link 2

Canton WMA and Lake Recreation Area. Applicant Proposed Route Link 2 would be located 6.5 miles to the north of this KOP. Looking across the lake, the Project would most likely not be visible because of the large distance and dense vegetation on the other side of the lake. With no visibility, there would be no contrast and no overall visual impacts would occur at this location.

Cimarron River Crossing. Applicant Proposed Route Link 2 would cross the Cimarron River in the immediate FG. Strong contrast would be created by Project components where it crosses the road for moderate sensitive viewers represented by this KOP; therefore, viewer concern impacts would be moderate–high. Viewers at this location would see the transmission line running parallel to the road, crossing the river in a very rural area with little development and has moderate visual concern due to low numbers of viewers. The transmission line would be highly visible and dominant in view at this location. The large metal structures would be the only vertical elements on the landscape, resulting in strong contrast. The overall visual impact would be high. A visual simulation for this KOP is provided in Appendix K.

Fairview. Applicant Proposed Route Link 2 would be located 3.3 miles to the south. Weak contrast would be created by Project components in the BG distance zone for recreational and residential viewers represented by this KOP; therefore, viewer concern impacts would be low. Visitors to the park and fairgrounds may be able to see the transmission line structures appearing as a row of vertical objects on the distant horizon, where it is not blocked by vegetation. Because of the large distance, these proposed structures would appear smaller than the existing structures in view and there would be no change to landform or vegetation, resulting in weak visual contrast. The overall visual impact at this location would be low.

Gloss Mountain State Park. The HVDC Applicant Proposed Route Link 2 would be located 11 miles to the south and would not be visible to park visitors without the use of binoculars or other magnification resulting in no contrast. For this reason, there would be no overall visual impact. A visual simulation for this KOP is provided in Appendix K.

SR 60 West of Fairview. Applicant Proposed Route Link 2 would run parallel to the existing 115kV line as it crosses the landscape at a distance of 1 mile. The proposed transmission line structures would be larger in scale and differ in form, color, and texture than the existing wood structures of the 115kV line, and be dominant in MG views becoming less visible as it recedes in into the BG zone. Modifications to vegetation would also be visible as the line crosses the highway and would result in strong visual contrast. Because strong contrast would be created by the Project in the MG distance zone for high sensitive residential viewers represented by this KOP, viewer concern impacts would be moderate–high. The overall visual impacts at this location would be high.

3.18.6.2.3.2.3.3 Applicant Proposed Route Link 3

Ames. Applicant Proposed Route Link 3 would be visible and appear as small objects 2.5 miles to the southwest where it is not blocked by vegetation or terrain. The tall structures would introduce a new vertical element to the landscape, but at this distance, the transmission line would only introduce a weak level of contrast. Weak contrast created by the Project in the BG distance zone for high sensitive residential and recreational viewers associated with this KOP would result in low viewer concern impacts. Overall visual impact is low.

Bison. Applicant Proposed Route Link 3 would appear as small vertical elements on the horizon 1.4 miles to the south. The added structures would be taller and larger in form than the existing structures (as described in Section 3.18.5.2.1) in view, but would result in weak visual contrast due to existing cultural modifications to the landscape. Because the Project would appear subordinate in the landscape, landscape scenery impacts to this Common landscape would be moderate–low. Weak contrast created by Project components in the MG distance zone for high sensitive residential viewers represented by this KOP would result in low viewer concern impacts. The overall visual impact would be low.

3.18.6.2.3.2.3.4 Route Variations

Applicant Proposed Route Link 1, Variation 1, would cross a similar landscape setting as the original Applicant Proposed Route. Visual resources would also remain the same and include residences and Boiling Springs State Park.

Visual impacts are anticipated to be higher for high sensitive residential viewers because the Applicant Proposed Route Link 1, Variation 1, would be located approximately 650 feet closer (within 350 of residential structures), and while the original Applicant Proposed Route would be partially screened by vegetation, views of the Applicant Proposed Route Link 1, Variation 1 would be unobstructed. Impacts to high sensitive recreational viewers associated with the Boiling Springs Park KOP would be reduced because Variation 1 would be located farther from viewers in the park and because less of the structure would be visible given the rolling terrain and vegetation in the surrounding landscape. The Contrast Rating Worksheet for the Boiling Springs Park KOP is included in Appendix K.

Applicant Proposed Route Link 2, Variation 2, would cross a landscape setting similar to the original Applicant Proposed Route. Visual resources would also remain the same and include residences. Visual impacts would not change for high sensitive residential viewers as a result of this variation because they would still have unobstructed views of the Project crossing an open landscape in the FG distance zone.

3.18.6.2.3.2.4 Region 2 Conclusion

Region 2 contains a low density of sensitive viewers primarily associated with small rural communities and scattered rural residences. Visual impacts are anticipated to be mostly moderate–low to low for high sensitivity viewers where the Project is visible in the MG or BG distance zone. Higher impacts could occur for high sensitivity viewers associated with the community of Fairview where the Applicant Proposed Route would be located in the FG. Higher impacts could also occur for high sensitivity viewers associated with State Parks and other recreation areas (such as Boiling Springs State Park and the Cimarron River) within the region; however, views from some recreation areas, like Gloss Mountain State Park, would be obstructed due to variation in terrain and/or existing vegetation associated with these facilities.

3.18.6.2.3.2.5 Region 3

The landscape category in Region 3 is primarily Common, and is characterized by relatively level terrain in the western portion of the region transitioning to gently and moderately rolling hills in the western portion of the region. Vegetation also becomes varied transitioning from primarily grasses with low shrubs and scattered trees to wooded areas in the eastern portion of the region. Views are generally open within the western portion of the region where there is little variation in terrain and vegetation; and become more limited when hilly terrain and wooded areas become more prevalent in the eastern portion. In Region 3, the Applicant Proposed Route would parallel several medium and large transmission lines including a 69kV line (approximately 7 miles); 115kV line (approximately 4.5 miles); three 138kV lines (approximately 11 miles, 4 miles, and 30 miles); and a 345kV line (approximately 10 miles). The Applicant Proposed Route would also cross several transmission lines (138kV and 345kV) located throughout the region. The contrast introduced by the Applicant Proposed Route and visibility are similar to those described in Region 1 for the western portion of Region 3 (see Region 1 Conclusions Section 3.18.6.2.3.2). As noted above, visibility within the eastern portion of Region 3 becomes more limited with the increasing variation in terrain and wooded areas which can screen (partially or completely) transmission structures from viewers. The visual impacts for the Region 3 KOPs are listed in Table 3.18-11 and described below.

Table 3.18-11:
Visual Impact Summary of KOPs—Applicant Proposed Route—Region 3

KOP	Link	Distance (Miles)	Viewer Concern	Landscape Category	Visibility	Viewer Concern Impact	Contrast	Overall Impact
Marshall	1	3.1	High	Common	Yes	Low	Weak	Low
Mulhall	1	1	High	Common	Yes	Moderate	Moderate	Moderate
Stillwater	1	2.9	High	Developed	No	Low	No Contrast/ Not Visible	No Impact
Meehan	3	0.4	High	Common	Yes	High	Strong	High
Beggs	4	1.6	High	Common	Yes	Moderate	Moderate	Moderate
Cimarron River Crossing	4	0	Moderate	Distinct	Yes	Moderate–High	Strong	High
Cushing	4	1.4	High	Common	Yes	Moderate	Moderate	Moderate
Heyburn Lake	4	4.3	High	Distinct	No	Low	No Contrast/ Not Visible	No Impact
Ripley	4	0.7	High	Common	Yes	Moderate	Moderate	Moderate
Shamrock	4	1.2	High	Common	Yes	Moderate	Moderate	Moderate
Summit	5	0.15	High	Common	Yes	Moderate–High	Moderate	Moderate–High
Taft	5	3.5	High	Common	No	Low	No Contrast/ Not Visible	No Impact
McLain	6	0.7	High	Common	Yes	Low	Weak	Low
Webbers Falls	6	1.5	High	Distinct	No	Low	No Contrast/ Not Visible	No Impact

3.18.6.2.3.2.5.1 Applicant Proposed Route Link 1

Marshall. Applicant Proposed Route Link 1 would be faintly visible on the horizon 3.1 miles to the south and would appear smaller in scale than existing vertical elements. Weak contrast created by the Project in the BG distance zone for high sensitive residential viewers associated with this KOP would result in low viewer concern impacts. Because of the distance, the proposed structures would be highly noticeable resulting in weak contrast and low overall visual impact.

Mulhall. Applicant Proposed Route Link 1 would be located 1 mile to the south-southwest and would be visible as the transmission structures extend above the horizon line, resulting in a moderate increase in contrast. Moderate contrast created by the Project in the MG distance zone for high sensitive residential viewers associated with this KOP would result in moderate viewer concern impacts. Portions of the transmission line structures not screened by vegetation would appear as vertical elements spaced across the distant horizon above the vegetation, resulting in a moderate increase in contrast. This KOP represents a residential area with high visual concern and the overall visual impacts for this landscape would be moderate.

Stillwater. Applicant Proposed Route Link 1 would be located 2.9 miles to the south, but views would be screened by vegetation and houses in the FG, resulting in no visual impact. A visual simulation for this KOP is provided in Appendix K.

3.18.6.2.3.2.5.2 Applicant Proposed Route Link 3

Meehan. Applicant Proposed Route Link 3 would be located 0.4 mile to the south, just on the other side of the transmission line of trees in the FG. The height of the proposed structures would cause the upper portion to be clearly visible above the horizon line and larger in scale than the existing vertical elements, creating strong contrast. Strong contrast created by the Project in the FG distance zone for high sensitive residential viewers associated with this KOP would result in high viewer concern impacts. Overall visual impacts would be high.

3.18.6.2.3.2.5.3 Applicant Proposed Route Link 4

Beggs. The transmission line would be located 1.6 miles north of this KOP in the MG distance zone. Visitors to this site would have views of Applicant Proposed Route Link 4. Where the transmission line structures are not screened by FG vegetation, they would be visible on the horizon and would add moderate contrast to the landscape. Moderate contrast created by the Project in the MG distance zone for high sensitive recreational viewers associated with this KOP would result in moderate viewer concern impacts. The overall visual impacts would be moderate.

Cimarron River Crossing. Applicant Proposed Route Link 4 would cross the river at this point, running parallel to the existing line in view, but would be much larger in scale and highly visible in the FG distance zone. Strong contrast would be created by Project components where it crosses the road for moderate sensitive viewers represented by this KOP; therefore, viewer concern impacts would be moderate-high. In addition, vegetation would need to be cleared for the ROW, which would add to the strong visual contrast on the landscape. The overall visual impact at this location would be high.

Cushing. Applicant Proposed Route Link 4 would be located 1.4 miles to the southwest. Moderate contrast created by the Project in the MG distance zone for high sensitive residential viewers associated with this KOP would result in moderate viewer concern impacts. Portions of the transmission line structures would be visible on the horizon and would appear as dark vertical elements, resulting in moderate contrast. The visual impacts at this location would be moderate.

Heyburn Lake. Applicant Proposed Route Link 4 would be located 4.3 miles from this KOP. Because of distance and existing vegetation and terrain, structures would not be visible. There would be no visual impact at this location.

Ripley. Applicant Proposed Route Link 4 would be visible 0.7 mile to the northeast in the MG and appear as a row of objects on the horizon. Portions of the transmission line would be screened by vegetation and existing structures. Transmission line structures that are visible would be noticeably different from the existing landscape and result in moderate contrast. Moderate contrast created by the Project in the MG distance zone for high sensitive residential viewers associated with this KOP would result in moderate viewer concern impacts. Overall visual impact on the landscape would be moderate.

Shamrock. Applicant Proposed Route Link 4 would be located 1.2 miles to the northwest of this KOP. The visible transmission line structures would appear as dark objects, creating a repeating pattern across the forested ridgeline on the horizon. Moderate contrast created by the Project in the MG distance zone for high sensitive residential viewers associated with this KOP would result in moderate viewer concern impacts. This is a residential area and visual concern is high and the vertical elements of the transmission line would be noticeable with no other existing vertical features, resulting in moderate contrast. Overall visual impacts would also be moderate.

3.18.6.2.3.2.5.4 Applicant Proposed Route Link 5

Summit. Applicant Proposed Route Link 5 would be 0.15 mile to the south and would run parallel to the existing lattice transmission structure. From this view, the transmission line structures would be located and the near side of the existing line, so it would appear larger in scale and be more prominent in view, but with similar form. When added to the landscape, the additional structures would result in moderate contrast due to existing structures in view. Moderate contrast created by the Project in the FG distance zone for high sensitive residential viewers associated with this KOP would result in moderate–high viewer concern impacts. Overall visual impact would be moderate–high.

Taft. Applicant Proposed Route Link 5 is located 3.5 miles to the south and would be screened by vegetation and terrain resulting in no visual impact at this location.

3.18.6.2.3.2.5.5 Applicant Proposed Route Link 6

McLain. Applicant Proposed Route Link 6 is located 0.2 mile north and 0.7 mile east of this KOP in the FG and MG distance zones, respectively. The existing rolling terrain and dense vegetation would completely screen the transmission line to the north (located 0.2 mile from the KOP). The transmission line would be visible to the east (at 0.7 mile from the KOP); however, the lower portion of the transmission structures would be screened by vegetation. The upper portion of the transmission structures would be seen in the context of an existing 345kV transmission line that would parallel the Project and would be similar in form, line, and color. Because only a portion of the structures would be visible and seen in the context of existing similar structures, contrast introduced by the Project would be weak. Weak contrast created by the Project in the MG distance zone for high sensitive residential viewers associated with this KOP would result in low viewer concern impacts. Because the Applicant Proposed Route would be co-dominant in a Common landscape, landscape scenery impacts would be moderate–low. Because the Project would introduce a weak contrast in the MG distance zone to a Common landscape and from a KOP representing high sensitive viewers, the overall visual impact would be low.

Webbers Falls. The Applicant Proposed Route Link 6 would be located 1.5 miles to the southwest. Given the distance and existing vegetation, the transmission line structures would not be visible from this location and there would be no visual impact.

3.18.6.2.3.2.5.6 Route Variations

Applicant Proposed Route Link 1, Variation 2, and Applicant Proposed Route Links 1 and 2, Variation 1, would both cross a landscape setting similar to the original links of the Applicant Proposed Route, which includes croplands and scattered wooded areas. Visual resources would also remain the same and include a few residences in the FG/MG distance zone. Visual impacts are anticipated to be similar to those of the original Applicant Proposed Route Links 1 and 2 because the variations would be located farther from some high sensitive residential viewers but would be closer to others. These viewers would still have partially screened to unobstructed views of the variations crossing the landscape in the FG/MG distance zone. It should be noted that a route adjustment was made for HVDC Alternative Route 3-A to maintain an end-to-end route with this variation. Impacts to the HVDC Alternative Route 3-A are discussed in Section 3.18.6.3.2.2.3.1.

Applicant Proposed Route Link 4, Variation 1, and Applicant Proposed Route Link 4, Variation 2, would both cross a similar landscape setting as the original Applicant Proposed Route. Visual resources would also remain the same and include a few rural residences in the FG distance zone. Visual impacts are anticipated to be similar to those of Applicant Proposed Route Link 4 because the variations would be located in close proximity to the Link 4 alignment (approximately 0.2 mile or less) and would be farther from some high sensitive residential viewers but would be closer to others. These viewers would still have partially screened to unobstructed views of the variations crossing the landscape in the FG distance zone. Applicant Proposed Route Link 5, Variation 2, would cross a landscape setting similar to the original Applicant Proposed Route. Visual resources would also remain the same and include a few rural residences in the FG/MG distance zone. Visual impacts for some high sensitive residential viewers would be reduced because the variation would be located farther from the viewer and would be partially to completely screened by vegetation. However, other residences would have increased visual impacts because the variation would be located closer, and while vegetation in the immediate FG would screen the lower portions of the structures, more of the structures would be visible extending above the tree line.

3.18.6.2.3.2.6 Region 3 Conclusion

Region 3 contains a moderate density of sensitive viewers primarily associated with rural communities, scattered rural residences, and recreation areas. Visual impacts are anticipated to be mostly moderate for high sensitivity viewers where the Project is visible in the MG distance zone. The Applicant Proposed Route may be partially screened by vegetation and/or seen within the context of existing transmission lines. Low or no impacts are anticipated for high sensitivity viewers where the Project is located in the BG distance zone, where contrast would be weak due to viewing distance or the Project would be completely screened by existing terrain and/or vegetation. Higher impacts are anticipated for high sensitivity viewers associated with communities or recreation areas where the Project is located within the FG and is not seen in the context of other transmission lines.

3.18.6.2.3.2.7 Region 4

The landscape category in Region 4 is primarily Common and is characterized by varied terrain including undulating plains, rolling hills and terraces in the southern portion of the region. Landscapes categorized as Distinct occur throughout the region and are associated with more natural rugged terrain in the northern portion of the region and near water features (such as the Arkansas River, lakes and reservoirs). The rugged hills, mountains, rolling hills, and forested landscapes in the northern portion of the region limits distant views, whereas in the southern portion of the region the less varied terrain and lack of vegetation allows for expansive view across the landscape. In Region 4, the Applicant Proposed Route would parallel several medium and large existing transmission lines, including a 345kV line for approximately 5.5 miles north of Vian; a 138kV line for approximately 5 miles near the Oklahoma-Arkansas border; a 138kV line for approximately 5 miles northeast of Wiederkehr Village; a 138kV line for approximately 25 miles between Hunt and Big Piney Creek (this line would be between 0.25 and 0.5 miles away from the Applicant Proposed Route); and a 138kV line for approximately 3 miles north of Big Piney Creek. The Applicant Proposed Route would also cross or be located near several medium and large existing transmission lines that vary in size between 115kV and 345kV transmission lines.

The tall vertical geometric forms of the proposed structures would result in strong contrast with the horizontal lines of the relatively flat landscape found within the southern portion of the region. Contrast would be reduced in areas where the Applicant Proposed Route would parallel or be seen in context with existing transmission and electric distribution lines; the level of contrast would depend on the form, line, color and texture of the existing structures and the distance the existing structures are from the Applicant Proposed Route. In the northern region, transmission structures are often only visible in the FG/MG and tend to be partially obstructed by terrain and vegetation; however, structures often protrude above the terrain and trees and are silhouetted against the sky drawing viewer’s attention. The presence of other similar structures would reduce the contrast. Changes to the landscape and vegetation due to construction of access roads and ROW clearing may be visible but changes would generally not be noticeable in the MG and BG where terrain and vegetation may obscure these changes. In some instances, however, the Project may become visible as the viewer is elevated or as the transmission line traverses hilly terrain, ridges, or open spaces. Changes may also be noticeable to viewers where the Applicant Proposed Route is located in the FG in relatively flat terrain with minimal vegetation to obscure views. Contrast could be reduced in areas where existing access roads would be used and where the Applicant Proposed Route would parallel an existing transmission line corridor where vegetation clearing has previously occurred and additional clearing for the Project would make an existing corridor look wider. The visual impacts for the Region 4 KOPs are listed in Table 3.18-12 and described below.

Table 3.18-12:
Visual Impact Summary of KOPs—Applicant Proposed Route—Region 4

KOP	Link	Distance (Miles)	Viewer Concern	Landscape Category	Visibility	Viewer Concern Impacts	Contrast	Overall Impact
Arkansas River	1	0.2	Moderate	Common	Yes	Moderate	Moderate	Moderate
Arkansas River and Gore	1	3	High	Distinct	Yes	Low	Weak	Moderate–Low
Highway 10	1	0.2	Moderate	Common	Yes	Moderate–High	Strong	High
Tenkiller State Park	1	4	High	Distinct	No	Low	No Contrast/Not visible	No Impact
Trail of Tears State Route 100	1	0.2	High	Common	Yes	High	Strong	High
Brushy Creek Reservoir and Sallisaw State Park	3	2.8	High	Distinct	No	Low	No Contrast/ Not Visible	No Impact
Field of Dreams	3	2.6	High	Developed	No	Low	No Contrast/ Not Visible	No Impact
Highway 82	3	0.3	Moderate	Common	Yes	Moderate–Low	Weak	Moderate–Low
Lee Creek	3	0.5	High	Common	Yes	Moderate–High	Strong	High
Robert S Kerr Reservoir	3	7	High	Distinct	No	Low	No Contrast/ Not Visible	No Impact
Sallisaw	3	0.5	High	Common	Yes	Moderate	Moderate	Moderate
Sequoyah NWR Boat Launch	3	5	High	Common	No	Low	No Contrast/ Not Visible	No Impact
Sequoyah's Cabin	3	1.2	High	Distinct	Yes	Low	Weak	Moderate–Low
Van Buren PR	3	1.8	High	Common	Yes	Low	Weak	Low
Vian	3	0.7	High	Common	Yes	Moderate	Moderate	Moderate
Vian Lake	3	0.2	High	Distinct	Yes	High	Strong	High
Van Buren AR/PR	4, 5	2	High	Common	No	Low	No Contrast/ Not Visible	No Impact
Scott Farm	5	0.3	High	Common	Yes	Moderate–High	Moderate–High	Moderate–High
Alma	6	0.5	High	Common	Yes	Moderate	Moderate	Moderate
Bluff Hole Park	6	1.7	High	Common	Yes	Low	Weak	Low
City Park/Ball Fields and Rudy	6	2	High	Developed	No	Low	No Contrast/ Not Visible	No Impact

Table 3.18-12:
Visual Impact Summary of KOPs—Applicant Proposed Route—Region 4

KOP	Link	Distance (Miles)	Viewer Concern	Landscape Category	Visibility	Viewer Concern Impacts	Contrast	Overall Impact
Clear Creek Park	6	1.4	High	Distinct	No	Low	No Contrast/ Not Visible	No Impact
Dyer	6	0.3	High	Common	Yes	High	Strong	High
Mulberry Park	6	0.3	High	Common	Yes	High	Strong	High
Mulberry River and Trail of Tears	6	0.4	High	Distinct	Yes	High	Strong	High
Trail of Tears Wire Road	6	0.2	High	Common	Yes	High	Strong	High
Vine Prairie Park	6	1.5	High	Distinct	Yes	Low	Weak	Moderate–Low
Aux Arc Park	7	2.8	High	Distinct	Yes	Low	Weak	Moderate–Low
East Side City Park	7	2.1	High	Distinct	No	Low	No Contrast/ Not Visible	No Impact
Interstate 40 Rest Stop	7	0.04	Moderate	Common	Yes	Moderate–High	Strong	High
Ozark	7	0.8	High	Common	Yes	Low	Weak	Low
Ozark City Boat Launch	7	0.6	High	Distinct	No	Low	No Contrast/ Not Visible	No Impact
West Side City Park	7	2	High	Common	No	Low	No Contrast/ Not Visible	No Impact
White Oak	7	1.5	High	Common	No	Low	No Contrast/ Not Visible	No Impact
White Oak Park	7	3	High	Distinct	No	Low	No Contrast/ Not Visible	No Impact
Trail of Tears (Highway 352)	8	0.028	High	Common	Yes	High	Strong	High
Wiederkehr Village and Highway 186	8	0.7	High	Common	Yes	Low	Weak	Low
Big Piney Creek	9	0.2	High	Distinct	Yes	Moderate–High	Moderate	Moderate–High
Clarksville	9	2.5	High	Common	No	Low	No Contrast/ Not Visible	No Impact
Hagarville	9	1	High	Common	Yes	Moderate	Moderate	Moderate
Horsehead Lake Recreation Area	9	2.1	High	Distinct	No	Low	No Contrast/ Not Visible	No Impact
Hunt	9	0.2	High	Common	Yes	Moderate–High	Strong	High
Lake Ludwig	9	0.9	High	Distinct	Yes	Low	Weak	Moderate–Low
Route 21 (Scenic Byway)	9	0.1	High	Distinct	Yes	High	Strong	High

3.18.6.2.3.2.7.1 Applicant Proposed Route Link 1

Arkansas River. Applicant Proposed Route Link 1 would be located 0.2 mile away, running parallel to the existing transmission. Viewers at this location would be able to clearly see the lattice structures as well as a ROW cleared of vegetation on the river banks. The proposed transmission line structures would be located on the near side of the existing structures, and would appear more dominant in view. Since this is already a heavily impacted site, the proposed structures would be repeating form, line, color and texture and result in moderate contrast. Moderate contrast would be created by the Project in the FG distance zone for moderate sensitive viewers represented by this KOP; therefore, viewer concern impacts would be moderate. The overall visual impacts at this location would be moderate.

Arkansas River and Gore. Applicant Proposed Route Link 1 would be located 3 miles to the northwest. Portions of the structures may appear above the tree line in the distant BG, but would only be faintly noticeable, producing weak contrast. Because weak contrast would be created by the Project in the BG distance zone for high sensitive recreational viewers associated with this KOP, viewer concern impacts would be low. Overall visual impacts at this location would be moderate–low. A visual simulation for this KOP is provided in Appendix K.

Highway 10. Applicant Proposed Route Link 1 would be clearly visible as the line crosses the open field to the northwest and spans the highway. The structures would be a dominant element on the landscape and introduce new line, form, color, and texture. In addition, the clearing of vegetation near the sides of the highway would be clearly visible to motorists, introducing additional contrast. Strong contrast would be created by the Project in the FG distance zone for moderate sensitive viewers associated with this travel route; therefore, viewer concern impacts would be moderate–high. Overall visual impact at this location would be high. A visual simulation for this KOP is provided in Appendix K.

Tenkiller State Park. Applicant Proposed Route Link 1 would be located about 4 miles to the south of this KOP. From this vantage point, terrain and vegetation would screen all views of the transmission line and would result in no visual impact.

Trail of Tears State Route 100. Applicant Proposed Route Link 1 would be located 0.2 mile from this KOP. Transmission line structures would be clearly visible above tree line as the route crosses the highway and Trail of Tears. The Trail of Tears locations mapped by the NPS are representative of the historic location of the trail and the extent of the trail at each crossing location is not known. Transmission line structures would introduce new vertical elements into the landscape, becoming dominant as motorists approach, and the transmission line conductors would be visible crossing over the highway, resulting in strong contrast. In addition, ROW clearing would be visible to motorists as they approach the crossing, resulting in additional contrast. Because strong contrast would be created by the Project in the FG distance zone for high sensitive viewers associated with this travel route, viewer concern impacts would be high. The overall visual impact at this location would be high.

3.18.6.2.3.2.7.2 Applicant Proposed Route Link 3

Brushy Creek Reservoir and Sallisaw State Park. Applicant Proposed Route Link 3 would be located 2.8 miles to the south, but would not be visible due to distance, terrain, and vegetation. There would be no visual impact.

Field of Dreams. Proposed Route Link 3 would be located 2.6 miles to the north of the Field of Dreams ball field. Dense trees in the FG would obscure views of the Project from this location, resulting in no visual impact.

Highway 82. Applicant Proposed Route Link 3 would cross the highway 0.3 mile to the southwest. The Project would run parallel to an existing transmission line and the proposed transmission line would repeat the line, form, scale, and color. The proposed structures would be noticeable to viewers at this location, but since they would be additions to the existing structures, the contrast would be weak. Because weak contrast would be created by the Project in the

FG distance zone for moderate sensitive viewers associated with this travel route, viewer concern impacts would be moderate–low. The overall visual impact would be moderate–low.

Lee Creek. Applicant Proposed Route Link 3 would be located 0.5 mile to the north of this location. Recreationists standing at the boat launch or on the docks would most likely not see any of the structures due to vegetation and terrain. Once visitors were out on the lake, however, both the structures and vegetation clearing for the ROW would be clearly visible. The transmission line structures would introduce new vertical elements that would be visible above tree line and a cleared ROW would introduce lines in the vegetation inconsistent with the current natural landscape. Strong contrast would be created by the Project in the MG distance zone for moderate sensitive recreational viewers associated with this KOP; therefore, viewer concern impacts would be moderate–high. The visual contrast from many areas on or around the lake would be strong and the overall visual impact would be high.

Robert S. Kerr Reservoir. Applicant Proposed Route Link 3 would be located 7 miles to the north. From this location, the line would not be visible due to distance and FG terrain and vegetation. There would be no visual impact from this location.

Sallisaw. Applicant Proposed Route Link 3 would be located 0.5 mile to the north-northeast and be visible crossing the open field in the MG. Some of the structures would extend above tree line and be prominent in view. There are existing vertical elements, so the additional structures would result in moderate contrast. Because moderate contrast would be created by the Project in the MG distance zone for high sensitive recreational viewers associated with this KOP, viewer concern impacts would be moderate. Overall visual impact would be moderate.

Sequoyah NWR Boat Launch. Applicant Proposed Route Link 3 would be located 5 miles to the north, but would not be visible given the dense vegetation. There would be no overall visual impact at this location.

Sequoyah's Cabin. Applicant Proposed Route Link 3 would be located 1.2 miles to the south. The majority of the views from the historic site grounds would be screened by FG vegetation, but some transmission line structures would be visible on the horizon, extending above the trees. The transmission line structures would introduce some vertical elements to the landscape, but they would not be dominant elements. The visual contrast would be weak. Because weak contrast would be created by the Project in the MG distance zone for high sensitive viewers associated with this historic site, viewer concern impacts would be low. Overall visual impact would be moderate–low, since it is a sensitive historic site. A visual simulation for this KOP is provided in Appendix K.

Van Buren. Applicant Proposed Route Link 3 would be located about 1.8 miles to the northwest from this residential area with high visual concern. The rolling terrain and dense vegetation would screen views of the transmission line structures. If visible through breaks in the FG vegetation, the structures would appear as small dark objects extending above the trees on the horizon and would result in weak contrast. Because weak contrast would be created by the Project in the MG distance zone for high sensitive residential viewers associated with this KOP, viewer concern impacts would be low. The overall visual impact would be low.

Vian. Applicant Proposed Route Link 3 would be located about 0.7 mile to the north-northeast. There are several transmission line structures visible from this location, and the Project would be located parallel to the existing lattice structures that are just barely visible in the MG. The proposed structures would be similar in form to the existing lattice structures, but larger in scale introducing moderate contrast to the landscape. Because moderate contrast would be created by the Project in the MG distance zone for high sensitive residential viewers associated with this KOP, viewer concern impacts would be moderate. Overall visual impact would be moderate.

Vian Lake. Applicant Proposed Route Link 3 would be visible running parallel to the existing transmission line on the far side of the lake, 0.2 mile away. Because of the dense vegetation in the area, large amounts of trees would be cleared for the ROW, leaving open views of the existing structures as well as the proposed structures. The combination of vegetation clearing and introduction of vertical elements in the landscape would result in strong contrast. Because strong contrast would be created by the Project in the FG distance zone for high sensitive recreational viewers associated with this KOP, viewer concern impacts would be high. Overall visual impacts would be high. A visual simulation for this KOP is provided in Appendix K.

3.18.6.2.3.2.7.3 Applicant Proposed Route Link 4

Van Buren. Applicant Proposed Route Link 4 would be located 2 miles to the north of this KOP. Large trees and rolling terrain would obscure views of the transmission line structures from this location, resulting in no visual impact.

3.18.6.2.3.2.7.4 Applicant Proposed Route Link 5

Scott Farm. Applicant Proposed Route Link 5 would be located 0.3 mile to the north. Residents of the subdivision would be able to see the transmission line structures clearly from both the entrance and several of the residences. The subdivision is on high ground, so residents looking down towards the transmission line structures would see the structures at a reduced contract because of the backdrop of existing vegetation. Several other vertical structures such as communication structures and antennas occur within the existing landscape setting. Because of existing vertical elements in the landscape, the Project would introduce moderate contrast. Because moderate contrast would be created by the Project in the FG distance zone for high sensitive residential viewers associated with this KOP, viewer concern impacts would be moderate–high. Overall visual impacts would also be moderate–high. A visual simulation for this KOP is provided in Appendix K.

Van Buren. See description for Applicant Proposed Route Link 4.

3.18.6.2.3.2.7.5 Applicant Proposed Route Link 6

Alma. Applicant Proposed Route Link 6 would be visible crossing the open field 0.5 mile to the north. The transmission line structures would be visible just in front of the dense line of trees in the MG and would extend above tree line, adding vertical elements to the irregular line of the horizon. The transmission line structures would be visible to motorists and residents of Alma and would result in moderate contrast. Because moderate contrast would be created by the Project in the MG distance zone for high sensitive residential viewers associated with this KOP, viewer concern impacts would be moderate. Overall visual impact would be moderate.

Bluff Hole Park. Applicant Proposed Route Link 6 would be located about 1.7 miles to the north. Most views of the transmission line structures would be screened by FG vegetation, but if they were visible, they would appear as small dark objects and likely would not attract the attention of visitors at the park; therefore, resulting in weak contrast. Because weak contrast would be created by the Project in the MG distance zone for high sensitive recreational viewers associated with this KOP, viewer concern impacts would be low. Because the Project would not be readily noticeable to recreational viewers from this location, the overall visual impacts would be low.

City Park Ball Fields and Rudy. Applicant Proposed Route Link 6 would be located 2 miles to the southwest of the City Park Ball Fields in Rudy. People at the park would not be able to see any of the structures due to vegetation and terrain in the FG. There would be no visual impact at this location.

Clear Creek Park. Dense trees in the FG view from Clear Creek Park would screen all views of the Applicant Proposed Route 1.4 miles to the north. There would be no visual impact at this location.

Dyer. Applicant Proposed Route Link 6 would be clearly visible in the FG as it crosses the open field 0.3 mile to the southeast. The transmission line structures would introduce large vertical elements to an open landscape free of heavy modification, creating a dominant feature and resulting in strong visual contrast. Because strong contrast would be created by the Project in the FG distance zone for high sensitive residential viewers associated with this KOP, viewer concern impacts would be high. Overall visual impacts would be high.

Mulberry Park. Applicant Proposed Route Link 6 would be located 0.3 mile from this KOP in the FG distance zone. The proposed transmission line would be visible through scattered trees along the parks boarder as it crosses the open field. The transmission line structures would introduce new vertical forms into the landscape that would differ in size, line, color, and texture than existing structural features and would therefore appear as a dominant feature resulting in strong contrast. Because strong contrast would be created by the Project in the FG distance zone for high sensitive recreational and residential viewers associated with this KOP, viewer concern impacts would be high. Overall visual impacts would be high at this location.

Mulberry River and Trail of Tears. Applicant Proposed Route Link 6 would cross the river 0.4 mile from this KOP in the FG distance zone. Transmission line structures would primarily be screened by dense vegetation adjacent to the river; however, portions of the transmission line would be visible through breaks in vegetation. In addition, transmission structures would be clearly visible across the open field to the east. The proposed transmission line structures would be noticeably different than existing structures in view, introducing new form and line to the landscape resulting in strong contrast. Because strong contrast would be created by the Project in the FG distance zone for high sensitive viewers associated with this river and historic trail, viewer concern impacts would be high. Overall visual impact would be high.

Trail of Tears Wire Road. Applicant Proposed Route Link 6 would be located 0.2 mile to the southwest. The proposed transmission line structures would be visible across the open field and highway from this location and would introduce large vertical elements to an open landscape that differ in size, form, line, color, and texture of other existing vertical elements. The proposed transmission line would be a dominant feature in the landscape, resulting in strong visual contrast. Because strong contrast would be created by the Project in the FG distance zone for high sensitive viewers associated with this historic trail, viewer concern impacts would be high. Overall visual impact would be high.

Vine Prairie Park. Applicant Proposed Route Link 6 would be located 1.5 miles to the northwest of this park and boat launch area. Visitors using these facilities may be able to see the tops of the transmission line structures extending above the tree line, but they would appear as small dark objects, adding to the already irregular line of the horizon, therefore the Project would introduce weak contrast. Because weak contrast would be created by the Project in the MG distance zone for high sensitive recreational viewers associated with this KOP, viewer concern impacts would be low. Overall visual impacts would be moderate–low.

3.18.6.2.3.2.7.6 Applicant Proposed Route Link 7

Aux Arc Park. Applicant Proposed Route Link 7 would be across the river, 2.8 miles to the north of Aux Arc Park. The proposed transmission line would be visible on the far side of the Arkansas River; however, the transmission line would be seen in the context of existing urban development and would appear subordinate, resulting in weak contrast. Because weak contrast would be created by the Project in the MG distance zone for high sensitive recreational viewers associated with this KOP, viewer concern impacts would be low. Because of distance and weak level of contrast added, overall visual impacts would be moderate–low.

East Side City Park. Applicant Proposed Route Link 7 would be located 2.1 miles from East Side City Park, but would not be visible due to dense vegetation in the FG. There would be no visual impact at this location.

Interstate 40 (Scenic Highway) Rest Stop. Applicant Proposed Route Link 7 would be located 200 feet to the north of this location as it crosses the field in the immediate FG distance zone. The transmission line would dominate the view of anyone stopping at this rest stop and the clearing of the ROW would be clearly visible, resulting in strong contrast. Because strong contrast would be created by the Project in the immediate FG distance zone for moderate sensitive viewers associated with a rest area along a scenic highway, viewer concern impacts would be moderate–high. Overall visual impact would be high. A visual simulation for this KOP is provided in Appendix K.

Ozark. Applicant Proposed Route Link 7 would be located 0.8 mile to the north. The tops of the structures may be visible extending above the tree line, however, the majority of the transmission line structures would be screened by dense vegetation and the low ridgeline in the MG. Any structures extending above the tree line would be visible as small dark objects adding weak contrast to the irregular line and form of the existing tree line. Because weak contrast would be created by the Project in the MG distance zone for high sensitive residential viewers associated with this KOP, viewer concern impacts would be low. The overall visual impact would be low.

Ozark City Lake Boat Launch. Applicant Proposed Route Link 7 would be located 0.6 mile from the boat launch at Ozark City Lake. The dense trees and ridgeline on the far side of the lake would likely block all views of the transmission line structures from recreationists on the lake. Because there is no visibility, there would be no visual impacts at this location.

West Side City Park. Applicant Proposed Route Link 7 would be located 2 miles from this KOP. Tall trees and terrain in the FG/MG would obscure views of the transmission line structures from this park, resulting in no visual impact.

White Oak. Applicant Proposed Route Link 7 would be located 1.5 miles to the south. Dense trees line the road in this area and would screen all potential views of the transmission line structures, resulting in no visual impact.

White Oak Park. Applicant Proposed Route Link 7 would be located 3 miles to the north of White Oak Park. The dense vegetation on the banks surrounding the lake would obscure all views of the HVDC Applicant Proposed Route, resulting in no visual impact.

3.18.6.2.3.2.7.7 Applicant Proposed Route Link 8

Trail of Tears (Highway 352). Applicant Proposed Route Link 8, would cross Highway 352 and the Trail of Tears 150 feet to the northwest. The Trail of Tears locations mapped by the NPS are representative of the historic location of the trail and the extent of the trail at each crossing location is not known. The transmission line would run parallel to the existing H-frame structures and be highly visible to people in this area. The proposed structures would be much larger in scale and introduce a new dominant form to the landscape that would result in strong contrast. Because strong contrast would be created by the Project in the immediate FG distance zone for high sensitive viewers associated with this travel route, viewer concern impacts would be high. Overall visual impacts would be high.

Wiederkehr Village and Highway 186. Applicant Proposed Route Link 8 would be located 0.7 mile to the northwest of Wiederkehr Village. Viewers in this location may be able to see the transmission line structures extending above the tree line, appearing as small dark objects. The structures would not be very noticeable because of terrain and vegetation, however, and would result in weak contrast. Because weak contrast would be created by the Project in the MG distance zone for high sensitive residential viewers associated with this KOP, viewer concern impacts would be low. Overall visual impacts would be low.

3.18.6.2.3.2.7.8 Applicant Proposed Route Link 9

Big Piney Creek. Applicant Proposed Route Link 9 would cross Big Piney Creek 0.2 mile to the northeast. Recreationists on the creek may see the tops of the structures extending above the tree line. Portions of the proposed transmission structures would be visible, but these structures would be co-dominant with the existing line that crosses in the same place. In addition to the structures, vegetation would be cleared along the banks of the river, resulting in additional contrast as well as exposure to the proposed and current transmission lines. This KOP represents a sensitive area in a primarily natural landscape. Because the proposed transmission line structures would be adding contrast to existing, similar structures in view, the overall visual contrast would be moderate. Because moderate contrast would be created by the Project in the FG distance zone for high sensitive recreational viewers associated with this KOP, viewer concern impacts would be moderate–high. The overall visual impact would be moderate-high. A visual simulation for this KOP is provided in Appendix K.

Clarksville. Applicant Proposed Route Link 9 would be located 2.5 miles to the north of the Clarksville KOP. Due to the large amount of dense vegetation and rolling hills between the viewer and Project, there would be no visibility from this location and, therefore, no visual impact.

Hagarville. Applicant Proposed Route Link 9 would be 1 mile to the northeast, and much of the transmission line would be screened by terrain and vegetation. As the transmission line crossed the open fields, the structures would be highly visible and have different form than other structures in the area, resulting in moderate contrast. Because moderate contrast would be created by the Project in the MG distance zone for high sensitive recreational viewers associated with this KOP, viewer concern impacts would be moderate. The overall visual impact would be moderate.

Horsehead Lake Recreation Area. Applicant Proposed Route Link 9 would be 2.1 miles to the south. High ridges and dense vegetation border this dry lake bed and would screen views of the transmission line structures. There would be no visual impact at this location.

Hunt. Applicant Proposed Route Link 9 would be located 0.2 mile to the southeast. The tops of the transmission line structures would be visible above the tree line in the MG and different in form and scale than the existing H-frames which are barely visible through the trees. Because the proposed transmission line structures are taller than and differ in form, line, color and texture from other existing structures, the proposed structures would result in strong contrast. Because strong contrast would be created by the Project in the MG distance zone for high sensitive residential viewers associated with this KOP, viewer concern impacts would be moderate–high. Overall visual impacts would be high.

Lake Ludwig. Applicant Proposed Route Link 9 would be located 0.9 mile to the north. Looking out over the lake from the northern side, the transmission line structures would be visible extending above the tree line, appearing as dark vertical elements on the horizon. Many of the structures would be screened by dense vegetation, and the portion extending about the trees would result in weak visual contrast. Because weak contrast would be created by the Project in the MG distance zone for high sensitive recreational viewers associated with this KOP, viewer concern impacts would be moderate–high. Overall visual impacts would be moderate–low.

Route 21 (Scenic Byway). Applicant Proposed Route Link 9 would cross this scenic byway 0.1 mile to the north. The transmission line structures would be clearly visible to motorists traveling on the scenic byway. The tall structures would introduce a new element to the rural landscape and dominate the view where the line crosses the highway. In addition, the ROW clearing would be visible on the sides of the highway and the Project would result in strong visual contrast at this location. Because strong contrast would be created by the Project in the FG distance zone for high sensitive viewers associated with this travel route, viewer concern impacts would be high. Contrast would be reduced the farther away viewers are from the transmission line crossing because the bottom portion of the structures would be screened by vegetation and the ROW clearing would not be as apparent. Overall visual impact would be high.

3.18.6.2.3.2.7.9 Route Variations

Applicant Proposed Route Link 3, Variation 1, would be shifted approximately 0.1 mile north, and although the variation would be located farther from some residences, it would be closer to others. Given the minimal shift in location, overall visual impacts are not anticipated to change for high sensitive residential viewers as a result of this variation. Viewers would still have intermittent and partially screened views of the transmission lines across the landscape in the FG and MG distance zone in approximately the same location.

Applicant Proposed Route Link 3, Variation 2, crosses more wooded area than the original Applicant Proposed Route Link 3, and parallels an existing transmission line for the majority of its length, and although the variation crosses more wooded area, overall visual impacts are not anticipated to change for high sensitive residential viewers. Viewers would still have unobstructed or partially screened views of the Project crossing and croplands in the FG distance zone. Residences located greater than 0.5 mile (MG and BG distance zones) from the Applicant Proposed Route Link 3, Variation 2 would most likely have views that would be completely screened by heavily wooded areas in the landscape setting. For example, impacts to high sensitive residential viewers associated with the Sequoyah County KOP (included in Appendix K) are not anticipated because the variation would be located approximately 0.6 mile from the viewers and would be completely screened by vegetation in the FG distance zone.

Applicant Proposed Route Link 3, Variation 3, crosses less wooded area than the original Applicant Proposed Route Link 3 and would not parallel an existing transmission line. Impacts to high sensitive recreational viewers associated with the Lee Creek (Scenic River) KOP (included in Appendix K) would be reduced because the variation would be located approximately 0.7 mile farther from the viewer and would be screened by vegetation in the FG. However, the variation would be located closer to residences. Visual impacts to high sensitive residential viewers would increase because they would have unobstructed to partially screened views of the transmission line across an open field in the FG distance zone.

Applicant Proposed Route Link 6, Variations 1, 2, and 3, would be shifted approximately 500 feet from the original Applicant Proposed Route. Visual resources would remain the same and include rural residences within the FG and MG distance zones. Although the variations would be located farther from some residences, it would be closer to others. Given the minimal shift in location, overall visual impacts are not anticipated to change for high sensitive residential viewers as a result of these variations. Viewers would still have unobstructed or intermittent views of the Project crossing croplands in the FG and MG distance zone.

Applicant Proposed Route Link 9, Variation 1, would be shifted approximately 350 feet to the east and would cross a landscape setting similar to the original Applicant Proposed Route. Visual resources would remain the same and include rural residences and Big Piney Creek. Given the minimal shift in location, overall visual impacts are not anticipated to change for high sensitive residential viewers. Impacts to high sensitive recreational viewers associated with Big Piney Creek are also not anticipated to change. The Big Piney Creek KOP and the Big Piney Creek KOP (Route Variation) are included in Appendix K. Both KOPs are in the same location adjacent to the Big Piney Creek looking towards the Project.

3.18.6.2.3.2.8 Region 4 Conclusion

Region 4 contains a high density of visual resources primarily associated with rural and suburban communities, scattered rural residences, creeks, bayous, lakes, and reservoirs associated with recreation areas, wild and scenic rivers, scenic byways, NWR, national forests, state and local parks and historic landmarks. Visual impacts are anticipated to be mostly moderate–low for high and moderate sensitive viewers where the Project is located in the MG/BG distance zone. Typically, the Applicant Proposed Route is either seen in the context of other existing transmission lines or viewers are partially to completely obstructed by terrain and/or vegetation. Higher impacts are anticipated for high sensitivity viewers associated with communities or recreation areas where the Applicant Proposed Route is located within the FG and is not seen in the context of other transmission lines.

3.18.6.2.3.2.9 Region 5

The landscape category in Region 5 is primarily Common and is characterized by varied terrain with low rugged hills, mountains, and benches in the northern portion transitioning to undulating plains, terraces, cuestas, and floodplains associated with the Arkansas River in the south. Landscapes categorized as Distinct occur throughout the region and are associated with more natural rugged terrain in the northern portion of the region and the Arkansas River. In Region 5, existing transmission lines are not common within the landscape setting; therefore, the Applicant Proposed Route would cross and/or parallel fewer transmission lines than in Regions 1 through 4. The Applicant Proposed Route would parallel a 138kV line for approximately 1 mile and a 500kV line for approximately 4 miles and would cross two 161kV transmission lines. The contrast introduced by the Applicant Proposed Route and the visibility are similar to the conditions described for Region 4 in Section 3.18.6.2.3.2.

The visual impacts for the Region 5 KOPs are listed in Table 3.18-13 and described below.

Table 3.18-13:
Visual Impact Summary of KOPs—Applicant Proposed Route—Region 5

KOP	Link	Distance (Miles)	Viewer Concern	Landscape Category	Visibility	Viewer Concern Impact	Contrast	Overall Impact
Dover and JP Lovelady	1	2.8	High	Common	No	Low	No Contrast/ Not Visible	No Impact
Hector	1	2.5	High	Common	No	Low	No Contrast/ Not Visible	No Impact
Highway 7 (Scenic Byway)	1	0.1	High	Common	Yes	High	Strong	High
Pope Co. Residential Cluster	1, 2	0.8	High	Distinct	Yes	Low	Weak	Moderate–Low
Boy Scout Campground	3	0.5	High	Common	No	Low	No Contrast/ Not Visible	No Impact
Damascus	3	0.7	High	Common	Yes	Moderate	Moderate	Moderate
Guy	3	2.8	High	Common	No	Low	No Contrast/ Not Visible	No Impact
Highway 9 Scenic Highway	3	0.2	High	Common	Yes	High	Strong	High
Twin Groves	3	3	High	Common	No	Low	No Contrast/ Not Visible	No Impact
Wonderview School	3	1.8	High	Distinct	Yes	Low	Weak	Moderate–Low
Quitman	4	0.2	High	Common	Yes	High	Strong	High
Rose Bud City Park	4	3.4	High	Developed	No	Low	No Contrast/ Not Visible	No Impact
Letona	5	0.6	High	Developed	Yes	Moderate–High	Strong	Moderate–High
Highway 16 (Scenic Highway)	6	0.3	High	Common	Yes	High	Strong	High
Steprock	7, 8	0.6	High	Developed	Yes	Low	Weak	Low
Bradford	9	0.9	High	Common	No	Low	No Contrast/ Not Visible	No Impact
White River	9	0.06	High	Distinct	Yes	High	Strong	High

3.18.6.2.3.2.9.1 Applicant Proposed Route Link 1

Dover and JP Lovelady Ball Park. Applicant Proposed Route Link 1 would be located 2.8 miles to the north-northwest. Looking out from the ballpark in Dover, the transmission line structures would be screened from view given the low forested ridges in the distance and the dense vegetation in the FG. There would be no visual impact at this location.

Hector. Looking south from Hector, Applicant Proposed Route Link 1 would be located 2.5 miles away at its closest point. Dense vegetation in the FG/MG would screen all views of the HVDC Applicant Proposed Route at this location, resulting in no visual impact.

Highway 7 (Scenic Byway). Applicant Proposed Route Link 1 would cross the highway 0.1 mile to the north. Motorists traveling on the Highway 7 would have clear views of the transmission line structures as the line crossed the highway. The structures would extend above tree line and introduce large vertical elements that would differ greatly from anything within the current landscape setting. When approaching the line, motorists would have clear views of the vegetation clearing for the ROW, resulting in strong contrast. Because strong contrast would be created by the Project in the FG distance zone for high sensitive viewers associated with this travel route, viewer concern impacts would be high. Contrast would be reduced the farther away viewers are from the transmission line crossing because the bottom portion of the structures would be screened by vegetation and the ROW clearing would not be as apparent. The overall visual contrast would be strong and overall visual impacts high at this location.

Pope County Residential Cluster. Applicant Proposed Route Link 1 would be located 0.8 mile to the north of this KOP. Views would likely be screened by terrain and vegetation, but if visible, the transmission line structures would appear as dark vertical elements extending above the trees in the distance as the line goes down the ridge and into the valley. At this distance and because most of the transmission line would be screened, contrast introduced would be weak. Because weak contrast would be created by the Project in the MG distance zone for high sensitive residential viewers associated with this KOP, viewer concern impacts would be low. Overall visual impacts would be moderate–low because it is considered a Distinct landscape with high visual sensitivity.

3.18.6.2.3.2.9.2 Applicant Proposed Route Link 2

Pope County Residential Cluster. Views looking north-northwest from this location towards Applicant Proposed Route Link 2 would be screened by FG vegetation, resulting in no visual contrast.

3.18.6.2.3.2.9.3 Applicant Proposed Route Link 3

Boy Scout Campground. Applicant Proposed Route Link 3 would be located 0.5 mile to the north of the Boy Scout Campground. Dense vegetation in the FG and MG would screen all potential views of the Project, resulting in no visual impact at this location.

Damascus. This KOP represents views looking north-northwest from the community of Damascus and represents residential views, so visual concern is high. Applicant Proposed Route Link 3 would be located in the MG 0.7 mile to the north. The transmission line structures would be visible crossing open fields and extending above existing structures and appear as a repeating vertical element on the rural landscape. The structures would introduce a new form to the existing elements of the landscape (as described in Section 3.18.5.5). The area does have some existing transmission line structures and other cultural modifications, so the proposed transmission line structures would result in moderate contrast. Because moderate contrast would be created by the Project in the MG distance zone for high sensitive residential viewers associated with this KOP, viewer concern impacts would be moderate. Overall visual impact at this location would be moderate.

Guy. Applicant Proposed Route Link 3 would be located 2.8 miles to the north. A low ridge line covered in dense vegetation would screen all views of the transmission line structures from this location resulting in no visual impact. A visual simulation for this KOP is provided in Appendix L.

Highway 9 Scenic Highway. Applicant Proposed Route Link 3 would be located 0.2 mile to the south, where it crosses over Highway 9. The transmission line structures would be highly visible above trees and where the lines cross the highway. The structures would be dominant in the FG view and would introduce new form and line to the landscape at a much larger scale than existing features (as described in Section 3.18.5.5.1); therefore, contrast is strong. Strong contrast created by the Project in the FG distance zone for high sensitive viewers associated with this scenic travel route would result in high viewer concern impacts. Overall visual impact would be high.

Twin Groves. Applicant Proposed Route Link 3 would be located 3 miles north of the Twin Groves KOP. Dense vegetation and terrain features in the FG/MG would screen all views of the Project, resulting in no visual impact.

Wonderview School. Applicant Proposed Route Link 3 would be located 1.8 miles to the north. Viewers in this location may be able to see the transmission line structures in the valley through breaks in the trees. The structures would be mostly screened by vegetation and terrain, with the possibility of some structures extending above trees. The structures would not be highly noticeable and weak contrast would be created for portions that are visible. Weak contrast created by the Project in the MG distance zone for high sensitive residential viewers associated with this KOP would result in low viewer concern impacts. Overall visual impacts would be moderate–low.

3.18.6.2.3.2.9.4 Applicant Proposed Route Link 4

Quitman. Applicant Proposed Route Link 4 would be visible crossing the open field 0.2 mile to the south. Due to scale and form, the transmission line structures would be a dominant feature in the FG. The structures would be different in line and form than existing elements on the landscape (as described in Section 3.18.5.5.1 and would result in strong visual contrast. Strong contrast created by the Project in the FG distance zone for high sensitive residential viewers associated with this KOP would result in high viewer concern impacts. Overall visual impacts would be high. A visual simulation for this KOP is provided in Appendix K.

Rose Bud City Park. Applicant Proposed Route Link 4 would be located 3.4 miles north of the Rose Bud City Park KOP. Views of the transmission line structures from this location would be screened by tall trees and rolling terrain, resulting in no visual impact.

3.18.6.2.3.2.9.5 Applicant Proposed Route Link 5

Letona. Applicant Proposed Route Link 5 would be located 0.6 mile to the north and would be partially visible through breaks in trees and extending above tree line in places. The structures would introduce a new form to the landscape that is noticeably different than existing forms on the landscape (as described in Section 3.18.5.5.1), resulting in strong contrast. Strong contrast created by the Project in the MG distance zone for high sensitive residential viewers associated with this KOP would result in moderate–high viewer concern impacts. Overall visual impacts would be moderate-high from this KOP.

3.18.6.2.3.2.9.6 Applicant Proposed Route Link 6

Highway 16 (Scenic Highway). The Applicant Proposed Route Link 6 would cross Scenic Highway 16 0.3 mile from this KOP. Transmission line structures would be clearly visible and noticeable across the open field in the FG and extended above tree line introducing new, vertical elements to the landscape. This KOP represents views from a scenic highway, so visual concern is high and because of the scale of the structures, at this distance they would be a dominant form on the landscape and result in strong contrast. Strong contrast created by the Project in the FG distance zone for high sensitive viewers associated with this travel route would result in high viewer concern impacts. Overall visual impacts would be high.

3.18.6.2.3.2.9.7 Applicant Proposed Route Link 7

Steprock. Applicant Proposed Route Link 7 would be located 0.6 mile to the south. Dominant in the view at this location is an existing 500kV transmission line. The proposed transmission line structures would be similar in form and scale, but farther away and partially screened by FG trees causing them to appear subordinate on the landscape, resulting in weak contrast. Weak contrast created by the Project in the MG distance zone for high sensitive residential viewers associated with this KOP would result in low viewer concern impacts. Overall visual impacts would be low.

3.18.6.2.3.2.9.8 Applicant Proposed Route Link 8

Steprock. See description of Steprock KOP for Applicant Proposed Route Link 7. Distance and visibility are the same.

3.18.6.2.3.2.9.9 Applicant Proposed Route Link 9

Bradford. Applicant Proposed Route Link 9 would be located 0.9 mile to the north. Tall trees, dense vegetation, and rolling terrain in the FG would block all potential views of the transmission line structures from this location, resulting in no visual impact.

White River. Applicant Proposed Route Link 9 would be located 300 feet to the southeast and would run parallel to the highway. The transmission line would be highly visible above existing FG vegetation as it crosses the river and open fields. Because the transmission line would introduce new elements into a natural landscape, the large metal structures would become a dominant feature; therefore, contrast is strong. Strong contrast created by the Project in the immediate FG distance zone for high sensitive viewers, concerned with a scarce natural resource, would result in high viewer concern impacts. The Project would result in strong visual contrast and high overall visual impact.

3.18.6.2.3.2.9.10 Route Variations

Applicant Proposed Route Link 1, Variation 2, would be shifted approximately 0.4 mile to the south and would cross a heavily wooded area, similar to the original Applicant Proposed Route. Overall visual impacts are not anticipated to change for high sensitive residential viewers as a result of this variation. Although the variation would be located farther from some residences, it would be closer to others and viewers would still have partially screened views of the Project extending above the tree line in the FG distance zone.

Applicant Proposed Route Link 2, Variation 2, would cross a heavily wooded area, similar to the original Applicant Proposed Route. This variation would be located farther from high sensitive residential viewers, and although the tops of the structures would still be visible above the tree line, less of the structure would be visible because of the distance. Therefore, overall visual impacts to high sensitive viewers are anticipated to be reduced.

Applicant Proposed Route Links 2 and 3, Variation 1, would be shifted approximately 150 feet from the original Applicant Proposed Route where it crosses near residences. Given the minimal shift in location, overall visual impacts are not anticipated to change for high sensitive residential viewers as a result of this variation. It should be noted that a route adjustment was made for HVDC Alternative Route 5-B to maintain an end-to-end route with this variation. Impacts to the HVDC Alternative Route 5-B are discussed in Section 3.18.6.3.2.2.5.2.

Applicant Proposed Route Links 3 and 4, Variation 2, would be shifted approximately 400 feet from the original Applicant Proposed Route. Although the variation would be shifted away from some residences, it would be located even closer to others. Overall visual impacts are anticipated to be higher for high sensitive residential viewers where a greater portion of the structures would be visible extending above the tree line given the closer proximity of the line to the viewer. It should be noted that a route adjustment was made for HVDC Alternative Route 5-E to maintain an end-to-end route with this variation. Impacts to the HVDC Alternative Route 5-E are discussed in Section 3.18.6.3.2.2.5.5.

Applicant Proposed Route Link 7, Variation 1, would be shifted approximately 500 feet or less and would cross a landscape setting similar to the original Applicant Proposed Route. Visual resources would remain the same and include rural residences. Given the minimal shift in location, overall visual impacts are not anticipated to change for high sensitive residential viewers.

3.18.6.2.3.2.10 Region 5 Conclusion

Region 5 contains a moderate density of sensitive viewers primarily associated with rural communities, scattered rural residences, the Ozark National Forest, recreation areas (state and local parks), scenic byways, and conservation and wildlife management areas. Visual impacts are anticipated to be mostly moderate–low for high sensitivity viewers where the Applicant Proposed Route is located in the MG distance zone. No visual impacts are anticipated for many sensitive viewers where the Project is located in the edge of the MG and BG and views would be completely obstructed given the variation in terrain and heavily wooded areas. Higher visual impacts are anticipated to occur within this region though they would typically occur where the Project crosses scenic byways or is located in the FG distance zone.

3.18.6.2.3.2.11 Region 6

The landscape category in Region 6 is primarily Common and is characterized by predominately agricultural, croplands, and natural areas including riparian woodlands and wetlands. The terrain is relatively flat to gently undulating with several meandering streams, branching channels, and other drainages. Views are generally open given the level terrain, although wooded areas and trees planted along the edges of field, roadways, and drainages and channels can limit expansive views in some areas. In Region 6, existing transmission lines are not common within the landscape setting; however, the Applicant Proposed Route crosses two 161kV transmission lines and parallels another 161kV transmission line for approximately 2 miles.

The tall vertical geometric forms of the proposed structures would result in strong contrast with the horizontal lines of the relatively flat landscape found throughout most of the region. Contrast would be reduced in areas where the Applicant Proposed Route would parallel or be seen in context with existing transmission and electric distribution lines; the level of contrast would depend on the form, line, color and texture of the existing structures and the distance the existing structures are from the Applicant Proposed Route. Views of structures in some areas are limited to the upper portions that extend above tree lines and other vegetation. Changes to the landscape and vegetation due to construction of access roads and ROW clearing may be visible but changes would generally not be noticeable in the MG and BG where terrain and vegetation may obscure these changes. Changes may be noticeable to viewers where the Applicant Proposed Route is located in the FG in relatively flat terrain with minimal vegetation to obscure views. Contrast could be reduced in areas where existing access roads would be used and where the Applicant Proposed Route would parallel an existing transmission line corridor where vegetation clearing has previously occurred. The visual impacts for the Region 6 KOPs are listed in Table 3.18-14 and described below.

Table 3.18-14:
Visual Impact Summary of KOPs—Applicant Proposed Route—Region 6

KOP	Link	Distance (Miles)	Viewer Concern	Scenic Quality	Visibility	Viewer Concern Impact	Contrast	Overall Impact
Weldon	1	2.6	High	Common	Yes	Low	Weak	Low
Fisher and Park	4	1	High	Developed	Yes	Moderate	Moderate	Moderate–Low
Cherry Valley	6	0.9	High	Common	Yes	Moderate	Moderate	Moderate
Crowley's Ridge Byway	6	0.1	High	Distinct	Yes	High	Strong	High

3.18.6.2.3.2.11.1 Applicant Proposed Route Link 1

Weldon. Applicant Proposed Route Link 1 would be located 2.6 miles to the north. The flat open landscape would allow for multiple visible transmission-line structures, but at a distance of 2.6 miles, they would appear as a row of dark vertical elements and would be co-dominant with the existing structures on the landscape. Given the distance of 2.6 miles and the co-dominance with the existing transmission line, contrast introduced by the Project would be weak. Weak contrast created by the Project in the MG distance zone for high sensitive residential viewers represented by this KOP would result in low viewer concern impacts. Overall visual impacts would be low. Applicant Proposed Route Link 4

Fisher and Park. Applicant Proposed Route Link 4 would be located 1 mile to the east. Vegetation in the FG distance zone would screen some of the transmission line structures, but the structures would be visible across the open land just on the other side of the trees. There are existing vertical elements on the landscape, so combined with the partial screening, the contrast would be moderate. Because moderate contrast would be created by the Project in the MG distance zone for high sensitive recreational and residential viewers associated with this KOP viewer concern impacts, would be moderate. The overall visual impact would be moderate–low. The impact may be higher, however, in other locations in town where there is no screening.

3.18.6.2.3.2.11.2 Applicant Proposed Route Link 6

Cherry Valley. Applicant Proposed Route Link 6 would be located 0.9 mile to the north of town. A line of dense vegetation would partially screen the transmission line structures, but due to the large scale of the structures they would be clearly visible above tree line, creating a pattern of vertical elements on the irregular line of the horizon and resulting in moderate contrast at this location. Moderate contrast created by the Project in the MG distance zone for high sensitive residential viewers represented by this KOP would result in moderate viewer concern impacts. Overall visual impacts would be moderate.

Crowley's Ridge Scenic Byway. Applicant Proposed Route Link 3 would cross the byway 0.1 mile to the north of this KOP in the FG distance zone. Where viewers are in close proximity to the transmission line crossing, the transmission structures would be visible as would be the areas where vegetation has been cleared for the ROW, resulting in strong contrast. Contrast would be reduced the farther viewers are from the transmission line crossing because the transmission structures would be screened by vegetation and the ROW clearing would not be as apparent. Because strong contrast would be created by the Project in the FG distance zone for high sensitive viewers associated with this scenic travel route, viewer concern impacts would be high. Strong contrast and high impacts to sensitive viewers would result in high overall visual impacts.

3.18.6.2.3.2.11.3 Route Variations

Applicant Proposed Route Link 2, Variation 1 would cross a similar landscape setting as the original Applicant Proposed Route. Visual resources would also remain the same and include a few residences within the FG/MG distance zone. Visual impacts would not change for high sensitive residential viewers as a result of this variation because they would still have intermittent views of the Project crossing the FG/MG distance zone in approximately the same location. It should be noted that a route adjustment was made for HVDC Alternative Route 6-A to maintain an end-to-end route with this variation. Impacts to the HVDC Alternative Route 6-A are discussed in Section 3.18.6.3.2.2.6.1.

3.18.6.2.3.2.11.4 Region 6 Conclusion

Region 6 contains a low density of sensitive viewers primarily associated with rural communities and scattered rural residences, recreation areas and scenic byways. Visual impacts are anticipated to be mostly moderate–low for high sensitivity viewers where the Project is located in the MG distance zone and would either be seen in the context of existing transmission structure or would be partially screened by existing vegetation. Higher impacts are anticipated to occur for Distinct landscapes associated with Crowley's Ridge, where the Applicant Proposed Route would be located in the FG and would introduce vertical elements into the landscape setting creating strong contrast.

3.18.6.2.3.2.12 Region 7

The landscape category in Region 7 is primarily Common and is characterized by flat floodplains associated with the Mississippi River in the western and central portions and transitioning to gently undulating plains and low hills in the eastern portion. Although the terrain is primarily flat within this region, views are typically limited given the numerous forested areas, vegetation associated with surface waters, waterways, drainages, wetlands, and trees planted along agricultural fields and along roadways. In Region 7, the Applicant Proposed Route crosses two 161kV and one 500kV transmission lines and parallels a 161kV transmission line for approximately 2 miles.

The tall vertical geometric forms of the proposed structures would result in strong contrast with the horizontal lines of the relatively flat landscape found within the southern portion of the region. Contrast would be reduced in areas where the Applicant Proposed Route would parallel or be seen in context with existing transmission and electric distribution lines; the level of contrast would depend on the form, line, color and texture of the existing structures and the distance the existing structures are from the Applicant Proposed Route. Views of structures in some areas are limited to the upper portions that extend above tree lines and other vegetation. Changes to the landscape and vegetation due to construction of access roads and ROW clearing may be visible but changes would generally not be noticeable in the MG and BG where terrain and vegetation may obscure these changes. Changes may be noticeable to viewers where the Applicant Proposed Route is located in the FG in relatively flat terrain with minimal vegetation to obscure views. Contrast could be reduced in areas where existing access roads would be used and where the Applicant Proposed Route would parallel an existing transmission line corridor where vegetation clearing has previously occurred. The visual impacts for the Region 7 KOPs are listed in Table 3.18-15 and described below.

Table 3.18-15:
Visual Impact Summary of KOPs—Applicant Proposed Route—Region 7

KOP	Link	Distance (Miles)	Viewer Concern	Landscape Category	Visibility	Viewer Concern Impact	Contrast	Overall Impact
Birdsong	1	0.4	High	Common	Yes	High	Strong	High
Highway 61 (Scenic Byway)	1	0.4	High	Common	Yes	High	Strong	High
Joiner	1	1.7	High	Common	Yes	Low	Weak	Low
Marked Tree	1	2.2	High	Developed	No	Low	No Contrast/ Not Visible	No Impact
Mississippi River and Trail of Tears	1	0.7	High	Common	Yes	Moderate–High	Strong	High
Tyronza	1	2	High	Developed	Yes	Low	Weak	Low
Wilkinsville	4	0.1	High	Common	Yes	High	Strong	Moderate–High
Atoka	5	0.7	High	Common	No	Low	No Contrast/ Not Visible	No Impact
Atoka Community Park	5	4	High	Developed	No	Low	No Contrast/ Not Visible	No Impact
Edmund Orgill Park	5	1	High	Distinct	Yes	Low	Weak	Moderate–Low
Harold Park and Millington	5	2	High	Developed	No	Low	No Contrast/ Not Visible	No Impact
Munford	5	2	High	Developed	No	Low	No Contrast/ Not Visible	No Impact
Rhodes Estates	5	0.6	High	Developed	Yes	Moderate	Moderate	Moderate–Low

3.18.6.2.3.2.12.1 Applicant Proposed Route Link 1

Birdsong. Applicant Proposed Route Link 1 would be located 0.4 mile to the north. The transmission line structures would be highly noticeable crossing the open field. The tall vertical structures would create a pattern on the landscape different in form from existing structures (as described in Section 3.18.5.7.1) and much larger in scale, resulting in strong visual contrast. Because strong contrast would be created by the Project in the FG distance zone for high sensitive residential viewers associated with this KOP, viewer concern impacts would be strong. Overall visual impact would be high.

Highway 61 Scenic Byway. Applicant Proposed Route Link 1 would cross the Highway 61 Scenic Byway 0.4 mile to the northeast. The FG vegetation would partially screen the transmission line structures in this view, but due to their large scale, they would be visible extending above tree line. As motorists travelling the Scenic Byway approached the highway crossing, the structures would be a dominant feature on the landscape because of their scale and form, resulting in strong visual contrast and high overall visual impacts. Since most viewers in this location would be traveling on the highway, views would be primarily of short duration.

Joiner. Applicant Proposed Route Link 1 would be located 1.7 miles to the south and would appear as a pattern of vertical elements along the horizon, where not screened by FG vegetation. Visual contrast at this distance would be weak. Weak contrast created by the Project in the MG distance zone for high sensitive residential viewers associated with this KOP would result in low viewer concern impacts. Overall visual impact would be low.

Marked Tree. Applicant Proposed Route Link 1 would be located 2.2 miles to the south. Foreground vegetation and structures would screen all views of the transmission line structures, resulting in no visual impact.

Mississippi River and Trail of Tears. Applicant Proposed Route Link 1 would cross the open field 0.7 mile at the closest point. The transmission line structures would be highly visible and introduce a repeating geometric form to the landscape. Structures on either side of the river crossing would also be visible from this location and would be taller than the transmission structures leading up to the river crossing due to clearance requirements. In addition, markers (which may be orange, yellow, or white) on the transmission lines crossing the river would be added for safety reasons and would add additional contrast. The introduction of transmission structures and crossing markers in a relatively natural setting, would result in strong visual contrast. Because strong contrast would be created by the Project in the MG distance zone for high sensitive recreational viewers, viewer concern impacts would be moderate–high. The Trail of Tears locations mapped by the NPS are representative of the historic location of the trail and the extent of the trail at each crossing location is not known. At this location, overall visual impacts would be high. A visual simulation for this KOP is provided in Appendix K.

Tyronza. Applicant Proposed Route Link 1 would be located 2 miles southwest of the Tyronza KOP in the MG distance zone. The transmission line structures would be visible through openings in vegetation in the FG distance zone and would extend above the tree line. The structures would appear as dark vertical objects on the horizon at this distance and would result in weak visual contrast. Because weak contrast would be created by the Project in the MG distance zone for high sensitive residential viewers represented by this KOP, viewer concern impacts would be low. Overall visual impacts would be low.

3.18.6.2.3.2.12.2 Applicant Proposed Route Link 4

Wilkinsville. Applicant Proposed Route Link 4 would be visible as it traverses the open field 0.1 mile east of this KOP. The structures would be prominent features on the landscape as they cross the field. The proposed structures would be considerably larger than existing structures in view (as described in Section 3.18.5.7.1), and would result in strong visual contrast. Because strong contrast would be created by the Project in the FG distance zone for high sensitive residential viewers represented by this KOP, viewer concern impacts would be high. Overall visual impacts on the landscape would be high.

3.18.6.2.3.2.12.3 Applicant Proposed Route Link 5

Atoka. Applicant Proposed Route Link 5 would be located 0.7 mile to the south from this location, but views of the transmission line structures would be screened by FG vegetation and terrain, resulting in no visual impact.

Atoka Community Park. Applicant Proposed Route Link 5 would be located 4 miles to the southwest of the Atoka Community Park, but views of the transmission line structures would be screened by FG vegetation resulting in no visual impact.

Edmund Orgill Park. Applicant Proposed Route Link 5 would be located 1 mile to the south. From here, the transmission line structures would likely be screened. If visible, the view would be a small portion of the top of the structures extending above the tree line, resulting in weak contrast and moderate–low visual impact since this is a natural environment.

Harold Park and Millington. Applicant Proposed Route Link 5 would be located 2 miles to the north and would be screened by FG structures and trees, resulting in no visual impact.

Munford. Applicant Proposed Route Link 5 would be located 2 miles to the south. Due to existing structures and dense vegetation in the FG, the proposed transmission line structures would not be visible from this location and there would be no visual impact.

Rhodes Estates. Applicant Proposed Route link 5 would be located 0.6 mile to the southeast. Most of the transmission line structures would be partially screened by vegetation and terrain, leaving the tops visible extending above tree line. The portions of the transmission lines that would be visible would be seen in the context of other existing vertical structures; however, the transmission lines would be taller than and differ in form, line, and color from existing vertical features; therefore, contrast would be moderate. Because moderate contrast would be created by the Project in the MG distance zone for high sensitive residential viewers associated with this KOP, viewer concern impacts would be moderate. Overall visual impacts would be moderate–low.

3.18.6.2.3.2.12.4 Route Variations

Applicant Proposed Route Link 1, Variation 1, would cross a similar landscape setting as the original Applicant Proposed Route. Visual resources would also remain the same and include rural residences in the FG/MG distance zone. Visual impacts are anticipated to be higher for high sensitive residential viewers because the Applicant Proposed Route Link 1, Variation 1, would be located approximately 700 feet closer (within 300 feet of a residential structure). Although vegetation in the immediate FG would screen the lower portions of the structures because the variation is closer, more of the structures would be visible extending above the tree line, resulting in higher impacts.

Applicant Proposed Route Link 1, Variation 2, would cross a similar landscape setting as the original Applicant Proposed Route. Visual resources would also remain the same and include a few rural residences in the MG distance zone. Visual impacts are anticipated to be lower for high sensitive residential viewers because the Applicant Proposed Route Link 1, Variation 2, would be located farther away and would be partially to completely screened by vegetation.

Applicant Proposed Route Link 5, Variation 1, would cross a similar landscape setting as the original Applicant Proposed Route. Visual resources would also remain the same and include rural residences in the FG/MG distance zone. Visual impacts would not change for high sensitive residential viewers as a result of this variation because the variation would be located in close proximity (approximately 600 feet or less) to the original Applicant Proposed Route, and because of the rolling terrain and wooded areas, viewers would still have partially to completely screened views of the Project.

3.18.6.2.3.2.13 Region 7 Conclusion

Region 7 generally contains a low density of sensitive viewers in the western portion of the region (west of the Mississippi) and a higher density of sensitive viewers in the eastern portion (east of the Mississippi River) near Millington. Sensitive viewers are typically associated with rural and suburban communities and scattered residences and recreation areas associated with the communities and the Mississippi River. Visual impacts are anticipated to be mostly moderate–low to low for high sensitivity viewers where the Project is located in the MG distance zone and would either be seen in the context of existing transmission structure or would be partially screened by existing vegetation. Higher impacts are anticipated where the Applicant Proposed Project is located in the FG and would introduce vertical elements into the landscape setting creating strong contrast and where it crosses Distinct landscapes such as the Mississippi River.

3.18.6.2.3.3 Decommissioning Impacts

Project facilities would be removed at the end of the operational life of the transmission line. Conductors, structures, and related facilities would be removed. Foundations would be removed to below the ground surface level. There would be temporary visual impacts during decommissioning of the Project. There would be residual visual impacts for many years after the Project has been decommissioned and structures removed such as vegetative cutbacks, cut and fill scars from construction activities, and access roads, which all add to the visual impact, though these impacts would be at ground level. These areas would be apparent after the removal of structures but are expected to diminish over time as vegetation returns to the area.

3.18.6.3 Impacts Associated with the DOE Alternatives

3.18.6.3.1 Arkansas Converter Station Alternative Siting Area and AC Interconnection Siting Area

3.18.6.3.1.1 Construction Impacts

Construction would result in the short-term visual intrusion of construction vehicles, equipment, materials, and a work force in staging areas, and final converter station and substation location. Vehicles, heavy equipment, structure components, and workers would be visible during converter station and substation construction and modification, access and spur road clearing and grading, structure erection, and cleanup and restoration. Affected viewers would be aware of the existing structures in the area adjacent to the Project and the temporary nature of Project construction impacts, which would decrease both scenic quality and viewer concern to the impact. It should be noted that the converter station would be similar to the proposed converter stations proposed in Oklahoma and Tennessee.

3.18.6.3.1.2 Operations and Maintenance Impacts

3.18.6.3.1.2.1 Arkansas Converter Station Siting Area and AC Interconnection Siting Area

The surrounding landscape is primarily rural and agricultural and other than rural residences, does not contain a high number of sensitive resources that would be impacted. When visible in the FG, the facilities associated with the converter station and the substation would result in high contrast on the rural landscape, but given low numbers of sensitive viewers in the area, it would have an overall low-moderate impact.

3.18.6.3.1.3 Decommissioning Impacts

Project facilities would be removed at the end of the operational life of the converter station. There would be temporary visual impacts during decommissioning of the Project. Structures, and related facilities would be removed and foundations removed to below the ground surface level. There would be residual visual impacts for many years after the Project has been decommissioned and structures removed such as vegetation removal and access roads, which all add to the visual impact, though these impacts would be at ground level. These areas would be apparent after the removal of structures but are expected to diminish over time as vegetation returns to the area.

3.18.6.3.2 HVDC Alternative Routes

3.18.6.3.2.1 Construction Impacts

Construction would result in the short-term visual intrusion of construction vehicles, equipment, materials, and a work force in staging areas, along access roads, and along the new transmission line ROW. Vehicles, heavy equipment, structure components, and workers would be visible during structure erection, conductor stringing, access and spur road clearing and grading, and cleanup and restoration. However, disturbance from construction activities would be transient and of short duration as activities progress along the transmission line route. Affected viewers would be aware of the temporary nature of Project construction impacts, which should decrease their concern to the impact.

3.18.6.3.2.2 Operations and Maintenance Impacts

3.18.6.3.2.2.1 Region 1

A description for Region 1 is provided in Section 3.18.6.2.3.2.1. Additional sensitive resources in proximity to HVDC Alternative Routes in region 1 include the Lake Schultz State Park and Optima NWR. The visual impacts for the Region 1 AR KOPs are listed in Table 3.18-16 and described below.

Table 3.18-16:
Visual Impact Summary of KOPs—HVDC Alternative Routes—Region 1

KOP	AR	Distance (Miles)	Viewer Concern	Landscape Category	Visibility	Viewer Concern Impact	Contrast	Overall Impact
Laverne	1-A	0.9	High	Developed	Yes	Moderate	Moderate	Moderate–Low
Hardesty	1-A, 1-C	0.8	High	Common	Yes	Moderate	Moderate	Moderate
Optima NWR	1-A, 1-C	2.5	High	Common	Yes	Low	Weak	Moderate–Low
Lake Schultz State Park	1-B	0.9	High	Distinct	Yes	Moderate	Strong	High
Local Historical Marker	1-D	0.8	Moderate	Common	Yes	Moderate–Low	Moderate	Moderate–Low

3.18.6.3.2.2.1.1 HVDC Alternative Route 1-A

HVDC Alternative Route 1-A corresponds to Applicant Proposed Route Links 2, 3, 4, and 5.

Laverne. DOE Alternative Route 1-A would be located 0.9 mile to the north. The transmission lines structures would be noticeable in open fields and extend above vegetation and low structures, but they would not dominate the view and there would be no change to landform or vegetation. The tall vertical structures would be larger in scale than surrounding structures, resulting in moderate visual contrast. Moderate contrast created by the Project in the MG distance zone for high sensitive residential viewers associated with this KOP would result in moderate viewer concern impact. The overall visual impact at this location would be moderate–low.

Hardesty. HVDC Alternative Route 1-A would be located 0.8 mile to the south. The transmission line structures would be a prominent feature on the flat landscape, but because of the distance, would appear at a similar scale to existing vertical elements and would be co-dominant in the view and there would be no change to landform or vegetation at this location; therefore, contrast would be moderate. Moderate contrast created by the Project in the MG distance zone for high sensitive residential viewers associated with this KOP would result in moderate viewer concern impacts. The overall visual impact at this location would be moderate. A visual simulation for this KOP is provided in Appendix K.

Optima NWR. HVDC Alternative Route 1-A would be visible about 2.5 miles to the southeast. Because of distance, transmission line structures would be faintly visible in the distance. Structures may be noticeable as they traverse open lands, but would only result in weak contrast. Weak contrast created by the Project in the MG distance zone for high sensitive residential viewers associated with this KOP would result in moderate viewer concern impacts. This KOP represents views from a wildlife refuge, so visual concern is high and the overall visual impact at this location would be moderate–low.

3.18.6.3.2.2.1.2 HVDC Alternative Route 1-B

HVDC Alternative Route 1-B corresponds to Applicant Proposed Route Links 2 and 3.

Lake Schultz State Park. HVDC Alternative Route 1-B would be located 0.9 mile to the north. The view from this KOP is panoramic and the transmission structures would extend above the horizon line, introducing new vertical elements into a very natural landscape free of cultural modifications, resulting in strong contrast. This KOP represents views from a public park, so visual concern is high. Strong contrast created by the Project in the MG distance zone for high sensitive residential viewers associated with this KOP would result in moderate–low viewer concern impacts, and the overall visual impact of HVDC Alternative Route 1-B would be high.

3.18.6.3.2.2.1.3 HVDC Alternative Route 1-C

HVDC Alternative Route 1-C corresponds to Applicant Proposed Route Links 2 and 3.

Hardesty. See description of Hardesty KOP for HVDC Alternative Route 1-A. Distance and visibility from HVDC Alternative Route 1-C are similar.

Optima NWR. See description of Optima NWR KOP for HVDC Alternative Route 1-A. Distance and visibility are the same.

3.18.6.3.2.2.1.4 HVDC Alternative Route 1-D

HVDC Alternative Route 1-D corresponds to Applicant Proposed Route Links 3 and 4.

Local Historical Marker. HVDC Alternative Route 1-D would be located 0.8 mile to the north. HVDC Alternative Route 1-D would run adjacent to the existing transmission line, which is located 0.6 mile from this location. The proposed transmission line structures would result in similar impacts as corresponding Applicant Proposed Route Link 4, but would have slightly less contrast due to distance. Moderate contrast created by the Project in the MG distance zone for high sensitive residential viewers associated with this KOP would result in moderate–high viewer concern impacts. The overall visual impact of HVDC Alternative Route 1-D would be moderate–low.

3.18.6.3.2.2.1.5 Region 1 Alternative Comparison

Table 3.18-17 provides a comparison of the visual impacts for Region 1.

Table 3.18-17:
Visual Impact Comparison Summary—Region 1

Proposed and Alternative Routes	Miles of Distinct Lands Crossed	Miles of Common Lands Crossed	Miles of Developed Lands Crossed	Residences within 0.5 mile
HVDC Alternative Route 1-A	10.5	105.6	7.1	89
APR Links Corresponding to 1-A	5.2	101.7	8.1	95
HVDC Alternative Route 1-B	2.7	44.1	5.4	37
APR Links Corresponding to 1-B	0.1	49.1	3.9	32
HVDC Alternative Route 1-C	1.9	45.1	5.4	63
APR Links Corresponding to 1-C	0.1	49.1	3.9	32
HVDC Alternative Route 1-D	1	30.3	2.3	45
APR Links Corresponding to 1-D	1.3	32.4	1	51

HVDC Alternative Route 1-A. Visual impact to public, private, and state lands resulting from the operations and maintenance of HVDC Alternative Route 1-A is anticipated to be mostly moderate–low with some high impacts at Lake Schultz State Park. The majority of the area that would be crossed by HVDC Alternative Route 1-A is flat to rolling terrain with dispersed residential areas. There are approximately 89 residences within 0.5 mile of the alignment of this alternative route. HVDC Alternative Route 1-A crosses more lands classified as Distinct (10.5 mile) than the corresponding links of the Applicant Proposed Route, although both cross a similar length of lands classified as Common.

HVDC Alternative Route 1-B. Visual impact to public, private, and state lands resulting from the operations and maintenance of HVDC Alternative 1-B is anticipated to be mostly high due to viewers at Lake Schultz State Park. The majority of the area that would be crossed by HVDC Alternative Route1-B is flat to rolling terrain with dispersed residential areas. There are approximately 37 residences within 0.5 mile of the alignment of this alternative route, which would be less than the corresponding links of the Applicant Proposed Route or HVDC Alternative Route 1-A. HVDC Alternative Route 1-B crosses more lands classified as Distinct (2.7 miles) than the corresponding links of the Applicant Proposed Route and crosses slightly fewer lands classified as Common (44.1 miles).

HVDC Alternative Route 1-C. Visual impact to public, private, and state lands resulting from the operations and maintenance of HVDC Alternative Route 1-C is anticipated to be mostly moderate with some moderate–low impacts at Optima NWR. The majority of the area that would be crossed by HVDC Alternative Route 1-C is flat to rolling terrain with dispersed residential areas. There are approximately 63 residences within 0.5 mile of the alignment of this alternative route. HVDC Alternative Route 1-C crosses more lands classified as Distinct (1.9 miles) than the corresponding links of the Applicant Proposed Route, and impacts approximately twice as many residences within 0.5 mile.

HVDC Alternative Route 1-D. Visual impact to public, private, and state lands resulting from the operations and maintenance of HVDC Alternative Route 1-D is anticipated to be mostly moderate–low because of a local historic marker identifying the 37th parallel and the 1854 boundary of the Territory of Kansas. The majority of the area that would be crossed by HVDC Alternative Route 1-D is flat to rolling terrain with dispersed residential areas. There are approximately 45 residences within 0.5 mile of the alignment of this alternative route, slightly less than the corresponding Applicant Proposed Route links. HVDC Alternative Route 1-D crosses fewer lands classified as Distinct (1.0 mile) and Common (30.3 miles) than the corresponding links of the Applicant Proposed Route.

3.18.6.3.2.2.2 Region 2

A description for Region 2 is provided in Section 3.18.6.2.3.2.2. Towns and residences would be the primary source of sensitive viewers in this region, although there are some additional sensitive resources such as state parks, the Cimarron River and Gloss Mountain State Park. The visual impacts for the Region 2 KOPs are listed in Table 3.18-18 and described below.

Table 3.18-18:
Visual Impact Summary of KOPs—HVDC Alternative Routes—Region 2

KOP	AR	Distance (Miles)	Viewer Concern	Landscape Category	Visibility	Viewer Concern Impacts	Contrast	Overall Impact
Cimarron River Crossing	2-A	0.7	Moderate	Common	Yes	Moderate–Low	Moderate	Moderate–Low
Cleo Springs	2-A	3	High	Common	Yes	Low	Weak	Low
Gloss Mountain State Park	2-A	0.8	High	Distinct	Yes	Moderate	Moderate	Moderate–High
Ames	2-A, 2-B	1.3, 2.6	High	Common	Yes	Low	Weak	Moderate–Low
Bison	2-B	1.8	High	Developed	Yes	Low	Weak	Low
Waukomis KOP	2-B	3.5	High	Common	Yes	Low	Weak	Low

3.18.6.3.2.2.2.1 HVDC Alternative Route 2-A

HVDC Alternative Route 2-A corresponds to Applicant Proposed Route Link 2.

Cimarron River Crossing. HVDC Alternative Route 2-A would cross the Cimarron River 0.7 mile to the south of this KOP in the MG distance zone. There are existing H-frame and T-frame structures prominent in FG in this view, and the proposed structures would appear as additional vertical elements on the horizon. The form of the proposed structures would be taller and wider than the existing monopole structures, resulting in moderate visual contrast. Because moderate contrast would be created by the Project in the MG distance zone for moderate sensitive viewers associated with this local roadway, viewer concern impacts would be moderate–low. Although this is a major river crossing, because visual concern is moderate and there are existing cultural modifications, overall visual impacts would be moderate–low.

Cleo Springs. HVDC Alternative Route 2-A would be located 3 miles to the south of this KOP. There are two existing wood H-frame 115kV lines visible from this location, and although the proposed transmission line would be larger in form, it would be located farther away from the viewer and would appear as small vertical elements on the horizon, similar to the existing transmission lines. Because these proposed structures would be adding to existing vertical elements and are not prominent in the view, they would result in weak visual contrast. Because weak contrast would be created by the Project in the BG distance zone for high sensitive residential viewers associated with this KOP, viewer concern impacts would be low. The overall visual impacts at this location would be low.

Gloss Mountain State Park. HVDC Alternative Route 2-A would be visible 0.8 mile to the northeast. Although the proposed transmission line would introduce new vertical elements to the open landscape, the Project would be seen in the context of existing transmission structures, so visual contrast would be moderate. Moderate contrast created by the Project in the MG distance zone for high sensitive recreational viewers associated with this KOP would result in moderate viewer concern impacts. Overall visual impacts for HVDC Alternative Route 2-A in this location would be moderate-high. A visual simulation for this KOP is provided in Appendix K.

Ames. HVDC Alternative Route 2-A would be located 1.3 miles to the south in the MG distance zone and would appear as small objects in the distance. Where the structures are not blocked by FG/MG trees and vegetation, they would appear similar in scale to existing structures and would introduce a weak level of contrast. Because weak contrast would be created by the Project in the MG distance zone for high sensitive residential viewers associated with this KOP, viewer concern impacts would be low. The overall visual impacts at this location would be low.

3.18.6.3.2.2.2.2 HVDC Alternative Route 2-B

HVDC Alternative Route 2-B corresponds to Applicant Proposed Route Link 3.

Ames. Views are similar to Ames KOP description for HVDC Alternative Route 2-A, but slightly less noticeable due to greater distance (2.6 miles).

Bison. Viewers looking to the north from this location would see the transmission line structures of HVDC Alternative Route 2-B appearing as small vertical objects on the horizon 1.8 miles away. Trees in the FG would obstruct the majority of the views and HVDC Alternative Route 2-B in this location, resulting in weak contrast. Weak contrast created by the Project in the MG distance zone for high sensitive residential viewers associated with this KOP would result in low viewer concern impacts. Overall visual impacts would be low.

Waukomis. HVDC Alternative Route 2-B would be located 3.5 miles to the south. From the Waukomis KOP, the line would be barely visible above the horizon, where it is not screened by FG trees, resulting in weak contrast. Weak contrast created by the Project in the BG distance zone for high sensitive residential viewers associated with this KOP would result in low viewer concern impacts. Overall visual impact at this location is low.

3.18.6.3.2.2.2.3 Region 2 Alternative Comparison

Table 3.18-19 provides a comparison of the visual impacts for Region 2.

Table 3.18-19:
Visual Impact Comparison Summary of KOPs—Region 2

Proposed and Alternative Routes	Miles of Distinct Lands Crossed	Miles of Common Lands Crossed	Miles of Developed Lands Crossed	Residences within 0.5 mile
HVDC Alternative Route 2-A	9	44.4	4	66
APR Links Corresponding to Alternative 2-A	8.5	43.9	2.2	155
HVDC Alternative Route 2-B	0.2	28.7	1	71
APR Links Corresponding to Alternative 2-B	1.2	26.1	4	29

HVDC Alternative Route 2-A. Visual impacts to public, private, and state lands resulting from the operations and maintenance of HVDC Alternative Route 2-A are anticipated to be mostly moderate–low and are associated with residences and towns and the Cimarron River. The majority of the area that would be crossed by HVDC Alternative Route 2-A is flat to rolling terrain with dispersed residential areas. There are approximately 66 residences within 0.5

mile of the alignment of this alternative route, less than the corresponding links of the Applicant Proposed Route, which have 155 residences within 0.5 mile. HVDC Alternative Route 2-A would cross approximately the same amount lands classified as Distinct and Common (9 miles and 44.4 miles, respectively) as the corresponding links of the Applicant Proposed Route, which cross 8.5 miles and 43.9 miles of lands classified as Distinct and Common, respectively.

HVDC Alternative Route 2-B. Visual impacts to public, private, and state lands resulting from the operations and maintenance of HVDC Alternative Route 2-B are anticipated to be mostly low to moderate–low and are associated primarily with residential viewers. The majority of the area that would be crossed by HVDC Alternative Route 2-B is flat to rolling terrain with dispersed residential areas. There are approximately 71 residences within 0.5 mile of HVDC Alternative Route 2-B, more than the corresponding links of the Applicant Proposed Route, which have 29 residences within 0.5 mile of the alignment. HVDC Alternative Route 2-B crosses fewer lands classified as Distinct (0.2 mile) but more lands classified as Common (28.7 miles) than the corresponding Applicant Proposed Route links which crosses 1.2 miles of lands classified as Distinct and 26.1 miles of lands classified as Common.

3.18.6.3.2.2.3 Region 3

A description for Region 3 is provided in Section 3.18.6.2.3.2.3. Towns and residences would continue to be the majority of the sensitive viewers, but there are additional resources in proximity to the HVDC Alternative Routes in this region including lakes and recreation areas that are considered sensitive resources. The visual impacts for the Region 3 KOPs are listed in Table 3.18-20 and described below.

Table 3.18-20:
Visual Impact Summary of KOPs—HVDC Alternative Routes—Region 3

KOP	AR	Distance (Miles)	Viewer Concern	Landscape Category	Visibility	Viewer Concern Impacts	Contrast	Overall Impact
Lake Carl Blackwell	3-A, 3-B	2.7	High	Distinct	No	None/ Not Visible	No Contrast/ Not Visible	No Impact
Marshall	3-A, 3-B	1	High	Common	Yes	Low	Weak	Low
Mulhall	3-A, 3-B	3	High	Developed	No	None/ Not Visible	No Contrast/ Not Visible	No Impact
Orlando	3-A, 3-B	2.7	High	Common	Yes	Low	Weak	Low
Stillwater	3-A, 3-B	2	High	Developed	No	None/ Not Visible	No Contrast/ Not Visible	No Impact
Mehan	3-B	0.7	High	Common	Yes	Moderate	Moderate	Moderate
Agra	3-C	1.5	High	Developed	Yes	Low	Weak	Low
Beggs	3-C	1.5	High	Distinct	Yes	Low	Weak	Moderate–Low
Bristow and Route 66	3-C	3.4	High	Common	No	None/Not Visible	No Contrast/ Not Visible	No Impact
Depew and Route 66	3-C	1.4	High	Common	Yes	Low	Weak	Low
Okmulgee	3-C	1.5	High	Common	Yes	Low	Weak	Low
Perkins	3-C	0.6	High	Common	Yes	Moderate	Moderate	Moderate
Preston	3-C	0.6	High	Common	Yes	Moderate–High	Strong	High

Table 3.18-20:
Visual Impact Summary of KOPs—HVDC Alternative Routes—Region 3

KOP	AR	Distance (Miles)	Viewer Concern	Landscape Category	Visibility	Viewer Concern Impacts	Contrast	Overall Impact
Shamrock	3-C	3	High	Common	No	None/ Not Visible	No Contrast/ Not Visible	No Impact
Boynton	3-C, 3-D	1.5	High	Common	Yes	Low	Weak	Low
Council Hill	3-C, 3-D	2.1	High	Common	Yes	Moderate	Moderate	Moderate
Honey Springs Battlefield Historic Site and Rentiesville South	3-C, 3-D	2.9	High	Common	Yes	Low	Weak	Low
Honey Springs Battlefield Historic Site North	3-C, 3-D	0.5	High	Common	Yes	Moderate–High	Moderate	Moderate–High
McLain	3-C, 3-D, 3-E	0.7	High	Common	Yes	Moderate	Moderate	Moderate
Oktaha School	3-C, 3-D	0.4	High	Common	Yes	Moderate	Weak	Moderate-Low
Webbers Falls	3-C, 3-D, 3-E	1.5 (APR), 2.5 (AR)	High	Distinct	No	None/ Not Visible	No Contrast/ Not Visible	No Impact

3.18.6.3.2.2.3.1 HVDC Alternative Route 3-A

HVDC Alternative Route 3-A corresponds to Applicant Proposed Route Link 1.

As described in Appendix M and summarized in Section 2.4.2.3, a route adjustment was developed for HVDC Alternative Route 3-A to maintain an end-to-end route with Applicant Proposed Route Links 1 and 2, Variation 1. The route adjustment would bring the route due south to connect with the modified Applicant Proposed Route. The route adjustment would be located within approximately 0.25 mile of the original Alternative Route 3-A alignment and would be located farther from some high sensitive residential viewers and located closer to others. Overall, viewers in the area would still have partially to unobstructed views of the line in the FG distance zone; therefore, no changes to visual impacts are anticipated as a result of the route adjustment.

Lake Carl Blackwell. HVDC Alternative Route 3-A would be located 2.7 miles to the south. Due to distance, terrain, and dense vegetation the transmission line structures are not likely to be visible from this location, resulting in no visual impact.

Marshall. HVDC Alternative Route 3-A would be located 1 mile to the north and would be visible above the FG trees and existing structures. The proposed structures would add to the existing vertical elements in the FG, resulting in weak contrast. Because weak contrast would be created by the Project in the MG distance zone for high sensitive residential viewers associated with this KOP, viewer concern impacts would be low. Overall visual impact would be low.

Mulhall. HVDC Alternative Route 3-A would be located 3 miles to the north, but would not be noticeable given the distance from the KOP and the surrounding dense vegetation. There would be no overall visual impact from this location.

Orlando. HVDC Alternative Route 3-A would be located 2.7 miles to the south. Views of the structures would be obscured by vegetation and terrain in many places, but where visible, the structures would be similar in form to the existing lattice structures in view and would therefore, introduce a weak level of contrast. Because weak contrast would be created by the Project in the MG distance zone for high sensitive residential viewers associated with this KOP, viewer concern impacts would be low. The overall visual impact would be low.

Stillwater. HVDC Alternative Route 3-A would be located 2 miles to the south, but views of the transmission line structures would be blocked by terrain and vegetation, resulting in no visual impact. A visual simulation for this KOP is provided in Appendix K.

3.18.6.3.2.2.3.2 HVDC Alternative Route 3-B

HVDC Alternative Route 3-B corresponds to Applicant Proposed Route Links 1, 2 and 3.

Lake Carl Blackwell. See description of Lake Carl Blackwell KOP for HVDC Alternative Route 3-A. Distance and visibility are the same.

Marshall. See description of Marshall KOP for HVDC Alternative Route3-A. Distance and visibility are the same.

Mullhall. See description of Mulhall KOP for HVDC Alternative Route 3-A. Distance and visibility are the same.

Orlando. See description of Orlando KOP for HVDC Alternative Route 3-A. Distance and visibility are the same.

Stillwater. See description of Stillwater KOP for HVDC Alternative Route 3-A. Distance and visibility are the same.

Mehan. HVDC Alternative Route 3-B would be located 0.7 mile to the northeast. Much of the transmission line would be obscured by FG vegetation, but portions would likely be visible extending above tree line and through clearings in vegetation. The form and line of the proposed lattice structures would differ from existing elements in the rural landscape and would therefore result in moderate contrast. Because moderate contrast would be created by the Project in the MG distance zone for high sensitive residential viewers associated with this KOP, viewer concern impacts would be moderate. Overall visual impacts at this KOP would be moderate.

3.18.6.3.2.2.3.3 HVDC Alternative Route 3-C

HVDC Alternative Route 3-C corresponds to Applicant Proposed Route Links 3, 4, 5 and 6.

Agra. HVDC Alternative Route 3-C would be located 1.5 miles to the north. The transmission line structures would be visible through openings in the vegetation and FG structures and would appear as dark vertical objects on the horizon. There are multiple existing vertical elements on the existing landscape, so these proposed structures would introduce only weak visual contrast. Because weak contrast would be created by the Project in the MG distance zone for high sensitive residential viewers associated with this KOP, viewer concern impacts would be low. Overall visual impacts at this KOP would be low.

Beggs. HVDC Alternative Route 3-C would be located 1.5 miles to the south of this KOP at the closest point. The transmission line may be visible in the distance, but would be mostly screened by FG vegetation and terrain, resulting in weak contrast levels. This KOP represents views from a residential area, so visual concern is high. Weak contrast created by the Project in the MG distance zone for high sensitive residential viewers associated with this KOP would result in low viewer concern impacts. Given the weak contrast introduced into the landscape for high sensitive residential viewers in the MG distance zone, overall visual impacts at this KOP would be moderate–low.

Boynton. HVDC Alternative Route 3-C would be located 1.5 miles to the west. Viewers at this location would be able to see the transmission line structures through breaks in the FG vegetation and they would appear as additional vertical elements. Much of HVDC Alternative Route 3-C in this location would be screened from this viewpoint, resulting in weak visual contrast. Weak contrast created by the Project in the MG distance zone for high sensitive residential viewers associated with this KOP would result in low viewer concern impacts. Given the weak contrast introduced into the landscape for high sensitive residential viewers in the MG distance zone, overall visual impacts at this KOP would be low.

Bristow and Route 66. HVDC Alternative Route 3-C would be located 3.4 miles to the south of this KOP. The terrain and dense vegetation would obscure views of the structures resulting in no visual impact.

Council Hill. HVDC Alternative Route 3-C would be located 2.1 miles to the north. An existing 345kV line is located 1 mile closer that is not visible from the KOP. The proposed transmission line structures would be considerably taller, and portions may be visible above tree line, but much of the structures would be screened by FG elements. Due to distance and screening, the visual contrast from this KOP would be moderate. Moderate contrast created by the Project in the MG distance zone for high sensitive residential viewers associated with this KOP would result in moderate viewer concern impacts. Given the moderate contrast introduced into the landscape for high sensitive residential viewers in the MG distance zone, overall visual impacts would be moderate.

Depew and Route 66. HVDC Alternative Route 3-C would be located 1.4 miles away and appear as vertical elements on the horizon. Views would be blocked by vegetation in many areas, but where visible the large scale of the structures would be noticeable. Due to distance and FG obstructions, HVDC Alternative Route 3-C in this location would result in weak contrast. Weak contrast created by the Project in the MG distance zone for high sensitive residential and recreational viewers associated with this KOP would result in low viewer concern impacts. Given the weak contrast introduced into the landscape for high sensitive residential/recreational viewers in the MG distance zone, overall visual impact at this location would be low.

Honey Springs Battlefield Historic Site and Rentiesville South. HVDC Alternative Route 3-C would be located 2.9 miles to the north. It is unlikely that the transmission line structures would be visible from this location because of terrain and vegetation screening. If visible, they would appear as small objects on the horizon and would introduce weak contrast. Weak contrast created by the Project in the MG distance zone for high sensitive recreational viewers associated with this KOP would result in low viewer concern impacts. Given the weak contrast introduced into the landscape for high sensitive recreational viewers in the MG distance zone, overall visual impact would be low.

Honey Springs Battlefield Historic Site North. HVDC Alternative Route 3-C would be located 0.5 mile to the north and would run parallel to an existing transmission line. HVDC Alternative Route 3-C in this location would be visible where not screened by FG vegetation and would repeat form similar to the existing structures. The proposed structures would be located on the near side of the existing line and introduce moderate contrast. Moderate contrast created by the Project in the MG distance zone for high sensitive recreational viewers associated with this KOP would result in moderate–high viewer concern impacts. This KOP represents a historic site, so visual concern is high. Given the moderate contrast introduced into the landscape for high sensitive (recreational) viewers in the MG distance zone, the overall visual impact is moderate–high.

McLain. HVDC Alternative Route 3-C would be visible, appearing as vertical objects above tree line where not screened by FG elements. The proposed structures would be parallel to an existing line and would be larger in form and scale, but be farther from the viewer resulting in co-dominance with existing structure in view. The proposed transmission line structures would be noticeable to viewers and result in moderate contrast. Moderate contrast created by the Project in the MG distance zone for high sensitive recreational viewers associated with this KOP would result in moderate viewer concern impacts. Given the moderate contrast introduced into the landscape for high sensitive recreational viewers in the MG distance zone, the overall visual impact would be moderate.

Okmulgee. HVDC Alternative Route 3-C would be located 1.5 miles to the north. At this distance, the transmission line would be partially visible on the horizon line and on top of the ridgeline and appear as dark vertical shapes silhouetted against the sky. The structures however, would not distract from the view and would result in weak contrast. Weak contrast created by the Project in the MG distance zone for high sensitive residential viewers associated with this KOP would result in low viewer concern impacts. Given the weak contrast introduced into the landscape for high sensitive (recreational) viewers in the MG distance zone, the overall visual impact on the landscape would be low.

Oktaha School. HVDC Alternative Route 3-C would be 0.4 mile to the southeast and would be visible above tree line. This is a recreational facility in a residential area, so visual concern is high. There are multiple vertical elements on the existing landscape including an existing transmission line, and these structures would introduce additional contrast. Since HVDC Alternative Route 3-C would be located behind an existing transmission line in this location, the contrast would be weak. Weak contrast created by the Project in the MG distance zone for high sensitive recreational and residential viewers associated with this KOP would result in moderate viewer concern impacts. Overall visual impacts would be moderate–low. A visual simulation for this KOP is provided in Appendix K.

Perkins. HVDC Alternative Route 3-C would be 0.6 mile to the east of this location. The transmission line structures would be visible above the trees in the MG and in the open fields to the southeast. The introduction of additional vertical elements and difference in form of the proposed structures would result in moderate contrast. Moderate contrast created by the Project in the MG distance zone for high sensitive residential viewers associated with this KOP would result in moderate viewer concern impacts. Given the moderate contrast introduced into the landscape for high sensitive residential viewers in the MG distance zone, overall visual impacts on this landscape would be moderate.

Preston. HVDC Alternative Route 3-C would be visible 0.6 mile to the south. The transmission line structures would be clearly visible on the horizon, above the tree line adding vertical elements to the landscape resulting in strong contrast. This KOP represents views from a park in a residential area, so visual concern is high. Strong contrast created by the Project in the MG distance zone for high sensitive residential viewers associated with this KOP would result in moderate–high viewer concern impacts. Given the strong contrast introduced into the landscape for high sensitive (residential) viewers in the MG distance zone, overall visual impacts would be high.

Shamrock. HVDC Alternative Route 3-C would be located 3 miles to the southwest of this location. Given the vegetation and terrain, the transmission line structures would not be visible from this location and there would be no visual impact.

Webbers Falls. See the Applicant Proposed Route Link 6 description.

3.18.6.3.2.2.3.4 HVDC Alternative Route 3-D

HVDC Alternative Route 3-D corresponds to Applicant Proposed Route Links 5 and 6.

Boynton. See description of Boynton KOP for HVDC Alternative Route 3-C. Distance and visibility are the same.

Council Hill. See description of Council Hill KOP for HVDC Alternative Route 3-C. Distance and visibility are the same.

Honey Springs Battlefield Historic Site and Rentiesville South. See description of Honey Springs Battlefield Historic Site and Rentiesville South KOP for HVDC Alternative Route 3-C. Distance and visibility are the same.

Honey Springs Battlefield Historic Site North. See description of Honey Springs Battlefield Historic Site North KOP for HVDC Alternative Route 3-C. Distance and visibility are the same.

McLain. See description of McLain KOP for HVDC Alternative Route 3-C. Distance and visibility are the same

Oktaha School. See description of Oktaha School KOP for HVDC Alternative Route 3-C. Distance and visibility are the same.

Webbers Falls. HVDC Alternative Route 3-D would be located 2.5 miles to the southwest. Given the distance and existing vegetation, the transmission line structures would not be visible from this location and there would be no visual impact.

3.18.6.3.2.2.3.5 HVDC Alternative Route 3-E

McLain. See description of McLain KOP for HVDC Alternative Route 3-C. Distance and visibility are the same.

Webbers Falls. See description of Webbers Falls KOP for HVDC Alternative Route 3-D. Distance and visibility are the same.

3.18.6.3.2.2.3.6 Region 3 Alternative Comparison

Table 3.18-21 provides a comparison of the visual impacts for Region 3.

Table 3.18-21:
Visual Impact Comparison Summary—Region 3

Proposed and Alternative Routes	Miles of Distinct Lands Crossed	Miles of Common Lands Crossed	Miles of Developed Lands Crossed	Residences within 0.5 Mile
HVDC Alternative Route 3-A	4.4	30.5	2.8	186
APR Links Corresponding to Alternative 3-A	5.5	32.5	2.1	168
HVDC Alternative Route 3-B	4.9	39.7	3.3	476

Table 3.18-21:
Visual Impact Comparison Summary—Region 3

Proposed and Alternative Routes	Miles of Distinct Lands Crossed	Miles of Common Lands Crossed	Miles of Developed Lands Crossed	Residences within 0.5 Mile
APR Links Corresponding to Alternative 3-B	18.9	41.2	2.5	520
HVDC Alternative Route 3-C	15.9	102.3	3.7	1,450
APR Links Corresponding to Alternative 3-C	28.4	98.2	4.9	1,545
HVDC Alternative Route 3-D	1.8	36.0	1.6	600
APR Links Corresponding to HVDC Alternative Route 3-D	1.5	32.2	1.5	552
HVDC Alternative Route 3-E	1.2	6.9	0.4	162
APR Links Corresponding to Alternative 3-E	1.2	6.1	0.5	137

HVDC Alternative Route 3-A. Visual impact to public, private, and state lands resulting from the operations and maintenance of HVDC Alternative Route 3-A is anticipated to be mostly low and associated with towns or scattered residences. The majority of the area that would be crossed by HVDC Alternative Route 3-A is flat to rolling terrain with dispersed residential areas. There are approximately 186 residences within 0.5 mile of the alignment of this alternative route. HVDC Alternative Route 3-A would cross less land classified as Distinct (4.4 miles) and Common (30.5 miles) than the corresponding links of the Applicant Proposed Route, which cross 5.5 miles of land classified as Distinct and 32.5 miles of land classified as Common.

HVDC Alternative Route 3-B. Visual impact to public, private, and state lands resulting from the operations and maintenance of HVDC Alternative Route 3-B is anticipated to be mostly low because of the distance of the Project to towns and scattered residences. The majority of the area that would be crossed by HVDC Alternative Route 3-B is flat to rolling terrain with dispersed residential areas. There are approximately 476 residences within 0.5 mile of the alignment of this alternative route, which would be less than the corresponding links of the Applicant Proposed Route links and more than twice as many as HVDC Alternative Route 3-A. HVDC Alternative Route 3-B crosses more lands classified as Distinct (4.9 miles) and lands classified as Common (39.7 miles) than HVDC Alternative Route 3-A.

HVDC Alternative Route 3-C. Visual impact to public, private, and state lands resulting from the operations and maintenance of HVDC Alternative Route 3-C is anticipated to be mostly moderate because of the towns and scattered residences; impacts would be moderate–high at the Honey Springs Battlefield site. The majority of the area that would be crossed by HVDC Alternative Route 3-C is flat to rolling terrain with dispersed residential areas. There are approximately 1,450 residences within 0.5 mile of the alignment of this alternative route, the most of any of the other HVDC route alternatives. HVDC Alternative Route 3-C crosses fewer lands classified as Distinct (15.9 miles) than the corresponding links of the Applicant Proposed Route (28.4 miles). HVDC Alternative Route 3-C would also cross more lands classified as Common (102.3 miles) than the corresponding Applicant Proposed Route links (98.2 miles) and any of the HVDC Route Alternatives

Alternative 3-D. Visual impact to public, private, and state lands resulting from the operations and maintenance of HVDC Alternative Route 3-D is anticipated to be mostly moderate because residential development and towns are dispersed, although there would be moderate–high impacts at the Honey Springs Battlefield Historic Site. The majority of the area that would be crossed by HVDC Alternative Route 3-D is flat to rolling terrain. There are approximately 600 residences within 0.5 mile of the alignment of this alternative route, more than the corresponding links of the Applicant Proposed Route (552 residences within 0.5 mile) and more than any HVDC alternative routes except HVDC Alternative Route 3-C. HVDC Alternative Route 3-D crosses more lands classified as Distinct (1.8 miles) and Common (36 miles) than the corresponding links of the Applicant Proposed Route.

Alternative 3-E. Visual impact to public, private, and state lands resulting from the operations and maintenance of HVDC Alternative Route 3-E is anticipated to be mostly low because residential development and towns are dispersed. The majority of the area that would be crossed by HVDC Alternative Route 3-E is flat to rolling terrain. There are approximately 162 residences within 0.5 mile of the alignment of this alternative route, the least of any HVDC Alternative Route. HVDC Alternative Route 3-E crosses an equal amount of lands classified as Distinct (1.2 miles) and slightly more lands classified as Common (6.9 miles) than the corresponding links of the Applicant Proposed Route.

3.18.6.3.2.2.4 Region 4

A description for Region 4 is provided in Section 3.18.6.2.3.5. Region 4 has multiple sensitive resources including the Arkansas River, lakes and reservoirs, state parks, and Ozark-St. Francis National Forest land that would have sensitive viewers using the resources for recreation. HVDC Alternative Route 4-B would cross the Ozark-St. Francis National Forest and visual analysis related to USFS lands would be discussed after the HVDC Alternative Route 4-B KOP analysis. The visual impacts for the Region 4 KOPs are listed in Table 3.18-22 and described below.

Table 3.18-22:
Visual Impact Summary of KOPs—HVDC Alternative Routes—Region 4

KOP[1]	AR	Distance (Miles)	Viewer Concern	Landscape Category	Visibility	Viewer Concern Impacts	Contrast	Overall Impact
Arkansas River	3-C, 3-D	0.5	Moderate	Common	Yes	Low	Weak	Moderate–Low
Arkansas River and Gore PR	3-D, 3-C, 3-E, 4-B	3	High	Distinct	Yes	Low	Weak	Moderate–Low
Brushy Creek Reservoir and Sallisaw State Park	4-A	2.2	High	Distinct	No	Low	No Contrast/ Not Visible	No Impact
Highway 82	4-A	0.1	Moderate	Common	Yes	Moderate–High	Strong	High
Little Lee Creek (Scenic River)	4-A, 4-B	0.4	High	Distinct	Yes	High	Strong	High
Route 71 (Scenic Byway)	4-A	0.1	High	Common	Yes	High	Strong	High
Uniontown Highway (Scenic Highway)	4-A	0.1	High	Common	Yes	High	Strong	High
Marble City	4-A, 4-B	0.3	High	Common	Yes	High	Strong	High
Tenkiller State Park PR and AR	4-A, 4-B	4	High	Distinct	No	Low	No Contrast/ Not Visible	No Impact
Vian	4-A, 4-B	1.8	High	Common	Yes	Low	Weak	Low
Bluff Hole Park	4-A, 4-D	2.7	High	Common	Yes	Low	Weak	Low
Boys and Girls Camp	4-A, 4-D	0.3	High	Common	Yes	High	Strong	High
City Park/Ball Fields and Rudy	4-A, 4-D	3.2	High	Developed	No	Low	No Contrast/ Not Visible	No Impact

Table 3.18-22:
Visual Impact Summary of KOPs—HVDC Alternative Routes—Region 4

KOP[1]	AR	Distance (Miles)	Viewer Concern	Landscape Category	Visibility	Viewer Concern Impacts	Contrast	Overall Impact
Frog Bayou Creek	4-A, 4-D	0.1	High	Distinct	Yes	High	Strong	High
Mulberry River and Trail of Tears	4-A, 4-D	0.7	High	Distinct	Yes	Moderate–High	Strong	High
Fire Tower Lookout	4-B	0.9	High	Distinct	No	Low	No Contrast/ Not Visible	No Impact
Highway 82	4-B	0.2	High	Common	Yes	High	Strong	High
Mulberry River	4-B	0.1	High	Distinct	Yes	High	Strong	High
Route 220 (Scenic Byway)	4-B	0.1	High	Distinct	Yes	High	Strong	High
Trail of Tears (Highway 352)	4-B	0.1	High	Common	Yes	Moderate–High	Moderate	Moderate–High
Trail of Tears (Route 59)	4-B	0.1	High	Distinct	Yes	High	Strong	High
White Oak	4-B	0.9	High	Common	No	Low	No Contrast/ Not Visible	No Impact
Wiederkehr Village and Highway 186	4-B	3.4	High	Common	Yes	Low	Weak	Low
Ozark	4-B, 4-E	3.7	High	Common	No	Low	No Contrast/ Not Visible	No Impact
Field of Dreams	4-C	2.3	High	Developed	No	Low	No Contrast/ Not Visible	No Impact
Scott Farm	4-C	0.7	High	Common	Yes	Moderate	Moderate	Moderate
Cedarville	4-A, 4-D	0.8	High	Common	Yes	Moderate–High	Strong	High
Trail of Tears and Scenic Highway 220	4-D	0.1	High	Common	Yes	High	Strong	High
Van Buren	4-D, 4-C	1.1	High	Common	No	Low	No Contrast/ Not Visible	No Impact
Clarksville	4-E	0.4	High	Common	Yes	High	Strong	High
Coal Hill	4-E	3.2	High	Common	No	Low	No Contrast/ Not Visible	No Impact
Hagarville	4-E	2.3	High	Common	No	Low	No Contrast/ Not Visible	No Impact
Highway 21 Scenic Byway	4-E	0.4	High	Common	Yes	High	Strong	High
Lamar	4-E	3.25	High	Common	No	Low	No Contrast/ Not Visible	No Impact
Wiederkehr Village and Highway 186	4-E	0.6	High	Common	Yes	Low	Weak	Low

1 The Arkansas River and Arkansas River and Gore KOPs are located in Region 4, but HVDC Alternative Routes in Region 3 will potentially be visible from these KOPs. As a result, these KOPs are discussed in the Region 4 section, and the Region 3 HVDC alternative routes potentially visible from these KOPs are included in the impact analysis for Region 4.

3.18.6.3.2.2.4.1 HVDC Alternative Route 3-C

HVDC Alternative Route 3-C corresponds to Applicant Proposed Route Links 3, 4, 5 and 6.

Arkansas River. From this KOP, HVDC Alternative Route 3-C would be visible extending above the tree line 0.5 mile away on the far side of the river. The transmission line structures would be similar in form to the existing structures and would appear co-dominant on the horizon. Views represented are only of the HVDC Alternative Route section not including the river crossing, and would result in weak contrast. Weak contrast created by the Project in the MG distance zone for moderate sensitive viewers associated with this KOP would result in low viewer concern impacts. Given the distance of the Project from the KOP and the presence of existing high-voltage transmission lines in close proximity to the Project, the overall impact would be moderate–low.

Arkansas River and Gore. See description of Arkansas River and Gore KOP for Applicant Proposed Route Link 1. Distance and visibility are the same. A visual simulation for this KOP is provided in Appendix K.

3.18.6.3.2.2.4.2 HVDC Alternative Route 3-D

HVDC Alternative Route 3-D corresponds to Applicant Proposed Route Links 5 and 6.

Arkansas River. See description of Arkansas River KOP for HVDC Alternative Route 3-C. Distance and visibility are the same.

Arkansas River and Gore. See description of Arkansas River and Gore KOP for Applicant Proposed Route Link 1. Distance and visibility are the same.

3.18.6.3.2.2.4.3 HVDC Alternative Route 3-E

HVDC Alternative Route 3-E corresponds to Applicant Proposed Route Link 6.

Arkansas River and Gore. See description of Arkansas River and Gore KOP for Applicant Proposed Route Link 1. Distance and visibility are the same.

3.18.6.3.2.2.4.4 HVDC Alternative Route 4-A

HVDC Alternative Route 4-A corresponds to Applicant Proposed Route Links 3, 4, 5, and 6.

Bluff Hole Park. Looking north from Bluff Hole Park, the HVDC Alternative Route 4-A would be located 2.7 miles away. At this distance, the transmission line structures would be mostly screened by vegetation and terrain. If any of the structures are visible, they would appear as small dark vertical elements on the irregular horizon line and result in weak contrast. Weak contrast created by the Project in the MG distance zone for high sensitive recreational viewers associated with this KOP would result in low viewer concern impacts. Because the Project would not be readily noticeable to recreational viewers from this location, the overall visual impact at this location would be low.

Boys and Girls Camp. This KOP represents views from a youth camp in a rural landscape. HVDC Alternative Route 4-A would be located 0.3 mile to the north, just beyond the line of trees in the FG. The transmission line structures would be clearly visible to anyone traveling to or from the camp, extending above tree line and creating a pattern of vertical elements different from the existing landscape. This KOP represents views from a recreation area, so visual concern is high. The resulting contrast would be strong. Strong contrast created by the Project in the FG distance zone for high sensitive recreational viewers associated with this KOP, would result in high viewer concern impacts and overall visual impacts would be high.

Brushy Creek Reservoir and Sallisaw State Park. HVDC Alternative Route 4-A would be located 2.2 miles north of this recreation area at Brushy Creek Reservoir. People visiting the park would not be able to see the transmission line structures in this location because hills and dense trees around the lake screening views. There would be no visual impact at this location.

City Park/Ball Fields and Rudy. Looking out from the community ball field in Rudy, views of HVDC Alternative Route 4-A, 3.2 miles away, would be blocked by FG structures and vegetation resulting in no visual impact.

Frog Bayou Creek. HVDC Alternative Route 4-A would be highly visible crossing the valley and continuing up over the ridge in the MG. Structures would appear as tall vertical elements breaking up an otherwise mostly natural environment creating strong contrast. Additional contrast would be added to the landscape with the ROW clearing going up the ridge creating straight lines on the rolling hills. This KOP represents the crossing of a waterbody being viewed from a scenic highway, so visual concern is high. Strong contrast created by the Project in the FG distance zone for high sensitive viewers associated with this scenic byway would result in high viewer concern impacts. The overall visual impact in this area would be high. A visual simulation for this KOP is provided in Appendix K.

Highway 82. HVDC Alternative Route 4-A would be located 0.1 mile to the southwest of this viewpoint along Highway 82. The structures would be highly visible, extending above tree line and dominating the view of motorists as it crosses the highway. ROW clearing would be visible as straight lines of cleared vegetation along the sides of the road, adding additional contrast to the landscape. This KOP represents views from a well-traveled highway with moderate visual concern and the transmission line would result in strong contrast and high overall visual impact at this location.

Little Lee Creek (Scenic River). HVDC Alternative Route 4-A would cross this scenic river 0.4 mile to the northeast. Where not screened by FG vegetation, transmission line structures in this location would introduce tall vertical structures, and color, line and texture different from what exists currently (as described in Section 3.18.5.4.1 in this primarily natural landscape; therefore, contrast would be strong. On the sides of the river, ROW clearing of dense vegetation would create additional horizontal lines in the landscape visible to people using this river for recreation. Strong contrast created by the Project in the FG distance zone for high sensitive recreational viewers associated with this KOP would result in high viewer concern impacts. These impacts to the landscape would result in high overall visual impact. A visual simulation for this KOP is provided in Appendix K.

Marble City. HVDC Alternative Route 4-A would be located 0.3 mile to the southeast. The structures would be screened by a ridge until crossing the open field in the MG. Through breaks in the FG vegetation and structures, the transmission line structures would be prominent in view and appear as tall vertical objects much larger in scale than the existing wood power poles in view. This KOP represents views from a residential area with high visual concern and the transmission line would result in strong visual contrast. Strong contrast created by the Project in the FG distance zone for high sensitive residential viewers associated with this KOP would result in high viewer concern impacts. Overall visual impacts are anticipated to be high.

Mulberry River and Trail of Tears. HVDC Alternative Route 4-A would cross the river 0.7 mile from this location. Most of the transmission line structures would be screened because of the dense vegetation in the area, but when they were visible through breaks in vegetation, they would be clearly visible across the open field to the east. The proposed transmission line structures would be noticeably different than existing structures in view, introducing new form and line to the landscape; therefore, contrast introduced by the Project would be strong. Strong contrast created by the Project in the MG distance zone for high sensitive recreation viewers associated with the river and historic trail would result in moderate–high viewer concern impacts. Because this is a sensitive viewpoint representing a historic trail, and because the proposed structures would result in strong contrast, high overall visual impacts are anticipated. A visual simulation for this KOP is provided in Appendix K.

Route 71 (Scenic Byway). HVDC Alternative Route4-A would cross the scenic byway 0.1 mile to the south. The scale of the transmission structures would be much larger than anything in the current landscape in this area and would dominate the views of motorists traveling down the scenic byway as the transmission line crosses the road and cut across the open fields in the FG. This KOP represents views from a Scenic Byway, and strong contrast created by the Project in the FG distance zone for high sensitive viewers associated with this scenic travel route would result in high viewer concern impacts. The overall contrast at this location would be strong and the overall visual impact high.

Tenkiller State Park. See the Applicant Proposed Route Link 1 description.

Uniontown Highway (Scenic Byway). HVDC Alternative Route 4-A would cross the highway 0.1 mile from this point. The tall transmission line structures would dominate views in the area as they contrast the rural landscape free of tall man-made vertical structures. Combined with the ROW clearing of vegetation along the highway, HVDC Alternative Route 4-A would create strong contrast. Strong contrast created by the Project in the FG distance zone for high sensitive viewers associated with this scenic travel route would result in high viewer concern impacts. Overall visual impacts would also be high. Because most viewers in this location would be traveling on the highway, views would be primarily of short duration.

Vian. HVDC Alternative Route 4-A would be located 1.8 miles to the north. From this location, the transmission line structures would appear behind the ridge in the BG and most likely not be visible. If any of the structures appeared above the tree line, they would appear as dark objects on the horizon and be difficult to notice, resulting in weak contrast and low overall visual impact.

3.18.6.3.2.2.4.5 HVDC Alternative Route 4-B

HVDC Alternative Route 4-B corresponds to Applicant Proposed Route Links 2, 3, 4, 5, 6, 7 and 8.

Arkansas River and Gore. See the Applicant Proposed Route Link 1 description.

Fire Tower Lookout. This KOP represents views from the Ozark-St. Francis National Forest and was chosen by USFS staff to represent forest views. Surrounding the open field are tall trees that would block all views to HVDC Alternative Route 4-B, 0.9 mile to the south. There would be no visual impact at this location.

Highway 82. HVDC Alternative Route4-B would be located 0.2 mile to the south. The transmission line structures would be highly visible in the FG and extend above tree line. The form and scale would be much different than the existing landscape and create strong contrast combined with additional contrast created by the clearing of vegetation in the ROW. Strong contrast created by the Project in the FG distance zone for high sensitive residential viewers associated with this KOP would result in high viewer concern impacts. Overall visual impacts would also be high. This KOP represents views from a residential area, so visual concern is high and the overall visual impact would be high.

Little Lee Creek (Scenic River). Impacts would be similar to HVDC Alternative Route 4-A. See HVDC Alternative Route 4-A description.

Marble City. See description of Marble City KOP for HVDC Alternative Route 4-A. Distance and visibility are the same.

Mulberry River. HVDC Alternative Route 4-B, would be located 0.1 mile to the north. The transmission line structures would be highly visible on the banks of the river and as they cross over to the other side. This KOP represents views from a recreation area along a river, and the Project would appear in the near FG. The large vertical structures would be dominant in view, and combined with the vegetation being cleared for the ROW, there would be strong contrast. Strong contrast created by the Project in the FG distance zone for high sensitive recreation viewers associated with the river would result in high viewer concern impacts. Overall visual impacts would also be high.

Ozark. HVDC Alternative Route 4-B would be located 3.7 miles to the north and be screened by MG trees and rolling hills resulting in no visual impact.

Route 220 (Scenic Byway). HVDC Alternative Route 4-B would cross the Route 220 scenic highway less than 0.1 mile to the north. Large amounts of vegetation would need to be cleared for the ROW, resulting in straight lines cutting through the curves of the rolling hills and trees in the otherwise natural landscape. The transmission line structures would be larger in scale and form than anything in the vicinity (as described in Section 3.18.5.4.1) and dominate the views of motorists traveling the highway in this area. This KOP represents views from a Scenic Byway, and the Project would have strong visual contrast. Strong contrast created by the Project in the FG distance zone for high sensitive viewers associated with this travel route would result in high viewer concern impacts. Overall visual impacts would also be high. Since most viewers in this location would be traveling on the byway, views would be primarily of short duration.

Tenkiller State Park. See description of Tenkiller State Park KOP for Applicant Proposed Route Link 1. Distance and visibility are the same.

Trail of Tears (Highway 352). HVDC Alternative Route 4-B would cross Highway 352 and the Trail of Tears 0.1 mile to the northwest of this KOP. HVDC Alternative Route 4-B would cross the open field on the other side of the existing H-frame structures. The proposed transmission line structures would be larger in scale and considerably different in form than the existing and result in moderate contrast. Moderate contrast created by the Project in the immediate FG distance zone for high sensitive viewers associated with this travel route, would result in moderate-high viewer concern impacts. The overall visual impacts would be moderate-high.

Trail of Tears (Route 59). HVDC Alternative Route 4-B would be located 0.1 mile to the north and be highly visible to motorists traveling the route. The transmission line structures would introduce a vertical element different in form and scale to the existing structures in the area, and the clearing for the ROW would create strong lines in the dense vegetation, resulting in strong overall contrast. Strong contrast created by the Project in the FG distance zone for high sensitive recreational viewers associated with this scenic trail would result in high viewer concern impacts. Overall visual impacts would be high.

Vian. See HVDC Alternative Route 4-A description. Views are similar, but with a slightly longer distance (2.8 miles) to the transmission line structures.

White Oak. HVDC Alternative Route 4-B would be located 0.9 mile to the north of this KOP. The FG vegetation and terrain would screen any views of HVDC Alternative Route 4-B from this location, resulting in no visual impacts.

Wiederkehr Village and Highway 186. HVDC Alternative Route 4-B would be located 3.4 miles to the northwest of Wiederkehr Village. The upper portions of the transmission structures may be visible extending above the tree line and in front of the distant ridge line; however, the structures would be back-dropped by vegetation, which would help blend the transmission structures into the surrounding landscape. The visible portions of the transmission structures would be subordinate in the landscape, resulting in weak contrast. Because weak contrast would be created by the Project in the BG distance zone for high sensitive residential viewers associated with this KOP, viewer concern impacts would be low. Overall visual impacts would be low.

3.18.6.3.2.2.4.6 HVDC Alternative Route 4-B USFS SMS Compliance

HVDC Alternative Route 4-B was developed in response to comments received during scoping for the EIS for the Project. HVDC Alternative Route 4-B is 78.89 miles in length and located in Sequoyah County, Oklahoma, and Crawford and Franklin counties, Arkansas. Of this, 10.51 miles is within the Forest Service Administrative Boundary of the Ozark-St. Francis National Forest, in Crawford County, Arkansas; however, less than one-half of this length (4.19 miles) is on Ozark-St. Francis National Forest land within the Boston Mountains Ranger District. The remaining 6.32 miles is on private land holdings.

The USFS provided DOE with SIOs and the land management plan for the Ozark-St. Francis National Forest. No KOPs were chosen on USFS lands because no viewpoints were identified through consultation with the USFS or identified during the data collection field effort. For USFS lands, consistency with SIOs involves the comparison of existing landscape integrity with integrity that would occur with implementation of HVDC Alternative Route 4-B. Impacts to landscape scenery were determined by measuring the extent of effects of HVDC Alternative Route 4-B on the scenic landscape through USFS scenic attractiveness ratings, and scenic quality on private, state, and other federal lands. Impacts to viewers were determined by measuring the extent of effects of HVDC Alternative Route 4-B through USFS viewer concern levels and distances and viewer sensitivity levels. The intent of a Land and Resource Management Plan (LRMP) is to provide a framework for integrated resource management and for guiding all project and activity decision making on USFS lands.

The Ozark-St. Francis National Forests' LRMP divides the Ozark-St. Francis National Forest into management areas (MAs) (USFS 2005a). The purpose of these MAs is to identify allowable uses and opportunities within certain areas on the Ozark-St. Francis National Forest. HVDC Alternative Route4-B would cross the Pine Woodland and Oak Woodland MAs (see Figure 2, "Ozark National Forest Management Areas," from the Visual Resources Technical Report (Clean Line 2014; Appendix F).

Lands within these two MAs are primarily managed for timber production. The primary emphasis for both of these MAs is to restore and maintain a landscape mosaic of open woodland that approximates historical conditions. The common purpose for each MA is to provide habitat for associated plants and animals, and to create a setting for recreation that is different, uncommon, visually appealing, and rich in wildlife.

MA Standards are mandatory requirements that apply to site-specific activities such as the Project. There are no MA Standards for the Pine Woodland or Oak Woodland MAs that are relevant to the Project or potential effects on scenery resources.

Scenic Class 1 (Extremely High) Areas. HVDC Alternative Route 4-B crosses a total of 0.24 miles consisting of two small areas the Ozark-St. Francis National Forest inventoried and classified as having Extremely High public value associated with them. The first area occurs along HVDC Alternative Route 4-B approximately 0.35 mile southeast of where it crosses Route 220 (scenic highway). This is an area of uninterrupted forest and rolling terrain located within the Oak Woodland MA. No roads, trails, water, rock outcrops, or other distinctive landscape features are evident. Their scenic attractiveness is typical. The area is classified as Scenic Class 1 because it is within the FG view of the scenic highway and, consequently, also a high public concern area.

The second area occurs along HVDC Alternative Route 4-B approximately 0.38 mile west of where HVDC Alternative Route 4-B crosses Route 59. This is a densely forested area located within the Pine Woodland MA. No distinctive landscape features are evident. The area is classified as Scenic Class 1 because it is within the FG view of Route 59 and an area of high public concern because of its proximity to potential viewers.

With the introduction of Project elements, the landform, vegetation patterns, and cultural features would still combine to provide ordinary or common scenic quality in these areas. Because of the landscape's ability to absorb visual change (i.e., topography, tall trees, constrained views), the overall scenic attractiveness class would not change, so the total acreage of land classified as Scenic Class 1 would not be affected.

Scenic Class 2 (Very High) Areas. HVDC Alternative Route 4-B crosses a total of 2.01 miles consisting of several areas the Ozark-St. Francis National Forest inventoried and classified as having Very High public value. These areas are characterized by rolling terrain and forested areas within both the Oak and Pine Woodland MAs. A few unimproved roads or trails are evident. There are no distinctive landscape features. These areas are fairly homogenous, and their scenic attractiveness would be considered typical of this part of the Ozark-St. Francis National Forest. These areas are all classified as scenic Class 2 because they are within the FG view of secondary roads or rural residences adjacent to the Ozark-St. Francis National Forest.

With the introduction of Project elements, the landform, vegetation patterns, and cultural features would still combine to provide ordinary or common scenic quality in these areas. Because of the landscape's ability to absorb visual change, the overall scenic attractiveness class would not change and, therefore, the total acreage of land classified as Scenic Class 2 would not be affected.

Scenic Class 3 (High) Areas. HVDC Alternative Route 4-B crosses a total of 0.28 mile consisting of two small areas the Ozark-St. Francis National Forest inventoried and classified as having High public value. The areas occur along HVDC Alternative Route 4-B approximately 0.6 mile and 1 mile southeast of where it crosses Route 220 (scenic highway). These are typical forested areas located within the Oak Woodland MA. No roads, trails, water, rock outcrops, or other distinctive landscape features are evident. Their scenic attractiveness is typical. These areas are classified as Scenic Class 3 because they are within the MG view of the scenic highway as well as other secondary roads and are also of moderate public concern.

With the introduction of Project elements, the landform, vegetation patterns, and cultural features would still combine to provide ordinary or common scenic quality in these areas. Because of the landscape's ability to absorb visual change, the overall scenic attractiveness class would not change and, therefore, the total acreage of land classified as Scenic Class 3 would not be affected.

SIO Compliance. Transmission line structures and cleared ROWs would contrast with the landscape character in High, Moderate, and Low SIO areas. Gray-colored structures would extend above the tree line, disrupting the line of the landscape and introducing angular and coarse cultural (human) elements into an otherwise intact and natural-appearing setting. Cleared ROWs would create additional lines on the landscape that vary in terms of line, color, and texture from the surrounding visual landscape. These visual deviations would be most evident to viewers from a superior vantage point or areas where no vegetation was in the immediate FG. Due to their height, transmission line structures may be visible in these areas from Route 220 (scenic highway). Forest projects and activities should contribute to the achievement or attainment of desired conditions. The USFS desires for a certain percentage of projects occurring on NFS lands to meet the intended SIO as identified in the LRMP over the long term. Transmission lines cause visible disruption to the surrounding landscape from two primary actions:

- ROW clearing (visually disruptive through the removal of trees, shrubs, and ground cover, creation of unnatural openings, and abnormal vegetative edges)
- Installation of structures (utility structures typically oppose landscape forms because they are geometric, forceful, and large)

The landscape character for High SIO areas should appear unaltered and intact, and any deviations must "repeat the form, line, color, texture, and pattern common to the landscape character so completely and at such a scale that they are not evident" (USFS 2005b). Even with avoidance and minimization measures, the implementation of HVDC Alternative Route 4-B would not meet this standard and would degrade the Desired Condition for scenic resources described in the LRMP. Due to DOE Action Alternative resulting in high visual impacts HVDC Alternative Route 4-B would not comply with High SIOs. The HVDC Alternative Route 4-B would not be allowed to cross lands managed with non-complying objectives without changing the LRMP.

The landscape character for Moderate SIO areas may appear slightly altered, and deviations "must remain visually subordinate to the landscape character being viewed" (USFS 2005b). It may be possible, but is not likely, for Project elements to meet this standard in 100 percent of locations depending on the avoidance and minimization measures employed and local landscape conditions. With these measures, the implementation of HVDC Alternative Route 4-B would neither enhance nor degrade the Desired Condition for scenic resources described in the LRMP. Due to the DOE Alternative resulting in moderate–high and high visual impacts HVDC Alternative Route 4-B would not comply with Moderate SIOs.

The landscape character for Low SIO areas may appear moderately altered, and deviations may "begin to dominate the valued landscape character being viewed" provided they "borrow valued attributes such as size, shape, edge effect and pattern of natural openings, vegetative type changes, or architectural styles outside the landscape being viewed" (USFS 2005b). Project elements would meet this standard in 100 percent of locations depending on avoidance and minimization measures and local landscape conditions. With these measures, the implementation of HVDC Alternative Route 4-B would enhance the Desired Condition for scenic resources described in the LRMP. Due to the DOE Action Alternative resulting in moderate–high and high visual impacts, HVDC Alternative Route 4-B would comply with Low SIOs.

3.18.6.3.2.2.4.7 HVDC Alternative Route 4-C

HVDC Alternative Route 4-C corresponds to Applicant Proposed Route Link 5.

Field of Dreams. HVDC Alternative Route 4-C would be located 2.3 miles to the north of the Field of Dreams ball field. Dense trees in the FG would obscure views of the Project from this location, resulting in no visual impact.

Scott Farm. HVDC Alternative Route 4-C would be located 0.7 mile away in the FG. The large transmission line structures would be noticeable in view of the residences nearby and introduce a strong vertical element not present in the existing landscape (as described in Section 3.18.4.1). Portions of the structures would be screened by the rolling hills and tall vegetation, resulting in moderate contrast. Because moderate contrast would be created by the Project in the FG distance zone for high sensitive residential viewers associated with this KOP, viewer concern impacts would be moderate. Overall visual impacts would also be moderate. A visual simulation for this KOP is provided in Appendix K.

Van Buren. HVDC Alternative Route 4-C would be located 1.1 miles to the northeast of this KOP. Large trees and rolling terrain would obscure views of the transmission line structures from this location, resulting in no visual impact.

3.18.6.3.2.2.4.8 HVDC Alternative Route 4-D

HVDC Alternative Route 4-D corresponds to Applicant Proposed Route Links 4, 5 and 6.

Bluff Hole Park. See description of Bluff Hole Park KOP for HVDC Alternative Route 4-A. Distance and visibility are the same.

Boys and Girls Camp. See description of Boys and Girls Camp KOP for HVDC Alternative Route 4-A. Distance and visibility are the same.

Cedarville. HVDC Alternative Route 4-D would be located 0.8 mile to the southeast. Structures would be partially screened by FG vegetation and terrain, but the top portion would be clearly visible, extending above tree line. The addition of the proposed transmission line structures would introduce new vertical elements to the landscape and result in strong contrast. Because strong contrast would be created by the Project in the MG distance zone for high sensitive residential viewers represented by this KOP, viewer concern impacts would be moderate–high. Overall visual impacts are anticipated to be high because of the strong contrast introduced in the MG distance zone.

City Park/Ball Fields and Rudy. See description of Bluff Hole Park KOP for HVDC Alternative Route 4-A. Distance and visibility are the same.

Frog Bayou Creek. See description of Frog Bayou Creek KOP for HVDC Alternative Route 4-A. Distance and visibility are the same.

Mulberry River and Trail of Tears. See description of Mulberry River and Trail of Tears KOP for HVDC Alternative Route 4-A. Distance and visibility are the same.

Trail of Tears and Scenic Highway 220. HVDC Alternative Route 4-D would cross the highway about 0.1 mile to the southeast. The proposed transmission line structures would be much larger and different in form than existing elements on the landscape and be dominant in the view of people traveling the scenic highway. In addition to the structures, the ROW clearing would create strong lines in the landscape that would be highly visible from the roadway. This KOP represents views from the Trail of Tears and scenic highway, so visual concern is high and would result in strong visual contrast. Because strong contrast would be created by the Project in the FG distance zone for high sensitive viewers associated with this scenic travel route, viewer concern impacts would be high. Overall visual impacts would also be high. Because most viewers in this location would be traveling on the highway, views would primarily be of short duration.

Van Buren. See description of Van Buren KOP for Applicant Proposed Route Link 4. Distance and visibility are the same.

3.18.6.3.2.2.4.9 HVDC Alternative Route 4-E

HVDC Alternative Route 4-E corresponds to Applicant Proposed Route Links 8 and 6.

Clarksville. HVDC Alternative Route 4-E would be located 0.4 mile to the southeast of the Clarksville KOP, representing views from a residential area. The transmission line structures would be highly noticeable and visible across the open agricultural fields. The Project would introduce tall, vertical, geometric structures into a relatively rural and natural landscape, creating strong contrast. Strong contrast created by the Project in the FG/MG distance zone for high sensitive viewers associated with this scenic travel route would result in high viewer concern impacts. Overall visual contrast would be strong and HVDC Alternative Route 4-E would result in high overall visual impacts in this location.

Coal Hill. HVDC Alternative Route 4-E would be located 3.2 miles to the north and would not be visible due to rolling hills and dense vegetation. There would be no overall visual impact.

Hagarville. HVDC Alternative Route 4-E would be located 2.3 miles south. The transmission line structures of HVDC Alternative Route 4-E would not be visible from this location due to FG vegetation and terrain screening, resulting in no visual impact in this location.

Highway 21 Scenic Byway. HVDC Alternative Route 4-E would cross the highway approximately 0.4 mile to the south-southeast in the FG distance zone. The transmission line structures would be much greater in scale than the existing wood structures in view and introduce additional vertical elements into the landscape. The structures would be clearly visible above tree line across the highway, resulting in strong visual contrast. Strong contrast created by the Project in the FG distance zone for high sensitive viewers associated with this scenic travel route would result in high viewer concern impacts. Overall visual impacts would also be high. Because most viewers in this location would be traveling on the highway, views would be primarily of short duration.

Lamar. HVDC Alternative Route 4-E would be located 3.25 miles to the north of this KOP, but would not be visible due to FG vegetation and terrain, resulting in no visual impact.

Ozark. See description of Ozark KOP for HVDC Alternative Route 4-B. Distance and visibility are the same.

Wiederkehr Village and Highway 186. HVDC Alternative Route 4-E would be located 0.6 mile to the northwest. The transmission line structures may be partially visible from this location and, if so, would appear as small dark vertical elements appearing above tree line on the horizon, resulting in weak visual contrast. At this distance, weak contrast created by the Project in the MG distance zone for high sensitive residential viewers associated with this KOP would result in low viewer concern impacts. Overall visual impacts would be low.

3.18.6.3.2.2.4.10 Region 4 Alternative Comparison

Table 3.18-23 provides a comparison of the visual impacts for Region 4.

Table 3.18-23:
Visual Impact Comparison Summary—Region 4

Proposed and Alternative Routes	Miles of Distinct Lands Crossed	Miles of Common Lands Crossed	Miles of Developed Lands Crossed	Residences within 0.5 mile
HVDC Alternative Route 4-A	10.2	17.7	30.6	1,030
APR Links Corresponding to Alternative 4-A	11.6	47.3	1.7	1,039
HVDC Alternative Route4-B	19.6	15.1	44.2	1,094
APR Links Corresponding to Alternative 4-B	15.8	58.3	7.4	1,735
HVDC Alternative Route4-C	1.4	1.9	0.1	278
APR Links Corresponding to Alternative 4-C	0.9	1.2	0.1	123
HVDC Alternative Route 4-D	4.9	10.6	9.9	882
APR Links Corresponding to Alternative 4-D	3.8	20.4	1.2	719
HVDC Alternative Route 4-E	11.0	24.6	1.2	901
APR Links Corresponding to Alternative 4-E	7.6	11.0	20.3	527

HVDC Alternative Route 4-A. Visual impact to public, private, and state lands resulting from the operations and maintenance of HVDC Alternative Route 4-A is anticipated to be mostly moderate–high; higher impacts would be associated with Little Lee Creek, Mulberry River, and Frog Bayou Creek. The majority of the area that would be crossed by HVDC Alternative 4-A is flat to rolling terrain with dispersed residential areas. There are approximately 1,030 residences within 0.5 mile of the alignment of this alternative route. HVDC Alternative Route 4-A would cross fewer lands classified as Distinct (10.2 miles) and Common (17.7 miles) than the corresponding links of the Applicant Proposed Route, which cross 11.6 miles of lands classified as Distinct 47.3 miles of lands classified as Common.

HVDC Alternative Route 4-B. Visual impact to public, private, and state lands resulting from the operations and maintenance of HVDC Alternative Route 4-B is anticipated to be mostly high and are associated with Little Lee Creek and Mulberry River. The majority of the area that would be crossed by HVDC Alternative Route 4-B is flat to rolling terrain with dispersed residential areas. There are approximately 1,094 residences within 0.5 mile of the alignment of this alternative route, which would be less than the corresponding links of the Applicant Proposed Route (1,735 residences within 0.5 mile of the alignment).

HVDC Alternative Route 4-C. Visual impact to public, private, and state lands resulting from the operations and maintenance of HVDC Alternative Route 4-C is anticipated to be mostly moderate–low because towns and scattered residences are present. The majority of the area that would be crossed by HVDC Alternative Route 4-C is flat to rolling terrain with dispersed residential areas. There are approximately 278 residences within 0.5 mile of the alignment of this alternative route, the least of any of the other HVDC alternative routes. HVDC Alternative Route 4-C crosses more lands classified as Distinct (1.4 miles) and Common (1.9 miles) than the corresponding links of the Applicant Proposed Route, which cross 0.9 mile of lands classified as Distinct and 1.2 miles classified as Common.

HVDC Alternative Route 4-D. Visual impact to public, private, and state lands resulting from the operations and maintenance of HVDC Alternative Route 4-D is anticipated to be mostly high because of the abundance of sensitive sites such as Mulberry River, Frog Bayou Creek, and the Trail of Tears. The majority of the area that would be crossed by HVDC Alternative 4-D is flat to rolling terrain with dispersed residential areas. There are approximately 882 residences within 0.5 mile of the alignment of this alternative route, more than the corresponding links of the Applicant Proposed Route, in which there are 719 residences within 0.5 of the alignment. HVDC Alternative Route 4-D crosses more lands classified as Distinct (4.9 miles), but fewer land classified as Common (10.6 miles) than the corresponding links of the Applicant Proposed Route, which cross 3.8 miles of lands classified as Distinct and 20.4 miles of lands classified as Common.

HVDC Alternative Route 4-E. Visual impact to public, private, and state lands resulting from the operations and maintenance of HVDC Alternative Route 4-E is anticipated to be mostly moderate due to scattered residences and towns as well as Highway 21, a scenic byway. The majority of the area that would be crossed by HVDC Alternative 4-E is flat to rolling terrain with dispersed residential areas. There are approximately 901 residences within 0.5 mile of the alignment of this alternative route, more than the corresponding links of the Applicant Proposed Route, in which there are 527 residences within 0.5 mile of the alignment. HVDC Alternative Route 4-E crosses 11.0 miles of lands classified as Distinct and 24.6 miles of lands classified as Common, which is more than the corresponding Applicant Proposed Route links which crosses 7.6 miles of lands classified as Distinct and 11.0 miles classified as Common.

3.18.6.3.2.2.5 Region 5

A description for Region 5 is provided in Section 3.18.6.2.3.2.7. This region would have residential viewers as well as several parks and recreational areas where viewers would be more sensitive due to extended viewing periods at these resources. The visual impacts for the Region 5 KOPs are listed in Table 3.18-24 and described below.

Table 3.18-24:
Visual Impact Summary of KOPs—HVDC Alternative Routes—Region 5

KOP	AR	Distance (Miles)	Viewer Concern	Landscape Category	Visibility	Viewer Concern Impact	Contrast	Overall Impact
Dover and JP Lovelady Ball Park	5-A	3.2	High	Common	No	None	No Contrast/ Not Visible	No Impact
Hector	5-A	3	High	Common	No	None	No Contrast/ Not Visible	No Impact
Highway 7 (Scenic Byway)	5-A	0.1	High	Common	Yes	High	Strong	High
Pope Co. Residential Cluster	5-A	0.8	High	Distinct	Yes	Low	Weak	Moderate–Low
Boy Scout Campground	5-B	2.1	High	Common	No	None	No Contrast/ Not Visible	No Impact
Damascus	5-B	1.5	High	Common	No	None	No Contrast/ Not Visible	No Impact

Table 3.18-24:
Visual Impact Summary of KOPs—HVDC Alternative Routes—Region 5

KOP	AR	Distance (Miles)	Viewer Concern	Landscape Category	Visibility	Viewer Concern Impact	Contrast	Overall Impact
Highway 9 Scenic Highway	5-B	0.5	High	Common	Yes	Moderate–High	Strong	High
Twin Groves	5-B	0.1	High	Common	Yes	High	Strong	High
Wonderview School	5-B	0.7	High	Common	Yes	Moderate	Moderate	Moderate
Guy	5-B, 5-E	3	High	Common	No	None	No Contrast/ Not Visible	No Impact
Highway 25 Scenic Highway	5-B, 5-E	0.1	High	Common	Yes	High	Strong	High
Quitman	5-B, 5-E	1.4	High	Common	Yes	Low	Weak	Low
Highway 16 (Scenic Highway)	5-B, 5-E, 5-F	0.2	High	Common	Yes	High	Strong	High
Rose Bud City Park	5-B, 5-E, 5-F	2.1	High	Developed	No	None	No Contrast/ Not Visible	No Impact
Highway 16 (Scenic Highway)	5-C	0.3	High	Common	Yes	High	Strong	High
Steprock	5-C	0.4	High	Developed	Yes	Moderate	Weak	Moderate–Low
White River	5-D	1	Moderate	Distinct	Yes	Moderate–High	Strong	High

3.18.6.3.2.2.5.1 HVDC Alternative Route 5-A

HVDC Alternative Route 5-A corresponds to Applicant Proposed Route Link 1.

Dover and JP Lovelady Ball Park. See the Applicant Proposed Route Link 1 description. HVDC Alternative Route 5-A would be located 3.2 miles to the north-northwest.

Hector. HVDC Alternative Route 5-A would be located 3 miles to the south. Dense vegetation in the FG/MG would screen all views of the alternative route at this location, resulting in no visual impact.

Highway 7 (Scenic Byway). HVDC Alternative Route 5-A would be located 0.1 mile north in the FG of this view. Motorists would clearly see the structures as they travel the Scenic Byway, and at this distance, the structures would be a dominant element on the landscape. HVDC Alternative Route 5-A would also require vegetation clearing for the ROW in this area and would be visible from the Scenic Byway, appearing as strong lines in the vegetation. The visual concern is high because it represents views from a Scenic Byway and the overall visual contrast at this location would be strong. Strong contrast created by the Project in the FG distance zone for high sensitive residential viewers associated with this KOP would result in high viewer concern impacts. Given strong contrast introduced into the landscape for high sensitive residential viewers in the FG distance zone, overall visual impacts at this KOP would be high.

Pope County Residential Cluster. See description of Pope County Residential Cluster for Applicant Proposed Route Link 1. Distance and visibility are the same.

3.18.6.3.2.2.5.2 HVDC Alternative Route 5-B

HVDC Alternative Route 5-B corresponds to Applicant Proposed Route Links 3, 4, 5 and 6.

As described in Appendix M and summarized in Section 2.4.2.5, a route adjustment was developed for HVDC Alternative Route 5-B to maintain an end-to-end route with Applicant Proposed Route Links 2 and 3, Variation 1. Alternative Route 5-B route adjustment would shift the route west to connect with the modified Applicant Proposed Route. The route adjustment would be located within approximately 400 feet of the original HVDC Alternative Route 5-B alignment and would be located farther from some high sensitive residential viewers. Overall, visual impacts would be reduced for residential viewers because less of the structures would be visible extending above the tree line because of the increased distance.

Boy Scout Campground. HVDC Alternative Route 5-B would be located 2.1 miles to the south of the Boy Scout Campground. Dense vegetation in the FG would screen all views of HVDC Alternative Route 5-B in this location, resulting in no visual impact.

Damascus. HVDC Alternative Route 5-B would be located 1.5 miles to the south, but views would be screened by FG vegetation and terrain, resulting in no visual impact.

Guy. HVDC Alternative Route 5-B would be located 3.0 miles to the north. The rising terrain and dense vegetation in the FG would screen all views of HVDC Alternative Route 5-B in this location, resulting in no visual impact. A visual simulation for this KOP is provided in Appendix K.

Highway 9 Scenic Highway. HVDC Alternative Route 5-B would cross Highway 9, 0.5 mile to the south The structures would be highly visible as motorists approach the highway crossing and they would differ noticeably in scale, form, and line, than existing elements on the landscape (as described in Section 3.18.5.4.1). ROW vegetation would be noticeable along the sides of the highway, creating additional contrast. Strong contrast created by the Project in the MG distance zone for high sensitive recreational viewers associated with this KOP would result in moderate–high viewer concern impacts. Given the strong contrast introduced into the landscape for high sensitive recreational viewers in the MG distance zone, overall visual impacts at this KOP would be high.

Highway 16 Scenic Highway. HVDC Alternative Route 5-B would be located 0.2 mile away and be highly visible on the landscape. Transmission line structures would be seen crossing the open field in front of a line of trees in the FG. Because of their scale, the structures would be highly visible to motorists, extending above the trees and creating a dominant feature on the landscape. HVDC Alternative Route 5-B would introduce form and line to the landscape that is not currently present at this location, resulting in strong contrast. Strong contrast created by the Project in the FG distance zone for high sensitive viewers associated with this scenic highway would result in high viewer concern impacts. Overall impacts would be high.

Highway 25 Scenic Highway. HVDC Alternative Route 5-B would be visible on the landscape 0.1 mile to the south of this KOP. The tall vertical structures would create a repeating pattern different in form and scale than existing elements on the landscape. HVDC Alternative Route 5-B would be dominant in view when motorists traveled along Highway 25 in this location, and ROW clearing would become evident as motorists approached the highway crossing. The visual concern is high because it represents views from a scenic highway and the resulting contrast would be strong. Strong contrast created by the Project in the FG distance zone for high sensitive recreational viewers associated with this KOP would result in high viewer concern impacts. Given the strong contrast introduced into the landscape for high sensitive recreational viewers in the FG distance zone, overall visual impacts at this KOP would be high.

Quitman. HVDC Alternative Route 5-B would be located 1.4 miles to the south. Dense vegetation in the FG would screen much of transmission line structures from view, but some structures may be visible extending above the tree line. The visible structures would appear as small dark objects that would add to the already irregular line of trees on the horizon, resulting in weak contrast. Weak contrast created by the Project in the MG distance zone for high sensitive residential viewers associated with this KOP would result in low viewer concern impacts. Given the weak contrast introduced into the landscape for high sensitive residential viewers in the MG distance zone, overall visual impacts at this KOP would be low. A visual simulation for this KOP is provided in Appendix K.

Rose Bud City Park. HVDC Alternative Route 5-B would be located 2.1 miles to the north of Rose Bud City Park, but any potential views of the transmission line structures in this location would be screened by FG terrain and vegetation, resulting in no visual impact.

Twin Groves. HVDC Alternative Route 5-B would be located 0.1 mile to the northwest. Dense trees line the road in this area, but the transmission line structures would be visible through the trees and extend above the trees. The form and line of HVDC Alternative Route 5-B would be noticeably different than anything in the area and would result in strong contrast. Strong contrast created by the Project in the FG distance zone for high sensitive residential viewers associated with this KOP would result in high viewer concern impacts. Overall visual impacts at this KOP would be high.

Wonderview School. HVDC Alternative Route 5-B would be visible as it crosses the highway 0.7 mile to the south and the structures would be visible extending about trees. The vegetation in the FG and MG would absorb some of the impact and the overall contrast would be moderate. Moderate contrast created by the Project in the MG distance zone for high sensitive residential viewers associated with this KOP would result in moderate viewer concern impacts. Overall visual impacts at this KOP would be moderate.

3.18.6.3.2.2.5.3 HVDC Alternative Route 5-C

HVDC Alternative Route 5-C corresponds to Applicant Proposed Route Links 6 and 7.

Highway 16 Scenic Highway. HVDC Alternative Route 5-C would cross Scenic Highway 16, 0.3 mile to the southeast. Transmission line structures would be clearly visible and noticeable across the open field in the FG and extended above tree line introducing new, vertical elements to the landscape. Because of the scale of the structures, at this distance they would be a dominant form on the landscape and result in strong contrast. Strong contrast created by the Project in the FG distance zone for high sensitive viewers associated with this scenic highway would result in high viewer concern impacts. Given the strong contrast introduced into the landscape for high sensitive viewers in the FG distance zone, overall visual impacts at this KOP would be high.

Steprock. See the Applicant Proposed Route Link 7 description.

3.18.6.3.2.2.5.4 HVDC Alternative Route 5-D

HVDC Alternative Route 5-D corresponds to Applicant Proposed Route Link 9.

White River. HVDC Alternative Route5-D transmission line would be located 1 mile to the northeast. The structures on either side of the river would be visible, extending above tree line, and the conductors would be seen stretching across the river. Some vegetation clearing for the ROW may also be visible on the banks. This KOP represents views from a major waterbody, but potential viewers are low, so visual concern is moderate. HVDC Alternative Route 5-D would introduce large vertical structures to a very natural landscape and result in strong contrast. Strong contrast created by the Project in the MG distance zone for high sensitive recreational viewers associated with this KOP would result in moderate–high viewer concern impacts. Given the strong contrast introduced into the landscape for high sensitive recreational viewers in the MG distance zone, overall visual impacts at this KOP would be high.

3.18.6.3.2.2.5.5 HVDC Alternative Route 5-E

HVDC Alternative Route 5-E corresponds to Applicant Proposed Route Links 4, 5 and 6.

As described in Appendix M and summarized in Section 2.4.2.5, a route adjustment was developed for HVDC Alternative Route 5-E to maintain an end-to-end route with Applicant Proposed Route Links 3 and 4, Variation 2. The route adjustment would shift the route west to connect with the variation of the Applicant Proposed Route. The route adjustment would be located within approximately 700 feet of the original HVDC Alternative Route 5-B alignment and would be located farther from some high sensitive residential viewers. Overall, visual impacts would be reduced for residential viewers because less of the structures would be visible extending above the tree line because of the increased distance.

Guy. See description of Guy KOP for Alternative Route 5-B. Distance and visibility are the same.

Highway 16 Scenic Highway. See description of Highway 16 Scenic Highway KOP for HVDC Alternative Route 5-B. Distance and visibility are the same.

Highway 25 Scenic Highway. See description of Highway 25 Scenic Highway KOP for HVDC Alternative Route 5-B. Distance and visibility are the same.

Quitman. See description of Quitman KOP for HVDC Alternative Route 5-B. Distance and visibility are the same.

Rose Bud City Park. See description of Rose Bud City Park KOP for HVDC Alternative Route 5-B. Distance and visibility are the same.

3.18.6.3.2.2.5.6 HVDC Alternative Route 5-F

HVDC Alternative Route 5-F corresponds to Applicant Proposed Route Links 5 and 6.

Highway 16 Scenic Highway. See description of Highway 16 Scenic Highway KOP for HVDC Alternative Route 5-B. Distance and visibility are the same.

Rose Bud City Park. See description of Rose Bud City Park KOP for HVDC Alternative Route 5-B. Distance and visibility are the same.

3.18.6.3.2.2.5.7 Region 5 Alternative Comparison

Table 3.18-25 provides a comparison of the visual impacts for Region 5.

Table 3.18-25:
Visual Impact Comparison Summary—Region 5

Proposed and Alternative Routes	Miles of Distinct Lands Crossed	Miles of Common Lands Crossed	Miles of Developed Lands Crossed	Residences within 0.5 mile
HVDC Alternative Route 5-A	7.6	4.9	0.2	165
APR Links Corresponding to Alternative 5-A	7.9	4.3	0.2	136
HVDC Alternative Route5-B	12.2	57.2	1.8	975
APR Links Corresponding to Alternative 5-B	16.7	48.5	2.3	868
HVDC Alternative Route5-C	1.1	7.8	0.3	221
APR Links Corresponding to Alternative 5-C	1.5	7.6	0.3	175
HVDC Alternative Route5-D	3.8	17	1	382
APR Links Corresponding to Alternative 5-D	1.5	17.4	1.7	305
HVDC Alternative Route5-E	4.9	30.6	0.9	421
APR Links Corresponding to Alternative 5-E	5.2	26.6	1.4	578
HVDC Alternative Route5-F	3.0	18.7	0.6	239
APR Links Corresponding to Alternative 5-F	4.1	13.9	0.9	328

HVDC Alternative Route 5-A. Visual impact to public, private, and state lands resulting from the operations and maintenance of HVDC Alternative Route 5-A is anticipated to be mostly moderate with higher impacts associated with Highway 7 Scenic Byway. The majority of the area that would be crossed by HVDC Alternative Route 5-A is flat to rolling terrain with dispersed residential areas. There are approximately 165 residences within 0.5 mile of the alignment of this alternative route. The transmission line structures would cross slightly fewer lands classified as Distinct (7.6 miles) but more lands classified as Common (4.9 miles) than the corresponding links of the Applicant Proposed Route, which would cross 7.9 miles of lands classified as Distinct and 4.3 miles of lands classified as Common.

HVDC Alternative Route 5-B. Visual impact to public, private, and state lands resulting from the operations and maintenance of HVDC Alternative Route 5-B is anticipated to be mostly moderate–high and are associated with scattered residences and scenic highways. The majority of the area that would be crossed by HVDC Alternative 5-B is flat to rolling terrain with dispersed residential areas. There are approximately 975 residences within 0.5 mile of the alignment of this alternative route, fewer than in the corresponding links of the Applicant Proposed Route (868 residences within 0.5 mile of the alignment), but more than any other HVDC alternative route. HVDC Alternative Route 5-B crosses fewer lands classified as Distinct (12.2 miles) and lands classified as Common (57.2) than the corresponding links of the Applicant Proposed Route, which cross 16.7 miles of lands classified as Distinct and 48.5 miles of lands classified as Common.

HVDC Alternative Route 5-C. Visual impact to public, private, and state lands resulting from the operations and maintenance of HVDC Alternative Route 5-C is anticipated to be mostly moderate with higher visual impacts associated with Scenic Highway 16. The majority of the area that would be crossed by HVDC Alternative Route 5-C is flat to rolling terrain with dispersed residential areas. There are approximately 221 residences within 0.5 mile of the alignment of this alternative route, the least of any of the other HVDC alternative routes with the exception of HVDC Alternative 5-A. HVDC Alternative 5-C crosses fewer lands classified as Distinct (1.1 miles) than the corresponding links of the Applicant Proposed Route, HVDC Alternative Route 5-A, or Alternative Route 5-B. HVDC Alternative 5-C would also cross slightly more lands classified as Common (7.8 miles) than the corresponding links of the Applicant Proposed Route, which cross 7.6 miles of lands classified as Common.

HVDC Alternative Route 5-D. Visual impact to public, private, and state lands resulting from the operations and maintenance of HVDC Alternative Route 5-D is anticipated to be mostly high because of the abundance of sensitive sites like the White River as well as scattered residences and towns. The majority of the area that would be crossed by HVDC Alternative Route 5-D is flat to rolling terrain with dispersed residential areas. There are approximately 382 residences within 0.5 mile of the alignment of this alternative route, which is more than the corresponding links of the Applicant Proposed Route, in which there are 305 residences within 0.5 mile of the alignment). HVDC Alternative Route 5-D crosses fewer lands classified as Distinct (3.8 miles) than HVDC Alternative Routes 5-A or 5-B (7.6 miles and 12.2 miles, respectively). HVDC Alternative 5-C would still cross the least amount of land classified as Distinct. HVDC Alternative 5-D would cross slightly fewer lands classified as Common (17.0 miles), compared with the corresponding links of the Applicant Proposed Route, which cross 17.4 miles of land classified as Common.

HVDC Alternative Route 5-E. Visual impact to public, private, and state lands resulting from the operations and maintenance of HVDC Alternative Route 5-E is anticipated to be mostly moderate because of scattered residences and towns as well as scenic highways. The majority of the area that would be crossed by HVDC Alternative Route 5-E is flat to rolling terrain with dispersed residential areas. There are approximately 421 residences within 0.5 mile of the alignment of this alternative route. HVDC Alternative Route 5-E crosses 4.9 miles of lands classified as Distinct and 30.6 miles of land classified as Common. HVDC Alternative Route 5-E would cross fewer lands classified as Distinct than the corresponding links of the Applicant Proposed Route (5.2 miles), but more lands classified as Common (26.6 miles).

HVDC Alternative Route 5-F. Visual impact to public, private, and state lands resulting from the operations and maintenance of HVDC Alternative Route 5-F is anticipated to be mostly moderate because of scattered residences and towns as well as scenic highways. The majority of the area that would be crossed by HVDC Alternative Route 5-F is flat to rolling terrain with dispersed residential areas. There are approximately 239 residences within 0.5 mile of the alignment of this alternative route. HVDC Alternative Route 5-F crosses 3.0 miles of lands classified as Distinct and 19.7 miles of lands classified as Common. HVDC Alternative Route 5-F would cross fewer lands classified as Distinct than the corresponding links of the Applicant Proposed Route, HVDC Alternative Route 5-A, HVDC Alternative Route 5-B, HVDC Alternative Route 5-D, or HVDC Alternative Route 5-E but more than HVDC Alternative Route 5-C.

3.18.6.3.2.2.6 Region 6

A description for Region 6 is provided in Section 3.18.6.2.3.2.11. Rural residences and small towns would make up majority of the sensitive viewers in this location and the areas of flat, agricultural lands would increase the viewing distance in many of these areas. The visual impacts for the Region 6 KOPs are listed in Table 3.18-26 and described below.

Table 3.18-26:
Visual Impact Summary of KOPs—HVDC Alternative Routes—Region 6

KOP	AR	Distance (Miles)	Viewer Concern	Landscape Category	Visibility	Viewer Concern Impact	Contrast	Overall Impact
Fisher and Park	6-A	0.5	High	Developed	Yes	High	Strong	Moderate–High
Weldon	6-A	2.8	High	Common	Yes	Low	Weak	Low
Amagon	6-B	0.2/0.4	High	Developed	Yes	Moderate–High	Moderate	Moderate
Highway 14 Scenic Highway	6-B	0.3	High	Common	Yes	High	Strong	High
Crowley's Ridge Byway	6-C	0.2	High	Common	Yes	High	Strong	High
Crowley's Ridge Byway	6-D	2.8	High	Common	Yes	Low	Low	Low

3.18.6.3.2.2.6.1 HVDC Alternative Route 6-A

HVDC Alternative Route 6-A corresponds to Applicant Proposed Route Links 2, 3, and 4.

As described in Appendix M and summarized in Section 2.4.2.6, a route adjustment was developed for HVDC Alternative Route 6-A to maintain an end-to-end route with Applicant Proposed Route Link 2, Variation 1. The Applicant Proposed Route Link 2, Variation 1, includes extending the route east by the same length that the route variation is reduced; therefore, no changes to visual impacts are anticipated as a result of the route adjustment.

Fisher and Park. HVDC Alternative Route 6-A would be visible in the open field 0.5 mile to the south. The structures would be a dominate feature on the landscape and would add a pattern of vertical structures with larger form than existing vertical elements. Although portions of the transmission line may be screened by development and vegetation in the FG distance zone, contrast would be strong because of the distance of the structures. Strong contrast created by the Project in the FG distance zone for high sensitive residential viewers associated with this KOP would result in high viewer concern impacts. Overall visual impacts would be moderate-high.

Weldon. HVDC Alternative Route 6-A would be located 2.8 miles to the northeast. The flat open landscape would allow for multiple visible transmission-line structures, but at a distance of 2.8 miles, they would appear as a row of dark vertical elements and would be co-dominant with the existing structures on the landscape; therefore, contrast is weak. Weak contrast created by the Project in the MG distance zone for high sensitive residential viewers associated with this KOP would result in low viewer concern impacts. At this distance, and given the presence of existing transmission line structures, the overall visual impacts would be low.

3.18.6.3.2.2.6.2 HVDC Alternative Route 6-B

HVDC Alternative Route 6-B corresponds to Applicant Proposed Route Link 3.

Amagon. HVDC Alternative Route 6-B would be located 0.2 mile to the south/southwest, running parallel to the existing H-frame structures and 161kV transmission line near the community represented by this KOP. This KOP represents views from a residential area and the visual concern is high. The proposed transmission line structures would be considerably larger and different in form than the existing structures, making them visible above tree line and resulting moderate contrast. Moderate contrast created by the Project in the FG distance zone for high sensitive residential viewers associated with this KOP would be moderate–high. Given the presence of existing transmission structures in the landscape and the screening provided by development and vegetation, overall impacts are anticipated to be moderate.

Highway 14 Scenic Highway. HVDC Alternative Route 6-B would cross Highway 14 0.3 mile from this location and then run parallel to the roadway. This is a flat and open landscape and the transmission line structures would be dominant features in the FG where they cross the highway and then continue as a dominant element as they follow the road into the distance. This KOP represents views from a scenic highway, so visual concern is high. Strong contrast created by the Project in the immediate FG for high sensitive viewers represented by this scenic travel route would result in high viewer concern impacts. HVDC Alternative Route 6-B would result in high overall visual impact in this location. A visual simulation for this KOP is provided in Appendix K.

3.18.6.3.2.2.6.3 HVDC Alternative Route 6-C

HVDC Alternative Route 6-C corresponds to Applicant Proposed Route Links 3, 4 and 5.

Crowley's Ridge Scenic Byway. HVDC Alternative Route 6-C would be located 0.2 mile to the southeast, crossing the open field and Scenic Byway. Structures would be dominant features on the landscape and motorists traveling the Scenic Byway would have unobstructed views. The transmission line structures would attract attention as large vertical elements on an open landscape and result in strong visual contrast. Strong contrast created by the Project in the immediate FG for high sensitive viewers represented by this scenic travel route would result in high viewer concern impacts. Since this KOP represents views from a Scenic Byway, visual concern is high and the overall visual impact would be high at this location.

3.18.6.3.2.2.6.4 HVDC Alternative Route 6-D

HVDC Alternative Route 6-D corresponds to Applicant Proposed Route Link 7.

Crowley's Ridge Scenic Byway. HVDC Alternative Route 6-D would be located 2.8 miles southwest of this KOP in the MG distance zone. The transmission structures would mostly be screened by vegetation along the highway or along agricultural fields in the FG and MG distance zones. Where the transmission line is visible from along the highway, it would be back-dropped by vegetation in the BG distance zone and the structures would blend into the surrounding landscape. Since the transmission line would either be screened or appear subordinate in the landscape, contrast would be weak. Weak contrast created by the Project in the MG distance zone for high sensitive viewers associated with this scenic travel route would result in low viewer concern impacts. In addition, since the Project would be a subordinate feature where visible in a Common landscape, impacts to landscape scenery would be moderate–low. Overall visual impacts are anticipated to be low.

3.18.6.3.2.2.6.5 Region 6 Alternative Comparison

Table 3.18-27 provides a comparison of the visual impacts for Region 6.

Table 3.18-27:
Visual Impact Comparison Summary—Region 6

Proposed and Alternative Routes	Miles of Distinct Lands Crossed	Miles of Common Lands Crossed	Miles of Developed Lands Crossed	Residences within 0.5 mile
HVDC Alternative Route 6-A	0.1	15.3	0.9	45
APR Links Corresponding to Alternative 6-A	0.1	16.9	0.8	64
HVDC Alternative Route 6-B	0	13.3	0.8	141

Table 3.18-27:
Visual Impact Comparison Summary—Region 6

Proposed and Alternative Routes	Miles of Distinct Lands Crossed	Miles of Common Lands Crossed	Miles of Developed Lands Crossed	Residences within 0.5 mile
APR Links Corresponding to Alternative 6-B	0.1	9.3	0.3	24
HVDC Alternative Route 6-C	2.7	19.9	0.6	66
APR Links Corresponding to Alternative 6-C	3.9	20.5	0.53	66
HVDC Alternative Route 6-D	0.3	8.8	0.1	5
APR Links Corresponding to Alternative 6-D	0.2	8.1	0.2	0

HVDC Alternative Route 6-A. Visual impact to public, private, and state lands resulting from the operations and maintenance of HVDC Alternative Route 6-A is anticipated to be mostly moderate with towns and residences being the primary sensitive viewers. HVDC Alternative Route 6-A crosses almost entirely rural agricultural land with the exception of the Cache River crossing, but the area crossed does not have sensitive viewers associated with it. Similar to the corresponding links of the Applicant Proposed Route, HVDC Alternative Route 6-A crosses almost entirely lands classified as Common (15.3 miles) with very small lengths of lands classified as Distinct and Developed. The total number of residences within 0.5 mile with potential visual impacts is 45, compared to 64 residences within 0.5 mile of the corresponding links of the Applicant Proposed Route.

HVDC Alternative Route 6-B. Visual impact to public, private, and state lands resulting from the operations and maintenance of HVDC Alternative Route 6-B is anticipated to be mostly moderate–high with the majority of sensitive viewers being residences. The HVDC Alternative Route 6-B crosses almost entirely rural agricultural land except at the Cache River crossing, but the area crossed does not have sensitive viewers associated with it. Throughout the length of the HVDC Alternative Route 6-B, 141 residences are within 0.5 mile of the route, compared to only 24 with the corresponding links of the Applicant Proposed Route.

HVDC Alternative Route 6-C. Visual impact to public, private, and state lands resulting from the operations and maintenance of HVDC Alternative Route 6-C is anticipated to be mostly low as it crosses through the rural agricultural lands, but it would have high impacts in the Crowley's Ridge region. HVDC Alternative Route 6-C would cross 2.7 miles of lands classified as Distinct compared to 3.9 miles with the corresponding links of the Applicant Proposed Route; both would be within 0.5 mile of 66 residences.

HVDC Alternative Route 6-D. Visual impact to public, private, and state lands resulting from the operations and maintenance of HVDC Alternative Route 6-C is anticipated to be mostly low. The alternative would cross a rural agricultural landscape, but it would cross 0.3 mile of lands classified as Distinct compared to the corresponding links of the Applicant Proposed Route that only cross lands classified as Common and Developed. The area has low numbers of sensitive resources and the majority of viewers would be residences. The total residences within 0.5 mile of HVDC Alternative Route 6-D would be 5 compared to 38 in the corresponding links of the Applicant Proposed Route.

3.18.6.3.2.2.7 Region 7

A description for Region 7 is provided in Section 3.18.6.2.3.2.11. As the Project moves east, there would be areas of higher population and correspondingly higher amounts of sensitive residential viewers, although the more developed areas have more structures and vertical elements that would offer a higher level of screening and reduce the viewing distance for many of the sensitive viewing areas. The visual impacts for the Region 7 KOPs are listed in Table 3.18-28 and described below.

Table 3.18-28:
Visual Impact Summary of KOPs—HVDC Alternative Routes—Region 7

KOP	AR	Distance (Miles)	Viewer Concern	Landscape Category	Visibility	Viewer Concern Impact	Contrast	Overall Impact
Dyess	7-A	2.6	High	Common	Yes	Low	Weak	Low
Johnny Cash Home	7-A	3.5	High	Common	Yes	Low	Weak	Low
Lower Hatchie NWR	7-A	4.7	High	Distinct	No	Low	No Contrast/ Not visible	No Impact
Marked Tree AR	7-A	1	High	Developed	Yes	Low	Weak	Low
McGavock-Grider Park	7-A	1.8	High	Common	Yes	Low	Weak	Low
Mississippi River and Trail of Tears	7-A	0.3	High	Distinct	Yes	High	Strong	High
Tyronza	7-A	2.4	High	Common	Yes	Low	Weak	Low
Wilson Park	7-A	1.8	High	Common	Yes	Low	Weak	Low
Harold Park and Millington	7-B	2	High	Developed	No	Low	No Contrast/ Not visible	No Impact
Wilkinsville	7-B	0.7	High	Common	Yes	Moderate–High	Strong	Moderate–High
Atoka	7-C	0.7	High	Common	No	Low	No Contrast/ Not visible	No Impact
Aycock Park and Millington	7-C	0.2	High	Developed	Yes	Moderate–High	Moderate	Moderate
Harold Park and Millington	7-C	0.6	High	Developed	Yes	Moderate	Moderate	Moderate–Low
Millington East	7-C	0.3	High	Common	Yes	Moderate–High	Moderate	Moderate–High
Millington USA Baseball Stadium	7-C	0.5	High	Developed	Yes	Low	Weak	Low
Rockyford Park	7-C	2.9	High	Developed	No	Low	No Contrast/ Not visible	No Impact
Edmund Orgill Park	7-C, 7-B, 7-D	1.7	High	Distinct	No	Low	No Contrast/ Not visible	No Impact
Atoka	7-D	0.2	High	Common	Yes	High	Strong	High
Atoka Community Park	7-D	3.2	High	Developed	No	Low	No Contrast/ Not visible	No Impact
Munford	7-D	0.4	High	Developed	Yes	Moderate	Weak	Moderate–Low
Rhodes Estates	7-D	0.6	High	Developed	Yes	Low	Weak	Low

3.18.6.3.2.2.7.1 HVDC Alternative Route 7-A

HVDC Alternative Route 7-A corresponds to Applicant Proposed Route Links 2, 3 and 4.

Dyess. HVDC Alternative Route 7-A would be located 2.6 miles to the south. Since this is a very flat landscape with panoramic views, the transmission line structures may be visible in the distance and appear as a series of dark vertical objects on the horizon and would result in weak contrast. Weak contrast created by the Project in the MG distance zone for high sensitive residential viewers would result in low viewer concern impacts. Given the distance and partial/intermittent screening of the Project, overall visual impacts would be low from this location.

Johnny Cash Home. HVDC Alternative Route 7-A would be located 3.5 miles south of the Johnny Cash Boyhood Home Historic site, so the visual concern is high. The flat landscape in this area provides panoramic views and the transmission line structures would be faintly visible on the horizon. At this distance, the structures would appear as dark vertical objects creating a pattern on the horizon, resulting in weak visual contrast. Weak contrast created by the Project in the BG distance zone for high sensitive viewers represented by this KOP would result in low viewer concern impacts. Overall visual impacts are anticipated to be low.

Lower Hatchie NWR. HVDC Alternative Route 7-A would be located 4.7 miles to the west. Terrain and dense vegetation would screen all potential views of the transmission line structures at this location, resulting in no visual impact.

Marked Tree. HVDC Alternative Route 7-A would be located 1 mile to the southeast of this location. Existing structures and vegetation in view would screen most of the structures, leaving just the top portion of the HVDC Alternative Route 7-A structures visible. This KOP represents views from a park and recreation area and visual concern is high. There are several existing structures in view, so the proposed structures would result in weak contrast. Weak contrast created by the Project in the MG distance zone for high sensitive residential and recreational viewers represented by this KOP would result in low viewer concern impacts. Overall visual impacts are anticipated to be low. A visual simulation for this KOP is provided in Appendix K.

McGavock-Girder Park. HVDC Alternative Route 7-A would be located 1.8 miles to the south-southwest. The open landscape would offer views of the transmission structures, appearing as a pattern of vertical structures in the distance. The transmission line structures would not be a dominant feature on the landscape and would result in weak visual contrast at this location. Weak contrast created by the Project in the MG distance zone for high sensitive recreational viewers represented by this KOP would result in low viewer concern impacts. Overall visual impacts are anticipated to be low.

Mississippi River and Trail of Tears. HVDC Alternative Route would cross the Mississippi River 0.3 mile from this location. The transmission line structures would be highly visible crossing the open landscape leading up to the river and would introduce tall, vertical, geometric structures, evenly spaced across the landscape, resulting in strong contrast. Transmission line structures on either side of the river crossing would also be visible from this location and would be taller than the transmission structures leading up to the river crossing because of clearance requirements. In addition, markers (which may be orange, yellow, or white) on the transmission lines crossing the river would be added for safety reasons and would add additional contrast. Although an existing 500kV transmission line would be visible in the MG distance zone from this viewpoint, the proposed transmission structures would be closer and much larger in scale. Strong contrast created by the Project in the immediate FG distance zone for high sensitive viewers, concerned with a scarce natural resource, would result in high viewer concern impacts. At this location, the visual contrast would be strong and overall visual impacts would be high. A visual simulation for this KOP is provided in Appendix K.

Tyronza. HVDC Alternative Route 7-A would be located 2.4 miles to the north. Because the landscape in this area is flat and offers panoramic views, the transmission line structures would be visible above the trees in the distance. At this distance, they would appear on the horizon as dark vertical elements and would not appear substantially different than the FG structures, resulting in weak contrast. Weak contrast created by the Project in the MG distance zone for high sensitive residential viewers represented by this KOP would result in low viewer concern impacts. Overall visual impacts are anticipated to be low.

Wilson Park. HVDC Alternative Route 7-A would be located 1.8 miles to the northwest. This KOP represents views from a public park, so visual concern is high. The transmission line structures would be visible as a pattern of vertical objects, evenly spaced along the horizon with different form and line than the existing vertical elements. The proposed structures would be larger in scale than the existing structures, but because of distance, they would not be a dominant element on the landscape. HVDC Alternative Route 7-A would result in weak visual contrast. Weak contrast created by the Project in the MG distance zone for high sensitive residential viewers represented by this KOP would result in low viewer concern impacts. Overall visual impacts are anticipated to be low at this location.

3.18.6.3.2.2.7.2 HVDC Alternative Route 7-B

HVDC Alternative Route 7-B corresponds to Applicant Proposed Route Links 3 and 4.

Edmund Orgill Park. HVDC Alternative Route 7-B would be located 1.7 miles from Edmund Orgill Park. The dense trees and rolling terrain in the FG would screen all views of the transmission line structures, resulting in no visual impact at this location.

Harold Park and Millington. See the Applicant Proposed Route Link 5 description.

Wilkinsville. HVDC Alternative Route 7-B would be located 0.7 mile to the south. The structures would appear as a row of objects extending above the trees in the MG adding a strong vertical element to a landscape. Strong contrast created by the Project in the MG distance zone for high sensitive residential viewers represented by this KOP would result in moderate–high viewer concern impacts. Overall visual impacts are anticipated to be moderate-high.

3.18.6.3.2.2.7.3 HVDC Alternative Route 7-C

HVDC Alternative Route 7-B corresponds to Applicant Proposed Route Links 3, 4, and 5.

Atoka. See description of Atoka KOP for Applicant Proposed Route Link 5. Distance and visibility are the same.

Aycock Park and Millington. HVDC Alternative Route 7-C would be located less than 0.2 mile north of this KOP in the FG distance zone and would parallel an existing 161kV transmission line. Both the proposed and existing transmission lines would be partially screened by vegetation; the tops of the structures would be visible above the tree line and existing structures. Since the proposed structure would be seen in the context of an existing transmission line, with similar form, line, color and texture, and it would be partially screened, the Project would result in moderate contrast. Moderate contrast created by the Project in the FG distance zone for high sensitive recreational viewers represented by this KOP would result in moderate–high viewer concern impacts. Because the Project would be co-dominant in a Developed landscape setting, landscape scenery impacts would be moderate. Overall impacts would be moderate.

Edmund Orgill Park. See description of Edmund Orgill Park KOP for HVDC Alternative Route 7-B. Distance and visibility are the same.

Harold Park and Millington. HVDC Alternative Route 7-C would be located 0.6 mile west. Looking west, the transmission line structures would be visible through breaks in the FG trees, extending above the trees in the distance. The structures would differ in form than the existing low, primarily horizontal houses in the area, resulting in moderate contrast. Moderate contrast created by the Project in the MG distance zone for high sensitive residential viewers represented by this KOP would result in moderate viewer concern impacts. Overall visual impacts would be moderate–low. A visual simulation for this KOP is provided in Appendix K.

Millington East. HVDC Alternative Route 7-C would be located 0.3 mile to the southeast, running parallel to an existing 161kV transmission line. The proposed transmission line structures would be larger in scale than the existing transmission line structures and extend above tree line, with the bottom portion screened by vegetation in the FG. This KOP represents views from a residential area and visual concern is high. The structures would be prominent on the landscape and result in moderate contrast. Moderate contrast created by the Project in the FG distance zone for high sensitive residential viewers represented by this KOP would result in moderate–high viewer concern impacts. Given the moderate contrast introduced into the landscape for high sensitive viewers in the FG distance zone, overall visual impacts would be moderate–high.

Millington USA Baseball Stadium. HVDC Alternative Route 7-C would be located 0.5 mile to the south of the KOP in the MG distance zone and would parallel an existing 161kV transmission line. Given the dense vegetation surrounding the park, and at this distance, it is not likely that the Project would be visible. Views of the Project may include the tops of the transmission line structures extending above the tree line. However, given the existing structures and other vertical elements in the landscape, the Project would be subordinate and would not attract attention; therefore, contrast would be weak. Weak contrast created by the Project in the MG distance zone for high sensitive recreational viewers represented by this KOP would result in low viewer concern impacts. Because the Project would appear subordinate in a Developed landscape, impacts to landscape scenery would also be low. Overall visual impacts from this KOP would be low.

Rockyford Park. HVDC Alternative Route 7-C would be located 2.9 miles to the northwest. The dense trees and terrain would block all views of HVDC Alternative Route 7-C, resulting in no overall visual contrast at this location.

3.18.6.3.2.2.7.4 HVDC Alternative Route 7-D

HVDC Alternative Route 7-D corresponds to Applicant Proposed Route Links 4 and 5.

Atoka. HVDC Alternative Route 7-D would be located less than 0.2 mile to the southwest in the FG. This KOP represents views from a residential area and visual concern is high. The transmission line structures would be a dominant feature crossing the open fields in front of the FG trees and vegetation clearing may be visible. Because HVDC Alternative Route 7-D would be introducing new dominant features into an undeveloped landscape, it would result in strong visual contrast. Strong contrast created by the Project in the MG distance zone for high sensitive residential viewers represented by this KOP would result in high viewer concern impacts. Overall visual impacts would be high.

Atoka Community Park. See description of Atoka Community Park KOP for Applicant Proposed Route Link 5. Distance and visibility are the same.

Edmund Orgill Park. See description of Edmund Orgill Park KOP for HVDC Alternative Route 7-C. Distance and visibility are the same.

Munford. HVDC Alternative Route 7-D would be located 0.4 mile to the southwest. This KOP represents views from a residential area and visual concern is high. HVDC Alternative Route 7-D would run parallel to an existing 500kV transmission line and would be visible extending above the FG trees. The proposed structures would not introduce any new form, line, color, or texture but would add to existing elements, resulting in weak visual contrast. Weak contrast created by the Project in the FG distance zone for high sensitive residential viewers represented by this KOP would result in moderate viewer concern impacts. Overall visual impacts would be moderate–low.

Rhodes Estates. HVDC Alternative Route 7-D would be located 0.6 mile to the northeast and would run parallel to an existing 500kV transmission line, but at a farther distance. Given the increased distance to the structures, the structures would appear smaller in size and less dominant, resulting in weak visual contrast. Weak contrast created by the Project in the MG distance zone for high sensitive residential viewers represented by this KOP would result in low viewer concern impacts. Overall visual impacts would be low.

3.18.6.3.2.2.7.5 Region 7 Alternative Comparison

Table 3.18-29 provides a comparison of the visual impacts for Region 7.

Table 3.18-29:
Visual Impact Comparison Summary—Region 7

Proposed and Alternative Routes	Miles of Distinct Lands Crossed	Miles of Common Lands Crossed	Miles of Developed Lands Crossed	Residences within 0.5 mile
HVDC Alternative Route 7-A	1.9	40.5	0.8	127
APR Links Corresponding to Alternative 7-A	1.5	25.5	1.6	61
HVDC Alternative Route 7-B	1.8	6.2	0.6	503
APR Links Corresponding to Alternative 7-B	3.0	5.2	0.2	537
HVDC Alternative Route 7-C	2.1	20.5	1.2	1,536
APR Links Corresponding to Alternative 7-C	3.7	9.0	0.5	717
HVDC Alternative Route 7-D	0.3	6.0	0.2	1,400
APR Links Corresponding to Alternative 7-D	0.8	5.3	0.3	334

HVDC Alternative Route 7-A. Visual impact to public, private, and state lands resulting from the operations and maintenance of HVDC Alternative Route 7-A is anticipated to be mostly moderate–low with high impacts related to the crossing of the Mississippi River. HVDC Alternative Route 7-A would cross mostly agricultural areas with the crossing of the Mississippi River as a major component of this alternative. The route would be located within 0.5 mile of 127 residences that would have potential views of the Project compared to 61 residences with the corresponding links of the Applicant Proposed Route. HVDC Alternative Route 7-A would cross almost entirely lands classified as Common, but would cross slightly more lands classified as Distinct than the corresponding links of the Applicant Proposed Route.

HVDC Alternative Route 7-B. Visual impact to public, private, and state lands resulting from the operations and maintenance of HVDC Alternative Route 7-B is anticipated to be mostly moderate–high and sensitive viewers would primarily be residences. The landscape crossed by HVDC Alternative Route 7-B is primarily low rolling vegetated hills; the majority of the route land classified as Common (6.2 miles) mixed in with 1.9 miles of lands classified as Distinct, primarily around the Mississippi River Area. This route would cross 1.1 miles fewer lands classified as Distinct and impact 34 fewer residences than the corresponding links of the Applicant Proposed Route.

HVDC Alternative Route 7-C. Visual impact to public, private, and state lands resulting from the operations and maintenance of HVDC Alternative Route 7-C is anticipated to be mostly moderate and the most sensitive viewers would be residences. The route crosses primarily rolling vegetated hills because it starts just east of the Mississippi River and moves into more densely populated areas to the east. HVDC Alternative Route 7-C would cross slightly fewer lands classified as Distinct than the corresponding links of the Applicant Proposed Route, but there would be 1,536 residences within 0.5 mile of the route that would potentially have views of the transmission line structures, compared to 717 with the corresponding links of the Applicant Proposed Route.

HVDC Alternative Route 7-D. Visual impact to public, private, and state lands resulting from the operations and maintenance of HVDC Alternative Route 7-D is anticipated to be mostly moderate–low and the most sensitive viewers would be residences. The route would cross open agricultural land and low rolling vegetated hills with nearby residential development. The route would cross primarily lands classified as Common, with 0.3 mile of lands classified as Distinct compared to the 0.8 mile lands classified as Distinct for the corresponding links of the Applicant Proposed Route. The route would be near several residential developments: 1,400 residences within 0.5 mile compared to 334 for the corresponding links of the Applicant Proposed Route.

3.18.6.3.2.3 Decommissioning Impacts

Project facilities would be removed at the end of the operational life of the transmission line. There would be temporary visual impacts during decommissioning activities. Conductors, structures, and related facilities would be removed. Foundations would be removed to below the ground surface level. There would be residual visual impacts for many years after the Project has been decommissioned and structures removed such as vegetative cutbacks, cut and fill scars from construction activities, and access roads, which all add to the visual impact, though these impacts would be at ground level. These areas would be apparent after the removal of structures but are expected to diminish over time as the removed vegetation grows back.

3.18.6.4 Best Management Practices

The Applicant has developed a comprehensive list of EPMs that would minimize or avoid potential adverse impacts to visual resources. A complete list of EPMs for the Project is provided in Appendix F.

3.18.6.5 Unavoidable Adverse Impacts

Unavoidable impacts include the potential loss or alteration of sensitive views from public or private lands that are located within or adjacent to (within the FG/MG) the transmission line ROW or adjacent to converter station siting areas.

3.18.6.6 Irreversible and Irretrievable Commitment of Resources

Irreversible and irretrievable commitment of visual resources are anticipated where large trees are removed in the ROW, since trees would not be replanted or would be replanted and would result in age disparities, the effects of which would be noticeable to the casual observer. Removed trees would not be available for use by future generations even if new trees are replanted.

Impacts to visual resources from the introduction of structures (e.g., transmission structures and converter stations) and vegetation clearing would be irretrievable during the life of the Project. Once the Project has been decommissioned, however, visual resources could be restored; therefore, the introduction of structures would be not result in any irreversible commitment of visual resources.

3.18.6.7 Relationship between Local Short-term Uses and Long-term Productivity

Short-term vegetation management may impair long-term visual resources where trees or areas of thick vegetation are removed and take years to grow back.

3.18.6.8 Impacts from Connected Actions

3.18.6.8.1 Wind Energy Generation

The WDZs fall within a 40-mile radius from the Oklahoma Converter Station in Region 1, as described in Section 3.18.5.8. The region is primarily flat agricultural lands with open and expansive views and the tall vertical wind turbines would be potentially visible from large distances. Sensitive viewers in this area would be primarily rural residences and small towns, but there are several local parks, state parks, wildlife areas and the Rita Blanca National Grassland that would have possible views because of the panoramic views in the region. This region is free of heavy development and for the most part, cultural modifications are limited to grain silos, center pivots, and scattered transmission structures. The primarily horizontal lines of the landscape would have strong contrast with the tall vertical wind turbines when in the FG and near MG. Additionally, required FAA lighting would be visible for long distances and would likely attract attention when it is flashing. Most of the high sensitive resources, such as the national grassland and recreation areas, however, would be located in the BG distance zone, so impacts would not be as strong as turbines would not be a dominant feature at that distance.

3.18.6.8.2 Optima Substation

Construction and operations and maintenance of the future Optima Substation would result in low visual impacts because of the low visual sensitivity of viewers associated with local roads and existing cultural modifications in the area that have already introduced vertical elements in the a relatively flat landscape setting. High sensitive resources, such as viewers associated with the Optima National Wildlife Refuge, would be located in the BG distance zone, and views of the substation would be obstructed by the rolling terrain; therefore no visual impacts are anticipated to high sensitivity viewers in the BG.

3.18.6.8.3 TVA Upgrades

Upgrades to existing facilities related to terminal modifications and conductor replacement are not expected to result in high visual impacts because contrast would be weak because the existing facilities have already introduced vertical elements into the landscape that are similar in form, line, color, and texture. Increasing the heights of existing towers and constructing the new 500kV transmission line could have higher contrast and higher overall impacts depending on the specific locations of the towers that would be increased in height and location of the new transmission line. The level of potential visual impacts would depend on whether these upgrades were constructed in visually important or unique landscapes or near high sensitive viewer locations such as community enhancement areas (e.g., roadside parks, viewpoints and historic markers) or locations with special scenic, historic, recreation, cultural, and/or natural qualities that have been recognized as such through legislation or some other official declaration.

3.18.6.9 Impacts Associated with the No Action Alternative

Under the No Action Alternative, DOE assumes for analytical purposes that the Project would not be constructed. Current management across the Regions 1 through 7 of the Project would be maintained under the No Action Alternative. Under this alternative, there would be no Project construction or operation to impact visual resources.

3.19 Wetlands, Floodplains, and Riparian Areas

3.19.1 Regulatory Background

This section includes a summary of the federal and state surface water resource regulations and standards relevant to wetlands, floodplains, and riparian areas.

3.19.1.1 Federal

3.19.1.1.1 Clean Water Act

The EPA regulates discharges of pollutants into waters of the United States as well as quality standards for surface waters under the CWA (33 USC § 1251 *et seq*.).

A new Clean Water Act rule was published on June 29, 2015 in the *Federal Register* (80 FR 37054). The final rule becomes effective on August 28, 2015. The final rule expands and clarifies the definition of "waters of the United States." The final rule can be found at 33 CFR Part 328. The U.S. District Court for North Dakota imposed a preliminary injunction against EPA's implementation of its "Waters of the U.S. Rule" which defines the waterways and wetlands regulated under the Clean Water Act. Under the order issued by the District Court of North Dakota, the parties that obtained the preliminary injunction are not subject to the new rule, and instead continue to be subject to the prior regulation .The injunction was granted for 13 states including the state of Arkansas. The states of Texas, Oklahoma, and Tennessee were not included within this decision (USACE 2015).

Dredge and fill activities in waters of the United States, including wetlands, must be authorized through either a nationwide permit, a regional permit (covering various classes of routine activities), or through an individual permit. The Project's seven regions traverse the jurisdiction of the USACE Tulsa, Little Rock, and Memphis District offices. Impacts to wetlands and other waters of United States will be avoided, minimized, and mitigated for the Project through permit-based efforts in consultation with the aforementioned offices of the USACE. Additionally, EPMs (Section 3.19.6.1.1) and BMPs (Section 3.19.6.4) will be adhered to for construction, operations and maintenance, and decommissioning phases of the Project.

Under Section 401 of the CWA, a federal agency cannot issue a permit or license for an activity that may result in a discharge to waters of the United States until the state or tribe where the discharge would originate has granted or waived Section 401 water quality certification, indicating that the proposed discharge would comply with the state's water quality standards. Any USACE Section 404 Individual Permits applied for would require individual review and water quality certification by the appropriate state agency (i.e., the TCEQ, the ODEQ, the ADEQ, or the TDEC).

3.19.1.1.2 Rivers and Harbors Appropriation Act of 1899

Section 10 of the Rivers and Harbors Appropriation Act of 1899 (33 USC § 403) prohibits the unauthorized obstruction or alteration of any navigable water of the U.S. Pursuant to the implementing regulations, Section 10 permits must be obtained from the USACE for power transmission line crossings of navigable waters of the United States, with limited exceptions (33 CFR Part 322).

3.19.1.1.3 DOE Floodplain and Wetland Environmental Review Requirements

Executive Orders 11988 "Floodplain Management" (May 24, 1977) and 11990 "Protection of Wetlands" (May 24, 1977) direct federal agencies to undertake various actions to protect floodplains and wetlands, including preparing a floodplain or wetland assessment for any action proposed in a floodplain and new construction proposed in a wetland. DOE's regulations implementing these Executive Orders, Compliance with Floodplain and Wetland Environmental Review Requirements (10 CFR Part 1022) require that any floodplain or wetland assessment normally be included in an Environmental Assessment or EIS, if one is being prepared (10 CFR 1022.13(b)). A floodplain or wetland assessment includes a description of the proposed action, a discussion of its potential effects on the floodplain or wetland (including a discussion of floodplain or wetland values), and consideration of alternatives (10 CFR 1022.4). The outcome of a floodplain assessment is documented in a floodplain statement of findings, which may be incorporated into a final EIS or record of decision (10 CFR 1022.14(c)). A wetland statement of findings may be similarly prepared for a wetland assessment but is not required.

3.19.1.2 State of Oklahoma

Oklahoma protects wetlands through the efforts of four agencies: Oklahoma Conservation Commission ODEQ, ODWC, and Oklahoma Water Resources Board. The Oklahoma Conservation Commission is the lead agency for wetland planning and coordinates the Oklahoma Wetlands Working Group. The Oklahoma Wetlands Working Group is guided by the Oklahoma Comprehensive Wetlands Conservation Plan. The ODEQ regulates wetlands by providing CWA Section 401 water quality certification for federal permits or licenses that result in impacts to waters of the state, including CWA Section 404 dredge and fill permits. The ODWC reviews federal actions that may cause impacts to wetlands in the state, assists in coordinating wetlands mitigation, and acquires wetlands for protection through fee title acquisition. The Oklahoma Water Resources Board develops state water quality standards, which are applicable to jurisdictional wetlands and stream resources.

3.19.1.3 State of Arkansas

The state of Arkansas' wetland regulatory program efforts are tied to CWA Section 401 water quality certification. Arkansas has a Multi-Agency Wetland Planning Team that is a consortium of state agencies that work together on restoration and planning for wetlands conservation. The team is guided by the Arkansas Wetlands Strategy, which is a comprehensive planning document that outlines objectives and strategies for state wetland initiatives.

3.19.1.4 State of Tennessee

Wetlands in the state of Tennessee are regulated by the TDEC Division of Water Pollution Control. TDEC requires either a CWA Section 401 certification or a state permit for any impacts to wetlands within Tennessee. The Tennessee Wildlife Resources Agency collaborates with TDEC on mitigation banking for wetland impacts. Tennessee Wildlife Resources Agency also administers a program to acquire and restore wetland properties within the state. Various federal agencies, such as the USACE, EPA, USFWS, and the USDA/NRCS may take part on Mitigation Banking Interagency Teams (IRT) when impacts to wetlands or streams in Tennessee require mitigation.

The Tennessee Water Quality Control Act of 1977 and the Aquatic Resources Alteration Rule establish the state's Aquatic Resources Alteration Permit program. This program regulates wetlands and wetland activities apart from those covered by individual CWA Section 404 permits.

3.19.1.5 State of Texas

As with the other states discussed in Section 3.19.1, the primary form of wetland regulation at the state level in Texas is the CWA Section 401 water quality certification program. There are several state agencies involved in the regulation of wetland-related activities, including the TCEQ, which conducts CWA Section 401 water quality certification for most activities. The Texas General land Office manages coastal wetlands under the Coastal Zone Management Plan; however, no coastal wetlands are involved in the proposed Project.

3.19.2 Data Sources

The primary data sources for this section on wetlands, floodplains, and riparian areas include the national wetland inventory (NWI) (GIS Data Source: USFWS 2014g), the national hydrography dataset, the NLCD, the Farm Service Agency's National Agriculture Imagery Program, and the national flood hazard layer data (GIS Data Sources: USGS 2014a; Jin et al. 2013; NAIP 2013a, 2013b, 2012a, 2012b; FEMA 2014).

3.19.3 Region of Influence

The ROI for evaluation of impacts on wetlands, floodplains, and riparian areas from the Project and connected actions is the same as that identified in Section 3.1.1.

3.19.4 Affected Environment

This affected environment section details overall numbers and types of wetlands, the 100-year floodplains, and the associated riparian areas. Each of these three resource types is discussed within the context of the ROI. The ROI traverses four states: Texas, Oklahoma, Arkansas, and Tennessee.

Several route variations to the Applicant Proposed Route in Regions 2–7 were developed in response to public comments on the Draft EIS and are described in Appendix M and summarized in Sections 2.4.2.1–2.4.2.7. The variations are presented graphically in Exhibit 1 of Appendix M.

3.19.4.1 Wetlands

Wetlands within the ROI were identified utilizing USFWS NWI program data (GIS Data Source: USFWS 2014g). These data have provided the number of wetlands per region, as well as the Cowardin classification (Cowardin et al. 1979) for each of the identified wetlands. Deepwater habitats, defined as aquatic systems deeper than 2 meters (6.6 feet), are also included in the classification system, and several of these lake systems have been identified in the ROI. The Cowardin classification system is an alpha-numeric coding system that corresponds to the classification nomenclature that best describes various wetland habitats. Cowardin classes represented within the ROI are summarized in Table 3.19-1. This table represents a subset of the overall Cowardin classification system, limited here to the systems, subsystems, and classes applicable to NWI wetlands mapped in the ROI. NWI wetlands are depicted on Figures 3.15-2a through 3.15-2f in Appendix A.

Table 3.19-1:
Cowardin Classifications Identified for Wetlands and Deepwater Habitats in the ROI

System	Subsystem	Class	Code	Description
Palustrine		Emergent	PEM	Non-tidal wetlands less than 6.6 feet in depth dominated by erect, rooted, herbaceous vegetation.
		Scrub/Shrub	PSS	Non-tidal wetlands less than 6.6 feet in depth dominated by woody plants less than 20 feet in height.
		Forested	PFO	Non-tidal wetlands less than 6.6 feet in depth dominated by woody plants 20 feet in height or taller.
		Aquatic Bed	PAB	Non-tidal wetlands less than 6.6 feet in depth dominated by plants that grow principally on or below the surface of the water for most of the growing season in most years.
		Unconsolidated Bottom	PUB	Non-tidal wetlands less than 6.6 feet in depth. The substrate has at least 25 percent cover of particles smaller than stones and a vegetative cover less than 30 percent.
		Unconsolidated Shore	PUS	Non-tidal wetlands less than 6.6 feet in depth with substrates lacking vegetation except for pioneering plants that become established during brief periods when growing conditions are favorable.
Riverine	Lower Perennial	Unconsolidated Bottom	R2UB	All wetlands and deepwater habitats contained in well-formed channels and not dominated by trees, shrubs, and persistent emergent, emergent mosses or lichens. Lower perennial channels (R2) have low gradient, slow flows, and well-developed floodplains. The substrate has at least 25 percent cover of particles smaller than stones and a vegetative cover less than 30 percent.
		Unconsolidated Shore	R2US	All wetlands and deepwater habitats contained in well-formed channels and not dominated by trees, shrubs, persistent emergents, emergent mosses, or lichens.
	Intermittent	Streambed	R4SB	Intermittent stream wetlands where flow is restricted to limited portions of the year. All wetlands are contained in well-formed channels and not dominated by trees, shrubs, persistent emergents, emergent mosses or lichens.
	Unknown Perennial	Unconsolidated Bottom	R5UB	This Subsystem designation was created specifically for use when the distinction between lower perennial, upper perennial and tidal cannot be made from aerial photography and no data is available. The substrate has at least 25 percent cover of particles smaller than stones and a vegetative cover less than 30 percent.
Lacustrine	Limnetic	Unconsolidated Bottom	L1UB	Deepwater (>6.6 feet) lake habitats lacking trees, shrubs, and emergent vegetation and exceeding 20 acres in size. The substrate has at least 25 percent cover of particles smaller than stones and a vegetative cover less than 30 percent.
	Littoral	Unconsolidated Bottom	L2UB	Lake shoreline (<6.6 feet) wetlands lacking trees, shrubs, and emergent vegetation and exceeding 20 acres in size. The substrate has at least 25 percent cover of particles smaller than stones and a vegetative cover less than 30 percent.
		Unconsolidated Shore	L2US	Lake shoreline (<6.6 feet) wetlands characterized by substrates lacking vegetation except for pioneering plants that become established during brief periods when growing conditions are favorable.
		Emergent	L2EM	Lake shoreline (<6.6 feet) wetlands dominated by erect, rooted, herbaceous vegetation

3.19.4.2 Floodplains

Floodplain data for the ROI were collected from the National Flood Hazard Layer (GIS Data Source: FEMA 2014). This section describes the mapped base floodplains and critical action floodplains in the ROI. Under 44 CFR 9.4, base floodplains are defined as the 100-year floodplain (1-percent annual-chance floodplain), and critical action floodplains are defined as the 500-year floodplain (0.2-percent annual-chance floodplain). No 500-year floodplain data were available in this most recent FEMA national flood hazard layer for this Project's ROI. FEMA has not delineated 500-yeard floodplains in the most current data set and these areas are thus considered non-special flood hazard areas. Floodplains have been identified using FEMA's national flood hazard layer where available, and "Q3" data where there are gaps in national flood hazard layer coverage. "Q3" data are digital data that FEMA developed by scanning existing Flood Insurance Rate Map hardcopies and vectorizing select data features (including 100-year and 500-year flood zones) into a countywide format (FEMA 2013b). Q3 data were used where national flood hazard layer data were not available in Van Buren, Jackson, and Cross counties in Arkansas. FEMA floodplain mapping for Beaver, Harper, and Major counties in Oklahoma, and for Sherman, Hansford, and Ochiltree counties in Texas is not available (FEMA 2013a). Floodplains for these counties are not shown on mapping or in the floodplain tables. 100-year floodplains are depicted on Figure 3.15-2 in Appendix A and they are described for the ROI below.

3.19.4.3 Riparian Areas

This section describes the mapped streams that may have associated riparian areas located within the ROI. Section 3.15 also provides a listing of streams by watershed for each region of the Project. Riparian areas, which are those lands considered to be transitional between uplands and riverine ecosystems, were evaluated using information available from the National Hydrography Dataset (GIS Data Source: USGS 2014a). These areas are typically linear in shape and act as important buffer strips between flowing surface waters and the surrounding upland landscapes. Riparian areas may be dominated by a variety of vegetation types, from herbaceous plants to shrubs, and also by gallery or streamside forests. Riparian areas have several beneficial functions including the control of upland runoff, dissipation of flood flows, stabilization of streambanks, provision of valuable wildlife habitat and habitat connectivity corridors, and they can act as noise and visual buffering for streams. Some common riparian tree species to be found in the ROI may include bald cypress (*Taxodium distichum*), cottonwood (*Populus* spp.), willow (*Salix* spp.), box elder (*Acer negundo*), red maple (*Acer rubrum*), willow oak (*Quercus phellos*), sycamore (*Plantanus occidentalis*), American beech (*Fagus grandifolia*), sweetgum (*Liquidamber styraciflua*), green ash (*Fraxinus pennsylvanica*), and water oak (*Quercus nigra*) (USDA 2013; Williams 2005).

Table 3.19-2 provides the total number of streams (named and unnamed) that would be crossed by the Project within the ROI of the respective Applicant Proposed Route and the HVDC alternative routes.

Table 3.19-2:
Total Stream Crossings by Region

Project Region	Total Stream Crossings[1]
Region 1—APR (Links 1–5)	115
Region 1—Alternative Routes (1-A, 1-B, 1-C, and 1-D)	326
Region 2—APR (Links 1–3)	96
Region 2—Alternative Routes (2-A, and 2-B)	101
Region 3—APR (Links 1–6)	327
Region 3—Alternative Routes 3-A, 3-B, 3-C, 3-D and 3-E	578

Table 3.19-2:
Total Stream Crossings by Region

Project Region	Total Stream Crossings[1]
Region 4—APR (Links 1–9)	212
Region 4—Alternative Routes 4-A, 4-B, 4-C, 4-D, and 4-E	322
Region 5 —APR (Links 1–9)	205
Region 5—Alternative Routes 5A, 5-B, 5-C, 5-D, 5-E, and 5-F	353
Region 6—APR (Links 1–8)	87
Region 6—Alternative Routes 6-A, 6-B, 6-C, and 6-D	118
Region 7—APR (Links 1–5)	81
Region 7—Alternative Routes 7-A, 7-B, 7-C, and 7-D	135

1 The values in the table do not reflect the minor changes that would result from application of the minor route variations and adjustments.
GIS Data Source: USGS (2014a)

3.19.5 Regional Description

The following sections provide detailed descriptions of wetlands, floodplains, and riparian areas in the ROI for Regions 1 through 7. The regional descriptions in this section identify these resource types as they are found within the 1,000-foot-wide ROI of the HVDC transmission line routes. Information for the AC collection system (included in the Region 1 description) is similarly presented in terms of a 2-mile-wide ROI. This information is used in evaluating potential impacts of the Project in Section 3.19.6, which is based on a 200-foot-wide representative ROW within the ROI.

3.19.5.1 Region 1

Region 1 is referred to as the Oklahoma Panhandle Region and includes the proposed Oklahoma Converter Station Siting Area and AC Interconnection, Applicant Proposed Route, and the HVDC Alternative Routes 1-A through 1-D.

No route variations were proposed in Region 1.

3.19.5.1.1 Wetlands

Desktop analysis for NWI-mapped wetland resources determined no NWI wetland resources present in the ROI for either the Oklahoma Converter Station Siting Area or the AC interconnection.

Table 3.19-3 provides a summary of wetlands identified for the Applicant Proposed Route (Links 1–5 in Region 1). The definition of Cowardin classifications is provided in Table 3.19-1. All of the streams have the potential to have riparian areas associated with them. The stream crossing totals in Table 3.19-3 are derived from the National Hydrography Dataset data set.

3.19.5.1.2 Floodplains

Table 3.19-9 provides the number and acreage of 100-year floodplain crossings estimated for each of the HVDC alternative routes and for the Applicant Proposed Route within the ROI in Region 1. The Applicant Proposed Route is anticipated to cross two of these 100-year floodplains. No 100-year or 500-year floodplains are documented for the Oklahoma Converter Station Siting Area.

Table 3.19-9:
100-Year Floodplains in the 1,000-Foot Corridor for the HVDC Transmission Line—Region 1

Alternative Route	No. of Floodplain Crossings	Estimated Acreage of Crossings
APR	2	254
1-A	2	31
1-B	2	49
1-C	2	31
1-D	0	0

Note: No FEMA floodplain data were available for Beaver and Harper counties, Oklahoma.

The AC collection system routes are estimated to cross 113 floodplains as identified in Table 3.19-10. AC Collection System Routes NW-1, SW-2, and W-1 would cross the greatest number of floodplains (12 each).

Table 3.19-10:
100-Year Floodplains in the ROI for the AC Collection System Routes—Region 1

Route	No. of Floodplain Crossings	Estimated Acreage of Crossings
E-1	6	133
E-2	9	1025
E-3	9	604
NE-1	9	1199
NE-2	5	1172
NW-1	12	2083
NW-2	9	1199
SE-1	9	1025
SE-2	6	78
SE-3	9	1025
SW-1	6	78
SW-2	12	1934
W-1	12	1360

Note: No FEMA floodplain data were available for Beaver County, Oklahoma, or for Sherman, Hansford, and Ochiltree counties, Texas.

3.19.5.1.3 Riparian Areas

Table 3.19-2 includes a total number of potential stream crossings for Region 1. These streams may all have associated riparian area resources. The Oklahoma Converter Station and AC Interconnection Siting Areas include 1.6 miles of intermittent streams, no perennial streams, and no other major waterbodies. Table 3.19-11 provides information on surface water resources within the 2-mile-wide corridor of the AC collection system. Riparian areas may be associated with many of these surface water systems.

Table 3.19-11:
Potential Riparian Areas associated with Surface Water Features within the 2-Mile-Wide Corridors of the AC Collection System Routes

Route	Perennial Streams (miles)	Intermittent Streams (miles)	Major Waterbodies (miles)	Reservoirs, Lakes, and Ponds (acres)
E-1	9.2	100.2	0	33.8
E-2	13.5	100.1	0.1	149.0
E-3	10.1	137.6	0.0	36.7
NE-1	24.1	33.0	0.1	141.0
NE-2	7.8	78.3	0.1	70.8

W-1	6.2	45.1	0.1	9.3

GIS Data Source: USGS (2014a)

3.19.5.2 Region 2

Region 2 is referred to as the Oklahoma Central Great Plains Region and includes the Applicant Proposed Route and HVDC Alternative Routes 2-A and 2-B.

Two route variations to the Applicant Proposed Route were developed in Region 2 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.2. The variations are illustrated in Exhibit 1 of Appendix M. These variations represent minor adjustments to the Applicant Proposed Route and the number of, and acreages for, wetlands, floodplains, and riparian areas, would remain relatively consistent within the ROI. Link 1, Variation 1, and Link 2, Variation 2, would both have less than 1 acre of forested wetland within the ROI. Route Link 1, Variation 2, would also have less than 1 acre of non-forested wetland within the ROI. There would be no other change to the number of, nor the acreage for, wetlands, floodplains, and riparian areas.

3.19.5.2.1 Wetlands

Table 3.19-12 provides a summary of wetlands identified for the Applicant Proposed Route (Links 1-3 in Region 2).

3.19.5.2.2 Floodplains

Table 3.19-15 provides the number and acreage of 100-year floodplain crossings estimated for the Applicant Proposed Route and HVDC Alternative Routes 2-A and 2-B within the ROI in Region 2.

Table 3.19-15:
100-Year Floodplains in the 1,000-Foot Corridor for the HVDC Transmission Line—Region 2

Alternative Route	No. of Floodplain Crossings	Estimated Acreage of Crossings
APR	6	800
2-A	1	23
2-B	4	457

Note: No FEMA floodplain data were available for Major County, Oklahoma.

3.19.5.2.3 Riparian Areas

Table 3.19-2 includes a total number of potential stream crossings for Region 2. These streams may all have associated riparian area resources.

3.19.5.3 Region 3

Region 3 is referred to as the Oklahoma Cross Timbers Region and includes the Applicant Proposed Route and HVDC Alternative Routes 3-A through 3-E.

Five route variations to the Applicant Proposed Route were developed in Region 3 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.3. The variations are illustrated in Exhibit 1 of Appendix M. These variations represent minor adjustments to the Applicant Proposed Route and the number of, and acreages for, wetlands, floodplains, and riparian areas, would remain consistent within the ROI. Link 1, Variation 2, would have less than 1 mile of streams within the ROI. Links 1 and 2, Variation 1, would have less than 1 mile of streams and less than 1 acre of floodplains within a ROI. It should be noted that a route adjustment was made for HVDC Alternative Route 3-A to maintain an end-to-end route with the Links 1 and 2 variations, but this route adjustment would not add any additional numbers of, or acreages for, wetlands, floodplains, or riparian areas within the ROI. Link 4, Variation 1, would have three additional surface waterbodies within the ROI. The National Hydrography Dataset defines a waterbody as a hydrographic feature delineated using areas (e.g., ponds, lakes, and reservoirs). Link 4, Variation 2, would also add one additional surface waterbody within the ROI. Link 5, Variation 2, would have one additional surface waterbody within the ROI.

3.19.5.3.2 Floodplains

Table 3.19-22 provides the number and acreage of 100-year floodplain crossings estimated for each of the HVDC alternative routes and for the Applicant Proposed Route within the ROI in Region 3. The Applicant Proposed Route is estimated to cross twenty-four 100-year floodplains totaling an estimated 1,587 acres within the ROI for Region 3.

Table 3.19-22:
100-Year Floodplains in the 1,000-Foot Corridor for the HVDC Transmission Line—Region 3

Alternative Route	No. of Floodplain Crossings	Estimated Acreage of Crossings
APR	24	1587

3-B	14	328
3-C	32	1591
3-D	13	466
3-E	6	111

3.19.5.3.3 Riparian Areas

Table 3.19-2 includes a total number of potential stream crossings in Region 3. These streams may all have associated riparian area resources.

3.19.5.4 Region 4

Region 4 is referred to as the Arkansas River Valley Region and includes the Applicant Proposed Route, including the Lee Creek Variation, and HVDC Alternative Routes 4-A through 4-E.

Seven route variations to the Applicant Proposed Route were developed in Region 4 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.4. The variations are illustrated in Exhibit 1 of Appendix M. These variations represent minor adjustments to the Applicant Proposed Route and the number of, and acreages for, wetlands, floodplains, and riparian areas, would remain consistent within the ROI. Link 3, Variation 1, would have less than 1 mile of streams within the ROI, two forested wetlands of approximately 2 total acres, and 3 acres of floodplains with one crossing exceeding more than 1,000 feet in width. Link 3, Variation 2, would have less than 1 mile of streams and three floodplains totaling approximately 15 acres with two crossings exceeding more than 1,000 feet in in the ROI. Variation 2 would also result in decreases in stream mileage crossed, the number and acreage of floodplains crossed, and the number of designated waterbodies crossed. Link 3, Variation 3, would have less than 1 mile of streams within the ROI. Link 6, Variation 1, would have less than 1 mile of streams within the ROI. Link 6, Variation 2, would have less than 1 mile of streams and one floodplain totaling approximately 33 acres and having a width of more than 1,000 feet within the ROI. Link 6, Variation 3, would have no crossings of wetlands, floodplains, or riparian areas within the ROI. Link 9, Variation 1, would have less than 1 mile of streams, and one floodplain totaling approximately 43 acres and having a width of more than 1,000 feet within the ROI. This variation would also have two additional surface waterbodies within the ROI.

3.19.5.4.1 Wetlands

Table 3.19-23 provides a summary of wetlands identified for the Applicant Proposed Route (Links 1–9 in Region 4).

GIS Data Source: USFWS (2014g)

No NWI-mapped wetlands were documented in the desktop analysis for HVDC Alternative Route 4-C. NLCD land cover data were also reviewed and were determined to show 0.03 acres of woody wetlands present within the ROI for this alternative.

Table 3.19-26 provides a summary of wetlands identified for HVDC Alternative Route 4-D (corresponding to Applicant Proposed Route Links 4, 5, and 6 in Region 4) within the 1,000-foot-wide ROI.

Table 3.19-26:
Wetlands in the 1,000-Foot Corridor—Region 4, HVDC Alternative Route 4-D

Wetland Type	No. of Wetlands	Acreage of Wetlands
PUB	5	2
Total	5	2

GIS Data Source: USFWS (2014g)

No NWI-mapped wetlands were documented in the desktop analysis for HVDC Alternative Route 4-E. NLCD land cover data were also reviewed and documented a combined 14.3 acres of woody wetlands and emergent herbaceous wetland land cover in the ROI.

3.19.5.4.2 Floodplains

Table 3.19-27 provides the number and acreage of 100-year floodplain crossings estimated for each of the HVDC alternative routes and for the Applicant Proposed Route within the ROI in Region 4. The Applicant Proposed Route is estimated to cross thirty-six 100-year floodplains totaling an estimated 2,690 acres within the ROI for Region 4.

Table 3.19-27:
100-Year Floodplains in the 1,000-Foot Corridor for the HVDC Transmission Line—Region 4

Alternative Route	No. of Floodplain Crossings	Estimated Acreage of Crossings
APR	36	2,690
4-A	18	677
4-B	17	513
4-D	9	251
4-E	12	350

3.19.5.4.3 Riparian Areas

Table 3.19-2 includes a total number of potential stream crossings in Region 4. These streams may all have associated riparian area resources.

3.19.5.5 Region 5

Region 5 is referred to as the Central Arkansas Region and includes the Arkansas Converter Station Alternative Siting Area and AC Interconnection Siting Area, the Applicant Proposed Route, and the HVDC Alternative Routes 5-A through 5-F.

Five route variations to the Applicant Proposed Route were developed in Region 5 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.5. The variations are illustrated in Exhibit 1 of Appendix M. These variations represent minor adjustments to the Applicant Proposed Route and the number of, and acreages, for wetlands, floodplains, and riparian areas would remain consistent within the ROI. Link 1, Variation 2, would have less than 1 mile of streams within the ROI, two forested wetlands of approximately 0.5 acre, and 6 acres of floodplains with one crossing exceeding more than 1,000 feet in width. There is also one surface waterbody within the ROI for this variation. Applicant Proposed Route Link 2, Variation 2, would have less than 1 mile of streams within the ROI. Applicant Proposed Route Links 2 and 3, Variation 1, would have less than 1 mile of streams within the ROI and approximately 10 acres of floodplains with one crossing exceeding more than 1,000 feet in width. It should be noted that a route adjustment was made for HVDC Alternative Route 5-B to maintain an end-to-end route with Links 2 and 3, Variation 1. HVDC Alternative Route 5-B would have approximately 5 acres of floodplain within the ROI. Links 3 and 4, Variation 2, would have less than 1 mile of streams within the ROI. A route adjustment was made for HVDC Alternative Route 5-E to maintain an end-to-end route with Links 3 and 4, Variation 2. This route adjustment would cross one floodplain of less than 1 acre within the ROI. Link 7, Variation 1, would have less than 1 mile of streams within the RO, and would cross one more feature categorized as a surface waterbody.

3.19.5.5.1 Wetlands

Table 3.19-28 provides a summary of wetlands identified for the Applicant Proposed Route (Links 1–9 in Region 5).

Total	233	363

GIS Data Source: USFWS (2014g)

The Region 5 Applicant Proposed Route and HVDC Alternative Route 5-D have been evaluated using NWI wetland data. No NWI-mapped wetlands were documented in the desktop analysis for HVDC Alternative Routes 5-A, 5-B, 5-C, 5-E and 5-F, so NLCD land cover data were reviewed to estimate acreage within the respective ROIs to make an evaluation of wetland resources for the HVDC alternative routes.

Table 3.19-30 provides a summary of wetlands identified for HVDC Alternative Routes 5-A, 5-B, 5-C, 5-E, and 5-F within the 1,000-foot-wide ROI.

Table 3.19-30:
Wetland Land Cover in the 1,000-Foot Corridor—Region 5, HVDC Alternative Routes* 5-A, 5-B, 5-C, 5-E and 5-F

Alternative Route	Wetland Land Cover Type	Acreage of Wetlands
5-A	Woody wetlands	2.3
5-B	Woody wetlands	29.9
5-C	Woody wetlands	2.6
5-E	Woody wetlands	13.0
5-F	Woody wetlands	8.9

*NLCD data used due to lack of NWI data

Table 3.19-31 provides a summary of wetlands identified for HVDC Alternative Route 5-D (corresponding to Applicant Proposed Route Link 9 in Region 5) within the 1,000-foot-wide ROI.

Table 3.19-31:
NWI Wetlands in the 1,000-Foot Corridor—Region 5, HVDC Alternative Route 5-D

Wetland Type	No. of Wetlands	Acreage of Wetlands
PEM	3	6
PFO	3	20
PUB	26	18
R2UB	2	26
Total	34	70*

*Note: For comparative purposes, the NLCD land cover data records 72.4 acres of woody wetlands in Alt. Rt. 5-D.

3.19.5.5.2 Floodplains

Table 3.19-32 provides the number and acreage of 100-year floodplain crossings estimated for each of the HVDC alternative routes and for the Applicant Proposed Route within the ROI in Region 5. The Applicant Proposed Route is estimated to cross twenty-six 100-year floodplains totaling an estimated 1,564 acres.

Table 3.19-32:
100-Year Floodplains in the 1,000-Foot Corridor for the HVDC Transmission Line—Region 5

Alternative Route	No. of Floodplain Crossings	Estimated Acreage of Crossings
APR	26	1,564
5-A	3	81
5-B	10	793
5-C	2	109
5-D	14	677
5-E	6	486
5-F	3	378
Total	64	4,088

3.19.5.5.3 Riparian Areas

Table 3.19-2 includes a total number of potential stream crossings in Region 5. These streams may all have associated riparian area resources.

3.19.5.6 Region 6

Region 6 is referred to as the Cache River and Crowley's Ridge Region and includes the Applicant Proposed Route and HVDC Alternative Routes 6-A through 6-D. Straight Slough, a designated Ecologically Sensitive Waterbody (ESW), occurs at the lower limit of the St. Francis River in Region 6 in Arkansas. ESWs are designated based on their provision of habitat within the existing range of threatened, endangered, or endemic species of aquatic or semi-aquatic life forms. Straight Slough is discussed in more detail in Sections 3.14.2 and 3.20.2.5.6.

One route variation was developed in Region 6 in response to public comments on the Draft EIS to parallel more parcel boundaries to minimize impacts to agricultural operations and is shown in Exhibit 1 of Appendix M. This variation represents a minor adjustment to the Applicant Proposed Route and the number of, and acreages for, wetlands, floodplains, and riparian areas, would remain consistent within the ROI. Link 2, Variation 1, would have less than 1 mile of streams within the ROI, two forested wetlands of approximately 1 acre, one non-forested wetland of less than 0.5 acre, and approximately 1 acre and 6 acres of floodplains with one crossing exceeding more than 1,000 feet in width. The NLCD database reveals this variation would have four forested wetlands of approximately 2 total acres within the ROI. It should be noted that a route adjustment was made for HVDC Alternative Route 6-A to maintain an end-to-end route with Link 2, Variation 1. The route adjustment for HVDC Alternative Route 6-A would cross 12 forested wetlands totaling 21 acres and one non-forested wetland totaling less than 1 acre in the ROI. Finally, the route adjustment would have five surface waterbodies (ponds, lakes, etc.) within the ROI.

3.19.5.6.1 Wetlands

The Region 6 Applicant Proposed Route and HVDC Alternative Routes 6-A and 6-B have been evaluated using NWI wetland data. No NWI-mapped wetlands were documented in the desktop analysis for HVDC Alternative Routes 6-C and 6-D, so NLCD land cover data were reviewed to estimate acreage within the respective ROIs to make an evaluation of wetland resources for the HVDC alternative routes.

Table 3.19-33 provides a summary of wetlands identified for the Applicant Proposed Route (Links 1-7 in Region 6).

Alternative Route	Wetland Land Cover Types	Acreage of Wetlands
6-C	Woody wetlands	114.9
6-D	Woody wetlands and Emergent herbaceous wetlands	87.1

*NLCD data used due to lack of NWI data

3.19.5.6.2 Floodplains

Table 3.19-37 provides the number and acreage of 100-year floodplain crossings estimated for each of the HVDC alternative routes and for the Applicant Proposed Route within the ROI in Region 6. The Applicant Proposed Route is anticipated to cross 24 of these 100-year floodplains. The route adjustment for HVDC Alternative Route 6-A also would have one floodplain of 129 acres with one crossing of more than 1,000 feet in width within the ROI.

Table 3.19-37:
100-Year Floodplains in the 1,000-Foot Corridor for the HVDC Transmission Line—Region 6

Alternative Route	No. of Floodplain Crossings	Estimated Acreage of Crossings
APR	24	3319

6-B	4	762
6-C	7	507
6-D	6	560

3.19.5.6.3 Riparian Areas

Table 3.19-2 includes a total number of potential stream crossings for Region 6. These streams may all have associated riparian area resources.

3.19.5.7 Region 7

Region 7 is referred to as the Arkansas Mississippi River Delta and Tennessee Region and includes the Tennessee Converter Station Siting Area and AC Interconnection Tie, the Applicant Proposed Route, and the HVDC Alternative Routes 7-A through 7-D.

Three route variations to the Applicant Proposed Route were developed in Region 7 in response to public comments on the Draft EIS. The route variations are described in Appendix M and summarized in Section 2.4.2.7. The variations are illustrated in Exhibit 1 of Appendix M. Link 1, Variation 1, would not cross any wetlands, floodplains, or riparian areas within the ROI. Link 1, Variation 2, would have approximately 2 miles of streams within the ROI. There would be a crossing of 18 forested wetlands of approximately 30 acres and six floodplains totaling approximately 167 acres; three of the floodplain crossings would exceed more than 1,000 feet in width each. Link 5, Variation 1, would have less than 1 mile of streams within the ROI.

3.19.5.7.1 Wetlands

Table 3.19-38 provides a summary of wetlands identified for the Applicant Proposed Route (Links 1–5 in Region 7).

3.19.5.7.2 Floodplains

Table 3.19-44 provides the number and acreage of 100-year floodplain crossings estimated for each of the HVDC alternative routes and for the Applicant Proposed Route within the ROI in Region 7. The Applicant Proposed Route is estimated to cross forty-one 100-year floodplains totaling an estimated 1,712 acres. The ROI for the Tennessee Converter Station Siting Area and AC Interconnection Tie is estimated to cross 3 separate 100-year floodplains.

Table 3.19-44:
100-Year Floodplains in the 1,000-Foot Corridor for the HVDC Transmission Line—Region 7

Alternative Route	No. of Floodplain Crossings	Estimated Acreage of Crossings
APR	41	1,712

7-D	19	223
Tennessee Converter Station Siting Area	3	37

3.19.5.7.3 Riparian Areas

Table 3.19-2 includes a total number of potential stream crossings in Region 7. These streams may all have associated riparian area resources.

3.19.5.8 Connected Actions

3.19.5.8.1 Wind Energy Generation

The NWI database has provided data to document palustrine (depressional), lacustrine (lakes), and riverine wetlands within the various WDZs. These wetland types include emergent, scrub-shrub, forested, farmed, unconsolidated bottom, unconsolidated shore, intermittent stream, and lower perennial stream types. The overall wetland acreages within each zone are discussed in the following subsections.

FEMA's 100-year national flood hazard layer (GIS Data Source: FEMA 2014) was used to identify potential floodplain impact areas within each wind development zone.

Riparian areas may potentially occur in areas with perennial or intermittent streams, as well as ponds, lakes, or reservoirs.

3.19.5.8.1.1 WDZ-A
