Executive Summary

1.0   Introduction

This assessment report includes all of the land located within the project boundaries of the Moab Project Site, excluding the tailings pile, located at 2021 North Highway 191, Moab, Utah.

Following procedures described in the *Field Services Procedures Manual* (STO 203), radiological data were collected from November 2001 through February 2005, and evaluated to estimate the extent of contamination from residual radioactive material (RRM) in excess of the U.S. Environmental Protection Agency (EPA) "Health and Environmental Protection Standards for Uranium and Thorium Mill Tailings" (40 CFR 192). Thorium-230 (Th-230) clean-up standards are derived from Radium-226 (Ra-226) clean-up standards as per U.S. Department of Energy (DOE) Order 5400.5. The sliding scale for Th-230 comes from Uranium Mill Tailings Remedial Action (UMTRA) Program protocol used on millsite clean-ups, circa 1993. The analytical results for Total Uranium, found in Table 2 are presented only for information. If DOE determines that uranium cleanup will enhance the ground water cleanup strategy, the assessment report will be amended.

The measurement techniques, instrumentation, and procedures used in this radiological assessment are based primarily on protocols developed by the DOE Office of Remedial Action and Waste Technology's Technical Measurements Center, and on field implementation experience gained from the characterization of millsites and vicinity properties for the UMTRA Program. Detailed procedures for collecting assessment soil samples and taking radiological field measurements are presented in the *Field Services Procedures Manual* (STO 203). Samples submitted to subcontract laboratories were analyzed using approved procedures as specified in the *DOE Integrated Contractor Procurement Team Statement of Work for Laboratory Analytical Services*.

2.0   Background Gamma Exposure-Rate and Radiologic Determinations

The background gamma exposure-rate and Ra-226 concentration for the Moab Project Site was determined during the radiological characterization conducted in November 2001. Four off-site sample locations were selected to collect background data, located north, south, east, and west of the Moab Project Site. Two sample points were collected at each of the off-site locations. Measurements were collected using the Mount Sopris SC-132 crutch scintillometer, Bendix EL-0018B delta scintillometer, and a Bicron microrem exposure rate meter. Two 0-6" soil samples were also collected at each off-site background location and analyzed through the analytical lab for Ra-226, Th-230, and total uranium concentrations. All of the off-site background locations were also physically located using the Trimble GPS unit, for mapping purposes. This study concluded that the average background gamma exposure-rate measurement is 12 microroentgens per hour (μR/h), and that the background Ra-226 concentration is 1.0 picocurie per gram (pCi/g), Total Uranium is 1.2 pCi/g, and Th-230 is 0.47 pCi/g.

3.0　Gamma Exposure-Rate Survey

Discrete ground-level and waist-level gamma exposure-rate readings were collected at approximately 30-foot intervals across the exterior surface area of this property. In certain areas of interest, additional gamma exposure rate readings were collected at smaller grid spacings when required to adequately characterize the area.

All gamma exposure rate measurements were collected with Mount Sopris (Model SC 132) scintillation detectors. These instruments measure gross-gamma in counts per second and were cross-correlated with a pressurized ionization chamber to determine the correction factors used to convert the raw data to true gamma exposure rates, µR/h.

3.1　Exterior

Exterior ground-level gamma exposure rates measured on this property range from 14 µR/h to 4,500 µR/h.

3.2　Interior

General interior ground-level gamma exposure rates measured in the former office/lab/warehouse building (grid maps RN and SN) are 14 µR/h to 28 µR/h.

4.0　Radon/Radon Decay-Product Concentration (RDC) Measurements

RDC measurements are in the process of being collected in the former office/lab/warehouse building. The results of those measurements collected between January 2003 and October 2004 range from 0.008 working level (WL) to 0.022 WL. The average of the measurements are within acceptable criteria as set forth in 40 CFR 192.12[b]. The protocol and procedures for collection of the Alpha Track measurements and the subsequent results may have been compromised due to the ventilation measures that were employed in the warehouse building during the radon data collection periods. Ventilation would have caused the readings to be lower than expected in a normally occupied structure.

5.0　In-Situ Radiologic Measurements and Soil Samples

Plates 1 through 3 show the locations where subsurface borings and test pits were made, with the related radiological data presented in Tables 1 and 2. Ra-226 concentrations, as determined by the methods used in these characterizations, range from less than 1.0 to 1,283 pCi/g. Total Uranium concentrations range from less than 1.0 to 1,154 pCi/g and Th-230 concentrations range from less than 1.0 to 779 pCi/g. Brief descriptions of these measurement types are discussed in the following subsections:

5.1　Borehole Gamma Logging

Boreholes were drilled and gamma logged at approximately 90-foot intervals across the property (excluding the tailings pile) where physical conditions permitted. The boreholes were evaluated to determine if contamination exceeding

EPA guidelines was present below the surface 6-inch soil layer. All of the boreholes were drilled from surface to a depth where undisturbed native soils were encountered or where readings dropped to background values.

Boreholes were drilled using either a portable gasoline-powered auger or ATV-mounted hydraulic auger. Both methods used augers measuring 4.5 inches in diameter. Eberline E-600 scalers equipped with SPA-3 sodium iodide gamma detectors were used to log the holes in 6 to 12-inch depth intervals. The gamma counts were accumulated for 30 seconds at each interval. These readings were then reduced to Ra-226 concentrations (pCi/g) by applying conversion factors determined during instrument calibration.

Borehole gamma logging was also accomplished through the use of the Geoprobe Hydraulic Hammer-Drill (Geoprobe®). The Geoprobe is a vehicle-mounted, hydraulically operated hammer-drill capable of pushing hollow casing into the ground. Eberline (Model E-600) scalers, equipped with Bicron or Alpha-Spectra sodium iodide "pipe monitor" gamma detectors, were used to log the holes in 6 to 12-inch depth intervals. The gamma counts were accumulated for 60 seconds at each interval through the hollow casing. Where soil conditions permitted, the casing was removed and gamma counts were collected from the open borehole. These readings were then reduced to Ra-226 concentrations (equivalent pCi/g) by applying conversion factors determined during instrument calibration. An attenuation factor was also applied if readings were taken through the hollow steel casing.

5.2   Soil Samples

Soil samples were collected from 6-inch-thick soil layers using specially designed shovels to yield samples of equal vertical cross-section, size, and volume. For prompt radium concentration determinations, the soil samples collected were analyzed using the Opposed Crystal System (OCS). Of the total number of OCS soil samples analyzed, 10 percent were submitted to approved Analytical Laboratories as quality control samples to ensure the validity and accuracy of the OCS values, according to guidelines described in the *Field Services Procedures Manual* (STO 203), Procedure 4.

Total Uranium samples were analyzed on-site utilizing a High-Purity Germanium (HPGe) detector with the NOMAD (Model 92X-P) Gamma Spectroscopy system following guidelines described in the *Field Services Procedure Manual* (STO 203), Procedure 8. The sample analyses from this system were used as semi-quantitative type field measurements to aid the radiological technicians in interpreting borehole gamma log readings. Final quantitative sample analyses (Typically 5–10% of the total number of samples or as required) of Total Uranium and Th-230 are from approved Analytical Laboratories and analyzed by ICP mass spectrometry or alpha spectrometry, respectively.

6.0 Estimated Extent of Contamination

All radiological data available for this property were reviewed and evaluated according to guidelines described in the *Field Services Procedures Manual* (STO 203). The results of this evaluation indicate this property is contaminated with concentrations of Ra-226 exceeding the EPA guidelines for the first 6-inch-thick soil layer. The data collected indicate Ra-226 concentrations also exceed EPA radium guidelines for subsurface soil layers to a maximum depth of 240 inches.

6.1 Exterior

Plate 1 is an isopach contour map showing the estimated boundaries and associated depths of Ra-226 contamination determined for soil layers. Tables 1 and 2 show the Ra-226, Total Uranium, and Th-230 soil concentrations and associated depths at specific locations where samples and/or measurements were collected. Specific areas of contamination are discussed below:

The majority of the property adjacent to the north and south sides of North Highway 191 is contaminated with up to 12 inches of windblown contamination. Contamination is also adjacent to the roadbed in the utility corridors on the south side of North Highway 191. Contamination was remediated along a portion of the North Highway 191 right-of-way corridor (grid maps SI, SJ, SK, TI, TJ, and TK) in March and April of 2003. Additional clean up of the off-site right-of-way corridor was performed by the Utah Department of Transportation in August and September of 2003. During the excavation of the contaminated soils in the roadbed at the intersection of North Highway 191 and Highway 279 (Potash Road), contamination was documented going beneath the asphalt roadway at a depth of 72 inches and greater. Based on borehole data collected adjacent to Highway 279, approximately 800 feet of the highway has contaminated soils adjacent and possibly beneath the asphalt (grid maps SF, SG, TF, and TG).

Soil samples were collected of contaminated, windblown soil, on the surface of the asphalt parking lot and bike trail (old highway 191) (grid maps UL through UR, VO, and VP) which exceeds EPA surface standards (up to 35 pCi/g Ra-226) and was primarily wind-deposited in the cracks of the old and deteriorated portions of the described asphalt surfaces. If the contaminated soils were removed from the deteriorated asphalt surface, the subsequent asphalt and base materials appeared to be un-contaminated. A National Park Service (NPS) hiking trail which starts at this same parking lot and goes east to the end of the project boundary (grid maps VQ and VR) had contamination identified along the trail. It appears the contamination spills over to the east, into Courthouse Wash, along the north side of North Highway 191. Contamination identified on the north side of North Highway 191 spills over to the north on to NPS property.

Several major utilities, including underground gas, electric, fiber optic, and phone, cross the property on the south side of North Highway 191. Contamination is associated with all of these buried utilities based on elevated gamma readings recorded over the surface of the utilities. No holes were drilled within 30 feet of

these lines, so assessment data represent surface gamma and are interpolated between the closest boreholes.

There are a number of flood control dikes on the east side of the property that have been constructed using low-grade uranium ore as part of the fill material that exceeds standards. This same material was used in building the banks of the fresh water storage ponds (grid maps QO and RO). The dry storage pond, to the east, was constructed using a bentonite clay liner. Boreholes in the bottom of the dry pond indicate contamination beneath the bentonite liner to a depth of 120 inches. Another abandoned, dry pond was found in the dense brushy growth just to the east of the two storage ponds. The banks of this pond were also constructed using contaminated soils.

A very large area, located east and north of Moab Wash, (grid maps NM, NN, NO, OM, ON, OO, PL, PM, PN, PO, and QL) was used as a trash disposal area for the millsite and laboratory and contains associated debris and waste, some of which is extremely radioactive and contaminated (Ra-226 to 437 pCi/g, Uranium to 1,154 pCi/g, and Th-230 to 779 pCi/g). Some of the waste material was excavated and removed (former Trustee operations) but a sizeable amount is still present on the surface and buried in this area and is evident within the banks of the flood control dikes for Moab Wash (grid maps NM, NN, OL, OM, PL, PM, and QL). Buried waste and trash was also found beneath the river dike (grid maps NO and OO) and extending to the banks of the Colorado River. Boreholes indicated contamination on the riverside of the dike to a depth of 186 inches.

An additional trash disposal area was found on the south side of Moab Wash (grid maps MM and MN). Contamination was found to a depth of 72 inches.

During field investigations of grid maps QM and PM, a strong petroleum odor was detected in a number of boreholes. In a few of the boreholes, a black organic layer of soil was evident to a depth of 114 inches. This information has been forwarded to the Environmental Services Group.

Contaminated material was used in the backfill in and around the culvert in the vehicle crossing of Moab Wash on grid map QL.

Two historical settling ponds that were located between the east side of the tailings pile and Moab Wash were backfilled during the former Trustee capping operations and now lie beneath the access road to the top of the tailings pile. Borehole data indicates the presence of contamination to a depth of 192 inches (grid maps OM and NM).

The area to the southeast of the tailings pile, in the stressed tamarisk forest surrounding the Barium-Chloride settling pond, was found to be highly contaminated with RRM. Ra-226 and Uranium concentrations exceeding 1,000 pCi/g were found throughout this area. This contaminated material consists of a very fine-grained soil matrix. Contamination in this area spills over to the adjacent private property to the south, however, at lower concentrations.

The poles for the large overhead electric lines, located on the western side of the tailings pile, are embedded in contaminated soils. Contamination was evident in boreholes to a depth of 240 inches in this area. Of the remaining utility poles that are within the project site boundaries, all are, to some degree, buried in contaminated soils ranging in depth from 6 to 120 inches.

Windblown contamination and uranium ore was found on the west side of Highway 279. Large portions of this area could not be investigated due to the steep terrain and limited access conditions that are present. Data was only collected in the accessible areas and is presented in this report. Contamination also spills over to the adjacent Bureau of Land Management property, located north of the project boundary.

During the field investigations, it was discovered that the site perimeter fence posts were constructed using process pipe from the millsite. A gamma scintillometer was used to determine how many of these fence posts contained residual radioactive material (process related) inside the pipe. Twenty-one fence posts were identified as being contaminated and were physically located using a Trimble® Global Positioning System and are shown in Plate 1. The map coordinates for each individual contaminated fence post can be found in Table 1.

Windblown contamination and uranium ore was found in the Union Pacific Railroad right-of-way. Contaminated material was identified in the railroad track beds, in the 100-foot right-of-way, and in and around a metal framed building up to a depth of 18 inches. Fixed contamination was also identified on a metal-framed hoist, electric hoist motor, and concrete foundation of the hoist (grid maps OE and PE).

Contamination has also been identified beneath the asphalt, project site entrance driveway, and the parking lot for the project site support trailers. Contamination depths range from 6 to 18 inches for these areas. A contaminated (fixed contamination) 8-inch diameter steel pipe (process-related) was identified on the south side of the support parking lot. The pipe is approximately 156 feet long and was fixed to the asphalt using concrete anchors below the asphalt surface.

6.2   Interior

The gamma exposure rate in the warehouse ranged from 17–754 µR/h. The high gamma was attributed to a radium needle that was stored in the south end of the building in the RMMA, at the time of the assessment survey. Several radioactive sources are also stored in the same area. Elevated gamma readings were also found in the north end of the warehouse in the concrete floors of the garage and shop areas, and in the stem walls of the boiler room. Gamma exposure rates ranged from 17–58 µR/h for these areas. Subsurface radiologic measurements were not collected inside the building and the extent of contamination is undetermined at this time. Contamination up to 12-inches deep appears to extend up to the exterior of the building.

7.0   Remedial Action Recommendations

7.1   Exterior

Exterior contamination (Plate 1) should be removed to meet EPA standards and other applicable standards established for the Moab Project.

7.2   Interior

Insufficient information is available to make a determination at this time.

8.0   Suspected Hazardous Residual Radioactive Material Investigation

All wastes generated within the boundary of the posted contamination area (CA) is considered RRM. For the purposes of this report, suspected hazardous RRM refers to RRM suspected of containing a hazardous or toxic component other than radioactivity. A formal suspected hazardous RRM investigation has not been performed on this property at this time. Such materials may be encountered in trash disposal areas and areas with a petroleum odor that were previously noted in this report (Section 6.1).
