SUBJECT: Subarea 5B, Round 2 Soil Sample Results

CONTRACT NO: EP-S7-05-05
TASK ORDER NO: 0038

1.0 INTRODUCTION

HydroGeoLogic, Inc. (HGL) is conducting a comprehensive radiological characterization study of Area IV and the Northern Buffer Zone (NBZ) at the Santa Susana Field Laboratory (SSFL) site in Ventura County, California. This work is being executed under U.S. Environmental Protection Agency (USEPA) Region 7 Architect and Engineering Services Contract EP-S7-05-05, Task Order 0038. The technical lead on the project is USEPA Region 9.

As part of the radiological study, surface and subsurface soil samples were collected from locations identified from geophysical surveys, gamma scanning, historical aerial photographs and findings of the Historical Site Assessment. Sampling efforts in the study area were divided into Subareas. Analytical results from the Round 1 sampling activities were reviewed in conjunction with the aforementioned lines of evidence, and sample locations were identified for further investigation during the Round 2 soil sampling effort. This technical memorandum documents the soil sampling activities, analytical results, and conclusions of the Round 2 soil sampling. The primary objective of the Round 2 soil sampling effort was to further investigate potential radionuclide contamination by laterally and vertically delineating radionuclide concentrations that exceeded project established Radiological Trigger Levels (RTL) detected during the Round 1 sampling activities. This objective was achieved through the collection and analysis of step-out surface and subsurface soil sample locations, as described in Section 4.2 of the Final Field Sampling Plan (FSP) for Soil Sampling (HGL, 2012a). If an exceedance was isolated, a step-out location was placed approximately 15 feet north, south, east, and west of the Round 1 exceedance location. If there were multiple Round 1 exceedances grouped together, step-out sampling locations were targeted around the exceedances to best characterize the lateral and vertical extent of potential radionuclide impacted soils.

The approach for Round 2 soil sampling was to identify potential sample locations from the lines of evidence listed above, prepare a Round 2 FSP Addendum for the subarea, present the FSP to USEPA's SSFL Technical Stakeholder Workgroup, and review and finalize proposed locations with the Workgroup.

2.0 SOIL SAMPLING ACTIVITIES

2.1 Soil Sample Location Placement and Utility Clearance

A total of 20 surface and 20 subsurface samples were proposed based on Round 1 sample exceedances detected at 15 locations: Former Building 4010 Area (three locations) and 17th Street Drainage (12 locations). The rationale for soil step-out sample locations is detailed in the Subarea 5B Round 2 Addendum to the Final FSP for Soil Sampling (HGL, 2012b). Table 1 summarizes the proposed samples and the samples actually collected. Figure 1 illustrates soil sample locations and exceedances reported during the Round 1 and Round 2 sampling events within Subarea 5B. Deviations from the FSP for Soil Sampling are discussed in Section 2.3.

Table 1
Summary of Planned and Collected Step-out Samples by Area

Area	Surface		Subsurface		Total	
	Planned	Collected	Planned	Collected	Planned	Collected
Former Building 4010	6	9	6	9	12	18
17th Street Drainage	14	14	14	14	28	28
Total	20	23	20	23	40	46

The proposed sampling locations were discussed during a technical review meeting held on February 22, 2012, with members of USEPA's SSFL Technical Stakeholder Workgroup consisting of representatives of the Department of Energy (DOE), the State of California Department of Toxic Substances Control (DTSC), The Boeing Company (Boeing), USEPA, and the community.

After the locations were finalized with the Stakeholder Workgroup, proposed sampling locations were marked in the field using a SPS 852 handheld Trimble global positioning system (GPS) and magnetic survey spikes. Before sampling activities commenced, utility clearances were performed at each location by Underground Service Alert (Dig Alert) and a private utility locator.

2.2 Sample Collection

Surface soil samples were collected using a stainless steel trowel or shovel. Subsurface samples were collected using a Geoprobe 6600 Series direct-push technology unit or a hand auger. Soil samples were collected in accordance with the procedures detailed in the Final FSP for Soil Sampling (HGL, 2012a), and the FSP Addendum for Subarea 5B (HGL, 2012b).

Soil cores were logged and the boring logs are provided in Attachment 2. A total of 46 surface and subsurface soil samples were collected from March 6 to June 25, 2012.

During the February 22, 2012, technical review meeting, recommendations and action items including those on the topic of Likely Chemical Remediation Zones (LCRZ), were discussed. Former Building 4010 and the 17th Street Drainage were identified as LCRZs. USEPA understands that soil may be excavated and removed from areas identified as LCRZs. Therefore, USEPA placed a reduced number of surface and subsurface samples around the perimeter of these zones to better define the potential extent of contamination. In accordance with USEPA's role under the Administrative Order on Consent (AOC) for Remedial Action (DTSC, 2010) between DTSC and DOE for the SSFL site, USEPA will conduct confirmation soil sampling to verify that site remediation goals have been achieved at all such remediation zones. These follow-on efforts are not included in the current scope of work and will be accomplished using additional external funding.

2.3 Deviations from the Field Sampling Plan Addendum

Three step-out locations (six samples) were added due to a RTL exceedance of cesium (Cs)-137 at Location 5B-00289 within the Former Building 4010 Area. The exceedance was identified after the FSP Addendum for Subarea 5B (HGL, 2012b) was finalized. Table 2 summarizes the additional step-out locations where samples were collected.

Table 2
Summary of Additional Step-out Locations Sampled

Sample Location	Sample Identification	Sample Type	Sample Depth
5B-00364	20761	Surface	0.0 – 0.5
5B-00364	20762	Subsurface	1.0 – 5.0
5B-00365	20763	Surface	0.0 – 0.5
5B-00365	20764	Subsurface	1.0 – 4.0
5B-00366	20765	Surface	0.3 – 0.8
5B-00366	20766	Subsurface	1.0 – 5.0

Note:

Sample depth measured in feet below ground surface.

2.4 Soil Boring Summary

Twenty-three subsurface soil samples were collected from 23 subsurface borings. One boring was advanced to 10 feet below ground surface (bgs), 14 borings terminated between 5 and 10 feet bgs, and eight borings were completed at a depth less than 5.0 feet bgs. Boreholes were terminated at a depth less than 10 feet bgs due to refusal at bedrock.

Soil samples were classified and described in accordance with the Final FSP for Soil Sampling (HGL, 2012a). The most common soil types observed were sand, silty sand, silt, and silty

clay. Fill material was encountered in all or a portion of 10 borings. The fill material consisted of soils that exhibited a mottled texture and frequently contained material such as concrete, asphalt or glass. Native soil was encountered below the fill material in each of the 10 borings. Thirteen borings consisted solely of native soil. A summary of the Boring Log information is presented in Table A.1 and the boring logs are provided in Attachment 2.

3.0 ROUND 2 SOIL ANALYTICAL RESULTS

Soil samples were analyzed in accordance with the Final Quality Assurance Project Plan (QAPP) for Soil Sampling (HGL, 2012c). Six analytes were removed from the gamma spectrometry method after Round 1 sampling was complete and were not analyzed in Round 2 samples for the following reasons:

- silver (Ag)-108 is derived from Ag-108m,
- barium (Ba)-133, could not be resolved in the presence of naturally occurring radionuclides,
- Ba-137m is directly derived from Cs-137,
- tellurium (Te)-125m is derived from antimony (Sb)-125 (and is therefore duplicative),
- radon (Rn)-220, and Rn-222 were calculated from other radionuclides.

For a discussion of how the Round 2 analyte list was developed, see Section 2.2 of the Final FSP for Soil Sampling (HGL, 2012a).

Surface and subsurface soil sample Locations 5B-00344, 5B-00345, and 5B-00346 were analyzed for strontium (Sr)-90 based on the Sr-90 exceedance reported at Location 5B-00316 (surface sample) during the Round 1 soil sampling event.

Surface and subsurface soil sample Locations 5B-00347, 5B-00348, 5B-00364, 5B-00365, and 5B-00366 were analyzed for gamma spectrometry default analytical suites based on the europium (Eu)-152 and Cs-137 exceedances reported at Locations 5B-00289 and 5B-00332 (surface samples) respectively, during the Round 1 soil sampling event.

Surface and subsurface soil sample Locations 5B-00350 through 5B-00363 were analyzed for gamma spectrometry default analytical suites based on Cs-137 exceedances reported at Locations 5B-00211, 5B-00212, 5B-00214, 5B-00217 through 5B-00225 (surface/drainage samples) during the Round 1 soil sampling event.

All samples were collected and analyzed in accordance with the rationale presented in Table 2.3 of the Final FSP for Soil Sampling (HGL, 2012a).

Round 2 soil sampling locations were determined based on RTL exceedances detected in Round 1 soil samples. The Round 2 samples were tested for those analytes that were detected above the RTL in Round 1 samples.

Radiological trigger levels are reference soil concentrations for the radionuclides of concern for the SSFL Area IV Radiological Study. They were designed for screening analytical results of site soil and sediment collected during Round 1 sampling to inform decisions for Round 2 sampling (also called step-out sampling). Individual Round 1 analytical results were compared to RTLs and if results exceed an RTL step-out sampling was conducted. The primary purpose of the RTLs were to guide the placement of Round 2 sampling locations and will not be used to screen Round 2 sample results.

The Round 2 analytical results are documented in this technical memorandum; however, the analytical results have not been screened using the RTLs. The Subarea 5B Round 2 analytical results will be evaluated, along with Round 1 results, using Field Action Level (FAL) established specifically for the SSFL Area IV Radiological Study. The results of the evaluation will be presented in the Radiological Characterization of Soils in Area IV and NBZ report.

Figure 1 presents the locations of the soil samples collected during the Round 1 and Round 2 sampling events. A summary of the Round 2 analytical results is provided in Table A.2.

4.0 QUALITY ASSURANCE/QUALITY CONTROL SAMPLES

In addition to the environmental samples collected, quality control samples were collected as described in the QAPP (HGL, 2012c). The results of the quality control samples collected and their affect on data usability are described in the following subsections.

4.1 Field Duplicates

Field duplicate soil samples were collected at a frequency of 1 per 20 samples (5 percent). A total of three field duplicate samples were collected during the Round 2 sampling event. The field duplicate evaluation criterion includes an additional 1σ uncertainty factor of 10 percent to allow for heterogeneity of co-located, but non-homogenized, field samples.

The comparability of a field duplicate result to that of the original sample is assessed by evaluating the Z-score (Z_{DUP}). The Z-score is a statistical test that indicates how many standard deviations an observation is from the expected value. The Z-score is defined in the QAPP (HGL, 2012c), and the Z_{DUP} is calculated as follows:

$$Z_{DUP} = \frac{|X_s - X_d|}{\sqrt{u_s^2 + u_d^2}}$$

where:

- X_s = activity of the sample
- X_d = activity of the duplicate
- u_s = combined standard (1σ) uncertainty of the sample
- u_d = combined standard (1σ) uncertainty of the duplicate

Higher Z_{DUP} scores indicate greater disparity between the sample and the duplicate results. A Z_{DUP} score of 2.0, for example, indicates that the duplicate result differs from the sample result

by twice the overall uncertainty of the two results. By extension, a Z_{DUP} score of 1.96 (the warning level) indicates that the two results are statistically equivalent, at the 95 percent confidence interval. A Z_{DUP} score of 2.58 (the exceedance level) indicates that the two results are statistically equivalent, at the 99 percent confidence interval.

A Z_{DUP} evaluation is performed on each paired set of analytes for which parent and duplicate data are reported. This quality assurance/quality control assessment is performed on the validated laboratory results approved and accepted by the project data manager, and recorded in the project database as of August 28, 2012. Subsequent modifications to the approved data or the project database may not be reflected in this assessment.

Round 2 field duplicate sample data includes 118 individual radionuclide results from 59 sample/duplicate pairs. Those original reported results included analytes which were not evaluated for any of the following reasons: several radionuclides were removed from consideration (and do not have RTLs), results were rejected by data validation, and analytes that are simply inferred from previously reported results, such as yttrium-90, which is inferred from the reported Sr-90 results, are redundant.

The Z_{DUP} evaluation of the remaining 50 qualified pairs follows:

- 46 Z_{DUP} evaluation results (92.0 percent) were within the expected 95 percent confidence interval for this evaluation, with Z_{DUP} less than 1.96;
- Four Z_{DUP} evaluation results (8.0 percent) were between the 95 percent and 99 percent confidence interval with Z_{DUP} at or above 1.96, but below 2.58;
- Zero Z_{DUP} evaluation results (0.0 percent) exceeded the 99 percent confidence interval, with Z_{DUP} values at or above 2.58.

The Z_{DUP} statistical test predicts that, in a homogeneous sample/duplicate pairing, 4 percent of reported Z_{DUP} scores (approximately two Z_{DUP} evaluation results in this Z_{DUP} set) will be in the “warning” range between 1.96 and 2.58. In addition, 1 percent (approximately one Z_{DUP} evaluation result in this Z_{DUP} set) is expected to exceed a Z_{DUP} score of 2.58.

In a small dataset such as this, the occurrence of four Z_{DUP} results in the warning range is not unexpected. While the frequency may reflect a small underestimate in the laboratory’s reported uncertainty, the individual results have been reviewed and do not appear to indicate a significant data quality issue. A summary of the parent and associated duplicate sample results is provided Table A.3.

4.2 Equipment Rinsate and Source Water Blanks

Equipment rinsate blanks were collected at a frequency of one per day, for each type of sampling equipment used per field team. Equipment rinsate blanks were collected in accordance with the FSP for Soil Sampling (HGL, 2012a) and the QAPP (HGL, 2012c). A total of 15 rinsate and two source water samples were collected during the Round 2 sampling

event. Each sample was tested for isotopic uranium, as a surrogate indicator of cross-contamination. Any results that were rejected for laboratory quality reasons would have been removed from consideration, as in the evaluation of field duplicate samples. In this dataset, however, no sample results were rejected. Tritium analyses were not performed on the field samples in this subarea. Therefore, tritium results for the rinsate and source water samples were not evaluated or included in this report.

In all cases, the samples were analyzed by the laboratory as received and the Total activity is reported.

Round 2 rinsate and source water samples include 90 individual Total activity results, from which 45 data pairs were evaluated by Z-score duplicate comparison. The Z_{DUP} scores are summarized below.

- 43 Z_{DUP} evaluation results (95.6 percent) were within the expected 95 percent confidence interval for this evaluation, with Z_{DUP} less than 1.96;
- One Z_{DUP} evaluation result (2.2 percent) was between the 95 percent and 99 percent confidence interval with Z_{DUP} at or above 1.96, but below 2.58;
- One Z_{DUP} evaluation result (2.2 percent) exceeded the 99 percent confidence interval, with the Z_{DUP} value at or above 2.58.

As with the field duplicates, the Z_{DUP} statistical test predicts that approximately 4 percent of reported Z_{DUP} scores (two Z_{DUP} evaluation results) will be in the range between 1.96 and 2.58 and approximately one percent of the reported results (less than one Z_{DUP} evaluation result) will exceed 2.58. The single exceedance in this case includes a rinsate sample with an activity concentration less than the associated MDC. In a small sample set such as this one, the single exceedance, with a Z_{DUP} score of 2.69, and the single warning approximate the expected frequency.

The evaluation of equipment blank results indicates that the decontamination of the field sampling equipment is acceptable and there is no evidence of sample cross-contamination from the sampling equipment that would adversely affect the quality or usability of the reported field sample data. A summary of the rinsate and source water blank analytical results are provided in Table A.4.

5.0 CONCLUSIONS

The Round 2 analytical results are documented in this technical memorandum; however, the analytical results have not been screened using the RTLs. Radiological trigger levels were reference soil concentrations designed to be used as a decision making tool to guide the placement of Round 2 step-out sampling locations. No additional step-out sampling will be conducted as part of the EPA's SSFL Area IV Study; therefore, there is no technical reason to compare the data to RTLs.

The Subarea 5B Round 1 and Round 2 analytical results will be evaluated using FALs established specifically for the SSFL Area IV Radiological Study. The results of the evaluation will be presented in the Radiological Characterization of Soils in Area IV and NBZ report.

5B-00366	20766	Tl-208	0.38	0.0164	0.0226	1.00 - 5.00
5B-00366	20766	Tm-171	-11.8 U J	12.8	4.81	1.00 - 5.00

Notes:

Refer to Table 2.1 of the Final Field Sampling Plan for Soil Sampling (HGL, 2012a) for a definition of radionuclide symbols.

Reporting units in picocuries per gram.

bgs - below ground surface

ID - identification

MDC - minimum detectable concentration

RTL - radiological trigger level

TPU - total propagated uncertainty

J - The analyte was detected at the reported concentration; the quantitation is an estimate.

K - Analyte present. Reported value may be biased high. Actual value is expected to be lower.

S - Analyte result is subject to spectral interference. Unless otherwise qualified, the data is believed to be consistent with the background study results and may be used for its intended purpose.

U - Not considered detected. The associated number is the reported concentration.

UJ - Not considered detected. The associated number is the reported concentration, which may be inaccurate.

Z - The initial laboratory result was reported above its respective RTL (or Lookup Table value). The gamma spectrometry data has been inspected to determine whether the exceeding analyte is present at a quantity greater than the RTL. In the analyst's judgment, the result is unsupported by the analytical data and is therefore not considered an RTL exceedance.

Notes:

Refer to Table 2.1 of the Final Field Sampling Plan for Soil Sampling (HGL, 2012a) for a definition of radionuclide symbols.

Reporting units in picocuries per gram.

ID - identification

MDC - minimum detectable concentration

TPU - total propagated uncertainty

J - The analyte was detected at the reported concentration; the quantitation is an estimate.

K - Analyte present. Reported value may be biased high. Actual value is expected to be lower.

S - Analyte result is subject to spectral interference. Unless otherwise qualified, the data is believed to be consistent with the background study results and may be used for its intended purpose.

U - Not considered detected. The associated number is the reported concentration.

UJ - Not considered detected. The associated number is the reported concentration, which may be inaccurate.
